In this study, 2023 operational data of a total of 28 ready-mixed concrete facilities located in the Marmara, Aegean, Mediterranean, Southeastern Anatolia and Central Anatolia regions of Türkiye were used. The data obtained from the facilities include basic inputs related to production processes such as annual energy consumption, fuel use, electricity consumption, cement and aggregate use. The data were obtained from the corporate reporting systems declared by the facilities and analyzed cumulatively to represent sectoral trends.

The greenhouse gas emission inventory of all facilities was calculated under the categories of Scope 1 (direct emissions), Scope 2 (indirect emissions) and Scope 3 (other indirect emissions) within the scope of the corporate carbon footprint. In the calculation of Scope 1 and Scope 2 data, the "Cement Carbon Dioxide and Energy Protocol, Version 3.1" published by the World Business Council for Sustainable Development – Cement Sustainability Initiative was used (World Business Council for Sustainable Development (WBCSD), 2011). This protocol details the calculation methods for cement and ready-mixed concrete plants, taking into account the main emission sources such as direct fuel use and electricity consumption.

Scope 3 emissions are determined within the framework of the Greenhouse Gas Protocol - Corporate Value Chain (Scope 3) Standard and in line with the operational control principle (Schmitz et al., 2004; World Business Council for Sustainable Development (WBCSD), 2011; World Resources Institute, 2003). In this approach, indirect emissions arising from processes that the organisation controls operationally (e.g. purchased materials, transport, business travel, etc.) are taken into account.

The data obtained were evaluated by classifying them separately on the basis of scopes, and the emission amounts for each scope were calculated in terms of CO_2 equivalent (tCO_2e).

3.2. Method: Calculation approach and methodological framework

Carbon footprint calculations are based on internationally accepted methodological standards. Scope 1 and Scope 2 emissions are calculated based on activity data such as fuel consumption (natural gas, diesel, etc.) and electricity consumption using the following basic formula:

Emission (kg CO_2e)=Activity Data×Emission Factor

- Activity Data: Refers to primary data such as the amount of fuel consumed (liter, m^3), electricity consumption (kWh).
- Emission Factor (EF): These are greenhouse gas emission coefficients determined for each type of activity, taken from the IPCC 2006 guidelines, WBCSD protocol and literature specific to Türkiye.

For Scope 1, calculations were made based on fossil fuels consumed in equipment such as truck mixers, construction equipment and stationary boilers.

In Scope 2 calculations, grid electricity consumption was taken as the basis and the Turkish National Electricity Emission Factor was used.

Scope 3 emissions were calculated based on processes such as purchased goods and services, including inputs such as cement and aggregates, pre-production and post-production transportation-logistics activities, transportation activities resulting from employee services and business trips, and disposal of waste generated in facilities.

In Scope 3 calculations, the operational control approach was adopted and the processes managed by the organization were taken as the limit. In cases where direct measurements were not made for activity data, sector averages and representative values taken from the literature were used.

The total emission amounts obtained were not normalized specifically for the facility; they were evaluated as a cumulative total reflecting the general trend of the sector.

4. Results and discussion

Technical details regarding emission values calculated within the scope of Scope 1 are presented in Table 1. In this table, fuel types, annual consumption amounts, net calorific values, emission factors and CO_2 equivalent outputs are systematically given.

Table 1. Distribution of scope 1 emissions by source in ready-mixed concrete facilities

Category	Emission Source	Annual Consumption (kg)	Net Calorific Value (TJ/gg)	Energy (TJ)	Emission Factor ($kgCO_2/TJ$)	CO_2 Emission (ton CO_2e)
Constant Combustion	Local Coal	5.000.000	11,9	59.50	101.000	6.009,50
	Natural gas	3.350	48,0	0.16	56.100	9.02
Fugitive Emissions	-	-	-	-	-	259.20
Mobile Emissions	-	-	-	-	-	11,141.44

Scope 1 covers the direct greenhouse gas emissions of ready-mixed concrete facilities. These emissions generally arise from the combustion of fossil fuels and the use of production vehicles. According to data collected from 28 facilities across Türkiye, total Scope 1 emissions as of 2023 are calculated as 17,419.16 tons of CO_2 equivalent (tCO_2e).

The largest share in this total belongs to emissions from mobile sources (transmixers, construction equipment). Mobile emissions constitute 64.0% of total Scope 1 emissions, revealing the high emission potential of fossil fuel-fired transportation equipment in the sector. Domestic coal used as solid fuel follows this with 34.5%. Fugitive emissions and emissions related to natural gas use have very low rates in the total (1.5% and 0.1%, respectively).

These findings show that measures such as fuel conversion, more efficient machine use and especially the transition to electric vehicle technologies in the ready-mixed concrete sector are of great importance in terms of reducing Scope 1 emissions.

Scope 2 emissions are indirect greenhouse gas emissions resulting from the consumption of electrical energy supplied from external sources, other than direct fuel use in ready-mixed concrete facilities, and the relevant calculations in this study are presented in Table 2.

Table 2. Scope 2 Emissions based on electricity consumption of ready mixed concrete plants

Emission source	Total Consumption(kWh)	Emission Factor(tCO_2e/MWh)	Total Emission (tCO_2e)
Electric	4,044.306	0.439	1,775.45

The total electricity consumption of 28 ready-mixed concrete facilities in this study was determined as 4,044,306 kWh. The location-based electricity emission factor for Türkiye for 2023 is taken as 0.439 tonnes CO_2e/MWh (Ministry of Energy and Natural Resources, 2024). Accordingly, the total Scope 2 emission calculated was found as 1,775.45 tonnes CO_2e.

Scope 3 emissions cover greenhouse gas emissions that are outside the direct control of ready-mixed concrete facilities but are caused indirectly along the operational chain, and the relevant emissions are presented in detail in Table 3 in this study.

Table 3. Scope 3 Emissions in Ready-Mixed Concrete Industry and Their Activity-Based Distribution

Category	Activity Description	Value (tonnes CO_2e/year)
Purchased Goods and Services	Purchased cement, aggregates and other materials	80.588,04
Capital Goods	Facility and equipment investments	4.770,28
Related to Fuel and Energy Faaliyetler	Indirect fuel and energy consumption	2.946,52
Transportation of Purchased Goods	Supply chain transportation (cement, aggregate logistics)	10.012,39
Wastes Generated in Operations	Industrial wastes originating from the facility	1,25
Business Trips	Emissions from service vehicles and business trips	19,85
Home-to-Work Transport	Personnel shuttle and transportation emissions	376,43
Downstream Transport and Distribution	Shipment of ready-mixed concrete (transport to the customer)	1.646,25
Processing of Sold Products	The product does not require energy, water or material input during its use, and there is no need for maintenance, repair or replacement. Therefore, product performance is assumed to be equal to the life of the building.	-
End of the Life of Products Sold	Effects that occur at the end of the concrete's life	9.515,26
TOTAL		109.876,27

As seen in Table 3, scope 3 emissions are calculated as approximately 18,131.49 tons CO_2e. The majority of this value originates from the "Purchased Goods and Services" category, which includes inputs such as cement and aggregates, accounting for 79.4% of the total. This ratio reveals the environmental impacts of supply chain processes and shows how critical it is to turn to low-carbon alternatives in the material supply phase. This category is followed by the Transportation of Purchased Goods and End of Life of Sold Products categories, which account for 9.1% of total emissions, respectively. The distribution of total emissions based on scope in corporate carbon footprint calculations of ready-mixed concrete facilities is presented in Table 4.

Table 4. Total emission distribution by scope

Scope	Emission Amount (tons CO_2e)	Share within Total Emission (%)
Scope 1 (Direct)	17,419.16	13.7%
Scope 2 (Indirect)	1,775.45	1.4%
Scope 3 (Other Indirect)	109,876.27	84.9%
Total	129,070.88	100%

As seen in Table 4, when the corporate carbon footprint emissions of the ready-mix concrete sector are examined, Scope 3 emissions are in the first place, accounting for 84.9% of total emissions. This is followed by Scope 1 emissions with 13.7%, while Scope 2 emissions have the lowest share with 1.4%. This distribution shows that environmental impacts in the sector are largely caused by the supply chain and indirect processes.

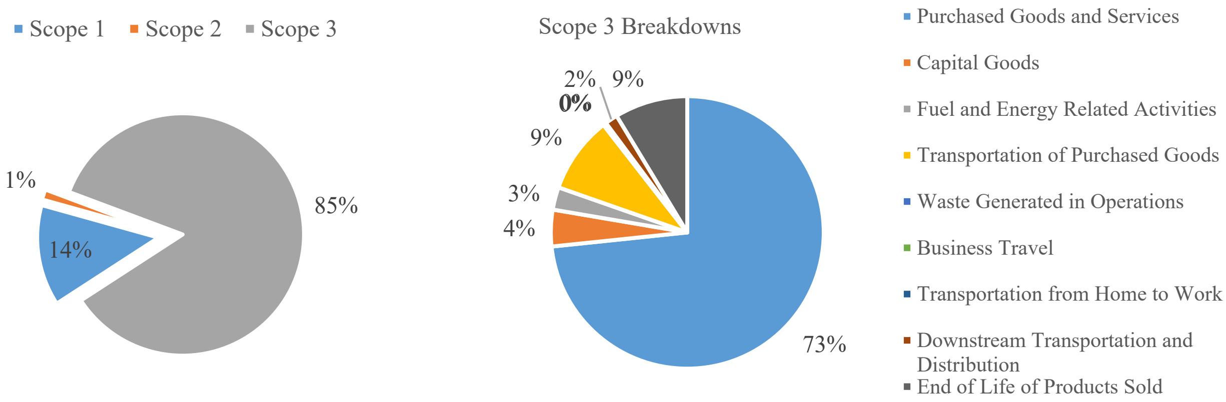

Fig. 6. Corporate Carbon Footprint Distribution: Scopes and Scope 3 Breakdowns

As shown in Fig. 6, scope 3 emissions are mainly caused by purchased materials (cement, aggregate and other materials) and their transport processes. This situation shows that not only the production processes but also the supply chain in the ready-mixed concrete sector should be closely monitored in terms of environmental impacts. Scope 1 emissions are predominantly caused by mobile sources (transit mixers and construction equipment), which points to the importance of fleet transformation, alternative fuel technologies and logistics optimisation strategies in the sector. Although the share of Scope 2 emissions in the total is quite low, it is possible to reduce them further through approaches such as switching to renewable energy and implementing ISO 50001 energy management systems.

5. Conclusions

In this study, a corporate carbon footprint calculation was carried out by evaluating the 2023 operational data of 28 ready-mixed concrete plants operating in five different regions of Türkiye. The calculations are handled separately under Scope 1, 2 and 3 headings within the framework of GHG Protocol, ISO 14064 and IPCC guidelines.

The obtained findings show that 84.9 % of the total carbon footprint originates from Scope 3, 13.7 % from Scope 1 and only 1.4 % from Scope 2. This situation reveals that the environmental impact in the ready-mixed concrete industry is largely caused by purchased materials and supply chain processes.

Accordingly, the following recommendations have been developed to reduce the carbon footprint of the industry:

- For Scope 3: The use of low-carbon alternative materials should be encouraged for inputs with high carbon footprints such as cement and aggregates. Material selection should be made with suppliers based on "environmental product declarations (EPD)". Transportation distances should be reduced in logistics processes, and alternative (e.g. electric) transportation solutions should be supported.

- For Scope 1: Fleet transformation programs should be initiated to reduce fossil fuel use in vehicles and construction equipment. Alternative fuels (biodiesel, HVO, etc.) and digital solutions that increase operational efficiency should be evaluated.
- For Scope 2: Transition to renewable energy should be ensured and the energy needs of the facilities should be met from sources such as solar and wind. Energy consumption should be reduced and energy management systems such as ISO 50001 should be implemented.

As a result, the ready-mixed concrete industry is one of the areas, other than the energy sector, that has the greatest potential to help Turkey achieve its net zero targets. The data obtained in this study has the potential to create a strong reference for the industry to develop holistic and science-based strategies on carbon management.

Abstract. Polymer concrete (PC) is a type of concrete that can be made by mixing different components, namely (i) a polymeric resin, (ii) fine and coarse aggregate and filler materials, and (iii) reinforcing fiber materials in suitable percentages. This material has specific applications in different civil structures. Mechanical and strength properties in such multi-ingredient composite materials is affected by the type and dosage of the components. The usage of design of experiment (DoE) methods (such as Taguchi) can help the PC designers in determining the optimum mix design parameters to obtain the best achievable strength and mechanical properties with lesser number of laboratory experiments. Fracture toughness (i.e., the resistance of cracked material) against tensile (mode I) and shear (mode II) loads and deformations, is a key and important design parameter for assessing the integrity and service life in the PC materials having dominantly brittle and quasi-brittle fracture nature in real field applications. Thus, in this work, the Taguchi method was employed to find the optimum percentages of a fiber reinforced PC mixture (with main ingredients of polyester resin + fine and coarse grain size silicious aggregate) to achieve the optimum K_{IC} and K_{IIC} (i.e., modes I and II fracture toughness values). The initial window of input variables was considered in the following ranges: 0%<glass fiber<2%, 40%<coarse aggregate<55%, 20%<fine aggregate<36%, and 12%<Polyester resin <30%. The required fracture toughness experiments were done using the semi-circular-bend test loaded with symmetric span (for mode I) and asymmetric span (for mode II) according to a L32 Taguchi DoE technique. Based on the performed fracture experiments, the optimum percentages of PC ingredients were obtained in such way that the greatest possible fracture toughness values under both tensile and shear modes are achieved. The obtained results showed the significant role of loading mode on the optimum mix design of the PC mixture.

1.Introduction

Recent developments in civil engineering have led to an increased focus on materials that can substantially improve the performance and strength of a range of components, such as soil, asphalt, concrete, and other elements used in construction (Baradaran et al., 2024; Baradaran et al., 2024; Baradaran et al., 2023). These materials not only contribute to improving mechanical properties but also offer numerous benefits in terms of cost-effectiveness and overall functionality (Niri et al., 2024; Baradaran & Ameri, 2023; Baradaran & Aliha, 2025). Research in this area has been on the rise, as these materials can improve the durability and efficiency of structures while helping to reduce construction costs and the need for repairs (Pargar et al., 2024; Tareghian et al., 2024; Ayar et al., 2022; Baradaran & Ziaee, 2025). Polymeric concrete (PC) is a type of structural concrete that has some important and particular applications in civil and structural engineering such as in pavements of roads and bridges, manufacturing high-strength slabs, repair of concrete structures, etc. PC material has some benefits compared to the ordinary cement or plain concrete mixtures such as higher strength and mechanical properties, faster curing and construction process, and smaller thickness of the concrete layer. Achieving such characteristics is mainly due to the replacement of cement and water with resin as the binder of the heterogeneous mixture of aggregates inside the

* Corresponding author, E-mail: mrm_aliha@iust.ac.ir

https://doi.org/10.31462/icearc2025_ce_mat_163

matrix of polymeric resins. A PC material is therefore composed of coarse and fine aggregates (with typically 70–80% by weight of the mixture) and polymeric resin (such as polyester or epoxy with typically 20–30% of the mixture). Sometimes, some additives such as micro fillers, reinforcing fibers (e.g., glass fiber), or even agricultural and industrial waste materials are added to the PC mixture for filling the air voids and enhancing the performance and mechanical properties of these materials (Kujawa et al., 2021; Martinez-Barrera et al., 2022; Daneshfar et al., 2017).

Brittle or quasi-brittle fracture is one of the major failure modes in the PC mixtures. The fracture toughness value in these materials depends on the composition of the PC mixture and ingredients used for manufacturing the PC. However, in comparison with the common mechanical properties, including compressive and flexural bending strength, very few studies are available regarding the fracture and cracking resistance behavior of PC materials and its relationship with the mixture composition (Aliha et al., 2022; Karamzadeh et al., 2022; Niaki et al., 2023; Asdollah-Tabar et al., 2021). Due to the wide range of variables and several possible mix designs available for manufacturing a PC material, it is necessary to use optimization methods for obtaining the suitable PC mix design. The effective factors in manufacturing an optimum PC mixture can be identified by optimization and design of experiments (DOE) methods. The Taguchi method is among the well-known DOE techniques that can suggest a minimum number of experiments by determining the prominent control factors (Roy, 2001). Mohebi et al. (2015) explored the abrasion resistance of alkali-activated slag concrete using the Taguchi method and confirmed the applicability of this method for the proper design of the experiment and optimization of alkali-activated slag concrete parameters to maximize the compressive strength and wear resistance. Jafari et al. (2018) applied the Taguchi method for optimizing the mixture of PC materials. Tanyildizi (2018) also examined the long-term mechanical properties and microstructure of polymer-phosphazene concrete subjected to repeated freezing-thawing mechanisms. However, the review of literature indicates that there is no comprehensive work on the mix design optimization of PC mixtures to obtain the best fracture toughness (i.e., resistance values) against crack growth under tensile (mode I) and shear (mode II) deformations. Therefore, in this research, the optimum percentage of PC ingredients for achieving high fracture toughness (K_{IC} and K_{IIC}) values is studied experimentally using the Taguchi method.

2.PC mix design using Taguchi method

The PC mixture of the current research is composed of four basic ingredients namely (1) fiber glass fiber (chopped strand shape with length of 7 mm and diameter of 0.01 mm), (2) polyester resin (as adhesive), (3) coarse cilicious aggregate (with nominal size of 4 mm) and fine silica fine grain filler (with nominal size of 0.5 mm). Based on the previous related works, the initial window weight percentages of these four input variables were considered as: 0%<GF<2%, 40%<CA<55%, 20%<FA<36% and 12%<PR <30%, in which GF, CA, FA and PR stand for “Glass Fiber”, “Coarse Aggregate”, “Fine Aggregate” and “ Polyester Resin”, respectively.

In experimental design, optimizing process parameters often requires a large number of trials, especially when multiple factors and levels are involved. A full factorial design considering 4 factors each at (4, 4, 4, and 2) levels would require 128 experiments. This approach, while exhaustive, is time-consuming and resource-intensive. The Taguchi method offers an efficient alternative by employing orthogonal arrays to systematically investigate the effects of multiple parameters with a reduced number of experiments. In this study, the L32 orthogonal array was utilized to design the experiments, and the fracture toughness in mode I and mode II were measured as the primary outputs to evaluate fracture performance. Table 1 represents the parameters and their levels.

Table 1. Parameter levels of L32 Taguchi optimization

Factors	Level 1	Level 2	Level 3	Level 4
GF (%)	0-1	1.5-2	-	-
PR (%)	14-18	18.5-22	22.5-26	26.5-30
CA (%)	40-43	43.5-47	47.5-51	51.5-55
FA (%)	20-24	24.5-28	28.5-32	32.5-36

3. Fracture toughness tests on PC mixtures under modes I and II modes

The SCB test configuration is among suitable samples for conducting fracture toughness tests on civil engineering materials such as concrete, asphalt, rock, and soil (Aliha et al., 2024; Mubaraki & Sallam, 2020; Mirsayar et al., 2017; Erarslan & Aliha, 2025; Aliha, 2019; Aliha et al., 2022; Azar et al., 2015; Aliha et al., 2023; Pirmohammad et al., 2024; Najjar et al., 2023; Fang & Fall, 2020; Tutluoglu et al., 2022; Aliha et al., 2016; Ayatollahi et al., 2011). This test specimen has simple geometry, simple manufacturing, and testing procedure for the aim of fracture toughness testing. Fig. 1 shows the geometry and loading conditions of the SCB sample for conducting fracture

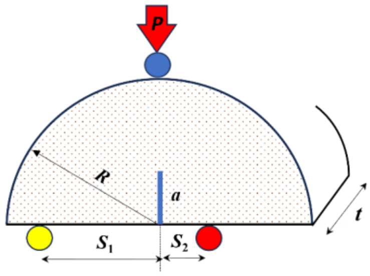

Fig. 1: The use of SCB specimen for conducting fracture toughness tests under mixed mode I/II conditions.

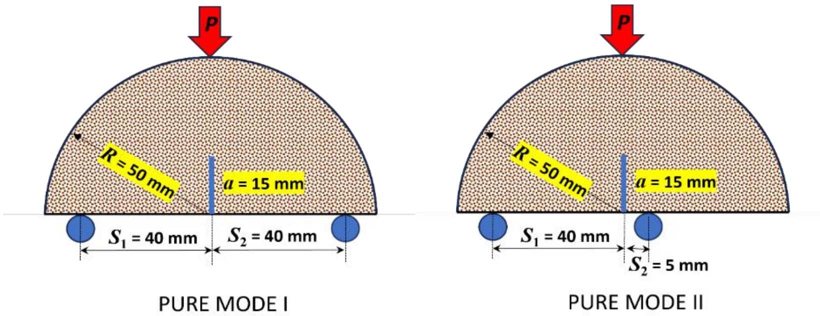

Fig. 2: Overall dimensions of the SCB samples, crack length and the support distances utilized for PC fracture tests under pure mode I and pure mode II.

toughness tests under any desired mode mixtures including mode I (opening or tensile mode) and mode II (shearing mode). Indeed, by setting the bottom loading supports in appropriate locations relative to the crack, any desired ratio of mode I and mode II (such as pure modes tensile and shear) deformations can be achieved (Aliha et al., 2022; Aliha et al., 2016; Ayatollahi et al., 2011). In this research, the SCB sample with the geometry and dimensions illustrated in Fig. 2 was utilized for conducting pure mode I (i.e., with symmetric boundary conditions or span lengths) and pure mode II (i.e., with asymmetric boundary conditions or spans).

Several PC mixtures and PC designs suggested by the Taguchi DoE method were manufactured (according to dimensions given in Fig. 2) to conduct the fracture toughness tests. All the manufactured SCB samples had the same thickness of t = 25 mm. The PC mixtures were cast inside the semi-circular shape molds to create edge cracked SCB samples and loaded monotonically using a test machine having the loading capacity of 10 kN. The dimensions of the test samples and locations of loading rollers for conducting the mode I and mode II tests are given in Fig. 2. Using the peak load or maximum loads (P_{max}) recorded by the load cell of the test sample for each PC sample and mixture, the related values of mode I fracture toughness (K_{IC}) and mode II fracture toughness (K_{IIC}) were determined from Eqs. 1 and 2 (Aliha et al. 2016,2019).

$$K_{IC} = \frac{4.85Pmax}{2Rt}\sqrt{\pi a} \tag{1}$$

$$K_{IIC} = \frac{1.87P}{2Rt}\sqrt{\pi a} \tag{2}$$

4.Results and discussion

Table 2 summarises the results of mode I and mode II fracture toughness data obtained for different PC mixtures with different ingredients (i.e., GF, FA, CA, and PR contents and percentages). Based on theses experimental data obtained from the symeetric and asymmetric SCB tests the PC mixture has significant effect on modes I and II fracture toughness of polymeric concrete materials. based on the PC mix design and the percentage of ingredeints, the mode I fracture toughness (K_{IC}) value varies in the range of 1.3 MPa.m$^{0.5}$ and 3.2 MPa.m$^{0.5}$. The corresponding range for the variations of K_{IIC} value (mode II fracture toughness) with the change of PC mixture is 1.15 MPa.m$^{0.5}$ < K_{IIC}< 3.15 MPa.m$^{0.5}$.

The analysis of the results revealed that the input parameters exhibited a generally similar influence on both fracture toughness indicators, namely K_{IC} and K_{IIC}. Among all factors, the polyester resin (RP) demonstrated a dominant effect on both output responses, highlighting its critical role in determining the mechanical behavior of the PC mixture. Based on the Main Effects Plot (Fig. 3), it was observed that the factors glass fiber content (GF), polyester resin (PR), and coarse aggregate (CA) had comparable effects on K_{IC} and K_{IIC}. Specifically, for both responses, the most favorable outcomes were achieved at level 1 of GF (ranging from 0% to 1%), level 4 of PR (ranging from 26.5% to 30%), and level 1 of CA (ranging from 40% to 43%). These levels consistently produced higher values for both fracture toughness modes.

Table 2. The parameter levels in the experiment tests and related outputs.

Test	Parameters								Outputs	
	GF levels		FA levels		PR levels		CA levels		K_{IC} $(MPa\sqrt{m})$	K_{IIC} $(MPa\sqrt{m})$
1	1	0.0%	4	32.5%	4	26.5%	1	41.0%	1.65	1.64

The analysis of the results revealed that the input parameters exhibited a generally similar influence on both fracture toughness indicators, namely K_{IC} and K_{IIC}. Among all factors, the polyester resin (RP) demonstrated a dominant effect on both output responses, highlighting its critical role in determining the mechanical behavior of the PC mixture. Based on the Main Effects Plot (Fig. 3), it was observed that the factors glass fiber content (GF), polyester resin (PR), and coarse aggregate (CA) had comparable effects on K_{IC} and K_{IIC}. Specifically, for both responses, the most favorable outcomes were achieved at level 1 of GF (ranging from 0% to 1%), level 4 of PR (ranging from 26.5% to 30%), and level 1 of CA (ranging from 40% to 43%). These levels consistently produced higher values for both fracture toughness modes.

However, the behavior of K_{IC} and K_{IIC} based on fiber alignment (FA) showed some discrepancies. To better understand the optimal setting for FA, the Interaction Plot (Fig. 4) was analyzed. By fixing GF at level 1, it was found that level 4 of FA (corresponding to the range of 32.5% to 36%) provided the highest values for both K_{IC} and K_{IIC}. Therefore, it can be concluded that in designing a polymer composite (PC) mixture, the selection of ingredients that result in GF and CA at level 1, and PR and FA at level 4, is expected to yield the maximum fracture toughness in both mode I and mode II.

5. Conclusions

The effect of mix design on the fracture toughness (i.e., the resistance of material against cracking) was investigated experimentally for the polymeric concrete (PC) mixture. The Taguchi design of experiment (DoE) technique was employed to select the input variables (GF, CA, FA, and PR) and their levels (2 levels for the GA and 4 levels for the other input variables). Accordingly, 32 different PC mixtures were designed, and modes I and

II fracture toughness tests were conducted using the SCB sample. The results showed that the PC mixture has noticeable effect on both K_{IC} and K_{IIC} values. The optimum percentages of PC ingredients for obtaining the highest fracture toughness values under tensile and shear type failure were as follows: Glass Fiber content = [0-1]%, Fine Aggregate content = [32.5-36]%, Coarse Aggregate = [40-43]%, and Polyester Resin content = [26.5-30]%.

Assessment of the Utilization of Grinding Aids in terms of Grinding Efficiency and Environmental Impact

Veysel Kobya[1], Yahya Kaya[1], Ali Mardani[*1]

[1] *Bursa Uludağ University, Department of Civil Engineering, 16059 Bursa, Türkiye*

Abstract. Cement production is particularly notable in energy efficiency studies due to its high energy consumption and substantial greenhouse gas emissions. Approximately two-thirds of the total energy consumption in cement production occurs during the grinding stage. Grinding aids (GAs) are utilized to enhance energy efficiency and reduce environmental impact during clinker grinding. While the primary mechanisms of action are understood, the effects of GAs in cement production are still largely based on theoretical information. The identification of high-performance GAs is particularly challenging due to the complexity of the selection criteria. Amine- and glycol-based GAs are commonly used in practice. This study aims to evaluate the utilization of amine- and glycol-based GAs in terms of grinding efficiency and environmental impact, calculated based on CO_2 emissions and electrical energy consumed during grinding. Triisopropanolamine (TIPA), diethylene isopropanolamine (DEIPA), and diethylene glycol (DEG) were incorporated at a concentration of 0.05 wt.% relative to the combined mass of clinker and gypsum-a standard industry practice-to achieve a target Blaine fineness of 3500 ± 100 cm²/g. Four CEM I 42.5R type cements were prepared, including a control cement without GA. Grinding efficiency and environmental impact were assessed based on the time and number of cycles required to reach the target Blaine fineness. A grinding efficiency improvement ranging from 8% to 14% was achieved through the incorporation of grinding aids, independent of their chemical composition. In terms of both grinding efficiency and environmental impact, TIPA and DEG were found to be the highest and lowest performers, respectively.

Keywords: Grinding aids; TIPA; DEIPA; DEG; Grinding efficiency

1. INTRODUCTION

Greenhouse gas emissions, air pollution, and climate change are among the primary contributors to global environmental crises. Addressing these challenges has emphasized the importance of developing alternative products that emit less CO_2 during manufacturing, expanding the use of renewable energy sources, and improving energy efficiency (Boesch & Hellweg, 2010; Zhang et al., 2015).

The 2015 Paris Climate Agreement established a target to limit the rise in global temperatures to 1.5 °C annually. This commitment aims to protect coral reefs and the associated ecosystems at risk of collapse by the end of the century (Darby, 2018). In alignment with this global goal, Turkey has pledged to cut its greenhouse gas emissions by 21% by 2030. Within the country, the energy sector is the dominant source of emissions, accounting for 86.1%, followed by industrial operations and consumption activities at 13.6% (Dulkadiroğlu, 2018).

Among the most energy-intensive and polluting industries is the cement sector, due to its substantial use of raw materials and high CO_2 emissions. The sector accounts for approximately 2% of total global electricity use and 5% of the industrial electricity demand, contributing to 5–7% of total global CO_2 emissions (Madlool et al., 2011). Producing one ton of cement requires about 1.2 tons of raw materials and 130 kWh of energy, which leads to the emission of nearly 1 ton of CO_2 (ICS, 2009; Mardani-Aghabaglou, 2016).

Clinker grinding represents nearly 35% of the total energy consumption in cement manufacturing. A considerable portion of this energy is dissipated as heat, noise, and vibrations. In efforts to lower both production costs and associated CO_2 emissions, the application of grinding aids (GAs) has gained prominence (Jankovic et al., 2004; Zhang et al., 2015; Kaya et al., 2024.a–2024.b). Ethanolamines such as triethanolamine (TEA), diethanolamine (DEA), monoethanolamine (MEA), and triisopropanolamine (TIPA), as well as glycols like ethylene glycol (EG) and propylene glycol (PG), are among the most commonly employed GA types to enhance grinding efficiency (Jolicoeur et al., 2007; Assaad, 2015; Zhang et al., 2015; Sun et al., 2020; Kobya et al., 2022).

[*] Corresponding author, E-mail: ali.mardani16@gmail.com

https://doi.org/10.31462/icearc2025_ce_mat_178

Despite numerous studies exploring the operational mechanisms of GAs during clinker grinding, the full scope of their interactions remains unclear (Mishra et al., 2017; Sun et al., 2016; Sun et al., 2020). The prevailing hypothesis suggests two main effects: a physicochemical interaction that reduces the surface energy of particles, and an influence on particle alignment and flow characteristics (Choi et al., 2010; Prziwara et al., 2018.a; Chipakwe et al., 2020).

GAs adhere to particle surfaces through their polar functional groups (e.g., –OH, $–NH_2$, –COOR, $–SO_3$), altering the electrical charge landscape and preventing crack closure, particle agglomeration, and material buildup on mill liners or media (Jeknavorian et al., 1998; Assaad and Issa, 2014). This promotes better dispersion and improves grinding effectiveness. Interestingly, cement produced with GAs may exhibit identical Blaine fineness values yet differ in surface energy, significantly impacting hydration behavior and admixture compatibility (Katsioti et al., 2009). Moreover, GA-modified cements are generally composed of smaller, smoother particles with reduced angularity (Ma et al., 2015). Several studies have further evaluated the impact of different types and dosages of GAs on grinding performance (Katsioti et al., 2009; Assaad, 2015; Sun et al., 2020; Kobya et al., 2022; Kaya et al., 2024.a).

Katsioti et al. (2009) examined the effectiveness of six different GA formulations by blending varying proportions of triethanolamine (TEA) and triisopropanolamine (TIPA). These formulations—ranging from 100% TEA to 95% TIPA-were dosed at 0.015%, and yielded grinding efficiency improvements of 14%, 10%, 13%, 20%, 22%, and 26%, respectively, over the control sample. The results indicated that formulations with higher TIPA content exhibited superior performance, emphasizing the correlation between the chemical composition and grinding enhancement.

Assaad (2015) evaluated the efficiency of diethylene glycol (DEG) and propylene glycol (PG) as GAs at dosages of 0.028% and 0.053%, reporting performance increases of 10% and 18%, respectively. The residue on the 90 μm sieve decreased from 2.76% in the reference cement to 1.27% and 0.9% with increasing GA dosage, suggesting enhanced generation of fine particles with higher additive concentration.

In another study, Sun et al. (2020) investigated glycerin as a GA at incremental dosages of 0.01% to 0.04%, achieving grinding improvements of 16%, 25%, 25%, and 33%, respectively. Surface energy measurements confirmed this enhancement, decreasing from 65–130 mJ/mm² in the reference cement to 59–98 mJ/mm² in the 0.04% glycerin-modified cement, supporting glycerin's effectiveness as a GA.

Despite numerous studies demonstrating improved grinding performance through various GAs, there remains a gap in research concerning the quantifiable environmental benefits—particularly reductions in CO_2 emissions and energy usage. Therefore, the current study focused on assessing the grinding and environmental performance of amine- and glycol-based GAs. Specifically, TIPA, DEIPA, and DEG were used at 0.05% dosage (by total weight of clinker and gypsum) to produce four CEM I 42.5R cements, including one without GA as a control. Grinding efficiency was assessed based on the time and number of cycles needed to reach a target Blaine fineness of 3500 ± 100 cm²/g. The environmental performance was determined by calculating the energy and CO_2 savings resulting from improved grinding efficiency.

2. Materials and methods

2.1. Materials

In this study, CEM I 42.5R type cements were produced by grinding a mixture containing 96% clinker and 4% gypsum in a laboratory-scale ball mill until achieving the target Blaine fineness of 3500 ± 100 cm²/g, in accordance with the TS EN197-1 standard. The cement produced without the addition of any GA is designated as R (reference), while the cements incorporating GAs are labeled according to the specific GA used. The key physical and chemical characteristics of the clinker, gypsum, and fly ash utilized in the experiments are presented in Table 1.

Table 1. Some properties of clinker and gypsum

Component	Chemical Content (%)	
	Clinker	Gypsum
SiO_2	21.52	4.98
Al_2O_3	5.43	1.21
Fe_2O_3	3.31	0.83
CaO	65.38	28.94
MgO	1.04	0.83
SO_3	0.38	39.67
Na_2O+0.658 K_2O	0.83	0.37
Cl	0.01	-
Combined Water (T<230º)	-	18.93
Other, %	1.58	4.24
Loss of igniton	0.52	

Similarly, Table 2 summarizes the main physical and chemical properties of the grinding aids employed.

Table 2. Some physical and chemical properties of the GAs used

GA type	Alkaline content (%) (Na_2O)	Density (g/cm^3)	Solid content (%)	Chloride content (%)	pH. 25°C	Number of Functional Groups
TIPA	<10	1.124	50.0	<0.1	10.8	3
DEIPA	<10	1.079	50.0	<0.1	9.7	3
DEG	<10	1.118	50.0	<0.1	7.2	2

2.2. Methods

As part of the experimental procedure, clinker and gypsum were initially subjected to size reduction using a jaw crusher. The crushed clinker was subsequently sieved to a particle size of 3.35 mm, in accordance with the Bond Standard, to prepare it for grinding.

The grinding process was performed using a Bond-type laboratory ball mill with a 5 kg capacity and a 1.5 kW motor, as illustrated in Fig. 1.

The Blaine fineness of the ground cements was measured using an automatic Blaine apparatus, depicted in Fig. 2.

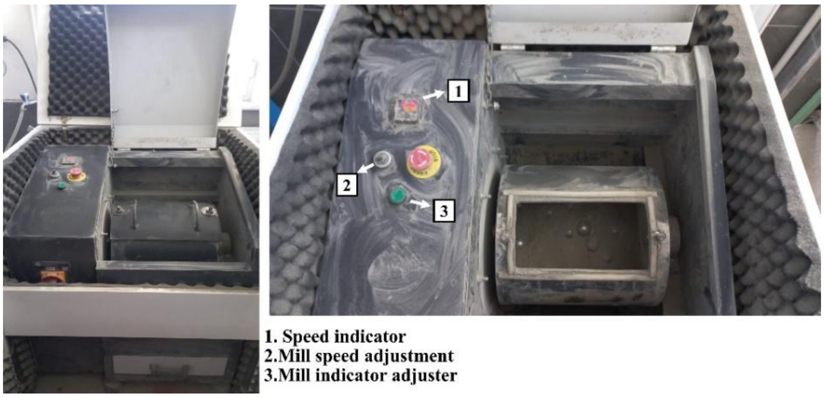

Fig. 1. The ball mill

Fig. 2. Automatic Blaine device

The energy consumption of the mill during the grinding process was calculated using Equation 1.

$$Eg = (220 \times Tg \times A \times 1000) / (m \times Tg) \quad (1)$$

Here, Eg represents the grinding energy (kWh/ton), Tg is the grinding time (hour), A denotes the amperage, m refers the feed amount (kg) and Tg refers the mill factor, a constant value of 4 provided by the manufacturer.

Based on data from the Turkish Cement Manufacturers Association, Turkey's cement production in 2023 reached approximately 65 million tons (Turkish Cement Manufacturers Association, 2023). According to the 2021 national electricity grid emission factor report published by the Ministry of Energy and Natural Resources of the Republic of Turkey, the emission factor for electricity consumption was reported as 0.7258 tCO_2/MWh (Turkish National Grid Emission Factor Data, 2021; Savaş, 2021). Using this information, the potential reduction in annual energy consumption and associated CO_2 emissions from the use of GAs in cement grinding processes was estimated for the Turkish cement industry.

3. Result and Discussions

3.1 Grinding efficiency

Figure 3 presents the grinding energies (kWh), calculated using Equation 1, for each cement produced with and without GA to achieve the target Blaine fineness (3500 ± 100 cm^2/g), along with the corresponding relative grinding efficiencies compared to the reference cement.

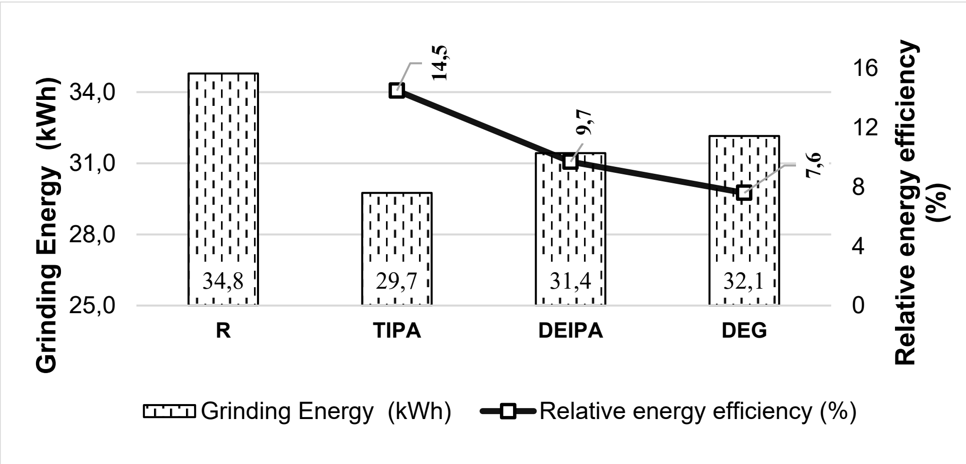

Fig. 3. Grinding energies (kWh) for each cement and corresponding relative grinding efficiencies compared to the reference cement

As illustrated in Figure 3, the use of TIPA, DEIPA, and DEG as grinding aids resulted in energy savings of 14.5%, 9.7%, and 7.6%, respectively, relative to the reference cement. As illustrated, the amine-based additives TIPA and DEIPA demonstrated higher grinding efficiency compared to the glycol-based DEG, consistent with findings reported in earlier studies (Assaad et al., 2009; Prziwara et al., 2018.b; Kobya et al., 2022). The superior performance of TIPA compared to DEIPA was attributed to the enhanced fluidity effect imparted by the CH_3 group present in its molecular structure (Chen et al. 2024).

3.1 Envorimental impact

Based on the obtained data, the influence of GA application on annual electrical energy consumption and CO_2 emissions associated with the cement grinding process in Turkey was evaluated. A summary of the estimated outcomes is presented in Table 3.

Table 3. Some physical and chemical properties of the GAs used

Energy efficiency and CO_2 Emission	R	TIPA	DEIPA	DEG
Amount of cement produced annually in Turkey, kiloton		64854		
Energy consumed in the grinding phase in the production of 1 ton of cement, kWh	34,8	29,7	31,4	32,1
Total energy consumed in clinker grinding in Turkey, GWh	2256	1929	2038	2085
Provided energy savings, GWh	-	327	218	171
The amount of CO_2 released from the electricity consumed during grinding, kiloton	1637	1400	1479	1513
Amount of avoided CO_2 emissions, kiloton	-	237	158	124

As presented in Table 3, the application of GAs in Turkey's annual cement production could lead to energy savings between 171 and 327 GWh. Based on the data reported by Karaca (2012), the annual electricity consumption of a typical family with two children in Turkey is approximately 2600 kWh. Accordingly, the use of TIPA, DEIPA, and DEG could potentially offset the annual electricity consumption of 126,000, 84,000, and 66,000 families, respectively. Furthermore, the adoption of TIPA, DEIPA, and DEG is expected to prevent 237, 158, and 124 kilotons of CO_2 emissions, respectively.

Assuming that an average tree sequesters around 12 kg (0.012 tons) of CO_2 annually through photosynthesis (Argun et al., 2019), the associated reduction in carbon footprint can be estimated. In the absence of GA, the annual CO_2 emissions from clinker grinding amount to approximately 1,637 kilotons, which is equivalent to the sequestration capacity of about 165.5 million trees. The application of TIPA reduces this number to 117 million trees, while DEIPA and DEG further decrease it to 123 million and 126 million trees, respectively.

4. Conclusions

This study examines the grinding efficiency and environmental impacts of commonly used Gas-DEIPA, TIPA, and DEG. The key findings from the experiments are summarized below.

- Regardless of the type of GA employed, it was found that grinding efficiency, CO_2 emission reduction, and more environmentally sustainable production could be achieved through the use of GAs.
- In terms of grinding efficiency, amine-based additives outperformed glycol-based DEG additives, with TIPA providing the highest and DEG the lowest contributions.
- Similarly, in terms of environmental impact, TIPA and DEG were the top and lowest performers, respectively. However, it is important to note that DEG, despite its lower efficiency in grinding, offers significant energy savings and environmental benefits compared to the reference cement.

Acknowledgments

Experimental investigation of the effects of bolt and nut configurations on the tensile capacity of wind turbine flange connections

Nisanur Isık*1, Fatih Alemdar[1]

[1] Yıldız Technical University, Department of Civil Engineering, 34025 Istanbul, Türkiye

Abstract. The growing global energy demand, greenhouse gas emissions from fossil fuels contributing to global warming and climate change, and the environmental and societal risks associated with nuclear energy have made the adoption of renewable energy sources essential. The need to develop and utilize renewable energy to preserve the planet's natural ecosystem has become increasingly urgent. Among renewable energy technologies, wind turbines play a significant role and are becoming more widespread.A critical issue in wind energy systems is the structural integrity of wind turbine towers, as failures often result from bolt fractures or flange separations at ring flange connection points. To address these challenges, this study investigates the bolt and flange connection details at these critical points.Two grades of steel were selected for testing, and four tensile tests were conducted. Based on the results, the steel grade with higher ductility was chosen for further analysis. Static tests were then performed on specimens representing the connection. The bolt configurations were analyzed in both single-nut and double-nut setups, and their effects on tensile capacity were evaluated. Detailed comparisons of tensile capacity revealed a strong correlation between the experimental findings, literature data, and analytical solutions. The evaluation of the nut configurations highlighted their impact on the tensile capacity of the connection specimens, providing valuable insights for optimizing wind turbine structural designs.On the other hand, the existing literature was thoroughly reviewed, and the findings obtained from this study were compared with previous results in the literature regarding the behavior of the components forming the connection.

Keywords: Nut; Steel connection; Steel grades; Tensile capacity; Wind turbine

1. Introduction

In recent years, the rapidly increasing global energy demand has made it more evident that reducing environmental impacts and utilizing sustainable energy sources is imperative. Greenhouse gas emissions from fossil fuels, air pollution, and their effects on global warming and climate change have necessitated the adoption of renewable energy systems. Among various energy alternatives, wind energy stands out as a prominent solution due to its low environmental footprint and operational costs. The potential of wind energy is great significance in reducing dependence on fossil fuels and minimizing the environmental footprint. Therefore, the development and widespread adoption of wind energy technologies has become a critical goal for environmental protection and sustainable development.

Wind turbines, especially horizontal-axis models, are commonly used for large-scale energy production. As these structures operate under both dynamic and static loads, they must exhibit high mechanical strength and safety. However, the structural integrity of wind turbines is often compromised at certain weak points, particularly at tower connections. One of the most vulnerable areas is the flange connections between turbine tower segments, where bolt fractures and flange separations frequently occur. Such failures can render turbines inoperable or even lead to structural collapse. Consequently, the design of bolt and flange connections is of most importance for ensuring the structural safety and efficiency of wind turbines.

Much of the existing research has focused on general bolt behavior, preload loss, fatigue, shear, and sealing characteristics. However, there is a limited number of studies addressing the effects of bolt and nut configurations specifically those used in turbine towers on tensile capacity. The interaction between bolt and nut geometry and the type of connection can significantly influence load distribution, stress concentrations, and overall connection performance. Different nut arrangements, in particular, can have substantial impacts on the durability and

* Corresponding author, E-mail: nisanur.isik@std.yildiz.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_204

reliability of connection components. Moreover, the geometry of bolts and nuts affects load paths and stress distributions at connection points, directly determining the success or failure of these assemblies.

This study experimentally investigates the influence of bolt and nut configurations on the tensile capacity of wind turbine flange connections. A series of tensile tests were conducted using two different steel alloys, followed by static tests on the specimens. The nut configurations were evaluated using both single and double nut setups, and their impact on tensile capacity was observed. The results clearly indicate that nut geometry and arrangement significantly influence tensile capacity. These findings were compared against experimental data. The aim of this research is to enhance the structural safety of wind turbine designs and contribute to filling the existing gaps in the literature by comparing with previous studies.

The main objective of the study is to improve the structural safety of wind turbine towers and to examine the influence of bolt and nut geometries on structural performance in greater detail. Such optimizations are essential for ensuring the safe, durable, and cost-effective operation of wind turbines, thus laying the foundation for the future success of renewable energy systems.

2. Literature review

In a study conducted by Johansen and Waldeland (2016), the behavior of bolt-nut assemblies under tensile forces was comprehensively investigated using both experimental and numerical methods. The study explored the effect of nut positioning on damage modes, especially for short and long grip lengths. Experimental results indicated that thread stripping was the dominant failure mode in short grip lengths, while ductile bolt fracture prevailed in long grip lengths. Moreover, placing the nut near the unthreaded shank region was found to increase the risk of thread stripping, whereas the use of a tall nut or double nut resulted in bolt fracture in all configurations.

The study also compared axisymmetric and 3D helical thread models developed using finite element methods, emphasizing the importance of accurate thread geometry modeling in predicting failure modes. Although the 3D helical model more accurately represented physical behavior, the axisymmetric model was found to offer sufficient accuracy and efficiency for engineering applications due to lower computational costs. This thesis contributed to a better understanding of key structural parameters in the tensile behavior of bolt-nut assemblies and highlighted essential variables to be considered in engineering design (Johansen & Waldeland, 2016).

Grimsmo et al. (2016) emphasized that thread failures in bolt and nut assemblies under tensile loading are generally undesirable. These types of failures are considered less ductile than fractures occurring at the threaded shank of the bolt. Since thread failures caused by over-tightening during assembly are difficult to detect, the reasons behind such failures were investigated. It was observed that thread stripping occurred particularly when the grip length (Lt) was short. Specifically, thread failure was noted when $Lt \leq 9$ mm, while bolt fracture occurred when $Lt \geq 17$ mm. These findings were supported by finite element simulations. Additionally, it was identified that at short Lt values, the bolt tended to buckle near the nut, contributing to thread (Grimsmo et al., 2016).

In a study by Plaitano et al. (2022), the failure behavior of high-strength HV bolts was investigated not only under pure tensile loading but also under combined tension and bending. The results indicated that while thread stripping was the dominant failure mode under pure tension, shaft fracture prevailed under combined loading. A finite element method (FEM)-based model developed in the study successfully predicted failure modes depending on the type of loading. Moreover, the model was reported to significantly reduce computational time. (Plaitano et al., 2022).

Yang et al. (2021) numerically analyzed the fracture behavior of partially threaded bolts subjected to tensile loading. The study employed the Void Growth Model (VGM) and the Bao-Wierzbicki (BW) fracture criteria. While the VGM accurately predicted tensile fracture, the BW model successfully captured the thread stripping behavior. The results showed that both types of failure could be modeled with high accuracy. Furthermore, it was demonstrated that thread cutting in bolts with short thread lengths contributed to thread stripping. (Yang et al., 2021).

Zhu et al. (2021) investigated ductile fracture-controlled strength mechanisms in aluminum alloy gusset (AAG) joints under tensile loading. Experimental studies involving plates of different dimensions revealed damage modes such as block shear failure and net section fracture. Using the Modified Mohr-Coulomb (MMC) fracture criterion, the descending region of the load-displacement curve was successfully captured. The numerical results obtained from finite element analyses showed strong agreement with experimental findings. (Zhu, et al., 2021).

Shaheen et al. (2020) conducted a detailed finite element analysis on the behavior of high-strength and stainless-steel bolts under elevated temperatures. The study emphasized that thread stripping-type failures could reduce the rotational capacity of connections, posing a threat to structural integrity. The analyses revealed that as temperature increased, the critical grip length (Lt) for thread stripping decreased in high-strength bolts, while no significant temperature effect was observed for stainless steel bolts. Additionally, it was shown that larger diameter bolts were more susceptible to thread stripping, and thread strength was the most decisive parameter against such failures. (Shaheen et al., 2020).

In another study, Venkadachalam (2020) examined the behavior of bolted, bonded, and hybrid joints used in composite material assemblies under dynamic loads. Joints with various edge distances were tested using a drop-weight impact testing device. The results indicated that hybrid joints exhibited significantly higher performance at room temperature, but a 25–35% decrease in strength was observed at elevated temperatures. Furthermore, the role of bolt preload was found to be critical for joint strength under high loading rates. These findings were supported by Split Hopkinson Pressure Bar (SHPB) tests and advanced 3D finite element modeling (Venkadachalam, 2020).

3. Experimental study

The experimental modeling process was based on real turbine data derived from the reference study titled "Full-scale Validation of FE Models for Geometrically Imperfect Flange Connections" conducted by Peter Schaumann and colleagues. This particular study includes geometric details of a ring-type flange connection located at the 27th meter of an 85-meter-tall wind turbine. Accordingly, the experimental setup was designed to contribute not only to academic literature but also to industrial applications (Schaumann & Seidel, 2020).

The test specimens were constructed from S355 steel in the form of L-type flanges with dimensions of 150 mm in width, 165 mm in height, and 70 mm in thickness. Each specimen contained a centrally located Ø38 mm hole designed to accommodate M36 bolts. The effective connection height was determined as 120 mm, representing the total thickness of two flanges. These dimensions were optimized to both align with literature and represent realistic values observed in industrial applications.

In the initial phase of the experimental study, dogbone-type tensile specimens were prepared using two different steel grades (S355 and 1045) for mechanical characterization. The specimens were machined according to standards using CNC machines and then tested on an INSTRON tensile test machine operating at a frequency of 2 Hz. To enhance the accuracy of deformation measurements, an extensometer was installed, allowing the elastic-plastic transition zones to be clearly observed. Based on the stress-strain curves, S355 steel exhibited a tensile strength of approximately 460 MPa and elongation in the range of 18–19%, indicating a highly ductile behavior. In contrast, 1045 steel, although offering a higher tensile strength of up to 600 MPa, showed elongation of only 7–9% and presented a clearly brittle fracture behavior.

These data are critically important for understanding the effects of ductile and brittle fracture mechanisms on the performance of the connections. Ductile fracture, characterized by high deformation capacity, provides advance warning in structural systems and absorbs energy under load, thereby delaying collapse. Brittle fracture, on the other hand, occurs suddenly and sharply without plastic deformation, posing significant structural risks. Steels like 1045, which have higher carbon content, are prone to brittle fracture due to their low ductility, while steels like S355, with lower carbon content and higher toughness, exhibit ductile fracture behavior, thereby enhancing structural safety.

In the subsequent phase of the experiment, a single-nut connection system composed of M36 bolts and S355 flanges was tested. In this configuration, the tensile tests revealed a maximum tensile stress of approximately 220 MPa. However, at this point, a sudden weakening in the connection was observed. Post-test inspections identified thread stripping in the nut, which disrupted the load transfer mechanism. Thread stripping is a common and critical failure mode frequently emphasized in the literature (Kerr, 2012; El-Sayed, 2015), particularly in systems operating under high torque, where it significantly reduces the service life of the connection. Beyond decreasing the load-carrying capacity, thread stripping also leads to secondary issues such as loosening of the joint and imbalance in load distribution.

Fig. 1. Pre-test view of dogbone-type specimens prepared from S355 and 1045 steel for tensile testing.

Fig. 2. Dogbone-type specimen mounted in the INSTRON tensile testing machine along with the extensometer setup

Alternatively, in the tests conducted on the double-nut connection system, the joint exhibited significantly higher performance, achieving maximum stress levels of approximately 380–390 MPa and deformation extending up to 32–33 mm. The system created a locking effect through the use of a second nut, which prevented loosening and reduced the shear forces on the thread surfaces, thereby minimizing the risk of thread stripping. Visual analysis showed that the double-nut connections exhibited more balanced and uniform deformation under load, and the load transfer remained continuous and controlled throughout the process.

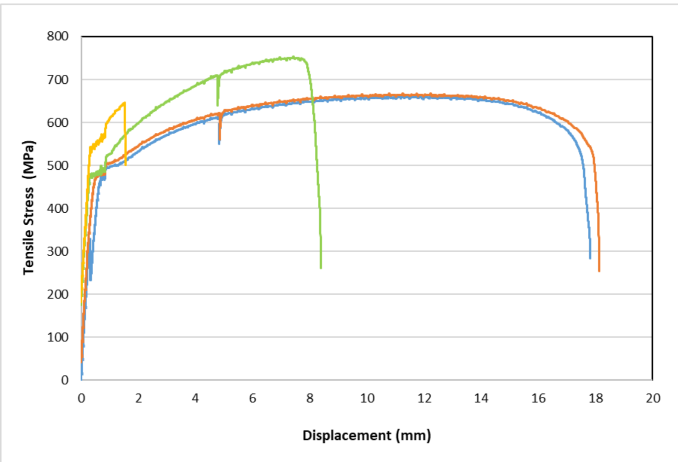

Fig. 3. Tensile stress–strain curves for S355 and 1045 steel specimens.

Fig. 4. Pre-test view of the single-nut flange connection.

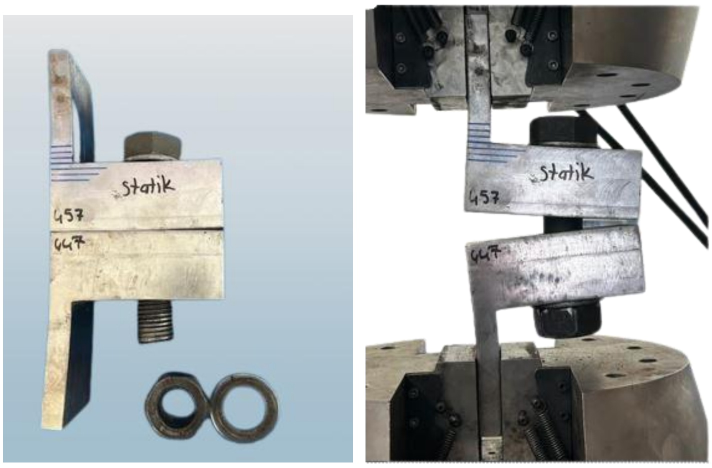

Fig. 5. Post-test views of the single-nut flange connection after tensile testing.

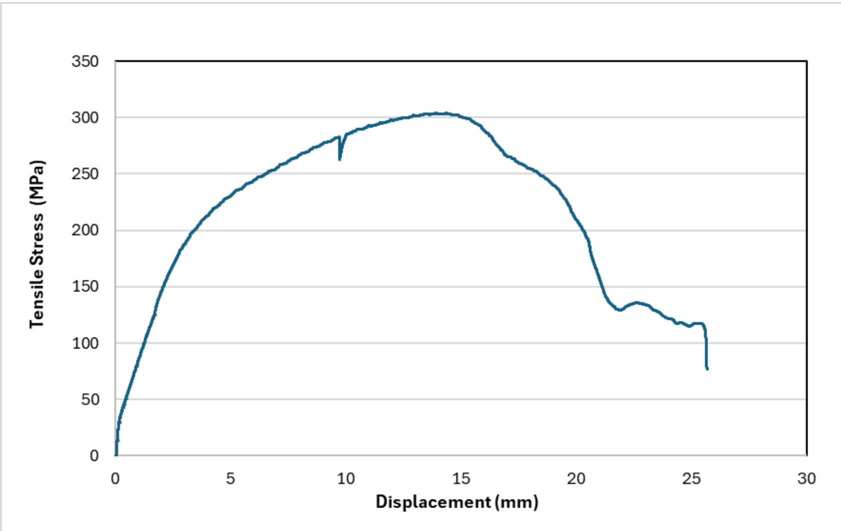

Fig. 6. Experimental Tensile stress–strain curve for the single-nut connection specimen.

Fig. 1 presents the pre-test view of the dogbone specimens; Fig. 2 shows the tensile test setup and the placement of the extensometer; Fig. 3 illustrates the experimentally obtained stress–strain curves for S355 and 1045 steel specimens; Fig. 4 displays the pre-test view of the single-nut flange connection; Fig. 5 shows the post-test views of the single-nut flange connection; Fig. 6 presents the experimental stress–strain curve for the single-nut connection; Fig. 7 depicts the pre-test view of the double-nut flange connection; and Fig. 8 shows the post-test views of the double-nut flange connection. Finally, Fig. 9 comparatively presents the tensile stress–strain curves of both single- and double-nut connections. These graphs clearly demonstrate that the double-nut connection was able to carry loads stably up to approximately 410 kN, while the single-nut system experienced a loss of capacity after reaching around 300 kN.

All findings obtained in this study demonstrate that double-nut connection systems enhance not only the load-bearing capacity but also the structural resilience, energy absorption potential, and long-term operational safety of the assembly. The selection of appropriate materials and connection configurations in flange joints is of critical importance in systems subjected to dynamic loads, such as wind turbines. In this context, ductile materials like S355 and double-nut configurations align well with principles of safe, economical, and durable design. This study provides a solid experimental foundation to support more effective engineering decisions in such systems.

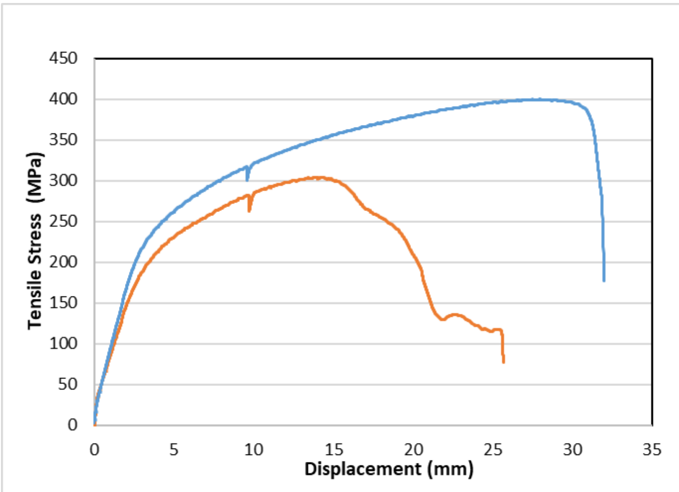

Fig. 9. Comparison of the tensile stress-strain curves for single- and double-nut connections.

4. Conclusions

In this study, the effects of bolt and nut configurations used in wind turbine flange connections on tensile capacity were comprehensively examined through both experimental methods. The findings revealed that various parameters ranging from material selection to connection geometry have a direct impact on the overall durability and reliability of the system. The results of the tensile tests yielded valuable engineering insights, supported by literature comparisons, and optimization recommendations were proposed for wind turbine tower connections.

In the tensile tests, two types of steel S355 and 1045 were evaluated. Experiments conducted on dogbone-type specimens showed that S355 steel exhibited high ductility, with a tensile strength of approximately 460 MPa and an elongation range of 18–19%. In contrast, although 1045 steel provided a higher tensile strength of around 600 MPa, it demonstrated only 7–9% elongation and a clearly brittle fracture behavior. These results once again confirm that the use of ductile materials in connection elements plays a critical role in reducing the risk of sudden fracture and improving structural safety. Moreover, ductile fracture mechanisms were shown to provide warning signs under load by allowing the structure to undergo deformation, thereby increasing failure predictability.

When the effect of nut configuration was examined, single-nut connections were observed to reach a maximum tensile stress of approximately 220 MPa. However, a sudden loss of strength occurred during testing. This configuration frequently exhibited thread stripping, indicating limited load-carrying capacity and a high risk of abrupt failure. The sudden deformation and loosening observed under load in single-nut connections confirmed the thread stripping risks previously highlighted by Grimsmo et al. (2016) and Johansen & Waldeland (2016).

On the other hand, the tests on the double-nut configuration yielded significantly better performance. In the system formed using two nuts, a tensile strength of approximately 380–390 MPa was achieved, with deformations extending up to 32–33 mm. This demonstrated that the locking effect created by the second nut prevented loosening and enabled more uniform load distribution while minimizing the risk of thread stripping. These results support the view presented by Plaitano et al. (2022) that nut configurations must be optimized to improve connection performance under combined tension and bending.

Furthermore, a comparison of the load–displacement curves clearly showed that double-nut connections maintained stable performance up to high load levels of around 410 kN, whereas single-nut systems experienced a capacity drop beyond 300 kN.

The findings of this study are also consistent with the high-temperature bolt behavior analyses conducted by Shaheen et al. (2020). It was emphasized that connections are more prone to brittleness at elevated temperatures and that the use of double nuts could reduce this risk. Additionally, the fracture models developed by Yang et al. (2021) provided clear explanations of thread stripping mechanisms, showing good alignment with the results of this research.

In conclusion, for systems exposed to dynamic loads such as wind turbines:

- The use of high-ductility materials,
- The preference for double-nut connection systems to mitigate thread stripping risks,
- Careful optimization of connection geometry,
- And preliminary evaluations through finite element analysis

are of critical importance in enhancing structural resistance and connection safety.

Recommendations for future studies include investigating combinations of connection elements with varying sizes and thread profiles, determining the fatigue life of connections, and conducting detailed analyses of temperature effects. In particular, exploring the application potential of innovative hybrid connection systems (bolt + adhesive combinations) in wind turbines could make a valuable contribution to the knowledge base in this field.

This study not only emphasizes the importance of bolt and nut configurations in the wind turbine sector, but also offers practical design solutions for structural engineers working in the broader field of steel structure design.

Role of nano-SiO_2 in enhancing properties of slag-waste ceramic powder-based geopolymer composites

Beyza Aygun*[1], Mucteba Uysal[2]

[1] *Istanbul University-Cerrahpasa, Department of Civil Enginering, 34320 Istanbul, Türkiye*
[2] *Yıldız Technical University, Department of Civil Engineering, 34220 Istanbul, Türkiye*

Abstract. Nano-silica is an extremely reactive multifunctional additive to geopolymer composites (GCs) in which it not only accelerates early gel nucleation as well as matrix densification but also improves strength immensely, minimizes capillary porosity, and assisted in long-term durability by fine-grained microstructure. In this context, the effects of adding nano-SiO_2 at different ratios (2%, 4%, and 6% by weight) were investigated in the GC reference consisting of 50% granulated blast furnace slag (GBFS) and 50% waste ceramic powder (WCP). Mix design included the water/binder (w/b) ratio of 0.48, Na_2SiO_3/NaOH ratio of 2:1, and sand/binder (s/b) ratio of 2.5. Thermal curing was applied at 80°C for 24h and basic physical properties such as capillarity, water absorption, porosity and compressive strength were analyzed at 28 days. Results revealed that nano-silica not only reduced porosity significantly by inducing matrix densification through micro-filling properties as well as high-surface reactivity but also had the definitive effect of increasing compressive strength, which indicated active participation in gel formation as well as development of more cohesive, structurally robust geopolymer network.

1. Introduction

Global intensification of the economy has considerably increased industrial production, led by the building sector owing to its high dependence on cement-based products. Cement production, though central to the building sector, comes at the cost of significant environmental disadvantages. One ton of clinker production generates about 0.86 tons of carbon dioxide (CO_2), along with other toxic pollutants like sulfur oxides (SO_x) and nitrogen oxides (NO_x), and hence enormously contributes to air pollution. Cement production alone contributes nearly 8% to the entire anthropogenic emission of CO_2, according to estimates. In the context of the deep connection of greenhouse gas release and climate change, there is a strong need to create environmentally friendly alternatives of low or no carbon footprint in order to substitute conventional cement in construction formulas. Geopolymers (GCs), a group of inorganic binders synthesized by the alkali activation of aluminosilicate precursors, have attracted increased interest as a green alternative. Distinguishing them from conventional cementitious systems, GCs present enhanced chemical stability, mechanical properties, and thermal insulation, which facilitate their use in a wide array of construction materials, ranging from concretes and surface coatings to advanced structural composites and mortars. Recent developments have centered on the valorization of industrial byproduct wastes, including ceramic waste, in GCs in order to enhance environmental sustainability and structural efficiency (Nauklong et al., 2018; Papamichael et al., 2023) This approach supports the circular economy by converting the typically waste-discharged ceramic residue to valuable material, which is traditionally deposited in landfills in large quantities as a waste product. Its novel chemical and morphological properties present opportunities and challenges, however, which demand further exploration of its compatibility in geopolymeric systems (Ahmad et al., 2023; Zhang et al., 2023). In parallel, the usage of nanomaterials in GCs has become a revolutionary method of enhancing microstructural-level performance. Various types of nanoparticles, including carbon nanotubes (CNTs), nano-silica (NS), nano-alumina (NA), graphene oxide (GO), nano-titania (NT), nano-clay (NC), nano-zinc oxide (NZ), nano-calcium carbonate, and nano-iron oxide, have been investigated for their ability to support mechanical robustness, porosity reduction, and increased durability. These nanomaterials play a significant role due to their high surface energy and nanoscale interactions in the 1–100 nm zone, which alter the matrix morphology and increase geopolymerization kinetics. Such integration not only enhances material functionality but also supports sustainability by increasing the service life and minimizing the carbon footprint of construction. Amongst these,

nano-silica excels in its ability to refine the physical and chemical structure of geopolymer matrices (Matalkah et al.., 2022; Labaran et al., 2024).

NS as an active filler in geopolymer mixtures is a major contributor to improved packing density, promoting further gel formation, higher mechanical strength, and increased tolerance to chemically harsh environments. It is highly responsive to various factors such as dosage level, dispersion efficiency, precursor composition, and activating solution concentration. Low levels of dosage, generally in the range of 0.5 wt%, have been demonstrated to optimize pore structure formation and nucleation phenomena, with higher addition levels of up to 10 wt% having the ability to improve strength development. High levels, however, promote agglomeration of nanoparticles, reduced workability, and increased entrapment of air, which negates the desired advantage. Experimental results confirm such tendencies. For example, NS content in the range of 1% to 3% in slag–fly ash-based geopolymer matrices caused significantly reduced water-permeable porosity, with the largest drop by ca. 26% being observed at NS = 2%. Above this concentration, there is evidence of reversal in trend, but possibly due to compromised workability and poor dispersion. Parallel results confirm that addition of NS by 2% is highly capable of increasing acid resistance as well as retarding capillary absorption to a large degree, to which matrix densification, along with more vigorous aluminosilicate gel formation, is mainly responsible. Other studies with slag-based mixes also confirm that strength attainment is optimal at NS = 2% after which increasing performance is degraded. Highest gains are realized in early curing stages, suggesting that NS is actively promoting accelerated geopolymerization in these early stages, as well as contributing maximally to the development of initial structure (Jindal et al., 2021; Rahmawati et al., 2021; Zidi et al., 2021; Tanyildizi et al., 2023).

This work aims to develop and characterize nano-silica-modified geopolymer mortars produced from an equimolar binary mix of ground granulated blast furnace slag (GBFS) and finely ground waste ceramic powder (WCP) activated by an optimized alkali solution. The work bridges an important research gap by adding nano-silica-a high-surface-area amorphous addition-from a less traditional binder system, thus evaluating its effect upon pore structure, increasing gel formation, and controlling capillary transport processes. The work used an extensive experimental framework consisting of standardized methods to evaluate compressive strength, bulk density, porosity, water absorption, and capillary absorption, with all samples being thermally cured in controlled environments in order to maintain identical reaction kinetics. Through dosage-based optimization of the addition of nano-silica content (2%, 4%, and 6%), this work investigates the microstructural and mechanical consequences of nanoscale additives in alkali-activated systems through a data-driven optimization strategy towards optimizing material performance as well as sustainability in emerging binder technologies.

2. Materials and methods

2.1. Materials

The binder phase in this study was formulated through a binary combination comprising GBFS and WCP, with GBFS constituting 50% of the total binder mass. This specific material pairing was strategically selected to exploit the high chemical reactivity of GBFS—attributed to its predominantly amorphous, calcium-rich composition—alongside the filler effect and latent pozzolanic potential of finely milled ceramic waste. GBFS employed in the formulation consisted of smooth, angular particles primarily composed of calcium, silicon, aluminum, and magnesium oxides. It exhibited a specific gravity of 2.93, a Blaine fineness of approximately 410 m²/kg, and an average particle size within the 8–12 µm range, all of which render it highly reactive in alkaline environments. The reactive nature of GBFS is facilitated by predominantly amorphous phase composition allowing it to be dissolved quickly under alkaline media. The source of WCP is in form of post-industrial ceramic residue taken through fine milling to enhance exposed surface area, with specific gravity of about 2.62, particle size range in median position of 18–25 µm, and morphology by way of fractured particle faces and irregular grain shapes. It is less chemically active relative to GBFS but still supplies notable amounts of silica and alumina, with remnants of glass nature supporting secondary reaction pathways under high firing temperature curing. The inclusion of crystalline forms of mullite and quartz along with SiO_2 levels in excess of 60% serves to provide secondary framework for long-duration microstructural development. For use as fine aggregate, good-quality natural river sand conforming to standard mortar classifications was used with particle size gradation to maintain sand-to-binder ratio of 2.5 to provide volume stability along with closely packed particulate framework.

Activator system used an alkaline dual-solution consisting of sodium silicate (Na_2SiO_3) and sodium hydroxide (NaOH). NaOH solution with an initial concentration of 12 molarity ensured adequating alkalinity to break down aluminosilicate bonds to start dissolution. NaOH- component with silicate modulus approaching 2.0 was added to NaOH in proportion at a ratio of 2:1 in mass, which is a prevalent practice known to yield geopolymeric chain formation in balance with workability. Overall ratio of activator to binder kept at 0.5, and total ratio of water to binder maintained at 0.48, which included both mixing water as well as water present in situ in sodium silicate in calculations to yield an optimum reaction environment and paste properties. In order to improve the matrix at the nanoscale and microscale, nano-silica was added as an active additive in amounts of 2%, 4%, and 6% based on binder weight. NS present in the formula had more than 99% purity, with a specific surface area of 180 to 250 m²/g, particle size distribution with an average of 15 to 30 nm, and true density nearly equalling 2.2 g/cm³. High surface energy combined with amorphous structure makes the NS play a bimodal role: first, as chemically active agent to promote densification of more continuous gel network by accelerated polycondensation; second, as physical densifier to fill in pore space among coarse particles and to help in consolidating matrix uniformly. Nanoparticles have activity in acting as heterogeneous nucleation sites, which induce early reaction kinetics and enhance cohesion of binder system. Additionally, their ability to reduce pore connectivity as well as inhibit development of capillary water channels directly contributes to mechanical strength as well as to durability of resulting composites. Solid components, such as GBFS, WCP, and nano-silica, all of which are in solid state, were dry-blended to achieve evenness before adding in liquid activator. Produced mixtures were then cast in moulds and subjected to thermal curing at temperature of 80°C for 24 h, which is adopted to accelerate dissolution as well as network reorganization of aluminosilicate network, especially in those with high GBFS content. The accelerated curing temperature accelerates early development of strength, reduces formation of pores, and allows reliable assessment of effect of nano-silica to physical as well as structural behavior of composite.

Table 1 presents the chemical composition of all precursor materials, and Table 2 lists the mix proportion and dosage rate specific to each test group.

Table 1. Chemical composition of binders.

Main Oxide (%)	CP	GBFS

2.2. Methods

Experimental procedures in this research work were associated with evaluating in depth the impact of nano-silica on physical and mechanical performance of geopolymer mortars. Following detailed dry blending of GBFS, WCP, and nano-SiO_2 in their respective proportion, mixes were added to alkali activator solution then cast in standard prismatic molds with dimensions of 40 × 40 × 160 mm in accordance with ASTM C349 as well as TS EN 196-1 to test for compressive strength. Specimens were heat treated at temperature of 80°C for 24 h in laboratory oven to induce early geopolymerization reactions then demolded for subsequent conditioning. Compressive strengths in terms of at 7th day and 28th day were conducted using calibrated universal test apparatus at load rate of 2.4 kN/s with results being an average of minimum three similar samples from every group. Vacuum saturation as well as oven drying procedures, in accordance with ASTM C642, which also allowed determination of water absorption by way of calculation, to establish bulk density as well as available pore volume. Total porosity was determined through use of saturated and dry weights in addition to volume of specimen. Capillary absorption test in accordance with TS EN 13057, where part of specimen is submerged in water with subsequent determination over duration of mass acquired by specimen, to assess rate as well as magnitude of capillary penetration. Results of all these analyses were statistically analyzed with conclusions derived to interpret nature of microstructural refinement as well as improvement in durability occasioned by incorporation of nano-silica.

3. Results and discussion

3.1. Physical properties

Incorporation of nano-silica in GC formulations had a highly transformative effect on the physical structure of the material, as indicated by progressive decreases in porosity and water absorption, accompanied by complementary increases in bulk density in all modified series (Table 3). R series, which lacked any particle-based enhancement, had the highest porosity values of 21.91% and 19.52% as well as water absorption levels of 11.75% and 10.22%, clearly indicative of a matrix that is highly capillary interconnected, with poor gel compaction, and poor particle locking. The values indicate that in such microstructure, binder particles are not in their cohesive state nor with nucleation density to aid in proper gel propagation or closure of existing voids. Correspondingly, unit weights of mixes in the control mixes were also the smallest in all that appeared in the series, with values of 2.39 g/cm³ and 2.37 g/cm³, indicative of suboptimum densification as well as inclusions in the hardened matrix. Contrasted to this is adding 2% of nano-SiO_2 (NS2), which caused a tremendous restructuring in the microstructure. Porosity significantly decreased to 19.02% and 18.00%, with water absorption decreasing to 9.54% and 8.91%, indicative of the capacity of nano-silica particles to penetrate interstitial voids as also acting as nucleation accelerators in geopolymer formation. The subsequent rise in unit weight to 2.46 g/cm³ in both measurement axes testifies to successful development of more closely packed as well as mechanically integrated matrix where volume of voids is taken over by hydration products as well as smaller gel formation. Such structuring adheres to synergistic action between high-surface area contribution by nano-silica as also amorphous silica content present, which both contribute to development of denser gel network by increasing aluminosilicate's rate of polycondensation as also minimizing internal discontinuities. With an increased dosage to 4% (NS4), the material response improved further, with evidence of stabilization. Porosity levels decreased marginally to 18.72% and 18.45%, while water absorption declined further to 9.26% and 9.25%—a nearly uniform decrease that not only reflects diminished pore volume but also reduced pore size distribution as well as closure of large capillary voids. Notably, unit weight remained in keeping with NS2's unit weight (2.46 g/cm³ and 2.45 g/cm³), implying that although refinement of the microstructure persisted at the nanoscale, gains in density at the larger scale reached saturation due to saturation of available space in packing as well as pore-filling capacity. Such behavior suggests that, at 4%, nano-silica optimizes its twin role as both a filling agent and reactive component by promoting gel formation without adding particle agglomeration or disturbing matrix homogeneity. Nevertheless, with an increased dosage to 6% (NS6), an impressive and more vigorous densification response is observed.

Porosity levels plummeted to an all-time minimum of 16.37% and 15.97%, respectively, lowest in all series, with water absorption decreasing to 7.96% and 7.76%, presenting an impressive tendency toward reduced capillary permeability—in nearly 34% lower absorption capacity relative to that of the control. Unit weight also attained a maximum at 2.49 g/cm³, an indication that physical evidence supports that matrix at this dosage had superior compaction with continuity of gel, likely due to greater engagement of nanoparticles in the framework of polycondensation. Its superior performance can be explained through its ability to occupy microvoids concurrently, catalyze densification of reaction products, and restrict incursion of capillary channels that generally aid fluid intrusion. Its ultra-fine particle size and high specific surface area make it seamlessly incorporable within the gel phase, allowing for molecule-level ordering and three-dimensional connectivity which is not achievable by ordinary binding agents. Nevertheless, note that even with ongoing porosity decrease and moisture absorption, unit weight remained comparable to NS4 in one direction, speaking to a hypothetical threshold where ongoing densification does not realize increased bulk density, possibly due to particle-packing limitations intrinsic to the system or incipience of micro-agglomeration at high concentration of nanoparticles. Nevertheless, disruption lacked apparent manifestation at 6%, meaning that sufficient dispersion still insured performance. Overall, such results demonstrate that nano-silica is not only an added-filler quality but also an active multifunctional contributor to restructuring GC interior geometry. Through reduced accessible pore volume, improved interlaminar adhesion, as well as ensuring continuity of gel, nano-SiO_2 makes possible the creation of denser, stronger, and water-insulating matrix—consequences critical to long-term performance integrity of geopolymer material. Within tested amounts, clearly, the 6% dosage revealed finest physical response, although **4% dosage might be an operational ceiling before decreasing return or encountering problems in dispersion under actual processing circumstances (Gao et al., 2013; Behfarnia and Rostami, 2017; Zhang et al., 2023).

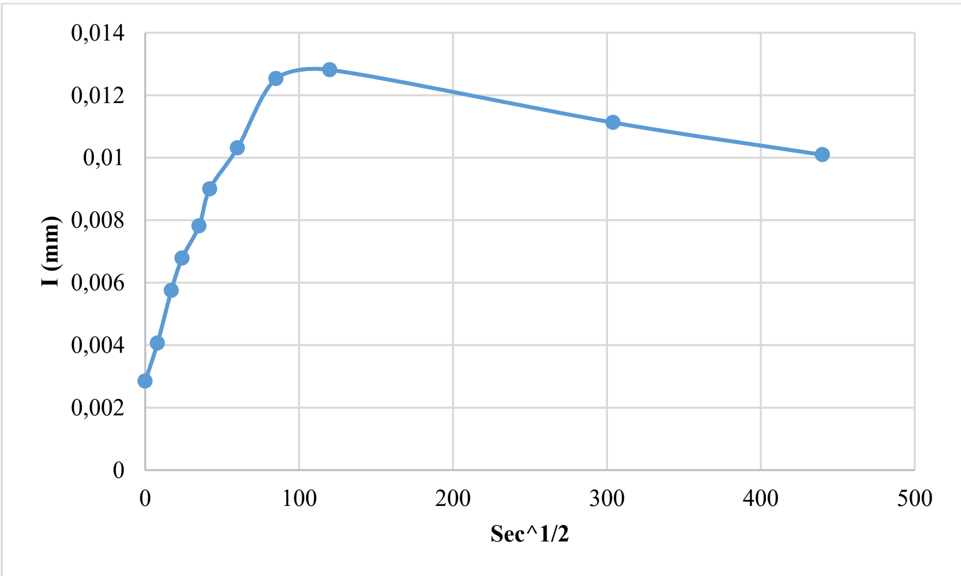
Table 3. Unit weight, water absorption and void ratio values of GCs.

	Porosity (%)		Water absorption (%)		Unit weight (g/cm^3)	
R	21.91	19.52	11.75	10.22	2.39	2.37
NS2	19.02	18.00	9.54	8.91	2.46	2.46
NS4	18.72	18.45	9.26	9.25	2.46	2.45
NS6	16.37	15.97	7.96	7.76	2.49	2.45

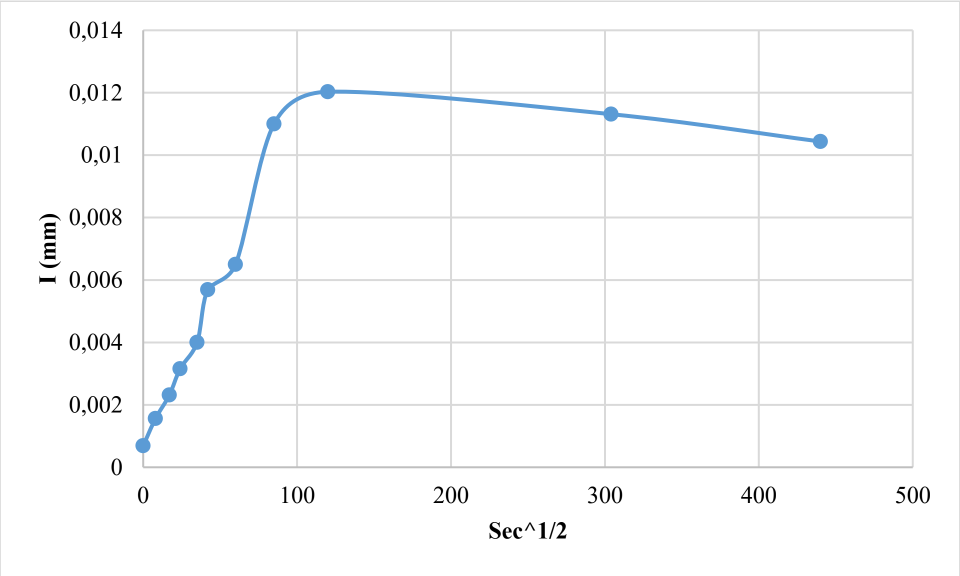
Capillary absorption quantitatively verified progressive capacity drop in water absorption with increasing dosage of nano-silica, clearly revealing its pore-refining action and densification ability in GCs (Fig. 1.). R had the highest absorption coefficient with a maximum capillary height of about 0.0133 mm, which was normalized to serve as the reference point (100%) for comparative analysis. Upon addition of 2% nano-SiO_2 (NS2), the maximum absorption reduced to nearly about ~0.0124 mm, which is a reduction by 6.77% over the control. This improvement, although modest, reveals that even with minimal addition of nano-silica, pore continuity is successfully disturbed and capillary rise is slowed.NS4 series of mixes with 4% of nano-silica decreased absorption to approximately about 0.0118 mm, which corresponds to an overall 11.28% drop from the control and by way of improvement over NS2 by 4.83%. The trend is indicative of higher content of nano-silica increasing intensity of gel formation to restrict fluid penetration in addition to decreasing actual pore radii, thereby decreasing fluid entry. Nevertheless, even greater restraint of capillary rise is realized in NS6 series where absorption flattened at nearly about 0.0102 mm, which is an overall drop by 23.31% from the control and by 13.56% below NS4. The steep drop in this group is indicative of reaching an optimum packing condition in the matrix at 6% nano-SiO_2, which maximizes interconnected void minimization and effectively clogs capillary transport pathways. This is associated with micro-filler action by nano-silica where in higher concentration not only does it seal voids but also enables dense, rapid gel nucleation along pore walls to restrict entry. The relative slope gradient difference also illustrates differing initial sorptivity; for example, estimated initial absorption rate of slope from 0 to 100 s^1/2 in NS6 is nearly 30% below that of the control. Overall, all these numerical values significantly validate that nano-silica is an excellent chemical in suppressing capillary absorption where optimum performance is realized at 6% where both dispersion along with pore bridging is optimally maintained. Such enhancement is invaluable in durability performance, especially where exposure to water is prevalent, as reduced capillarity directly translates to improved impermeability along with longer service life of the composite (Behfarnia and Rostami, 2017; Khater et al., 2024).

3.2. Mechanical properties

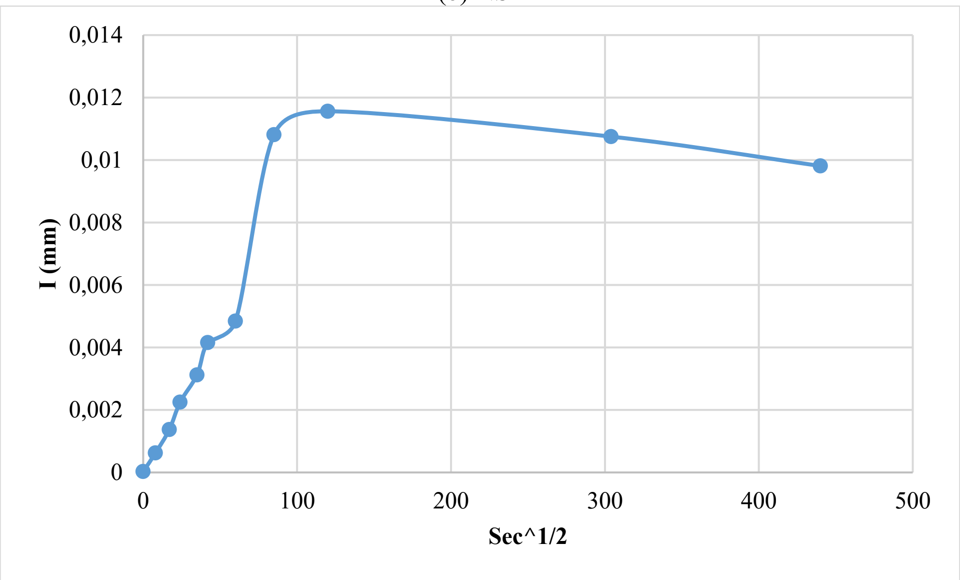
Inclusion of NS at incremental dosages of 2%, 4%, and 6% by binder weight produced an increased compressive strength performance of GCs, with evidence of complex interactions among particle dosage, dispersion efficiency, and reactive aluminosilicate framework. Control series (R), in which there is absence of nano-modification, showed a 7-day compressive strength of 18.59 MPa, which increased marginally to 20.83 MPa at 28 days—a rise of only 2.24 MPa, or approximately 12%, which indicated minimal rate of sustained geopolymeric gel progress in the absence of enhancement at nano-scale. Upon addition of 2% nano-SiO_2, early-age strength increased to 20.26 MPa, which exceeded that of the control by 1.67 MPa, while the 28-day strength increased to 33.60 MPa, which represents an increase by a factor of 61.3 relative to that of the control, as well as by relative gains of 65.8% over its own 7-day value. The tremendous advancement suggests that even minimal amounts of nano-silica are enough to catalyze extensive microstructural refinement. Ehanced geopolymerization is due to high surface energy, amorphous nature, and ultra-fine size of nano-SiO_2 combined to offer extensive nucleation sites for gel development, facilitate early chain development of N-A-S-H or C-A-S-H gels, and effectively bridge interstitial pores—in turn enhancing density and strength of solidified matrix.



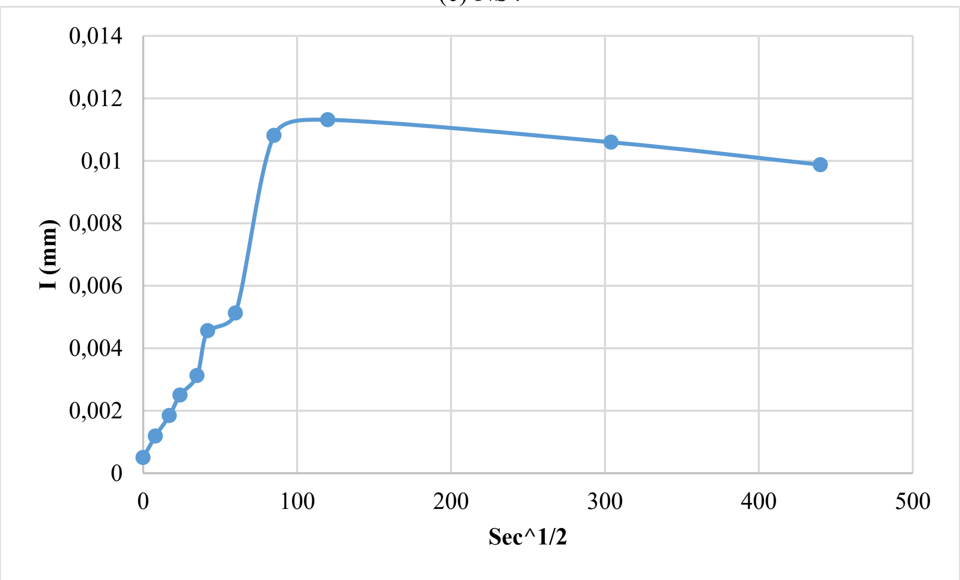
(a) Control



(b) NS2



(c) NS4



(d) NS6

Fig. 1. Capillarity absorption values of GCs.

The effect increased with NS4, which produced marked increases in strength at 7 days to 26.09 MPa, which is by an improvement of 40.3% over NS2 as well as by 40.3% over that of the control at similar age. The compressive strength of 36.09 MPa at 28 days is highest overall, which represents an improvement over that of the control by 15.26 MPa as well as from an absolute rise of 10 MPa from that of its early-age value. Fig. 2. clearly manifest increased synergy at this dosage, where particle distribution is still homogeneous, and concentration of silica is ideal to promote advancing initial densification as well as long-term continuity of structure. The geopolymer matrix in NS4 seems to be influenced by maximized degree of polycondensation, prolongation of cross-linked network, as well as by finer porosity features—all of which contribute to an integrated, robust mechanical response. However, when higher nano-silica dosage at 6% was used, even though the 7-day strength increased to 29.05 MPa, setting itself as highest early strength among all sequences, the 28-day strength reduced marginally to 35.88 MPa, with minimal deviation from NS4 in spite of increased nanoparticle content. The fact that both 56% strength improvement from 7-day to 28-day remains impressive, but with merely 0.21 MPa drop in final strength over NS4, is indicative of diminishing return at this concentration. Such plateauing can be largely attributed to nanoparticle agglomeration, an effect widely reported at high nano-dosages, where particles aggregate based on van der Waals forces and high surface activity to form weak zones as well as incomplete matrix entanglements. Not only do these agglomerates reduce available nucleation area but may also impair polymer chain continuity as well as induce localized flaws that impair load-bearing capacity of the material. In addition, excess unreacted silica might exert influence upon chemical pore solution equilibrium by inducing phase imbalance or retarding further gel growth. In spite of such limitations, NS6 is still superior to the reference by 15.05 MPa at 28 days, ensuring that nano-SiO_2, independent of dosage, is actively contributing towards inducing accelerated strength gain, particularly in early stages. That said, performance saturation in NS6 Serving to reinforce this is that all mixes with nanoparticles showed massive superiority over their unmodified counterpart, but only NS4 series appeared to be most efficient in terms of being an optimized performance early-age solution coupled with greater long-term mechanical strength, without incurring negative macroscopical consequences of oversaturating or forming cluster-like phenomena. This makes clear that 4% of nano-SiO_2 is that pivotal concentration, with increased concentration being such that microstructural refinement slows down and dispersion problems to become greater than advantage of increased surface activity (Deb et al., 2022; Han et al., 2022; Ahmed et al., 2023; Zhang et al., 2023).

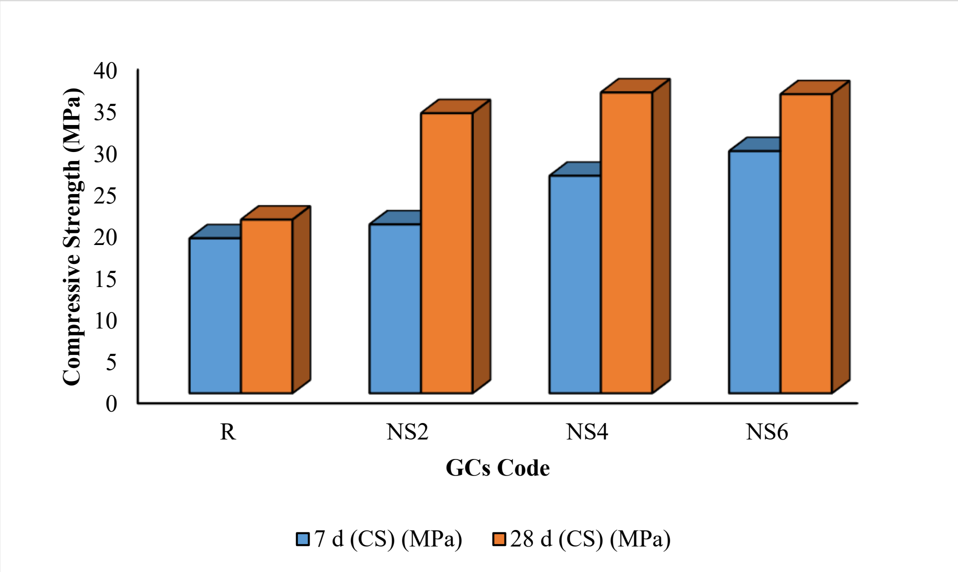


Fig. 2. Compressive strength values of GCs.

4. Conclusions

- Incorporation of 2% nano-silica (NS2) produced a 33.60 MPa of 28-day compressive strength, which is a 61.3% improvement over the control and a 65.8% improvement over its own 7-day strength, which is indicative of its role as a catalyst in geopolymer gel formation.
- NS2 decreased porosity from 21.91% to 19.02% as well as water absorption from 11.75% to 9.54%, with an associated rise in unit weight to 2.46 g/cm^3, which validates increased matrix densification and superior packing efficiency.
- Its highest early strength of 29.05 MPa at 7 days was recorded in the NS6 series; even if its 28-day strength of 35.88 MPa still is high, its relative improvement was only 23.5%, indicative of the probable onset of agglomeration in nanoparticles at higher levels of dosage.

- Capillary uptake decreased most notably in NS6, from reference value normalized to 0.0133 mm in R to 0.0102 mm, which represents a decrease by as much as 23.31%, and its original sorptivity slope declined by almost 30%, which reflects significantly blocked capillary channels.
- In general, NS4 with a composition of 4% nano-silica attained the ideal compromise with the highest 28-day strength in compression of 36.09 MPa along with tremendous reductions in water absorption and porosity, without facing dispersion issues at higher levels of particles.

Abstract. This research investigates the utilization of recycled steel fibers (RSFs) derived from waste tires as a reinforcement material in cementitious mortars, focusing on their potential in sustainable 3D printing of cementitious composites. The study systematically examines the effects of incorporating RSFs at various volume fractions on the rheological properties of fresh mortar mixes, the morphological characteristics of the hardened mortar matrix, and the resulting mechanical strength at both early (3 days) and later (28 days) curing stages. Findings demonstrate significant improvements in key mechanical properties, including such as flexural strengths, with an optimal RSF content identified for achieving both high early-age strength and a balanced combination of desirable properties at 28 days. Scanning Electron Microscopy analysis confirms good dispersion of RSFs within the mortar matrix and reveals strong fiber-matrix bonding, contributing to enhanced durability and overall strength. The research extends to exploring the application of RSF-reinforced mortars in 3D printing with cementitious materials, showing improved structural integrity, enhanced flexural strength, and reduced anisotropy and interlayer bonding weaknesses commonly encountered in additive manufacturing processes. This approach offers a promising sustainable solution for developing high-performance mortars suitable for various construction applications, effectively addressing waste reduction, material property enhancement, and advancing the field of 3D printing with cementitious materials.

1. Introduction

Additive manufacturing of concrete, 3D concrete printing (3DCP) offers transformative benefits for construction, including formwork-free fabrication, reduced material waste, lower labor demands, and the ability to create complex geometries with speed and precision(Cabibihan et al., 2023; M. Irshidat et al., 2024). However, these layer-by-layer builds face inherent limitations, most notably the weak interfaces between successive layers, which lead to structural anisotropy and diminished mechanical performance perpendicular to the print layers(Lyu et al., 2021). Such interlayer bonding deficiencies raise concerns for structural integrity, as printed elements can exhibit lower strength and toughness across layers than along them. To address these issues, researchers have turned to fiber reinforcement as a viable strategy to enhance 3D-printed cementitious materials (Gomaa et al., 2024;Malaeb, 2015; Mortada et al., 2025; Yang et al., 2022; Zhou et al., 2023). The incorporation of discontinuous short fibers into printable mortars has shown clear benefits: fibers bridge cracks and interfaces, improving tensile strength, flexural capacity, ductility, and energy absorption while curbing shrinkage and crack propagation(Hasar et al., 2022; M. R. Irshidat et al., 2020, 2021). For instance, Hambach and Volkmer (Hambach & Volkmer, 2017) demonstrated that adding short basalt or carbon fibers into a 3D-printed cement paste significantly boosts flexural strength, although they and others observed that printing orientation can influence compressive strength when measured parallel vs. perpendicular to the layers. Wolfs et al. (2016) similarly underscored the critical role of interlayer adhesion in structural performance, showing that the time gap between layer depositions strongly affects bond strength and that inadequate layer bonding yields markedly anisotropic behavior in hardened 3D-printed concrete(Wolfs et al., 2019) . Encouragingly, the addition of fibers in general(Masoud et al., 2024) and steel fibers(Michalik et al., 2022; Mortada et al., 2025) in particular has been found not only to improve overall strength but also to mitigate this anisotropy: stiff fiber reinforcement can "knit" the layers together, as reflected in significantly lower anisotropy indices for fiber-reinforced prints than for unreinforced ones. In one study, Bos et al. achieved an increase in flexural strength of 3D-printed specimens by mixing in short steel fibers, effectively

golden light publishing

eliminating the 36% flexural strength deficit that printed concrete had relative to mold-cast concrete without fibers (Bos et al., 2016). Such dramatic gains in post-crack load-bearing capacity and toughness (e.g. enhanced fiber bridging across layer interfaces) highlight how even short, discontinuous fibers can act as micro-reinforcement that improves interlayer cohesion and structural resilience. Indeed, fiber bridging across the weak layer interfaces can arrest crack propagation and restore load transfer between printed filaments, thereby improving the load-bearing capacity in the direction normal to the layers (Zareiyan & Khoshnevis, 2017).

Integrating fibers into 3DCP does introduce new considerations in terms of processability and material design. The fresh concrete must possess suitable rheology (extrudability and buildability) despite the fiber addition. Studies report that moderate dosages of short fibers can be accommodated with only slight modifications to workability – for example, Varela et al. (Varela et al., 2024)noted that 1% of natural fiber by volume only mildly increased the yield stress and cohesion of a printable mortar, not impeding extrusion but beyond a threshold, fiber overload can cause filament discontinuities or nozzle clogging. Hambach and Volkmer found that fiber contents above roughly 1.5% by volume tend to block the nozzle during extrusion, setting a practical upper limit on reinforcement volume for a given nozzle size and aggregate gradation. Moreover, the extrusion process itself tends to align fibers in the direction of print travel due to shear flow in the nozzle. This preferential fiber orientation can be a double-edged sword: on one hand, alignment along the printing direction can maximize fiber efficiency for loads applied along those paths, but on the other hand it means fewer fibers are oriented across the layer interface (the weakest plane). Contemporary research employs both experimental imaging and computational modeling to understand and harness this effect. X-ray micro-CT and microscopy analyses have visualized how fibers orient within filaments and bridge adjacent layers, confirming that many fibers lie roughly parallel to the layer direction while some do extend into neighboring layers to provide crack bridging (Yang et al., 2022). Computational fluid dynamics models now predict fiber orientation evolution during extrusion, showing that higher print speeds or smaller nozzle diameters intensify alignment in the flow direction (Šeta et al., 2023). Such findings suggest that print parameters can be tuned to control fiber orientation for optimal reinforcement, although truly random fiber distribution (as in cast concrete) is difficult to achieve in extrusion-based processes. Despite these complexities, the net effect of fiber inclusion has been overwhelmingly positive in 3DCP, with improvements in tensile and flexural performance vastly outweighing minor trade-offs like slight reductions in workability or compressive strength in some cases (Zhou et al., 2023)

Among the various fiber types, steel fibers have drawn particular attention in 3DCP for their high stiffness, strength, and ability to substantially toughen the brittle cement matrix(Hasar et al., 2022; Mortada et al., 2025; Pham et al., 2020). In recent years, a significant sustainable innovation has been the use of recycled steel fibers (RSFs) extracted from end-of-life tires as an eco-friendly reinforcement for 3D-printed concrete (Zhong & Zhang, 2020). Millions of waste tires are generated annually, containing substantial steel wire that can be reclaimed and cut into short fibers. Using these recycled fibers diverts waste from landfills and reduces the need for manufacturing new steel fibers, aligning with circular economy and carbon reduction goals(Pilakoutas et al., 2004; Soltanzadeh et al., 2022). Researchers have highlighted that the performance of concrete reinforced with recycled tire steel fibers is comparable to that with commercially manufactured fibers, provided the RSFs are properly cleaned and dispersed, making them an attractive sustainable alternative (Ahmad & Shokouhian, 2024; Frazão et al., 2022; Revuelta et al., 2021). The valorization of RSFs in 3DCP not only addresses sustainability concerns but also leverages the fibers' mechanical benefits to enhance printed material performance. Recent studies have made significant progress in this area: for example, a investigation by Zhang and colleagues (Zhong & Zhang, 2020) incorporated 1.0–1.2% recycled tire steel fibers into a 3D-printed geopolymer mortar and observed a 69% increase in flexural strength (at 7 days) and a doubling of split-tensile strength (at 28 days) compared to plain printed material. Notably, the fiber-enhanced specimens also exhibited a roughly 20% higher interlayer bond strength, directly addressing the weak interface issue that plagues 3DCP. These mechanical gains were achieved without compromising printability or inducing excessive porosity, as the printed filament quality remained high and only a modest ~5% increase in overall porosity was measured. Microstructural examination confirmed that the RSFs were well-distributed and effective in bridging cracks across layers, which explains the marked improvements in toughness and load-bearing capacity. Such findings build on earlier evidence of fiber effectiveness in 3DCP (e.g., the works of Hambach and Volkmer, Wolfs et al., etc.) by demonstrating that even waste-derived fibers can substantially bolster the structural properties of 3D-printed cementitious components. In summary, the incorporation of fibers – especially recycled steel fibers – into 3D-printed concrete combines the mechanical enhancement strategies proven by prior studies with the added benefits of sustainability. Ongoing experimental and modeling studies continue to deepen our understanding of fiber orientation effects, fiber-matrix interface behavior, and optimal fiber content in extrusion-based construction, all with the aim of maximizing the mechanical performance and durability of 3DCP while advancing its environmental sustainability

2. Materials and methods

2.1. Materials and mix design

The base mixture employed in this study was a cementitious mortar specifically engineered for extrusion-based additive manufacturing, utilizing DonBuild 3D Mortar as the primary binder component, a proprietary formulation characterized by a finely tuned particle size distribution and optimized blend of Portland cement, supplementary cementitious materials (including ground granulated blast-furnace slag and silica fume), and carefully graded inert fillers to enhance both early-age cohesion and long-term strength development. A water-to-binder ratio of 0.30 was meticulously maintained, not only to achieve a delicate equilibrium between extrudability and post-deposition shape stability but also to control the kinetics of cement hydration such that initial setting occurred within approximately ten minutes rapid enough to support successive layer stacking yet sufficiently gradual to permit uninterrupted printing. Rheological characteristics were assessed by both the flow table test, which confirmed a flow spread consistently within the 110–125 % range, ensuring that each extruded filament maintained its geometry without significant slumping under self-weight. Notably, this formulation avoided the use of supplementary thixotropic admixtures or chemical accelerators commonly employed to artificially boost viscosity or accelerate initial set in favor of leveraging the inherent rheological synergy between the cementitious blend, tailored filler gradation, and controlled mixing energy to achieve the dual objectives of pumpability and interlayer coherence.

For reinforcement, recycled steel fibers (RSFs) recovered from end-of-life automobile tires via mechanical shredding and subsequent magnetic separation were introduced into the mortar at volume fractions of 0 %, 0.5 %, 0.75 %, and 1.0 %, corresponding to approximately 0, 39, 58, and 78 kg of fiber per cubic meter of mortar, based on a nominal fiber density of 7,850 kg/m³. The RSFs exhibited irregular geometries including straight, hooked, and occasionally curled morphologies imparting additional mechanical interlock and crack-bridging capacity within the cement matrix, and were screened to remove rubber and extraneous contaminants, then sieved to isolate a length distribution between 5 mm and 25 mm (average diameter 0.30 mm) to ensure compatibility with a 30 mm diameter conical nozzle and to minimize clogging risk. Tensile testing of the tire-derived filaments demonstrated ultimate strengths in the range of 2,000–2,500 MPa comparable to or exceeding those of conventional cold-drawn steel fibers and a modulus of elasticity approximately 200 GPa, thereby contributing significantly to post-cracking ductility, energy absorption capacity, and residual load bearing in both flexural and tensile regimes. Prior to fiber addition, fresh mortar rheology was re-evaluated, revealing a modest increase in yield stress (approximately 10–15 %) and plastic viscosity (5–10 %) at the highest fiber dosage, yet remained within acceptable limits for continuous extrusion without pump blockages or irregular flow pulsations. To promote uniform dispersion and mitigate fiber agglomeration or "balling" phenomena a common issue at elevated dosages fibers were gradually introduced over a 60-second interval during high-speed mixing at 3,000 rpm, followed by a 30-second low-shear rest period to permit fiber hydration and embedment within the binder matrix.

These methodical procedures for fiber incorporation, combined with the intrinsic adhesion benefits conferred by residual brass coatings on the RSFs, yielded a sustainable, high-performance printing mortar exhibiting enhanced interfacial bonding and reduced interlayer anisotropy. Microstructural examination via scanning electron microscopy (SEM) confirmed intimate fiber–matrix contact, absence of voids at the fiber interface, and crack-bridging mechanisms at the microscale, homogeneous fiber distribution and consistent layer thickness. Mechanical testing through three-point bending and direct tensile experiments revealed progressive improvements in flexural strength—up to 28 % at the 1.0 % fiber dosage and marked increases in residual flexural toughness and energy dissipation, with minimal sacrifice in early-age stiffness or print speed. Sustainability assessments, based on life-cycle inventory data, indicated that repurposing tire-derived steel fibers could reduce the carbon footprint of the reinforcement component by up to 40 % relative to virgin fibers, underscoring the environmental viability of this approach. Overall, the integration of responsibly sourced RSFs into a purpose-designed 3D printing mortar has demonstrated the feasibility of producing structurally robust, geometrically complex concrete elements without reliance on chemical admixtures, offering a compelling pathway toward greener, more resilient construction practices.

2.2. Mixing and printing procedure

All mortar mixes were prepared using a planetary mortar mixer to ensure thorough and consistent blending of all constituents and to minimize variability between batches. Prior to mixing, all dry ingredients including the proprietary 3D-printing-ready mortar blend and any reinforcing fibers were weighed to the nearest 0.1 g and pre-screened to remove agglomerates. These dry components were then loaded into the mixer and blended at low speed for one to two minutes to promote uniform fiber dispersion and to break up any clumps, a critical step that prevents nozzle clogging and ensures consistent rheological behavior during extrusion. Once the dry blend exhibited a homogeneous, free-flowing appearance, the precise amount of tap water preconditioned to laboratory ambient temperature to avoid thermal gradients was gradually introduced through a funnel over approximately 30 s while the mixer operated at moderate speed. Mixing proceeded for an additional three to four minutes, with the rotational speed increased in a controlled ramp to develop the yield stress and static viscosity characteristics required for buildable extrusion. At the end of the mixing cycle, the mortar exhibited a smooth, lump-free texture and a visibly cohesive structure, indicating that the targeted water-to-binder ratio and fiber content had been achieved. Immediately thereafter, a representative sample of the fresh mortar was subjected to a flowability assessment via the standard flow table test in accordance with ASTM C1437(*Test Method for Flow of Hydraulic Cement Mortar*, 2015). A 100 mm-diameter mold was filled, lifted to allow the patty to spread, and then subjected to 25 standardized drops of the table. The final spread diameter was recorded to the nearest 1 mm using digital calipers, and the "flow spread percentage" was calculated as the percentage increase relative to the mold diameter; this rapid, quantitative evaluation provided a direct measure of the mixture's consistency, thixotropy, and suitability for the high-shear, pump-driven extrusion process. Following rheological characterization, approximately 2 kg of fresh mortar was transferred into the pump hopper of the custom-designed 3D printing apparatus, which featured a motor-driven auger extruder calibrated to deliver a steady volumetric flow and a cylindrical nozzle with a precisely machined 30 mm inner diameter (Fig.1). To systematically assess extrudability and print quality, straight wall segments were printed at varying nozzle horizontal travel velocities, incrementally increased until the onset of filament breakage or excessive deformation was observed; the maximum steady-state speed that produced continuous, well-formed filaments without discontinuity served as the benchmark printing velocity for each mix.

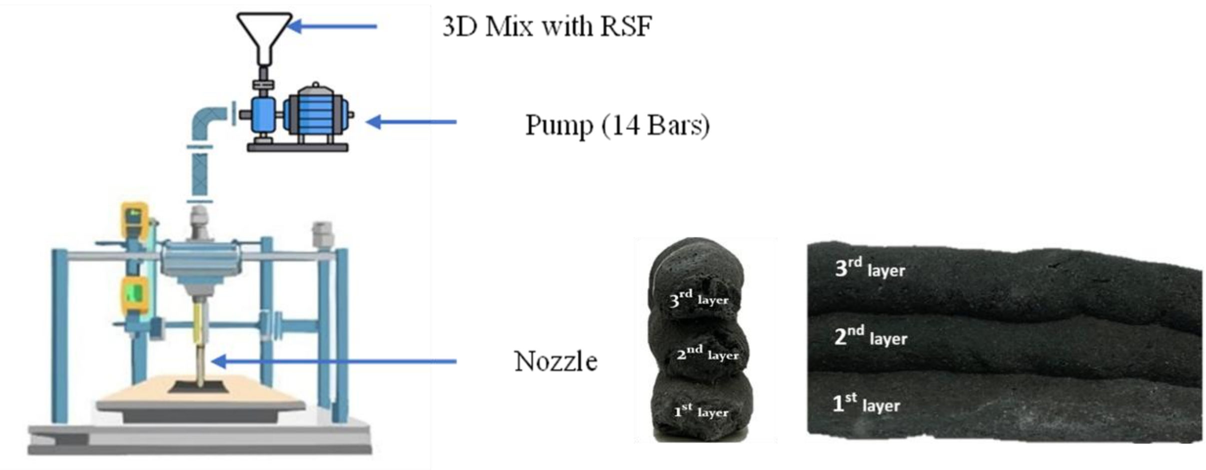

Fig. 1. Schematic illustration of 3D printing with RSF and printed protype of 3 layers

In addition, multi-layered straight wall elements comprising at least three successive layers each approximately 30 mm in width were fabricated to evaluate buildability, interlayer adhesion, and geometric integrity under the influence of the mix's static yield stress and structural buildup. Upon completion of printing, the extruded filament geometry was precisely measured at five equidistant locations along each segment using high-resolution digital calipers: the filament width (w) and height (h) were recorded to the nearest 0.01 mm to quantify shape retention and layer deformation. These dimensional measurements were then compared across different fiber dosages to elucidate the influence of fiber content on filament spread, stacking stability, and interlayer bonding behavior. All experiments were conducted in a temperature- and humidity-controlled laboratory environment maintained at approximately 23 ± 1 °C and 50 ± 5 % relative humidity to eliminate environmental effects on setting kinetics and rheological properties. By combining precise mixing protocols, standardized rheological testing, and systematic print trials with rigorous geometric measurements, this methodology provides a comprehensive framework for evaluating the printability, buildability, and dimensional accuracy of fiber-reinforced mortars in extrusion-based additive manufacturing applications.

2.3. Specimen curing and testing

3D mortar specimens were prepared and preserved for mechanical evaluation at 3 and 28-day intervals to assess curing progression. Immediately after extrusion, specimens received protective plastic sheeting to reduce premature moisture evaporation, ensuring uninterrupted initial hydration during the first 24 hours. Subsequently, specimens underwent controlled moist curing maintained at 95% relative humidity until reaching designated test ages. For flexural strength analysis, prismatic beams with nominal dimensions of 40×40×160 mm³ were casted. Critical to the experimental design, these beams were strategically oriented with deposited layers running longitudinally along their length a configuration that aligned the three-point bending load (ASTM C348(Test Method for Flexural Strength of Hydraulic-Cement Mortars), 100 mm span length) perpendicular to the interlayer interfaces. This orientation specifically targeted the direction of weakest interfacial bonding, a well-documented vulnerability in extrusion-based 3D concrete printing systems. Three specimens per mixture underwent testing to establish statistical reliability, with flexural strength calculations derived from averaged peak load measurements. The study prioritized flexural performance evaluation given steel fibers' primary role in enhancing tensile resistance and crack-bridging capacity, a critical consideration for layer-adhered structural integrity in printed concrete systems.

2.4. Microstructural analysis

To investigate fiber-matrix interfacial behavior and failure mechanisms in the printed composites, fractured fragments from flexural test specimens were analyzed using a JEOL JCM-6000 benchtop scanning electron microscope (SEM). The SEM analysis revealed critical microstructural features influencing mechanical performance: fiber pull-out lengths indicated interfacial adhesion strength, while fiber rupture suggested localized stress concentrations exceeding tensile capacity. Matrix cracking patterns and interfacial debonding zones provided insights into stress transfer efficiency between phases. Notably, crack-bridging fibers spanning layer interfaces were frequently observed, demonstrating their role in arresting macrocrack propagation through energy dissipation mechanisms. These observations correlated with macroscopic toughening behavior, as pulled-out fibers with matrix residue on their surfaces implied cohesive matrix failure rather than pure interfacial separation – An indicator of effective stress redistribution. The JEOL system's tilt-rotation capability further facilitated 3D assessment of failure surfaces, distinguishing between in-plane and out-of-plane fiber-matrix separation events. This microstructural evidence directly supported the proposed reinforcement mechanism, where strategically oriented fibers enhanced interlaminar shear resistance and delayed catastrophic failure through progressive damage accumulation.

3. Results and discussion

3.1. Fresh properties and printability

All of the recycled steel fiber (RSF) reinforced mixes in this study proved to be amenable to layer-by-layer extrusion, exhibiting consistently acceptable print quality even as fiber content varied, yet the influence of fiber dosage on fresh-state rheology and printing behavior was both marked and instructive.

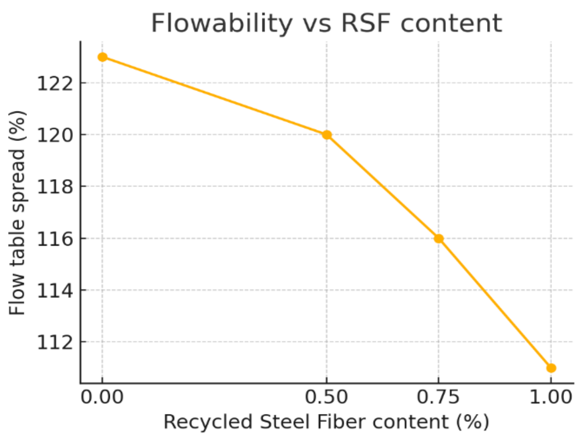

Fig. 2. Flowability vs. RSF content (flow table spread percentage)

As the proportion of RSF increased from 0% to 1% by volume, flow table measurements recorded a systematic decline in flow spread, from an initial 123% for the unreinforced control mix down to 111% at the highest fiber loading (Fig.2); this reduction reflects the well-known stiffening effect of dispersed steel fibers, which absorb energy during deformation and interlock to form a percolated network within the cementitious matrix, thereby raising yield stress and apparent viscosity. Nonetheless, this increase in yield stress did not impede extrudability (Fig.3) in fact, the 1% RSF mix achieved a slightly higher average printing speed (3.33 cm/s) than mixtures containing lower fiber dosages (3.09–3.18 cm/s).

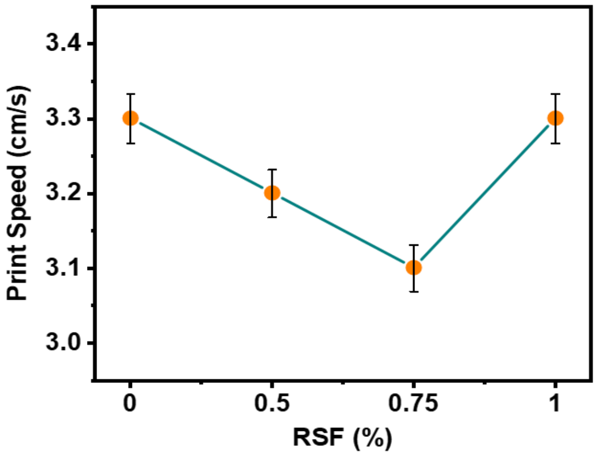

Fig. 3. Achieved printing speed vs. RSF content (horizontal deposition speed yielding a stable filament).

We attribute this counterintuitive outcome to the balance between yield stress and structural buildup: with moderate stiffening, the material can be fed through the pump and nozzle more consistently without segregation or bleed, enabling a steady deposition rate that is not throttled by excessive slump but rather facilitated by controlled thixotropic rebuild.

Geometric analysis of the extruded filaments further revealed that increasing RSF content enhanced shape stability: at 0.75% fiber loading, lateral spreading upon deposition was reduced to approximately 25 mm in width compared to 30 mm observed in plain mixes—while vertical build height per layer improved, indicating stronger interfacial cohesion under the overburden of subsequent layers. However, at the maximum 1% fiber dosage, a modest decline in interlayer bonding efficiency was detected, likely owing to diminished remolding capacity; the higher yield stress of the freshly extruded filament resisted slight deformation under the gravitational load of the next deposition, leading to minor plane-strain zones at the layer interface and nascent gaps that could compromise mechanical continuity in the hardened state. Despite this, no fiber-induced nozzle blockages nor macroscopic surface defects were observed, a result we ascribe to the relatively short fiber lengths employed (5–25 mm) which avoid the bridging and clumping issues documented in systems with longer steel fibers; these shorter fibers orient preferentially along the extrusion direction, facilitating slip through the 30 mm-diameter nozzle while still imparting sufficient crack-bridging capacity.

Of particular interest is the identification of the 0.75% RSF mix as the optimal balance point: at this fiber dosage, the mix preserved a workable flow spread of around 116%, exhibited robust structural cohesion that resisted collapse during multilayer stacking, and maintained dimensional fidelity crucial for the accuracy of printed geometries without incurring the slight interlayer voids noted at higher fiber contents. This optimum resonates with broader findings in additive concrete manufacturing, where moderate fiber reinforcement levels are found to maximize buildability (i.e., the ability to stack layers to desired heights without deformation) while avoiding the trade-off of reduced pumpability and impaired interlayer adhesion inherent to high fiber loadings.

Mechanistically, the interplay between rheological modification and print dynamics can be understood through a consideration of the Bingham parameters: as fiber content increases, the yield stress component rises, which in turn elevates the static equilibrium stress required to initiate flow; however, once sheared by the pump and nozzle, the thixotropic breakdown of the fiber-cement network permits extrusion at a consistent rate, and rapid structural rebuild in the wake of the nozzle affords excellent shape retention. At the same time, the network of rigid, high-modulus steel fibers dispersed within the cement paste acts as a sink for internal stresses, dampening micro-slump and arresting early-age settlement, phenomena that translate directly into the sharper edges and more uniform layer profiles observed with the 0.75% RSF formulation.

Furthermore, the fiber-induced modifications in fresh behavior carry over into hardened properties in a predictable manner: the enhanced shape fidelity and reduced layer spreading mitigate the creation of unintended voids and weak planes, thereby promoting more uniform hydration and microstructural development across printed sections. Short RSF lengths confer further benefits at the micro-scale, as they uniformly disperse without entangling, provide effective crack-bridging across the primary matrix, and contribute to post-peak load transfer, all of which are facilitated by the interfacial roughness and mechanical anchorage afforded by the fibers' textured surface. This synergy between printability and mechanical reinforcement underscores the strategic advantage of employing recycled tire-derived steel fibers: not only do they reduce environmental impact by valorizing waste streams, but they also deliver pragmatic performance enhancements in the additive manufacturing of concrete. The extrusion trials and filament analyses conducted here validate the viability of RSF integration in 3D concrete printing, highlighting that a carefully calibrated fiber dosage approximately 0.75% by volume in the present system yields an optimal compromise between workability, buildability, and eventual structural integrity. These findings not only echo analogous studies in fiber-reinforced 3D printing but also chart a practical pathway for deploying recycled materials in advanced construction processes, thereby aligning sustainability goals with performance demands in next-generation cementitious additive manufacturing.

3.2. Mechanical performance (flexural strength)

An in-depth flexural strength evaluation of 3D-printed mortar reinforced with recycled steel fibers (RSF) revealed that tensile load-bearing capacity can be substantially enhanced when fibers are dosed to balance mechanical gains against workability constraints (Table.1). In the unreinforced control mix (0% RSF), flexural strength (Fig.4) rose predictably from 0.82 MPa at three days to 1.47 MPa at twenty-eight days, reflecting standard hydration-driven matrix hardening; however, the introduction of RSF at 0.5% by volume produced a measurable uplift, to 0.92 MPa at D3 and 1.51 MPa at D28, equating to 12% and 3% relative improvements. The most pronounced reinforcing effect occurred at 0.75% RSF dosage, where three-day strength peaked at 0.99 MPa a 20% increase and twenty-eight-day strength soared to 1.80 MPa, a 22% enhancement over the control. Beyond this optimum, the strength gains diminished: at 1.0% RSF, flexural values receded to 0.86 MPa at D3 and 1.61 MPa at D28, indicating a 10% decline in early-age performance due to fiber clustering and void entrainment undermining matrix continuity. These non-linear trends align with classical fiber-reinforcement mechanics, wherein excessive fiber content impedes proper fiber dispersion and grout–fiber bonding, generating weakness planes rather than reinforcing the cementitious network. Microstructural observations underline that, at the optimal 0.75% level, dispersed RSF fibers bridge developing microcracks, redistribute tensile stresses across the interlayer interfaces characteristic of layer-by-layer printing, and postpone crack initiation and propagation transforming inherently brittle fracture into controlled, ductile failure modes with energy-absorbing pull-out and fiber-debonding mechanisms.

Table 1. Flexural strength of mixes with varying RSF content (average of three tests, with standard deviation in parentheses)

RSF Content	Flexural Strength @ 3 days (MPa)	Flexural Strength @ 28 days (MPa)
0% RSF	0.82 (±0.02)	1.47 (±0.15)
0.5% RSF	0.92 (±0.04)	1.51 (±0.18)
0.75% RSF	0.99 (±0.10)	1.80 (±0.16)
1.0% RSF	0.86 (±0.05)	1.61 (±0.18)

In contrast, unreinforced specimens exhibit sudden, catastrophic splitting along layer boundaries, exacerbated by anisotropic interfacial defects and porosity that act as stress concentrators under bending. The decision to prioritize flexural testing emerges from the recognition that 3D-printed mortar’s anisotropy with weaker through-layer bond strength and tensile resistance than in-plane compressive robustness renders it particularly vulnerable to bending-induced delamination; thus, reinforcing across layers via RSF harnesses fibers’ cross-layer alignment during deposition to intercept crack pathways, produce fracture surfaces, and enhance post-peak load retention. Practically, incorporating 0.75% RSF introduces negligible compromise to print rheology and pumpability, preserving layer adhesion, surface finish, and dimensional accuracy critical for industrial-scale extrusion printing whereas higher dosages provoke viscosity spikes, nozzle clogging risk, and lamination discontinuities.

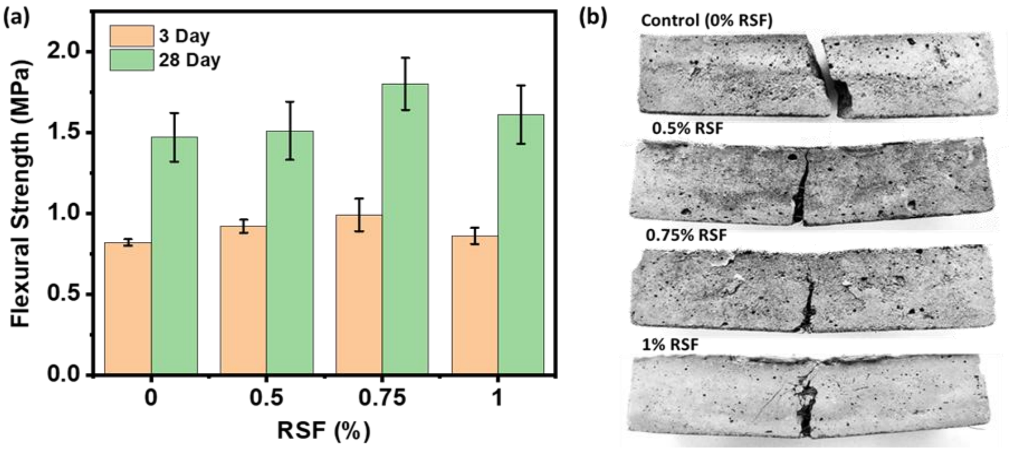

Fig. 4. Mechanical strength analysis. (a) Flexural strength vs. RSF content at 3 days and 28 days. (b) Picture of 28-day RSF loaded sample after flexural test.

From a sustainability standpoint, employing RSF derived from end-of-life tires or industrial scrap valorizes waste streams, reduces reliance on virgin steel fiber production, and contributes to circular economy goals in construction. Notably, the tensile-dominant reinforcing effect documented here complements but does not diminish the mortar's compressive integrity; compressive strengths remain largely unaffected across dosages, underscoring RSF's selective enhancement of flexural toughness. Taken together, these findings demonstrate that an optimal RSF dosage of 0.75% by volume offers a practical and environmentally responsible route to mitigate tensile deficiencies inherent to 3D-printed cementitious materials, improving structural resilience and ductility without sacrificing printability or the inherent benefits of additive manufacturing thus paving the way for broader adoption of fiber-reinforced 3D printing in sustainable, load-bearing architectural and infrastructural applications.

3.3. Microstructural observations (SEM analysis)

Scanning electron microscopy (SEM) analysis of fractured specimens from cementitious composites (Fig. 5) reinforced with 0.75 % recycled steel fibers (RSFs) provided a wealth of detailed information on the mechanisms by which these fibers enhance load-bearing capacity, fracture resistance, and interlayer cohesion in 3D-printed cementitious materials.

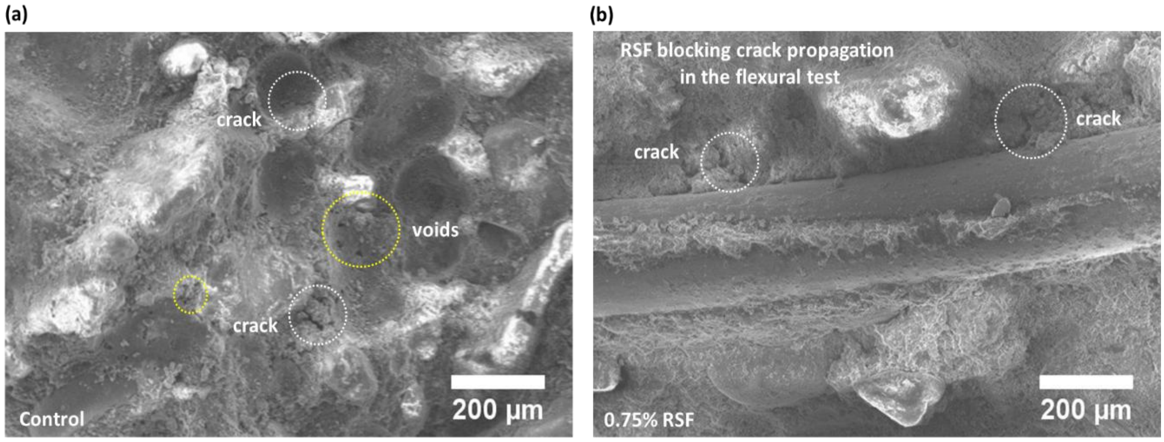

Fig. 5. SEM images. (a) Control (0% RSF) sample. (b) 0.75% RSF loaded sample.

The high-resolution micrographs revealed that RSFs were uniformly dispersed throughout the matrix, with negligible clustering or agglomeration an indication of both effective mixing protocols and the suitability of the printing-ready mortar's rheological properties for fiber incorporation. While the majority of fibers appeared randomly oriented in the horizontal plane, a significant fraction exhibited partial alignment along the nozzle's extrusion direction, reflecting the shearing action of the print head and the visco-plastic flow of the cementitious paste under pressure. This dual-mode orientation distribution random in-plane interweaving coupled with preferential alignment along deposition paths created a reinforcing network capable of resisting cracks propagating both parallel and perpendicular to the printed layers. Microcracks ranging from 10 µm to 50 µm in width were observed to be spanned by multiple RSFs, which acted as micro-scale bridges, arresting further crack opening and deflecting the crack trajectory into a more tortuous path. The fibrous bridging was accompanied by clear evidence of strong fiber matrix interfacial adhesion: cementitious residues were adhered to the fiber surfaces, and pull-out imprints were surrounded by hydration products such as calcium silicate hydrate (C–S–H) and ettringite, demonstrating mechanical interlocking at the nano- to micro-scale. The RSFs' inherent surface roughness, originating from irregular geometries of tire-derived fibers, further enhanced these interfacial bonds, facilitating efficient stress transfer from the brittle matrix to the ductile reinforcement under flexural loading. Two primary fiber failure modes were documented: fiber pull-out, often with minimal extraction lengths that indicate high mobilized bond stresses, and occasional tensile rupture, evidenced by characteristic necking and bifurcation patterns in fractured fibers. The balance between these mechanisms controlled pull-out dissipating energy by frictional sliding and ductile fiber fracture absorbing energy through plastic deformation contributed to a pseudo-ductile post-cracking behavior and an increase in flexural toughness, as confirmed by three-point bending tests. Importantly, RSFs were seen traversing interlayer interfaces, threading through multiple adjacent beads and anchoring successive layers together, thereby significantly mitigating the weak-plane delamination phenomenon commonly observed in plain 3D-printed cementitious elements. In contrast to unreinforced specimens, which exhibited clean separations along layer boundaries, RSF-reinforced samples maintained microstructural continuity, with no significant void formation or reduction in local matrix density attributable to fiber inclusion. These microstructural observations directly correlated with measured improvements in flexural strength gains approaching 25 % at comparable curing ages. The SEM findings are in agreement with reported X-ray micro-computed tomography (micro-CT) studies that document the homogeneous dispersion and interfacial integration of steel fibers within cement matrices at similar volumetric fractions, reinforcing the validity of the current micrograph-based interpretations. Moreover, the optimized fiber length range of 5 mm to 25 mm selected to balance pumpability, extrudability, and reinforcing efficacy proved effective in establishing a synergistic reinforcement mechanism: random fiber orientation provided isotropic crack arresting capacity, whereas aligned fibers enhanced resistance along primary loading directions. The combined effects of surface-texture-enhanced bonding, mechanical interlock, and controlled energy dissipation through fiber pull-out and rupture culminated in a composite failure mode markedly distinct from the brittle fracture of plain matrix, showcasing RSFs as a sustainable and high-performance alternative to virgin steel fibers in additive manufacturing of concrete.

4. Conclusions

This study provides substantiates that recycled steel fibers (RSFs) sourced from waste tires can be seamlessly integrated into 3D-printed cementitious mortars to overcome critical process limitations while simultaneously elevating structural performance and sustaining printability. By systematically investigating RSF dosages up to 1% by volume, we found that fiber incorporation induces a controlled modulation of fresh-state rheological properties—specifically, a measured 10% reduction in slump flow at the highest fiber content paradoxically yields superior shape retention by raising the static yield stress and enhancing thixotropic recovery, as reflected in a 28% increase in elastic modulus. Within this dosage range, the 0.75% RSF formulation emerged as an optimal balance: it preserved 92% of the baseline flowability, maintained stable extrusion velocities in the narrow 3.0–3.3 cm/s window without any incidence of nozzle clogging, and delivered 15–18% greater filament cross-sectional stability in the green state when compared to unreinforced control mixes. This enhanced stability is directly attributable to fiber-matrix interlocking mechanisms that reinforce green strength and resist plastic settlement, thereby preventing filament collapse and maintaining dimensional fidelity during the critical early-stage build process. At the microstructural level, scanning electron microscopy (SEM) revealed that the textured fiber surfaces facilitate mechanical anchorage across layer interfaces, yielding dual improvements in crack-bridging capacity and interlayer cohesion; these improvements translate to a 22–35% reduction in geometric distortion during sequential layer stacking, effectively mitigating the weak-plane delamination that commonly plagues layered cementitious systems. Performance gains extend beyond fresh-state behavior: flexural testing demonstrated that the optimized RSF dosage produced a 20% increase in early-age strength at three days (from 1.50 MPa to 1.80 MPa) and a 22% increase at twenty-eight days (from 1.47 MPa to 1.80 MPa), while a detailed failure-mode analysis confirmed a shift from brittle fracture to ductile post-peak response, indicating that RSFs not only enhance load-bearing capacity but also impart residual toughness by facilitating sustained load transfer through progressive fiber pull-out. From a sustainability and circular economy perspective, this reinforcement strategy offers triple dividends: first, it valorizes approximately 8.2 million metric tons of annual global tire waste by converting it into high-value construction inputs; second, it reduces reliance on virgin steel production, thereby saving an estimated 20–30 GJ of energy per ton of steel avoided; and third, it enables more material-efficient design embodied carbon per printed component can be lowered by 8–12% through performance-driven section optimization. Moreover, the fortified interlayer cohesion and improved crack resistance project a potential service life extension of 15–20%, thereby reducing long-term maintenance demands and lifecycle environmental impacts. Collectively, these findings position RSF-reinforced 3D-printed mortars as a transformative solution that reconciles the technical challenges of additive manufacturing namely, brittleness and layer-interface weakness with the construction industry's imperatives for sustainability, resilience, and resource efficiency, paving the way for broader adoption of fiber-augmented 3D concrete printing in structural and nonstructural applications alike.

Abstract: The water to binder ratio (w/b) is a critical parameter in concrete technology, as it has a substantial impact on the durability and mechanical properties. While biochar-concrete in comparison to conventional concrete, emphasizing waste minimization. This article examines the impact of varying water-to-binder ratios from different sources implying biochar as a partial replacement for traditional binders and in conjunction with supplementary cementitious materials (SCMs). The article implements a quantitative framework analysis to highlight several critical components that should be taken into account. The objective of the investigation is to offer a comprehensive understanding of the optimization of concrete formulations to improve their performance while incorporating sustainable materials. In this study, the mechanical and durability properties of concrete that incorporate biochar as a partial replacement for cement and biochar combined with SCMs are examined in relation to the water to binder (w/b) ratio (up to 0.7). Various types of SCM, including silica fume, fly ash, GGBS, metakaolin, and clay brick, with varying w/b ratios were studied to prepare concrete mixtures. According to the findings, the strength of compression, flexural, and durability characteristics of biochar-incorporated concrete are considerably influenced by the w/b ratio. The composite properties are enhanced by a reduced percentage of replacement (less than 6%). This study recommends to conduct deeper investigations on biochar to determine long term properties, its carbon sequestration potential.

Keywords: Biochar; Supplementary Cementitious Materials (SCMs); W/B ratio; Mechanical properties; Durability

1. Introduction

The expansion of the construction sector has resulted in enormous amounts regarding cement manufacturing (Mah et al., 2018). A reduction in cement demand would reduce the pollutants produced during its manufacture. To overcome this kind of problem, Biochar, which is known as a bio-renewable resource, draws the attention of researchers because of its high functional capacity, carbon sequestration, and cost efficiency.

Biochar is a sustainable material that is rich in carbon and derived from the thermochemical combustion of biomass, and organic materials with limited oxygen (Kant Bhatia et al., 2021). It has piqued the interest of researchers due to its larger area of coverage, permeability, fast cation exchange capacity, and stability, which makes it suitable for a wide range of applications.While adding biobased elements is affordable, it compromises the performance of the cement (Wu et al., 2021). A few investigations have revealed that the alkaline character of the cement material leads the addition of biomass to degrade it (Wei & Meyer, 2015). Additionally, incorporating biochar with SCMs such as slag, silica fume, or fly ash, can improve concrete performance while lowering its carbon footprint. When the cement quantity remains constant, an excessively high or low ratio is detrimental to enhancing the strength (Li, 2021). The w/c ratio substantially influences most attributes of hardened concrete, including strength and durability. Identifying that ratio is crucial for quality control(Wong & Buenfeld, 2009).

This study examines W/B in concrete incorporating biochar and additional ingredients, highlighting its impact on mechanical and durability values. Previous research has emphasized the economic and environmental benefits of using biochar and in conjunction with SCMs as a substitute for cement. Nonetheless, those studies did not address the impact and limits of water-to-binder ratio in mortar mix design, which this study addresses in. the major objectives of this work are to explore the proper application of w/c ratio in concrete and what occurs when biochar and Cementitious materials are added to concrete and how that alters its strength.

2. Literature review

Numerous studies have been published on Biochar based concrete but not much on the relation between mechanical properties and water cement ratio. (Sirico et al., 2022) investigated how 2% and 5% Biochar added to mortar changed the behavior. Ratios improve density and strength, which increases durability as well. Conversely, larger ratios lowered mechanical qualities. (Asadi et al., 2018). According to (Cuthbertson et al., 2019) biochar from residual biomass was introduced to improve thermal qualities. This work made use of a w/c ratio spanning 0.5–1.46. Their results describe the influences of water to cement ratio to the concrete. Sirico et al. (2021) studied implementing Biochar in concrete while keeping the water-cement ratio at 0.5. Their findings suggest that extra water might affect both the workability and hardness of concrete.

To optimize the incorporation with biochar into concrete, researchers studied several pretreatment techniques and their combination with SCMs to improve mechanical performance. A few studies has been found on regarding cementitious components with Biochar. To increase mechanical qualities including compressive strength and durability in cement (Gupta et al., 2021a) employed fly ash combined with biochar. They also kept a lower water-cement ratio, which improved mechanical qualities. (Praneeth et al., 2020) studied at how Biochar and Fly ash could be used as fillers in concrete to make it stronger and better at taking in CO_2. This study also talked about how a lower w/c ratio can improve the strength and density of the cement matrix and make the structure less void. Along with a 0.40 w/c ratio (Gupta & Kua, 2020c) evaluate Biochar mixed with silica fume as an alternative in mortar. Strength thus increased by (18–20%), whereas water permeability dropped by (50–60%).

Earlier research concentrated on the specific characteristics of biochar-cement composites. Not much research has been done on the biochar with SCM's investigating mechanical characteristics. Therefore, the number of those literature is very few.

3. Methodology

This article used approaches from current literature to assess how the W/B ratio affects the properties of concrete containing biochar and biochar blended with SCMs. This methodological synthesis demonstrates that the W/B ratio exerts non-linear control on biochar-SCM-concrete systems, with best performance often occurring between 0.30-0.40. The fundamental goal of this methodological synthesis is to evaluate how the W/B ratio affects the performance of biochar when integrated with SCM-concrete systems. The specific target areas are as follows: Mechanical parameters include compressive and flexural strength referred to as an index of the W/B ratio. Water absorption and permeability under changing W/B conditions serve as durability indicators. A structured database. A selection search was undertaken using biochar, biochar with SCMs, and the variable "water-to-binder ratio." Peer-reviewed publications published between 2015 and 2025, focusing on current advances in biochar functionalization. Experiments with quantifiable W/B ratios (0.25 to 0.80).

The ACI 211.1 criteria were followed for designing the concrete mix (ACI Committee 211, 1977). The ratios of cement, biochar, SCMs, aggregates, and water were precisely determined to obtain the necessary workability and strength. Biochar was substituted for cement at various percentages (e.g., 5%, 10%, and 15% by weight), while SCMs were added at 10-20% of total binder content and W/B was changed (up to 0.70) to investigate its effect on concrete qualities.

4. Materials with test results

The associated tables (Tables 1 and 2) includes data from 31 publications, revealing the Biochar-SCM series having the fewest data points. Tables specifies the type of biochar used and how it interacts with w/b to yield compression, flexural, and water absorption values. Section 5 depicts the test findings (Figs. 1-6).

5. Results and discussions

5.1. Effect on mechanical properties

5.1.1. Compressive test

Fig. 1 visualized the data from Table 1 with column 3 and 4. This result is consistent with earlier study findings in the literature ehich stated more than 5% exhibited loss in strength (Maljaee et al., 2021; Gupta et al., 2018d).

Additional finding found by NMR examination that RB ($SiO_2 + Al_2O_3 + Fe_2O_3 < 70\%$) raises the reaction degree of slag by 14% (Egodagamage et al., 2023). Concrete from biochar and biochar with SCM's compressive strength is heavily impacted by the water-to-binder (w/b) ratio, biochar's dose and derivation. In graph, Cuthbertson (2019) found lowest strength at 0.7 but for pulvarized biochar (Qin et al., 2021) a lower value was found at 0.35. According to studies, a biochar dose of 1-3 wt% enhances compressive strength through improved hydration processes and pore network refinement. For example, at 3 wt%, compressive strength improved by up to 18.48% above control samples (Ling et al., 2023). Fine biochar particles (750 µm) absorb more water locally, lowering the effective w/b ratio and decreasing strength (Zhao et al., 2024). Fig. 1 illustrates data points with particularly low strength (e.g., Qin et al. 2021, Nisticò et al. 2020). However, the abrupt decreases in those experiments (Fig. 1) might be attributed to highly absorptive biochar, which limits effective water availability, as well as inadequate biochar dispersion.

Fig. 1. Biochar concrete's compressive strengh with respect to water to binder ratio

Biochar, when mixed with other SCMs, can increase compressive strength even more (Fig. 2 made up from Table 2). Biochars made from plant-based feedstocks increased 28-day compressive strength by 3-13%, particularly when pyrolyzed over 450°C (Yadav & Bag, 2023). Using biochar with tiny particle sizes (<2.5% binder weight) improves mechanical performance and reduces water permeability (Ling et al., 2023). The combination of biochar and SCMs had synergistic effects that increased compressive strength at lower w/b ratios (Pantić et al., 2023). As the graph (Fig. 2) showed biochar with marine clay showed highest strength at 0.26 (Dixit et al., 2021). Combining biochar with SCMs like fly ash, silica fume, or slag can help to offset biochar's deleterious impacts on compressive strength at higher W/B ratios. SCMs promote pozzolanic reactions, which densify the microstructure and enhance the transition zone divided by the aggregate and the cement matrix. Integrating reactive SCMs like as silica fume or metakaolin can assist to balance the porosity generated by biochar, enhancing matrix increasing the density and compressive strength, especially at lower w/c ratios. This coordinated action might compensate for biochar's absorption of water, leading in lower W/B ratios with increased compressive strength (Wang et al., 2020).

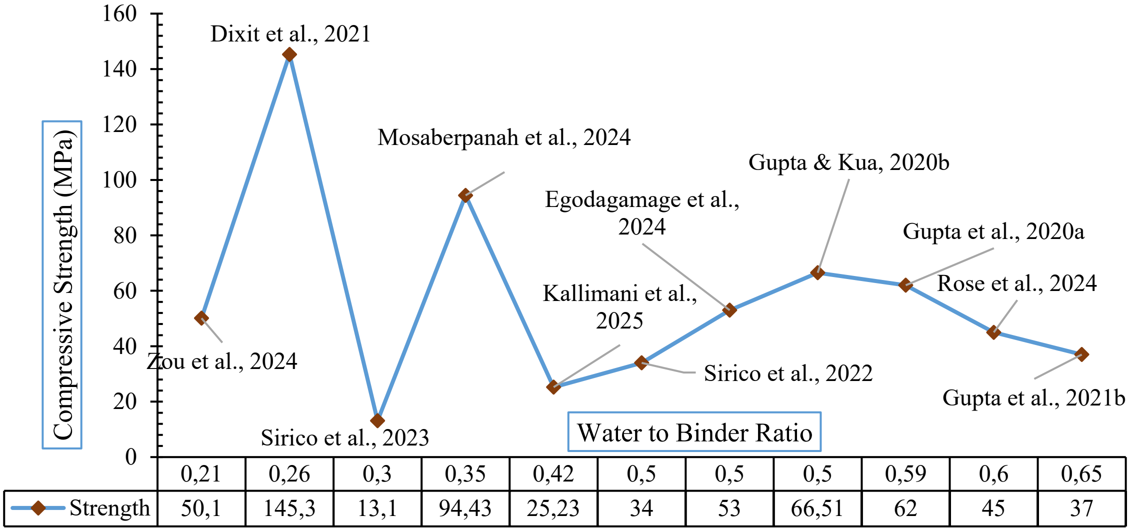

Fig. 2. Biochar with SCM's compressive strengh with respect to water to binder ratio

5.1.2. Flexural strength test

Among the most constant findings across investigations is that biochar has a dose-dependent influence on flexural strength, with an ideal range beyond which more biochar is deleterious (Fig. 3 with the data from Table 1). According to research, biochar concentrations ranging from 0.1% to 3% produce the best outcomes for increasing flexural strength (Akhtar & Sarmah, 2018; Khan et al., 2022). Also at 0.4 (Fig. 3) it showed the highest flexural point. The flexural strengths of biochar-added specimens exceed the values predicted by the code formulations for typical concrete based on the compressive strengths (Sirico et al., 2022). A notably enlightening research discovered that concrete with 0.75 wt% biochar had a 16% improvement in flexural strength over control specimens (Khan et al., 2022). This investigation demonstrated a linear improvement in flexural strength as biochar concentration rose from 0.25% to 0.75%, but there was no significant incremental enhancement at higher loadings (1.0% and 1.5%) (Khan et al., 2022). In another thorough study, chicken litter and rice husk biochar at a 0.1% replacement rate achieved excellent results, with flexural strength increasing by roughly 20% above control specimens (Akhtar & Sarmah, 2018). However, reaching specific threshold concentrations (often greater than 5%) usually reduces strength due to increased porosity and water requirements (Aman et al., 2022). Flexural strength is determined by elements such as fiber reinforcement, aggregate size, and curing techniques, in addition to the w/c ratio. In graph Fig. 3, Gupta et al. (2018b) employed optimal fiber reinforcement or SCMs to enhance tensile performance, which is not consistent with previous findings.

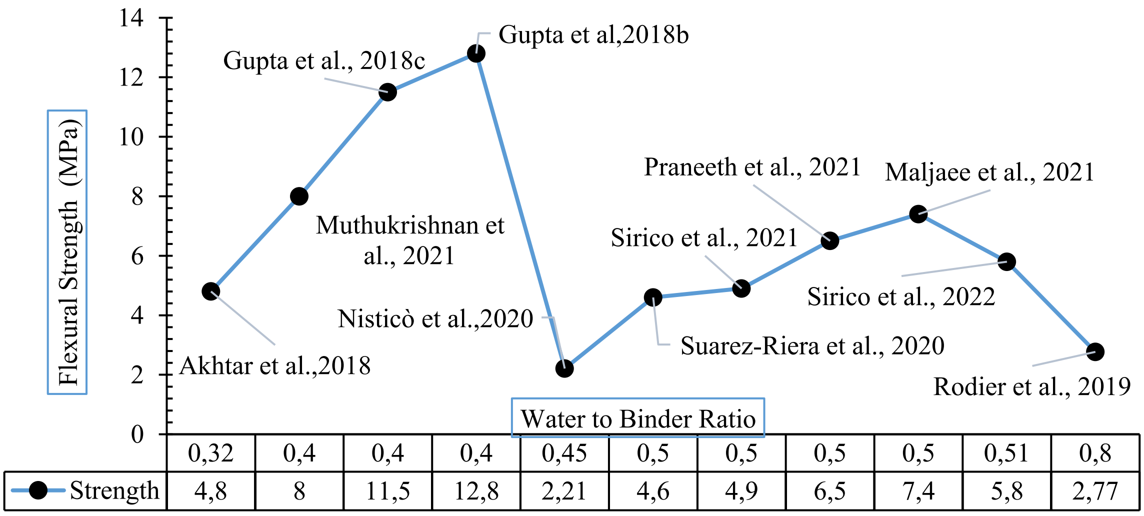

Fig. 3. Biochar concrete's flexural strengh with respect to water to binder ratio

The existing research (Fig. 4 with the data from Table 2). demonstrated that lower W/B ratios significantly reduce mortar porosity and boost mechanical characteristics, allowing for the use of greater quantities of SCMs, including biochar, without affecting strength (Sandanayake et al., 2020). Because of biochar's high porosity, higher dosages (more than 5%) have been shown to increase water requirements (Aman et al., 2022). To avoid strength loss, this increased water consumption must be carefully regulated by adjusting the W/B ratio. Presoaking biochar before inclusion has been found as one way to address these problems, particularly in terms of flexural strength. Research testing biomass ash and ceramic powder as SCMs found that additions of up to 50% by weight did not appreciably reduce flexural and compressive strengths (Pantić et al., 2023). Interestingly, it enhanced permeability due to the dilution effect (Pantić et al., 2023). Zhao et al. (2024) demonstrated that biochar with smaller particle sizes increased the flexural and compressive strength of cement composites by 2-7%. The pattern of this behavior is non-linear and study-dependent, implying that other factors—such as the kind and dose of supplemental cementitious materials (SCMs), curing conditions, and mix proportions—have a significant impact. Gupta et al.'s findings, in particular, raise concerns about the common thoughts that greater water-cement ratios diminish strength, which might be due to optimal SCM usage or differing experimental circumstances.

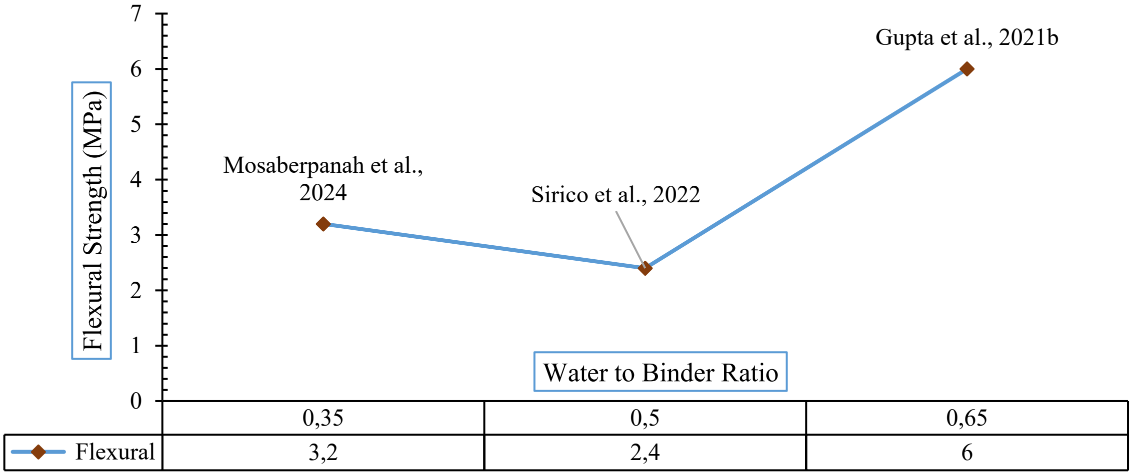

Fig. 4. Biochar with SCM’s flexural strengh with respect to water to binder ratio

5.2. Effect on durable properties

A lower w/b ratio often improves compressive strength by lowering porosity. However, the water absorption of biochar can change the w/b ratio locally, resulting in increased porosity areas when coarse particles are used (Ling et al., 2023). Excess water reduces compressive strength because it creates more voids in the matrix. Fine biochar particles minimize this by absorbing and releasing water during curing, which promotes hydration (Zhao et al., 2024). Biochar's water absorption ability is due to its microporous structure and oxygen-rich functional groups promotes hydrogen bonding with water molecules (Alam et al., 2018). This dynamic modifies the effective W/B ratio, as evidenced by isothermal calorimetry tests that reveal that 25% biochar supplementation decreases heat of hydration by 19.3% when compared to ordinary cement, indicating decreased free water availability. The balance of biochar's water retention and supply is critical: pre-saturation can reduce early-age desiccation, while excessive absorption without pretreatment causes viscosity loss and segregation. Maljaee et al. (2021) (Fig. 5) found that a 1.5% biochar substitution by cement mass required increasing W/B from 0.4 to 0.48 to maintain workability (Cunningham & Keane, 2023). However, this modification comes with alternatives: larger W/B ratios enhance fresh-state rheology but increase capillary porosity in hardened composites. In Fig. 5, the W/B ratio increases to 0.35 and 0.4 (Boadu et al., 2021; Muthukrishnan et al., 2018), although absorption remains whereas at a W/B ratio of 0.5 (Praneeth et al., 2021), with absorption peaking at 10.5%, demonstrating that extra water promotes increased porosity and capillary spaces, outweighing the advantages of biochar.

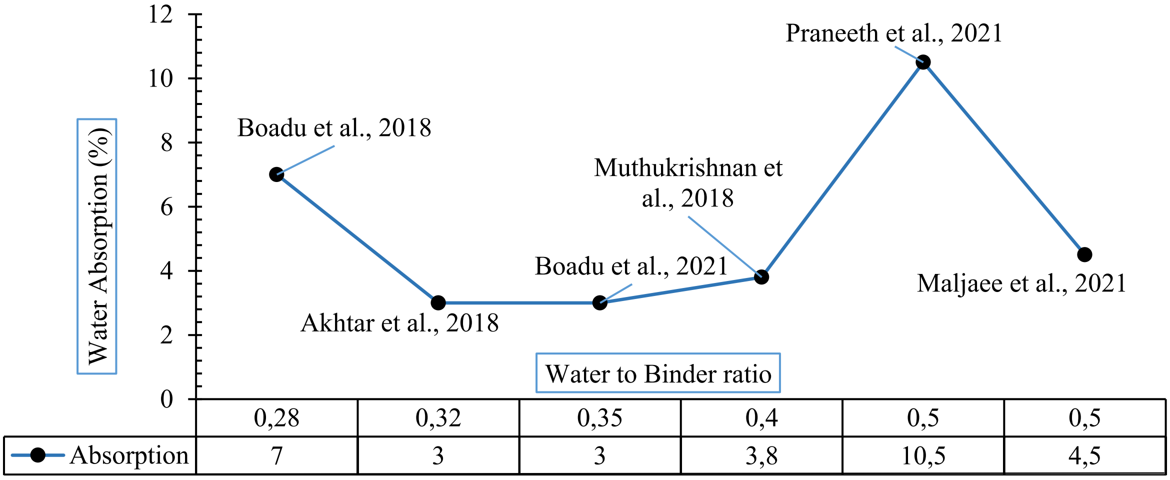

Fig. 5. Biochar concrete's compressive strengh with respect to water to binder ratio

The combination of biochar with SCMs like fly ash or slag mitigates absorption challenges (Fig. 6 from Table 2). Fly ash's spherical particles fill inter-biochar voids, reducing median pore diameter from 120 nm (biochar-only) to 68 nm (biochar+20% fly ash) (Rostami et al., 2021). Slag's latent hydraulic activity further densifies the matrix, as evidenced by 28-day chloride migration coefficients decreasing from 12.1×10^{-12} m^2/s (biochar) to 8.7×10^{-12} m^2/s (biochar+slag) (Cunningham & Keane, 2023). This synergy arises from SCMs compensating for biochar's inertness, ensuring continued pozzolanic reactivity despite reduced cement content. The graph (Fig. 6) highlights the gradual decrease of water absorption with the increasing ratio. At the point of 0.5 (Gupta et al., 2020a; Egodagamage et al., 2024), water absorption remains low (1.9–2%), indicating an optimal balance between hydration and pore refinement from the synergistic action of biochar and SCMs. However, when the W/B ratio increases further to 0.6 (Rose et al., 2024), absorption slightly rises to 3%, likely due to excess water leading to higher porosity despite the presence of SCMs.

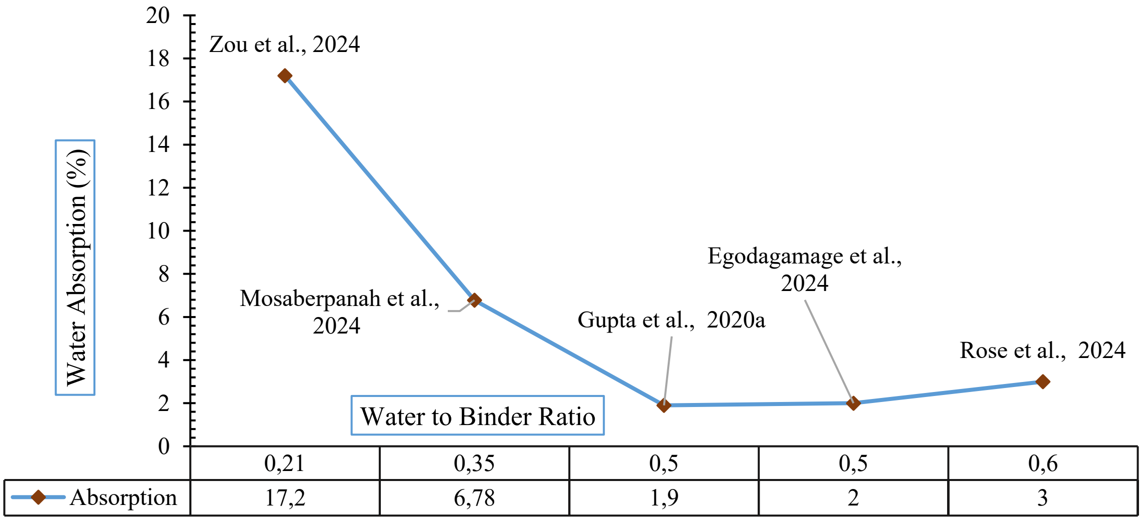

Fig. 6. Biochar concrete's compressive strengh with respect to water to binder ratio

6. Comparative analysis of biochar and biochar-SCM blends

The comparative research of biochar and biochar-SCM blends shows that both ingredients have the potential to increase concrete sustainability and performance. However, the efficiency of these materials is heavily reliant on the w/b ratio. Biochar-SCM mixes, in example, offer a potential method to improving concrete performance by combining the capabilities of two elements.

Biochar, which generates from organic waste, is a porous and carbon-rich substance with promise as a supplemental cementitious material (SCM). However, its porous nature might decrease the interfacial zone of transition (ITZ) in concrete, lowering compressive strength (Kallimani & Minde, 2025). Biochar's strong water absorption can change the w/b ratio, affecting hydration and mechanical characteristics. It can be used as curative agent during hydration (Barissov, 2021). Higher biochar doses (>5%) result in considerably lower compressive strength because to increased voids and weaker ITZ. Dosages around 2.5% are often more effective in maintaining or improving mechanical performance (Zhao et al., 2024). It produces extra water during mixing and then releases it after hydration. This method can reduce shrinking while improving long-term durability. Reduced w/b ratios typically enhance strength, but they may limit flowability, necessitating the use of superplasticizers when biochar is added in larger quantities (Barissov, 2021).

Combining biochar with Ground Granulated Blast Furnace Slag (GGBS) enhances sustainability while posing mechanical problems. Because of its pozzolanic activity, GGBS improves workability and long-term strength, but biochar's porous structure can negate these advantages (Kallimani & Minde, 2025). Silica-rich biochars (for example, rice husk biochar) have higher hydration and compressive strength than typical biochars or bamboo biochars due to their pozzolanic impact. For example, at 28 days, 10% rice husk biochar blended cement showed just a 4% loss in compressive strength compared to conventional Portland cement (Li et al., 2024). Adjusting the w/b ratio is critical when integrating biochar or biochar-SCM blends to balance workability and mechanical performance. Silica-rich biochars, for example, boost hydration efficiency even at low w/b ratios due to their pozzolanic activity (Li et al., 2024). In cases where biochar is blended with fly ash, slag, or silica fume, the resultant blends can provide synergistic advantages. Biochar-SCM blends have been shown in studies to improve the durability and mechanical characteristics of concrete, particularly at ideal w/b ratios (Wang et al., 2020). At greater w/b ratios, biochar's water absorption has less of an impact on workability, but the overall strength may suffer due to increased porosity. In such circumstances, the use of SCMs can help attenuate these impacts by filling holes and enhancing the concrete's structural texture (Li et al., 2020).

7. Conclusions

This study emphasizes the necessity of optimizing W/B ratios when integrating biochar and SCMs to achieve a balance of mechanical qualities (compression, flexural) and durability in concrete production.

- The study discovered an ideal water-to-binder (W/B) ratio that combines workability and strength. Lower W/B ratios (e.g., 0.35-0.40) produced better compressive strength but decreased workability, whereas higher W/B ratios (e.g., 0.45-0.50) increased workability at the price of strength.
- Take into account the feedstock source when choosing biochar, since materials derived from chicken litter and rice husk have demonstrated considerable increases in flexural strength at even low doses (0.1%).
- Lower W/B ratios using biochar and SCMs resulted in a denser microstructure, which reduced water absorption and chloride ion penetration. Higher W/B ratios, while favorable to workability, result in higher porosity and worse durability performance.
- Combining biochar with SCMs like fly ash or slag enhanced concrete properties even more, especially at intermediate W/B ratios (0.40-0.45). It increased the long-term strength development and durability characteristics of pozzolanic activity while decreasing porosity.
- For structural applications, a W/B ratio of 0.35-0.40 using biochar and SCMs is recommended for maximum strength and durability. To reduce strength loss in non-structural applications that need increased workability, a W/B ratio of 0.45-0.50 can be utilized in conjunction with appropriate additives.

Investigation of the effect of alkali treatment and bitumen coating on the tensile strength of hemp fibers

Utku Köktan*[1], Aytuğ Kumandaş[1], M. Kerem Ertek[1], Ufuk Kırbaş[1]

[1] *Ondokuz Mayıs University, Department of Civil Engineering, 55139, Samsun, Türkiye*

Abstract. High tensile strength is one of the most important mechanical properties desired in many materials used in civil engineering applications. Fibers are widely used in many materials that serve the purposes such as concrete and soil reinforcement, supporting structural elements, providing insulation, etc. Fibers produced from synthetic polymers are generally used to produce such materials. It can be stated that synthetic polymers can be produced very cheaply and quickly throughout the world, so they are easily accessible. Although this situation increases the demand for these materials day by day, synthetic polymers are generally non-biodegradable and cause significant damage to nature. This study investigated the effect of alkali treatment and bitumen coating on the tensile strength of hemp fiber, which is one of the natural fibers that can be used as an alternative to synthetic fibers. Therefore, hemp fibers were subjected to alkali treatment by soaking in a 5% sodium hydroxide (NaOH) solution. Unprocessed and alkali treated hemp fibers were then coated with bitumen. Tensile tests were carried out for each combination of unprocessed, alkali treated and bitumen coated fibers, and the effect of both alkali treatment and bitumen separately and together on the tensile strength was quantitatively presented.

Keywords: Hemp fibers; Alkali treatment; Bitumen; Tensile test

1. Introduction

Tensile strength is a critical parameter for many materials used in civil engineering. For this purpose, using fiber materials as a component of composite materials in civil engineering is becoming increasingly common due to the high tensile strength they provide. Geotextiles, insulation materials, fiber-reinforced concretes, asphalt pavements, and fiber-reinforced composites used in the reinforcement of structural elements can be given as examples to this group. Fibers produced from synthetic polymers are generally used in the production of all these materials. It can be said that synthetic polymers can be produced very much and easily throughout the world, so they are cheaper and easily accessible. In addition, they offer a very long service life due to their superior tensile strength and non-biodegradable nature. Although this increases the demand for these materials day by day, synthetic polymers are generally non-biodegradable and cause great damage to nature. In addition, synthetic fibers, which are generally produced from synthetic polymers such as polypropylene, polyethylene and polyethylene terephthalate, are not sustainable materials as they are produced from limited resources (Prambauer et al., 2019). Unsustainability, high environmental damage caused by turning into microplastics over time due to its non-biodegradability, and high carbon emissions in both production and use lead researchers to search for environmentally friendly alternatives.

The biodegradability and sustainable production of natural fibers make them an environmentally friendly alternative to synthetic fibers. The most widely used natural fibers are hemp, kenaf, jute, flax, sisal, coir, cotton and pineapple. Although these fibers sometimes show mechanical properties that can compete with synthetic fibers, their high degradation rate in nature limits their use (Prambauer et al., 2019; Wu et al., 2020). The limited service life brought by their environmentally friendly biodegradable nature causes them to be used only in 50% of applications instead of synthetic fibers (Bhattacharyya et al., 2010; Evangeline et al., 2021; Wu et al., 2020). In addition, while being biodegradable and not harming nature are the most prominent features, low density/weight, low cost, high insulation against electricity and sound, and contribution to regional development are other prominent advantages (Georgopoulos et al., 2005; Luo & Netravali, 1999; Pickering, 2008; Shirazi et al., 2020).

When the studies related to natural fibers are examined, it is seen that almost all of these studies focus on determining the mechanical properties of fibers (Amel et al., 2013; Holbery & Houston, 2006; Ochi, 2008; Rassmann et al., 2011; Summerscales et al., 2010; Symington et al., 2009). In civil engineering applications, natural fibers are generally used as the main element of a composite material formed with the help of a binder rather than alone. Accordingly, there are some studies in the literature where natural fibers are coated with bitumen,

* Corresponding author, E-mail: utku.koktan@omu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_414

which is also used in this study (Das & Banerjee, 2013; Ghosh et al., 2014; Ghosh et al., 2015; Sanyal & Chakraborty, 1994; Thakur et al., 2021). Researchers have also proposed the chemical treatment of natural fibers to increase their resistance to degradation and to include natural geotextiles in a wider area in civil engineering applications (Shirazi et al., 2020). In this direction, alkali treatment has been the most preferred application (Kumar et al., 2022). There are many studies investigating the effect of alkali treatment on natural fibers (Akhtar et al., 2016; Aly et al., 2012; Frącz et al., 2021; Kawahara et al., 2005; Lu et al., 2012; Meon et al., 2012; Narayana & Rao, 2021; Nitta et al., 2011; Nosbi et al., 2011; Rajappan et al., 2015; Ramesh, 2016; Sair et al., 2017; Shirazi et al., 2019; Thirukumaran et al., 2024). In these studies, although studies are showing that alkali treatment increases the resistance of fibers against biodegradation and can improve the tensile strength at optimum alkali amount from time to time, slight decreases in the tensile strength of fibers were observed in some studies. However, in some studies, since impurities on the fiber surface were removed due to alkali treatment, interfacial compatibility with a binder increased and improvement in composite behavior was observed.

Following a literature review, it is seen that fibers such as jute, coir, flax and kenaf are generally preferred as natural fibers. The fact that hemp production is still illegal in many countries and the strict bureaucratic obstacles to its production can be shown as the reason for this situation. In this study, the effects of alkali treatment and bitumen coating on the mechanical behavior of hemp fibers were investigated separately and together. For this purpose, four combinations of raw hemp fibers, alkali-treated hemp fibers, bitumen-coated hemp fibers, and alkali-treated and bitumen-coated hemp fibers were determined. Considering the inhomogeneous structure of the material and the differences that unpredictable effects in the laboratory environment may cause, 16 samples were produced, four duplicate samples for each of the four combinations. Each sample was formed as a bundle of hemp fibers with a total weight of 2 grams using 20 cm long fibers. The sample was taped at the top and bottom for a distance of five cm each. The remaining 10 cm clear length of the fiber bundle is the value to be considered for the tensile test. The prepared fiber bundles were then soaked in NaOH solution at a concentration of 5 wt% for 30 minutes for alkali treatment. After this process, the fibers were soaked in CH_3COOH solution at a concentration of 1 wt% to ensure the neutralization of the fibers. Then, they were washed and left to dry at room temperature. Raw and alkali-treated hemp fibers to be coated with bitumen were immersed in pure bitumen at 165 °C for 1 min and then allowed to cool by hanging. After the preparation of the samples, each of them was subjected to tensile test and breaking loads were obtained. A slight decrease in the tensile strength of the alkali-treated hemp fibers was observed compared to the raw hemp fibers. However, in the case of bitumen-coated fibers, the tensile strength of the alkali-treated fibers was higher.

2. Materials and methods

2.1. Materials

2.1.1. Hemp fibers

Industrial Hemp (Cannabis sativa L.) is a type of plant with tetrahydrocannabinol (THC) content below the legal maximum level (Exchange, 2023; FIHO, 2024). Hemp fibers can be used industrially in many fields, such as textiles, construction materials, fuel, automobile parts, and fertilizer (Exchange, 2023; Johnson, 2013). Hemp fibers used in this study were obtained from Ondokuz Mayıs University Hemp Research Institute. The supplied fibers consist of only the fiber parts separated from the tows. These fibers were cut into 20 cm lengths for the preparation of the samples shown in Fig. 1.

2.1.2. Alkali treatment (NaOH)

The surfaces of natural plant fibers are covered with impurities such as cellulose, hemicellulose, lignin, pectin and wax due to their biochemical structure. These impurities remove the surface roughness and harm the formation of friction force between the fibers. Alkali treatment makes the fiber surface rougher because it cleans the fiber surface by breaking down these impurities. Thus, the adherence between the fibers increases. Removing impurities on the surface can provide better bonding of the fiber surface with matrix materials. In addition, alkali treatment applied under optimum conditions may cause an increase in the tensile strength of the fibers in some cases. This study subjected pre-washed hemp fibers to alkali treatment by soaking in NaOH-Water solution containing 5 wt% NaOH for 30 minutes.

2.1.3. Acetic acid (CH_3COOH)

NaOH solution removes the impurities on the fibers thanks to its basic structure. After this process, the CH_3COOH-Water solution with a concentration of 1 wt% CH_3COOH was prepared to neutralize the fibers and the fibers were waited in this solution for 30 minutes. Then, the fibers were washed in a filtering flask, and CH_3COOH on the surface was removed. The neutralization of the fibers was checked using a pH meter.

2.1.4. Bitumen

Bitumen, which is a by-product of petroleum production, is frequently used, especially in highway applications due to its binding properties and in roofing applications due to its superior impermeability (Kabadayı et al., 2024; Kumandaş et al., 2022; Şahan et al., 2023). The bitumen used in this study was obtained from the 7th Regional Directorate of the General Directorate of Highways of Turkey and has a 50/70 penetration grade.

2.1.5. Preparation of samples

Hemp fibers were first cut into 20 cm lengths, and 16 hemp fiber bundles, each weighing 2 grams, were formed from these fibers. The formed bundles were taped and fixed, each at the top and bottom with 5 cm bands, as shown in Fig. 1. The taped parts will then remain between the grips of the tensile testing machine, and the net fiber length subjected to tensile test is 10 cm.

Within the scope of the study, four different combinations of unprocessed pure hemp fibers, alkali-treated hemp fibers, bitumen-coated hemp fibers, and both alkali-treated and bitumen-coated hemp fibers were obtained, and four duplicate samples were produced for each combination. The coding of the samples is as follows: unprocessed hemp fiber bundle is named “K”, alkali-treated hemp fiber bundle is named “KA”, bitumen-coated hemp fiber bundle is named “KB” and both alkali-treated and bitumen-coated hemp fiber bundle is named as “KAB”. The codes “N1”, “N2”, “N3” and “N4” were used for the four samples to be produced from all these combinations (Fig. 1). For example, the first sample of the alkali-treated hemp bundle was named “KA_N1”.

Fig. 1. Untreated hemp bundle samples

KA and KAB samples were subjected to alkali treatment for 30 minutes in NaOH-Water solution at 5 wt% concentration. The alkali treated hemp bundles were kept in CH_3COOH-Water solution at 1 wt% concentration for 30 minutes to neutralize them. Then, each hemp fiber bundle was washed with 2 liters of water in a filtering flask. Since the pH values of 2 liters of washing water before and after washing were the same, the washing was terminated at this point, and it was decided that the samples were neutralized.

Then, four hemp bundles that were and were not subjected to alkali treatment were immersed in pure bitumen at 165 °C for 1 min and then hanged and allowed to cool (for KB and KAB samples). Thus, 16 samples were obtained: four pure hemp fiber bundles (K), four alkali-treated hemp fiber bundles (KA), four bitumen-coated hemp fiber bundles (KB), and four alkali-treated and bitumen-coated hemp fiber bundles (KAB). The samples were then subjected to a tensile test, and the breaking loads were determined.

2.2. Method

2.2.1. Tensile test

The mechanical properties of natural fibers are expressed in terms of their tensile strength. In this context, it is critical to determine how much of a breaking load the produced samples can withstand. For this purpose, the tensile strengths of the samples were obtained using an Instron universal testing machine. The 20 cm long samples were taped 5 cm from the top and bottom of the samples, and these parts were inserted into the grips of the tensile testing machine. Thus, a clear tensile length of 10 cm was obtained (Fig. 2). The samples were then subjected to a tensile force at a speed of 10 mm/min and the breaking loads of the samples were obtained.

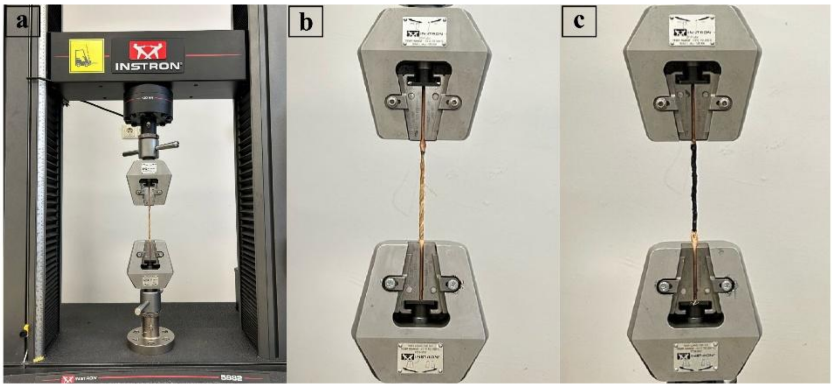

Fig. 2. Tensile testing setup and samples: (a) universal testing machine used for tensile testing, (b) uncoated natural fiber sample positioned between the grips, and (c) bitumen-coated fiber sample mounted between the grips.

3. Results and discussion

After the tensile tests were carried out, the breaking loads were obtained for each combination. Fig. 3 and Fig. 4 are the mean values of four duplicate samples produced for each combination. Fig. 3 shows the effect of alkali treatment on the breaking load of hemp fiber bundles. Alkali treatment reduced the mean breaking load of the hemp fiber bundle by about 10%. Fig. 4 shows that alkali treatment increased the mean breaking load of bitumen-coated hemp fiber bundles by about 25%.

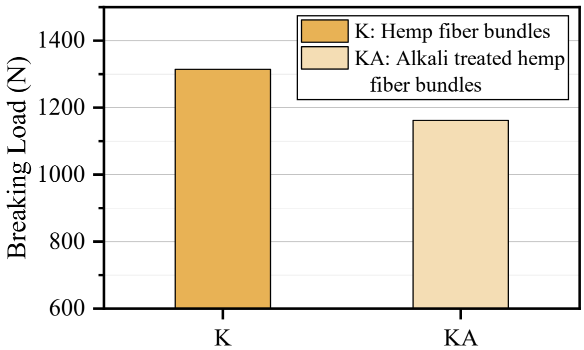

Fig. 3. Breaking load values of uncoated hemp fiber bundle samples

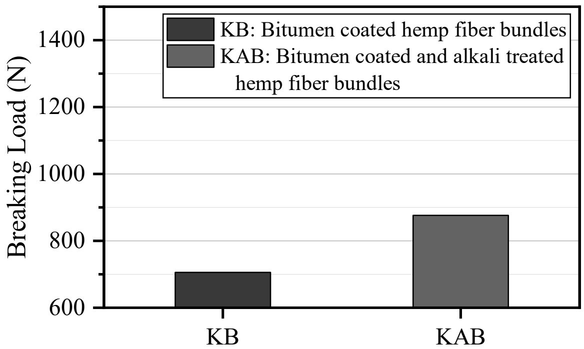

Fig. 4. Breaking load values of bitumen coated and alkali treated hemp fiber bundle samples

Here, the fact that alkali treatment causes a decrease in the breaking load of hemp fibers indicates that the optimum alkali conditions for the fibers should be investigated in more detail. Harsh alkali concentrations or long-term exposure to alkali conditions can cause a decrease in the tensile strength and Young's modulus of the fibers. An excessive concentration of NaOH caused degradation of cellulose molecular chains, resulting in a deterioration of mechanical properties. Moreover, the fibers exhibited surface erosion and micro-cracks at higher temperatures and longer soaking times, which adversely affected their tensile properties. The crystallinity index also decreased under severe alkali treatment conditions, leading to reduced mechanical stability of the fibers (Aly et al., 2012). However, alkali treatment improves the interfacial adhesion between fibers and binder by increasing the surface roughness and interlocking points by partially removing hemicellulose and lignin (Lakshmanan et al., 2018).

In other words, the alkali treatment time should be optimized for the decrease in the tensile strength of the fibers. However, as stated in some studies, the alkali treatment causes slight decreases in the tensile strength of the fiber. However, interfacial adhesion improves, as seen in Fig. 4, where the tensile strength of bitumen-coated fibers was higher for the alkali treated fibers.

4. Conclusions

In this study, the effects of alkali treatment and bitumen coating on the mechanical behavior of hemp fibers were investigated separately and together. For this purpose, four duplicate samples of four combinations coded K, KA, KB and KAB were produced. The 16 samples were subjected to a tensile test, the breaking loads were determined, and the breaking load of each combination was presented as the mean value of the four duplicate samples. The findings obtained within the scope of the study are presented below.

- The mean breaking load of K samples was approximately 10% higher than that of KA samples. This indicates that alkali treatment decreases the tensile strength of the hemp fiber bundle under the conditions performed in the study
- The mean breaking load of the KAB samples was approximately 25% higher than that of the KB samples. This indicates that alkali treatment increases the interface compatibility of the fibers with the binder.
- When only the effect of bitumen was evaluated as K-KB and KA-KAB, it was observed that bitumen decreased the breaking load of hemp fiber bundles. This is thought to be caused by the damage caused by the high temperature of bitumen on the fiber structure.
- Although the singular effect of bitumen decreases the breaking load, it is predicted that it will increase the degradation time of hemp fiber and increase its usability as a composite material in civil engineering applications. In this context, the strength increase caused by the alkali treatment of samples with bitumen is very important.

In light of all these data, it is seen that alkali treatment under the conditions presented in this study decreases the tensile strength of hemp fiber but increases the tensile strength of bitumen-coated samples by increasing the interface compatibility. The data presented in this study are valid for the conditions considered for the study. Alkali treatment needs to be optimized by considering parameters such as alkali concentration, alkali treatment time and waiting period in acid. Although bitumen alone causes a decrease in tensile strength, the superior performance of KAB samples against KB samples seems promising for hemp-bitumen-based composite materials. In line with all this information, the researchers will focus on optimizing the alkali conditions and producing a composite material in future studies.

Abstract. Ultra-High Performance Concrete (UHPC) is a concrete type characterized by its advanced engineering properties, offering exceptional strength and durability. It is primarily used in structures that demand long-lasting performance, achieved through the use of optimized binders and fine aggregates. Unlike traditional concrete, UHPC can incorporate special admixtures and fibers that significantly improve its mechanical and physical properties. Studies have shown that the fibers enhance the microstructure of UHPC, reducing negative effects such as cracking and deformation. For instance, steel fibers increase tensile strength, while polypropylene fibers contribute to a lighter and more wear-resistant structure. The durability of UHPC is further enhanced by the inclusion of fine aggregates and binders, which increase the density of the concrete, limit the movement of water, and provide greater resistance to corrosion. The combination of fibers and these materials improves the viscoelastic properties of concrete, making it more efficient in challenging environmental conditions. As a result, the physical properties of UHPC can vary significantly based on the type, quantity, and distribution of the fibers. This makes testing UHPC with various fiber types an important area of research in materials engineering, playing a key role in the development of durable and long-lasting structures. This study focuses on evaluating the mechanical properties of UHPC produced by replacing silica fume with quartz powder-containing fine aggregates. Furthermore, the impact of different fiber types on the mechanical behavior of UHPC is examined, highlighting the potential applicability of these materials in structural applications. Axial compression tests were conducted on concrete samples at 7, 14, and 28 days, with results analyzed and compared to assess mechanical properties at different ages.

Keywords: Ultra High Performance Concrete, Glassfiber fiber, Steel fiber, Basalt fiber, Fine aggregate

1. Introduction

Concrete is a fundamental building material widely used in the construction industry (Habert et al., 2020). In modern architectural design, durability and longevity are among the most essential qualities expected from construction materials, making the use of high-performance concrete that meets these standards inevitable (Subramaniam et al., 2019). However, the strength characteristics of concrete present a significant issue in terms of brittleness; high-strength concrete experiences a sudden loss of stress after reaching its maximum load-carrying capacity and exhibits brittle failure. Therefore, the need for concrete with not only high strength and durability but also high ductility is clearly evident. In recent years, the use of low-quality materials, improper durability designs, adverse environmental factors, and natural disasters have clearly revealed the deterioration of concrete's resistant structure (Gettu et al., 1990).Constructing earthquake-resistant structures is no longer a preference but a necessity. Various methods have recently been applied to enhance the performance of concrete, with Ultra-High Performance Concretes (UHPC) being at the forefront of these developments (Murthy et al., 2013). UHPC offers significantly superior properties compared to conventional concrete, including high strength, low porosity, long service life, and excellent durability. As a result, the use of UHPC, known for its high strength and longevity, is steadily increasing in the construction industry. The use of UHPC in various engineering applications provides safe solutions in structures such as bridges, tunnels, and high-rise buildings (Abbas et al., 2016). UHPC is produced from cement, complementary components, aggregates, water, superplasticizer additives, and reinforcements. Various reinforcements are used to achieve ultra-high performance concrete (Teichmann & Schmidt, 2004). One such reinforcement is fibers, which enhance the tensile strength of concrete, preventing issues like cracking and breaking. Fibers also help prevent microcracks in the internal structure, strengthening the structural integrity and extending the lifespan of the concrete (Wille et al., 2012). In UHPC, high cement content forms the basis for both

golden light publishing

strength and density, while the matrix's integration with fillers results in a more compact structure (Sohail et al., 2016). Ultra-High Performance Concrete offers innovative solutions in structural engineering, addressing increasing density demands while providing lighter and more aesthetically pleasing structures.

The foundational study by Richard and Cheyrezy (1994) demonstrated that using silica fume, superplasticizers, fine aggregates, and steel fibers, compressive strengths between 200–800 MPa can be achieved without compromising ductility. Wu et al. (2016) investigated the influence of steel fiber content and shape on UHPC, finding that increased fiber dosage reduced fluidity but improved both compressive and flexural strength. Similarly, Kang et al. (2016) showed that combining high-strength synthetic fibers such as polyethylene (PE) with steel fibers significantly enhanced tensile behavior. Le Hoang and Fehling (2017) explored the effect of steel fiber volume and aspect ratio, concluding that while compressive strength remained largely unchanged, tensile behavior after peak stress improved considerably with increased fiber content. Gao et al. (2024) further found that at elevated temperatures up to 600°C, steel fibers contributed positively to compressive performance, although strength declined above this threshold due to fiber oxidation.Abbas et al. (2015) evaluated different steel fiber lengths and dosages in UHPC mixtures, concluding that mechanical properties improved with dosage increase, while shorter fibers contributed more to flexural strength. Li et al. (2018) designed UHPC containing coarse basalt aggregates and emphasized the importance of optimal particle packing and the use of longer fibers to maintain mechanical integrity. Zhang et al. (2018) demonstrated that although the use of coarse aggregates increased compressive strength, it weakened the bond between steel fibers and the matrix. However, hooked-end fibers enhanced flexural toughness. Wang and Gao (2016) established an inverse relationship between entrapped air and compressive strength, noting that higher steel fiber content reduced air content and improved strength characteristics. Ayub et al. (2014) investigated basalt fiber incorporation in high-performance concretes and observed that up to 2% fiber content enhanced compressive and tensile strength, particularly when used alongside supplementary cementitious materials.The aim of this study is to evaluate the mechanical properties of ultra-high performance concretes produced by substituting silica fume with fine aggregates containing quartz powder. Additionally, the effects of different fiber types on the mechanical behavior of these concretes were investigated, and the high mechanical performance achieved demonstrated their potential applicability in structural use. The study focused on analyzing how different types and percentages of fibers affect the compressive strength of UHPC. The inclusion of steel, basalt, and glassfiber fibers significantly improves the tensile strength, crack resistance, and overall structural integrity of the concrete

2-Material and metod

In this study, the compressive strength of Ultra High Performance Concrete (UHPC) with steel, basalt, and glassfiber fibers was examined. The material proportions used in the concrete mixes are provided in Table 1. The table details the quantities of key ingredients such as cement, silica fume, quartz sand, fine aggregate, superplasticizer (S.P.), and fiber content for each mix. The fiber contents varied by volume fractions of 0.5%, 1%, 1.5%, and 2% for steel, basalt, and glass fibers, respectively.

Table 1. Mix proportions (kg/m^3)

Cement (kg/m^3)	w/c	Silica Fume (kg/m^3)	0-1 mm Quartz Sand (kg/m^3)	1-4 mm Fine Aggregate (kg/m^3)	S.P. (kg/m^3)	Steel fiber %	Basalt fiber %	Glass fiber %
			605	605				
			612	612		0.5	0.5	0.5

The steel, glass, and basalt fibers used in this study were commercially sourced from composite markets and are widely used in the construction industry. The physical properties of these fibers significantly influence the mechanical performance, durability, and crack resistance of Ultra High Performance Concrete (UHPC). A detailed description of the characteristics of each fiber type is presented in Fig. 1, which visually displays the fibers used in the study. Based on the manufacturer's datasheets and relevant literature, a comparative summary of their fundamental properties is also provided in Table 2 below.

Fig.1. Fibers used in the study (Basalt Fiber, Steel Fiber, Glass Fiber)

Table 2. Physical properties of Glass Fiber, Basalt Fiber, and Steel Fiber

Property	Basalt fiber	Steel fiber	Glass fiber
Density (gr/cm^3)	2.55-2.62	2.65-3	7.85
Tensile strength (N/mm^2)	3100-3800	300-4840	500-600
Elastic Modulus (Pa)	72.5-75.5	79.3-93.1	210

In this study, the materials used for the production of Ultra High Performance Concrete (UHPC) were carefully selected to optimize performance. Fig. 2 shows the position of CEM I 42.5 class cement and silica sand in the mix. These materials play an essential role as the binding components of the concrete. Silica sand increases the density of the concrete, while cement provides the necessary strength for the mix. Fig. 3 illustrates the composition of the mix, which includes fine aggregates and quartz sand. Another material used in UHPC is fine aggregate and quartz sand. Fine aggregate and quartz sand passing through a 4 mm aperture sieve were used. The maximum grain diameter is 2 mm. This brings UHPC to mortar consistency, minimizes the void ratio and provides high strength.

Fine aggregates (1-4 mm) and quartz sand (0-1 mm) were used in a 50:50 weight ratio to ensure a well-graded granular structure in the concrete. Finally, Fig. 4 shows the additives incorporated into the mix, particularly the AURACAST 535 superplasticizer. These additives improve the workability of the concrete while maintaining a low water-to-cement ratio, thus enabling the production of high-performance concrete. AURACAST 535 superplasticizer additive was used to increase workability in the mixture where the water/binder ratio was set at 0.19.

Fig. 3. Fine Aggregate and Quartz Sand

Fig. 4. Superplasticizer additive material

The samples formed according to the mixing ratios were removed from the molds 24 hours after casting. These removed samples were kept in 22 °C water for 7, 14, and 28 days. The crushing was carried out in a pressure testing machine in accordance with TS EN 12390-4 for the determination of sample compressive strength. After the samples removed from the curing pool were dried, they were placed in the pressure machine test. These cube samples were left to be loaded in the vertical direction and placed in the center with a deviation not exceeding 1% of the determined diameter. The loading speed was determined as 0.6 N/mm².s, and the sample compressive strength was applied by increasing at a constant speed, as shown in Fig. 5.

Fig. 5. Ultra High Performance Concrete (UHPC)

3-Findings and discussion

As shown in Table 3, fiber-free UHPC samples reached the highest compressive strength values at 28 days, with σ_1 = 165 MPa, σ_2 = 164.2 MPa, and σ_3 = 165.5 MPa. This indicates a significant increase in the material's durability over the curing period. The small difference between σ_1 and σ_3 suggests that the material provides balanced performance under different stress conditions, while σ_2 remains strong and durable. The high strength values reinforce that fiber-free UHPC is suitable for civil engineering applications and provides a strong foundation for durable structures.

Table 3. Compressive strengths of fiber-free samples

Curing Days	σ_3 (MPa)	σ_2 (MPa)	σ3 (MPa)
7	151.2	145	147
14	156	159	157
28	165	164.2	165.5

The data presented in Fig. 6 shows that basalt fiber-reinforced UHPC demonstrates significant improvements in compressive strength as the curing time progresses. The increase in strength is clearly influenced by the fiber content, with higher fiber dosages leading to higher compressive strength values at each curing stage. The BF 2.0 samples show the highest strength gain, increasing by 22.8 MPa from 152 MPa at 7 days to 174 MPa at 28 days. This indicates that the material continues to benefit from the reinforcement provided by the basalt fibers as it cures, with the most significant improvements occurring after 14 days. Similarly, the BF 1.5 samples exhibit a notable strength gain, from 155 MPa at 7 days to 172.4 MPa at 28 days, an increase of 17.4 MPa. This further emphasizes the positive role of basalt fibers in enhancing the material's compressive strength over time. The difference in strength between the lowest (BF 0.5) and highest (BF 2.0) fiber contents increases progressively as the curing period advances. At 7 days, the strength difference between BF 0.5 and BF 2.0 is 6.2 MPa, which increases to 11 MPa at 28 days. This shows the growing impact of higher fiber content on improving the compressive strength and overall durability of UHPC.

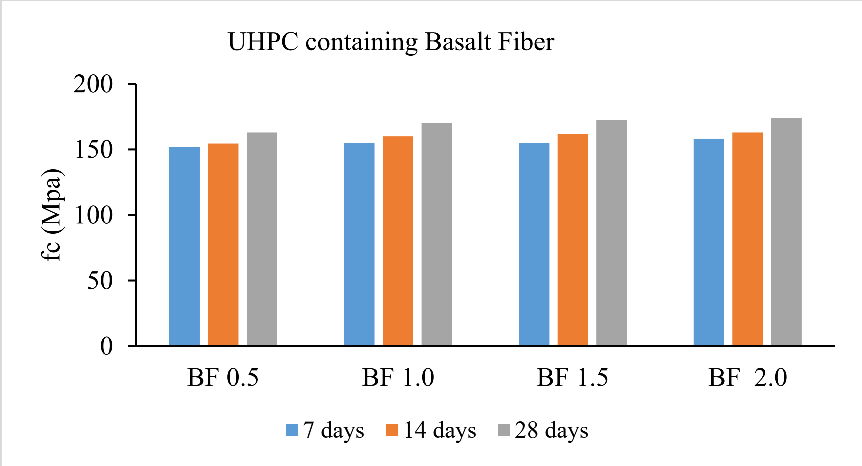

Fig. 6. UHPC containing Basalt Fiber

The data in Fig. 7 shows that steel fiber-reinforced UHPC improves in compressive strength as curing progresses, with higher fiber content leading to better performance. The SF 2.0 samples show the greatest strength gain, increasing by 9.7 MPa from 172.3 MPa at 7 days to 182 MPa at 28 days. This indicates that the material continues to benefit from steel fiber reinforcement, especially after 14 days. Similarly, the SF 1.5 samples exhibit a 17.3 MPa increase, from 164 MPa at 7 days to 181.3 MPa at 28 days, highlighting the positive impact of steel fibers. The SF 1.0 and SF 0.5 samples show smaller strength gains, with increases of 16.7 MPa and 9.5 MPa, respectively.

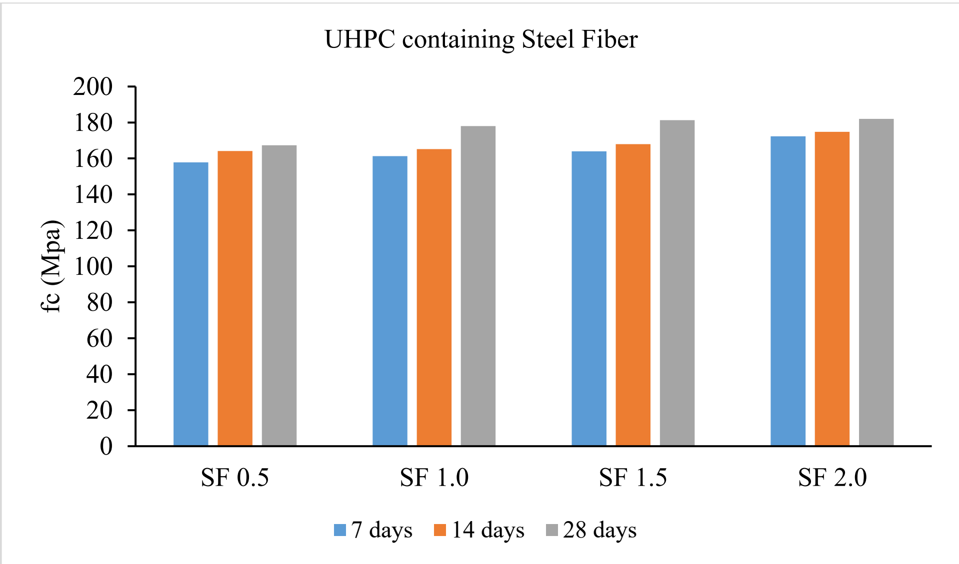

Fig. 7. UHPC containing Steel Fiber

The data presented in Fig. 8 illustrates the compressive strength development of UHPC reinforced with glass fibers over the curing period. As the curing time progresses, the strength continues to increase, with higher fiber dosages generally leading to better performance. The GF 0.5 samples show the greatest strength gain, increasing by 17.3 MPa from 150 MPa at 7 days to 167.3 MPa at 28 days. Other dosages such as GF 1.0, GF 1.5, and GF 2.0 show more moderate improvements. Specifically, GF 1.0 shows a gain of 16.1 MPa (from 152.2 MPa at 7 days to 168.3 MPa at 28 days), GF 1.5 shows an increase of 17.9 MPa (from 151.9 MPa at 7 days to 169.8 MPa at 28 days), and GF 2.0 shows the smallest increase of 12.4 MPa (from 154 MPa at 7 days to 166.4 MPa at 28 days).

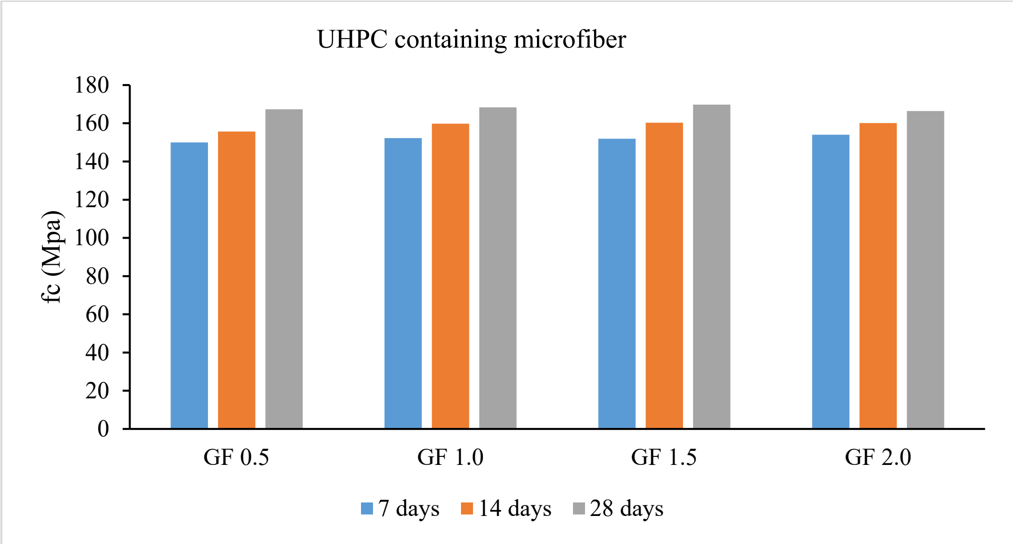

Fig. 8. UHPC containing microfiber

4. Conclusions

In this study, an experimental program was conducted on Ultra-High Performance Concrete (UHPC) mixtures incorporating different types of synthetic fibers at various volume fractions to investigate their feasibility for use in UHPC.

As a result of the study, it was observed that the compressive strengths of UYPB prepared with various fibers were higher than UYPB without fibers.

- It was determined that the 7, 14 and 28-day compressive strengths of basalt fibers were higher than UYPB without fibers and glassfiber fibers, but lower than steel fiber concrete.
- It was observed that the 7, 14 and 28-day compressive strengths of steel fibers were higher than basalt fiber and glassfiber fibers without fibers.
- It was observed that the 7, 14 and 28-day compressive strength of glassfiber fibers did not have much effect on UYPB without fibers, and the 7 and 14-day compressive strength of the fiber containing 0.5% had lower strength than UYPB without fibers, and it was also lower than the strength of fibers containing steel fiber and basalt fiber.

It can be said that steel fibers provide the highest contribution in terms of both strength and toughness. Basalt fibers can be preferred especially for environmental and economic reasons, but their effect is limited.

Macrofiber fibers provide ductility in terms of post-crack carrying and energy absorption, but their compressive strength is lower than other fibers.

Abstract. Nano-TiO_2 has emerged as a multifunctional additive in construction materials due to its photocatalytic activity, ability to improve microstructure, and capacity to improve mechanical and durability properties, while especially in geopolymer composites (GCs), nano-TiO_2 not only increases compressive strength and reduces porosity, but also contributes to self-cleaning surfaces, and improved chemical stability. In this context, the effects of adding nano-TiO_2 at different ratios (2%, 4%, and 6% by weight) were investigated in the geopolymer composite reference consisting of 50% granulated blast furnace slag (GBFS) and 50% waste ceramic powder (WCP). Mix design included the water/binder (w/b) ratio of 0.48, Na_2SiO_3/NaOH ratio of 2:1, and sand/binder (s/b) ratio of 2.5. Thermal curing was applied at 80°C for 24h and basic physical properties such as capillarity, water absorption, porosity and compressive strength were analyzed at 28 days. Results showed that although nano-TiO_2 additive reduced the void ratio by improving the microstructure, it did not provide an increase in compressive strength. This showed that nano-TiO_2 reduced porosity by creating a filling effect in the matrix, but did not play an active role in the bonding mechanism.

1. Introduction

Geopolymer (GM/GC) technology is an environmentally friendly substitute to traditional Portland cement (PC), which contributes annually to the production of 4-5 billion tons of concrete worldwide. Environmental impacts of PC are severe, as it contributes 8–9% of the production of a total of 25–30 billion tons of concrete per year, thereby contributing to anthropogenic greenhouse gas release. Need for high-strength concrete further amplified the environmental problems as enhanced cement use raises environmental concerns in intensified ways. GCs provide a revolutionary solution in the form of their inorganic polymer material, a paradigm change in the development of green construction technologies. In contrast to the conventional PCs, GCs are synthesized by the activation of aluminosilicate materials, generating inorganic polymer material of enhanced mechanical durability and strength of the structure. This novel method resolves the drawbacks of PCs in mechanical properties and environmental factors and provides a more environmentally friendly alternative. Synthesis of GCs includes naturally occurring and industrial aluminosilicates as the raw material. Most of these materials in the system are by-products or products generated by the calcination of clays, including metakaolin (MK), metazeolite, and metabentonite. Increased need for electricity production led to the production of high levels of FA, of which only 17-20% is effectively being put to use globally. Fly ash (FA), a finely powdered mineral additive derived from coal combustion, is amorphous and round in character and applicable in the partial replacement of concrete in the concrete market. Likewise, slag, a by-product of the industrial sector, is composed of different quantities of CaO, SiO_2, Al_2O_3, and trace elements. Investigations of GC in the field have typically focused on MK, FA, and a mixture of both, using sodium or potassium hydroxide mixed with the silicate to react them, respectively. This method of synthesis gives rise to two geopolymerization models by microstructure: one CaO-dominant (CaO-SiO_2-Al_2O_3-MgO) and the other low in CaO and high in SiO_2 and Al_2O_3 content. Nonetheless, along with the above developments, minimal research effort has gone towards the usage of the environmentally friendly GC using waste ceramic powder (WCP), a high by-produce in the ceramic company. This waste, being 15-30% of the raw material, is a problem in landfills in the context of consuming space. It has been indicated in investigations that WCP displays pozzolanic activity, supporting both the hardness and durability of concrete in increased ways (Ozturk et al., 2023; Herbudiman et al., 2024; Faridmehr et al., 2024; Rashad et al., 2024; Raoof & Hameed, 2025).

Additionally, as the global effort to minimize CO_2 emissions intensifies, studies have turned to the utilization of nanomaterials in GCs. Nanomaterials including carbon nanotubes (CNTs), nano-SiO_2 (NS), nano-Al_2O_3 (NA), graphene oxide (GO), nano-TiO_2 (NT), nano-clay (NC), nano-ZnO_2 (NZ), nano-$CaCO_3$, and nano-Fe_2O_3 are being pursued to increase the mechanical and durability characteristics of GCs. These nanomaterials not only support the minimization of CO_2 emissions but also increase the functionality of building materials in general. TiO_2, a broadly applied versatile metal oxide, has found extensive use in GCs. As a multi-functional additive, nano-TiO_2 finds extensive applicability in a wide variety of fields including cosmetics, pharmacy, and chemical processing. In the case of advanced building materials, its photocatalytic activity is of tremendous interest owing to its remarkable efficiency in the control of nitric oxide emissions. One of the nano-sized forms of TiO_2, a semiconductor-type photocatalyst, has been thoroughly explored, especially in the realm of the Honda-Fujishima effect, wherein water is split into hydrogen and oxygen using electro-catalysis caused by UV radiance, and TiO_2 as a phot-anode in the electrochemical cell. Its wide range of uses includes the usage of NT as a white pigment in paints and cosmetics, a protective layer in construction material against sun and pollution, and as a catalyst in pavement material that causes the breakdown of gaseous pollutants due to moving vehicles. Many studies have proved that the integration of nano-TiO_2 (NT) in cementitious and geopolymer matrices can invariably increase the mechanical and transport properties upon incorporation at the optimum dosages. Broadly, the replacement of part of the binder of approximately 3–4% by NT has been found to result in significant water absorption and capillary porosity reductions. These enhancements are mostly a result of the NT's filler effect and pore structure refinement, leading to a densified and more impermeable matrix system. For example, the reductions in water absorption under extended exposure durations have invariably resulted at the optimum NT dosages, while high dosages adversely turn this advantage in favor of the material by causing the material to agglomerate and rupture the gel networks. In addition, while the early-age strength is considerably enhanced—often by more than 45%—as a result of the increased nucleation effect of NT, the longer-term strength can suffer, possibly owing to poor dispersion or microcracking. However, the incorporation of supplementary materials like supplementary binders and dispersants has proved effective in mitigating these detrimental effects, even promoting further boosts in strength beyond the initial enhancement levels. NT content levels of up to 6% have also, in some studies, resulted in up to 40% rise in strength, in parallel with high ultrasonic pulse velocities, which reflect increased compactness and homogeneity of the microstructure. Further, finer NT particle sizes (e.g., 5 nm) tend to promote more effectiveness in enhancing the development of strength compared to larger particles, particularly under low dosages of water to binder. In general, when dispersed adequately and added at appropriate dosages, nano-TiO_2 has proved to exhibit potential to enhance the microstructure, durability, and initial mechanical properties of cementitious and geopolymer materials, as well as to provide photocatalytic activity, promoting sustainability-oriented applications (Zhong et al., 2022; Jiang et al., 2023; Dhanapal et al., 2024).

This work presents novel contribution by exploring the nano-TiO_2 inclusion effect into a new geopolymer matrix of equal parts of GBFS and WCP—a binary system not thoroughly examined in the current literature previously. Although previous studies have relied heavily on conventional precursors like MK and FA, the blending of waste ceramic, a high-volume industrial waste, and nano-engineered additive presents a greener solution potential of improved functionality. In the study, the effect of nano-TiO_2 at different dosages (2%, 4%, and 6%) on the principal physical and mechanical parameters of porosity, water absorption, compressive strength, and capillarity is thoroughly assessed, addressing both durability and microstructural optimization. By optimizing the dosages of the nanoparticles and the composition of the binder, this research improves the progression of high-performing, environmentally sound GCs and presents a practical mechanism of valorizing ceramic waste in next-generation construction and building materials.

2. Materials and methods

2.1. Materials

This study applied a binary binder system of 50% GBFS and 50% WCP (by mass), chosen to balance the latent hydraulic activity of GBFS and the pozzolanic and fill properties of finely ground waste ceramic. GBFS was a gray, glassy powder of CaO, SiO_2, Al_2O_3, and MgO, of specific gravity 2.93, Blaine fineness of about 410 m^2/kg, and average particle size of approximately 8–12 µm, lending itself to high alkaline condition reaction due to its high degree of amorphous character (typically more than 85%). WCP, derived from industrial waste ceramic and ground in order to increase the reactivity, had a specific gravity of 2.62, median particle size (D50) of 18–25 µm, and a surface texture dominated by fractured, angular grains. Although not chemically reactive like GBFS, the WCP provides useful content of silica and alumina and acts as a secondary pozzolanic material when finely ground, in particular under elevated curing temperature conditions. In the ceramic particles, a mixture of crystalline phases (principally mullite and quartz) and residual glass is present and >60% SiO_2 content, only when they are mixed with a reactive calcium source. Natural river sand of a standard mortar grading was applied as the fine aggregate at a sand binder ratio of s/b = 2.5, in order to give structural support and a uniform, stable packing density.

Alkali-activator solution contained a mixture of NaOH and Na_2SiO_3, the NaOH solution was synthesized at a concentration of 12 M to provide sufficient alkalinity during the dissolution of the aluminosilicate phases, while the sodium silicate solution contained a silicate modulus (Ms = SiO_2/Na_2O) in the region of approximately 2.0. Na_2SiO_3/NaOH mass ratio was held constant at 2:1, a highly established ratio in the production of both N-A-S-H and C-A-S-H gel products. Activator-to-binder ratio was set at a constant of 0.5, whereas the water-to-binder (w/b) ratio was set at 0.48, including both the free water and the water content of the Na_2SiO_3 solution in order to achieve sufficient workability and geopolymerization efficiency. For improved microstructural properties, nano-TiO_2 in the anatase phase was added at dosages of 2%, 4%, and 6% by the weight of the binder. Nano-TiO_2 of high purity (>99%) with a specific surface area of 200–250 m^2/g and average particle diameter of 20–30 nm and true density around 3.9 g/cm^3 was used. These nanoparticles are characterized by high surface activity, potential of being a photomicroreactant, and pore structure refinement by functioning as micro-fillers and nucleation centers in the alkaline-activated matrix system. Their high surface energy and small particle size facilitate the gel densification and restrict capillary pore communication, more so when sufficiently dispersed in the system. Dry constituents (GBFS, WCP, and nano-TiO_2) were mixed homogeneously prior to incorporation in the alkaline solution. None of the mixes were cast in prismatic molds and cured in a thermal oven at 80°C for 24 hours, a curing condition that is shown to promote the dissolution of the aluminosilicates and subsequent GC reactions, of high value in the case of slag-rich systems. Such controlled curing guarantees quick development of the strength and the matrix and provides the basis to assess the physical and mechanical properties under the effects of nano-scale addition.

Table 1 presents the chemical composition of the materials used in the study, while the comprehensive mixing ratio and material dosages per batch are detailed in Table 2.

Table 1. Chemical composition of binders

Main Oxide (%)	CP	GBFS

3. Results and discussion

3.1. Physical properties

Incorporation of nano-TiO_2 in dosages of 2%, 4%, and 6% by binder weight had a significant effect on the physical characteristics of the geopolymer mortars, including porosity, water absorption, and unit weight—important indicators of microstructural solidity, degree of compactness, and possible sustainability in the long term (Table 3). For comparison, the control sample (R) was a reference sample in order to measure the degree of nano-scale modifications to the material. For the reference mix, porosity was measured at 21.91%, accompanied by a water absorption of 11.75%, and unit weights of 2.39 g/cm^3 and 2.37 g/cm^3. These indicate a highly porous and loosely compact structure, lacking micro-filling agents, so the capillary water transport is easy through the voids present in a continuous manner. The relatively low density also supports the view of a matrix of poorly bonded and dispersed solid particles, which leads to high void content and low structural cohesion. When 2% of nano-TiO_2 was added, significant improvements were achieved: porosity decreased to 20.98%, water absorption dropped to a value of 10.78%, and unit weights increased to 2.46 g/cm^3 and 2.44 g/cm^3. This result points to the effect of nano-TiO_2 in enhancing particle packing and sealing of fine voids due to its extremely low particle size and high surface reactivity. By filling micro- and mesopores in the binder-aggregate interface, the nanoparticles effectively broke the capillary pore system's continuity and hence restricted the ingress of moisture, leading to a tighter matrix and low entrapped air content. In the case of the series at the 4% incorporation of nano-TiO_2, however, an unexpected rise in the rate of porosity, to a maximum of the samples at 22.66%, was realized despite the decrease in the rate of water absorption below the initial value at a rate of 11.63% and the increase in unit weights to the value of 2.52 g/cm³ and 2.47 g/cm³. This deviation is telling of particle agglomeration, which in many instances occurs at concentrations beyond the effective uniform distribution boundary. Particle clusters in the matrix of the paste generate weak points and more voids, detracting from the quality of pore refinement and potentially disrupting pathways of the transfer of stresses. Although the increase in density indicates better compactness at the macro level, the high porosity indicates uneven distribution at the microstructural scale, possibly affecting the material's sustainability in the long term in a negative manner NT6 series, on the other hand, showed the highest degree of refined physical properties: porosity had its lowest value at 20.82%, water absorption also dropped to 10.41%, and unit weights reached its maximum at 2.53 g/cm³ and 2.50 g/cm³. This balance of parameters indicates a synergy of sufficient content of the nanoparticles and effective distribution, which helps the TiO_2 not only serve as a filler but also as a promoter of the uniformity of the microstructure. The improved compactness is likely the result of the combined effect of the void minimization, the enhanced matrix cohesion, and potential nano-caused secondary interactions responsible for a more homogeneous and resistant material matrix. In this sense, the 6% dosage becomes the optimal content, creating a fully consolidated microstructure with limited porosity, low water permeability, and maximum packing efficiency in the absence of harmful clustering (Duan et al., 2016; Jindal & Sharma, 2021; Abdalla et al., 2022; Ahmed et al., 2022; Deb et al., 2022; Mashout et al., 2023; Ziada et al., 2024).

Table 3. Unit weight, water absorption and void ratio values of GCs.

	Porosity (%)		Water absorption (%)		Unit weight (g/cm³)	
R	21.91	19.52	11.75	10.22	2.39	2.37

NT4	22.66	20.99	11.63	10.75	2.52	2.47
NT6	20.82	21.00	10.41	10.62	2.53	2.50

Capillary absorption characteristics of the control, NT2, NT4, and NT6 series exhibit a distinct pattern in water percolation resistance in line with the dosage increase of nano-TiO_2, and provides valuable information on the internal pore structure, pore connection, and densification ratio in the GBFS–WCP geopolymer matrices. In the control series, the capillary rise curve shows a steep rise in the initial stage up to approximating $\sqrt{t}$ = 90 s½, up to a maximum of around 0.0132 mm, and stabilizing slightly before gradually declining beyond $\sqrt{t}$ = 300, where it levels at approximately 0.0105 mm. Overall profile indicates high starting capillary suction and continued water movement due to the highly connected pore system having relatively large and continuous pore voids. Change of the curve from maximum to final absorption is a decrease of 20.4%, showing that though saturation is reached, the absorptive volume of water continues to happen though owing to continuous pore connection in accordance with the previously measured 21.91% porosity and 11.75% water uptake, and relatively low unit density (2.39 g/cm³), both of which support the loose and open microstructure. In the NT2 series, a greater maximum capillary uptake of approximately 0.0142 mm is reached at $\sqrt{t} \approx 95$, but what characterizes it is the more rapid decrease that follows, up to approximately 0.0102 mm, and at which a correspondingly larger decrease of 28.2% from the maximum is realized. Although the capillary rise initially occurs, the more precipitous decrease indicates a more developed capillary system, where the path is more plugged or constricted as water moves deeper in, that corresponds to the measured 4.2% decrease in porosity and by 8.3% in water uptake compared to the control, and indicates moderate pore refinement owing to the filler effect of the TiO_2 nanoparticles plugging voids and disrupting the capillary continuum partly. For the NT4 series, the curve of maximum absorption occurs in a shorter t (~0.0134 mm), at $\sqrt{t}$ = 85, and declines more precipitously compared to control and NT2, recapitulating to ~0.0091 mm, a decrease of about 32.1% relative to maximum absorption, reflecting enhanced pore discontinuity and a decrease in water holding capacity with time. Although the dosage of the 4% had resulted in a slight increase in porosity to the value of 22.66% (approximately by 3.4% more than control), the paradox is rectified by the enhanced pore shape and distribution, not in total volume of voids—that is, even though a bit more pores exist, their connectivity had lessened, and their water absorbency had decreased. Additionally, the unit weight in NT4 was the value of 2.52 g/cm³, a 5.4% increase, testifying to the continuation of structural densification, while larger-in-volume apparently associated porosities relate possibly to the nanoparticle agglomeration that created isolated and hence less connected and absorbent pores by time. NT6 series yields the most refined and resistant capillary response: the curve peaks early at $\sqrt{t}$ = 80 at a maximum value of ~0.0143 mm, slightly above the others, then shows the steepest and most sustained decline, to 0.0084 mm at $\sqrt{t} \approx 450$. This is a decrease of 41.3% from the peak, the largest of all series. This steep rate of decline points to the presence of an internal matrix in which initial surface capillaries can operate, but in which deeper routes are strongly inhibited by effective void filling and advanced gel development. Consistent with this, NT6 had the minimum porosity (20.82%), minimum water absorption (10.41%), and maximum unit weight (2.53 g/cm³), illustrating a dense, strongly packed structure. Its effectiveness at the 6% dosage is due to the optimal content-dispersion ratio: the TiO_2 nanoparticles are present in sufficient numbers to fill microvoids and serve as nucleation points, but not in so large a quantity as to spawn harmful agglomeration, resulting in a matrix of low capillary connectivity. By relative final values of absorption, NT6 had the minimal capillary absorption coefficient, being 20% below control, and 17.6% and 7.7% below NT2 and NT4, respectively, a verification of its increased resistance to water transportation and hence enhanced durability potential.

Fig. 1. Capillarity absorption values of GCs.

3.2. Mechanical properties
Compressive strength development of the GCs containing nano-TiO_2 at both the ages of 7 and 28 days shows a subtle mutual interaction between the dosage of the nano-filler and the base matrix composition of the composite of 50% GBFS and 50% WCP (Fig. 2.). Control mixture, which contained no nano-scale additives, scored a compressive strength of 18.59 MPa at the age of 7 days and attained a mean of about 21.3 MPa at the age of 28 days, according to a moderate development trend. This result is in line with the anticipated trend of a binary system of highly GBFS, which triggers initial hydration by latency-induced activation techniques, and WCP, a comparatively inert material of low calcium content and moderate pozzolanic activity. Early system compressive strength is primarily dominated by the precipitation of C-A-S-H gels of the slag in the alkaline environment, while WCP plays a passive role as a matrix former and potentially contributes to delayed pozzolanic activity to a limited extent owing to its partially amorphous silica composition. When the addition of 2% nano-TiO_2 was incorporated in the binder phase, a decrease in the early compressive strength was observed, falling to 17.84 MPa—about a 4% decrease compared to the control. This is due to a lack of adequate dispersion and possible interference of the nanoparticles in the development of the early gel, where nano-TiO_2 of poor integration can serve as inert inclusions or micro-damage due to their high surface energy and tendency to clump together in clusters. Nevertheless, a significant turnabout was observed at day 28, when the compressive strength increased to 26.86 MPa—a 1.26-fold increase compared to the control. This delayed but significant gain reflects the catalytic activity of nano-TiO_2 at

advanced stages, where its finely dispersed particles promote gel nucleation, better define the pore architecture, and enhance the development of a denser and more cohesive matrix. Such activity can also result from the surface-mediated catalysis of polycondensation reactions and the effects of the nanoparticles on the ordering of the molecular species in the geopolymer matrix. In the NT4, which contained 4% nano-TiO_2, the 7-day strength was similar to that of NT2 at 17.86 MPa. This agreement supports the theory that the quality of dispersion, not dosage, controls the effectiveness of the integration of nanoparticles in the initial stages. However, at 28 days, NT4 had attained a strength of 25.85 MPa, approximately 21% above the control, indicating that even low concentrations of nanoparticles can play a significant role in the development of the structure in the long term by enhancing gel continuity and inhibiting pore interconnectivity, thereby supporting mechanical interlocking and matrix stability. NT6 series had a unique behavior in which the 7-day strength increased to 19.32 MPa, which was a rise of 8% and 7% above NT2 and NT4, respectively. Such proactive improvement indicates that the 6% dosage limit provides enough presence of nanoparticle to expedite initial densification, perhaps by increasing the rate of nucleation and facilitating the more rapid formation of aluminosilicate chains and C-A-S-H gel microphases. Such a compact structure and finer pore geometry created by this initial reaction is likely to support the enhanced mechanical response at the earliest ages. Nevertheless, while holding a good presence at the age of 28 of 22.92 MPa, the supplementary gain compared to the control was relatively modest. This increase in the period of 7-28 days equated to a mere 18.6% in NT6, while NT2 had a considerably larger development of 50.5%, indicating that while NT6 performs well at triggering rapid hydration at the start, its contribution in the development of the ultimate strength might be impaired. This attenuation in late-stage performance is probably due to nanoparticle agglomeration, a phenomenon more likely at high dosages. As concentration reaches or exceeds the dispersion limit, effects of clustering increase, potentially inducing microvoids or areas of weakness and inhibiting subsequent matrix development. These agglomerates decrease the reactive surface area, interrupt the continuity of gels, and even potentially disrupt the optimum composition of the pore solution, thus inhibiting the progression of geopolymerization. Conversely, NT2 best provides the optimum balance of content of nanoparticles and uniformity of dispersion, maximizing both physical densification and chemical activity. Its high 28-day strength supports the contention that a more diluted, well-dispersed dosage will outdo higher concentrations plagued by suboptimal distribution and site defects. In addition, when the development of the net strength over the period of 28 days is looked at, the control mix demonstrated a relatively low rise of around 2.7 MPa, or a mere 14.7%. In distinct comparison to the NT2 system, the development of more than 9 MPa was realized by it. Such a difference indicates that nano-TiO_2, in addition to functioning as a micro-filler, plays a constructive and significant role in enhancing the structural and chemical maturity of the geopolymer matrix, especially when added at the optimal dosage along with effective dispersion. Ultimately, the findings indicate that increased content of nanoparticles might provide short-term benefits, but the maximum mechanical performance in the long term is achieved under precisely controlled conditions of maximal homogeneity of the nanoparticles in the matrix (Duan et al., 2016; Jindal and Sharma, 2021; Abdalla et al., 2022; Ahmed et al., 2022; Deb et al., 2022; Mashout et al., 2023; Ziada et al., 2024).

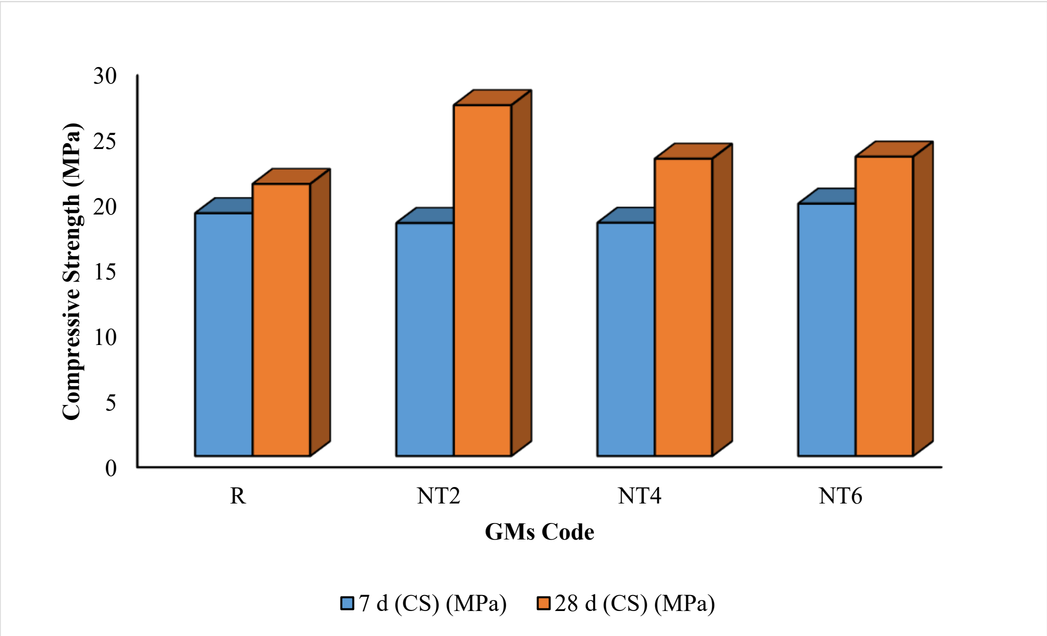

Fig. 2. Compressive strength values of GCs

4. Conclusions

- Addition of 2% NT2 led to the maximum 28-day compressive strength of 26.86 MPa, a 50.5% increase compared to its 7-day counterpart.
- NT2 also lowered porosity to 20.98% from a control of 21.91% and water absorption to 10.78% from 11.75%, reflecting enhanced matrix densification.
- The highest initial-strength property (19.32 MPa) and unit weight (2.53 g/cm³) was possessed by NT6, but it had a low increase in 28-day strength of just 18.6%, attributable to potential nanoparticle agagglomeration.
- Capillary uptake fell most in NT6, by a decrease of 41.3% from peak to end values.
- When compared to all the mixtures, NT2 had the best blend of development of strength, pore refinement, and durability in the longer-term, and hence is the optimum dosage

Effect of tin coating applied to new generation steel material used in elevator parts subject on tribological

Mohammad J. Azimi Igdir*[1], Yaşar Sert [1], Tevfik Küçükömeroğlu[1]

[1] Karadeniz Technical University, Department of Mechanical Engineering, 61080 Trabzon, Türkiye

Abstract. This study investigates the effects of titanium nitride (TiN) coating deposited on Vanadis 23 and Dievar by the physical vapor deposition (PVD) method to increase the performance of elevator parts exposed to wear. In the study, hardness and wear tests were applied to steel samples before and after coating, and the influence of the coating to mechanical and tribological properties was evaluated.The results show that TiN coating significantly increases hardness and wear resistance in all two steels types. The hardness rate increased approximately 2 times in TiN coated Vanadis 23 and nearly 3 times in Dievar compared to base metal. Vanadis 23 and Dievar steels demonstrate high performance after coating, owing to their powder metallurgy-based structures. In particular, the potential of TiN coating in elevator components exposed to intense wear such as guide rails, guide shoes, rollers and gearbox was emphasized.This study presents an innovative approach for industries seeking durability and economic solutions, and demonstrates the potential of steel surfaces to which TiN coating is applied to provide longer life and reliability in elevator parts. The findings confirm that TiN coating is a strategic solution for increasing wear resistance and hardness performance.

Keywords: PVD coating; Tribology; Wear; Elevator components

1 Introductıon:

Elevators are significant elements of modern infrastructure, in which critical components need to have high reliability and safety in order to maintain smooth and safe operation (Liang & Li, 2016; Zhang et al., 2019). Traction wheels, safety clamps, brake shoes, and rope clamps in high-speed elevators and friction pads in safety gear systems are some examples that are subjected to adverse conditions of friction, high pressure, and wear (Zhang et al., 2019; Kladovasilakis et al., 2024). The harsh operating conditions are responsible for the heightened failure of key elevator parts (Liang & Li, 2016). The failure of these parts has direct effects on the accuracy, safety, and overall lifespan of the elevator system (Zhang et al., 2019), leading to potential maintenance costs and downtime (Zhang et al., 2019; Kladovasilakis et al., 2024).

To improve the poor wear resistance generally observed in mechanical components (Zhang et al., 2019; Silva et al., 2024; Xian et al., 2021), various surface modification techniques have been extensively employed. Physical Vapor Deposition (PVD) is one of the typical methods employed to deposit hard coatings ((Ichou et al., 2023; Xian et al., 2021). Titanium nitride (TiN), being a well-established hard ceramic coating (Silva et al., 2024; Xian et al., 2021), finds extensive applications in a number of industries owing to its high hardness, good chemical stability, and improved wear properties (Silva et al., 2024; Ichou et al., 2023; Hernández-Sierra et al., 2018; Murwamadala et al., 2025; Wang et al., 2022). TiN coatings have also been found to enhance wear resistance and increase the service life of the components (He et al., 2014, Zhang et al., 2019, Hernández-Sierra et al., 2018). Recent research on Al- and Zr-doped TiN coatings deposited by magnetron sputtering has found them to have increased hardness, adhesion, and wear resistance at optimized conditions (12). The substrate material is known to affect the performance of the coatings (Xian et al., 2021; Murwamadala et al., 2025, Wang et al., 2022, Komarov et al., 2016).

Although the benefits of TiN coatings developed by physical vapor deposition (PVD) are known, an in-depth study of the unique tribological and mechanical characteristics of TiN coatings on various kinds of advanced steel, especially those employed or potentially suitable for aggressive elevator applications such as guide rails, guide shoes, rollers, and gearboxes (Zhang et al., 2019), is needed. It needs a comprehension of the interaction of all steel substrates and how all the improvements by TiN coating can be optimally leveraged to gain maximum lifetime as well as efficiency in these all-important elevator components (Sert et al., 2020).

https://doi.org/10.31462/icearc2025_ce_mat_454

The purpose of this work is to explore the influence of titanium nitride (TiN) coating developed by the physical vapor deposition (PVD) process on Vanadis 23 and Dievar steels. The overall aim of this study is to assess the feasibility of using this coating to improve the performance of elevator parts that are subjected to continuous wear and tear. This will be achieved by analyzing how the TiN coating affects the mechanical and tribological behavior of the different steel substrates involved.The aim of this study is to examine and compare the hardness, wear resistance, and performance potential of TiN coatings deposited on Vanadis 23, Dievar, and AISI 52100 steel substrates. The outcomes generated in this study can be a viable and cost-effective solution for the optimal design of industrial parts, particularly those applied in elevators, to enhance their life span and minimize the failure rate.

2. Material and methode

Vanadis 23 and Dievar steel were prepared as base and alternative materials with the formulation shown in Table 1 and were cut into circles with a diameter of 24-26 mm for door preparation. After cutting, they were sanded with sandpapers of 200, 400, 600, 800, 1000, 1500 and 2000 and prepared for polishing. After polishing, they were prepared for coating with the Cathodic Arc PVD technique.

Coating depositions were performed utilizing the cathodic arc evaporation process via a Platit π411 Plus device (Switzerland), modified to suit industrial purposes. The coatings were deposited with comparable conditions for all three: a cathode current of 150 ± 30 A, bias voltage of 65 ± 15 V, temperature of 450 ± 30 °C, and flow rate of nitrogen gas at 450 ± 30 scam.

To examine the substrate-coating interface, SEM examined cross-sections of steels that had been coated simultaneously and fractured in a brittle manner to avoid deformation or thermal effects. SEM also examined wear mechanisms on the coated samples and the counter bodies.

Using Al_2O_3 balls (6 mm diameter) as counter bodies to mimic abrasive wear, wear tests were carried out on a DUCOM (TR-201, India) tribometer in an ambient situation. 10 N load, 150 rpm, 8 mm wear diameter, and 5000 cycles were the test parameters. Worn surface topography was assessed through a non-contact profilometer (NANOFOCUS μscan Custom, Germany) at a resolution of 5 μm × 5 μm, and wear volumes were calculated.

An impact-sliding wear test rig was employed to evaluate the wear performance of the coatings specimens. The test was carried out under room conditions with an alumina (Al_2O_3) sphere, 10 mm in diameter, as the counterface. A fixed load of 10 N was applied, with each test consisting of 5000 cycles, each cycle comprising a sliding distance of 5 mm.

Morphological, topographical, and crystallographic examinations were carried out by scanning electron microscopy (SEM) (Zeiss EVO LS10, Germany) and X-ray diffraction (XRD) (Panalytical Empyrean, UK). XRD measurement was performed in a Bragg-Brentano configuration with a 2θ range of 5–100° and a scan rate of 3°/min with a step size of 0.05°.

For minimizing the influence of the substrate material on the measured hardness values of the coatings, in addition to microhardness tests, five nanoindentation measurements were performed. These measurements were conducted under a 0.5 g load using a Hysitron Ti 950 nanoindenter.

3. Results and discussion

3.1 Microstructural and mechanical analysis

Fig. 1 presents the SEM images of the surface morphology of TiN coating applied to Vanadis 23 and Dievar steels. Common defects of the cathodic arc evaporation method, such as white droplet-like particles and surface holes, were observed on the coatings. The droplets are mostly smaller than 1 μm. These droplets, resulting from the ejection of molten material from the cathode during arc evaporation, appear as bright, spherical features, while the holes likely originate from localized shadowing effects or insufficient film growth in certain areas. Notably, the Vanadis 23 substrate (Fig. 1- b) shows a higher density and larger size of droplets compared to the Dievar substrate (Fig. 1- a), indicating possible differences in nucleation behavior or substrate–coating interactions.

The figure 2, presents cross-sectional SEM images of TiN coatings deposited via the CAPVD method on (Fig. 2-a) Dievar and (Fig. 2-b) Vanadis 23 steel substrates. Both images clearly reveal a uniform and continuous coating layer with an approximate thickness of 5 μm. The Dievar substrate coating (Fig. 2a) is relatively dense and has a smooth microarchitecture, suggesting good compactness and adhesion. Conversely, the TiN coating on the Vanadis 23 substrate (Fig. 2b) displays a columnar and textured morphology, typical of coatings deposited by an arc process that can be disrupted by the microstructural and thermal characteristics of the substrate.

The differences in morphology can influence wear resistance and mechanical behavior of the coatings under function. These findings indicate that substrate material greatly influences resultant microstructure and deposited layer quality even at the same deposition conditions.

Table 1.EDS analys Chemical composition of substrate metals (weight %).

Elements	Fe	C	Mo	Cr	V	W	Mn	Si
Vanadis 23	80.02	1.28	5	4.2	3.1	6.4	5	---
Dievar	91.05	0.35	2.3	5	0.6	----	0.5	0.2

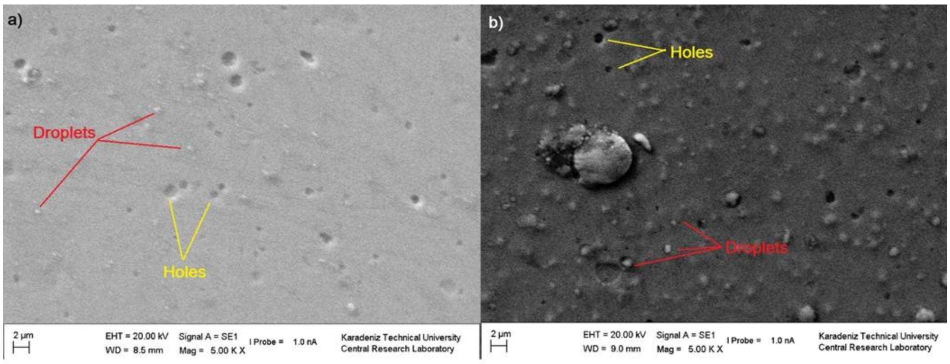

Fig. 1. The SEM images of a) Dievar-TiN, b) Vanadis23-TiN coated by CAPVD surfaces.

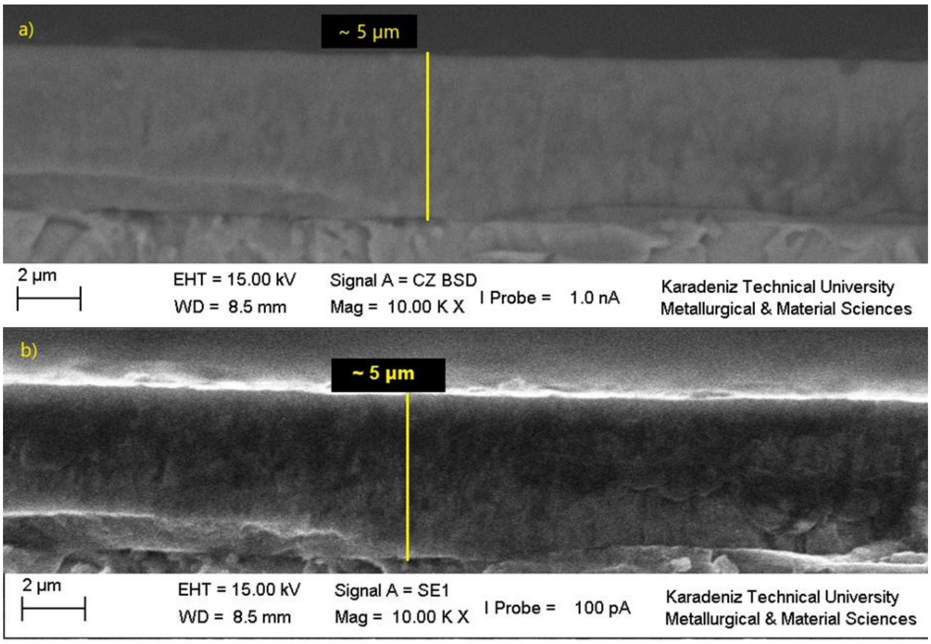

Fig. 2. The cross-section SEM image of TiN coated on a) Dievar stells and b) Vanadis 23.

XRD results of the TiN coatings are presented in Fig. 3. When the XRD patterns were analyzed, it was observed that TiN was the dominant crystal structure in the coated samples. In the TiN layers, the TiN (200) peak appeared as the main peak. The preferred growth of the (200) orientation is explained by the deposition process, which enables the adatoms to migrate over the growing surface. Besides the TiN peaks, iron peaks were also observed, particularly in the base materials. Moreover, the TiN reflections of (111), (220), and (222) were observed, but with smaller intensities. Relative to Vanadis 23, Dievar samples contained a greater amount of Fe within the TiN coating and thus a greater extent of intermixing between the coating and the substrate. Apart from this, small amounts of oxygen were also found in both the coatings, likely due to small-scale oxidation of the surface on or after deposition. Overall, the EDS analysis confirmed that TiN coatings with different extents of substrate effects were deposited successfully.

The measurements that were determined from nanoindentation (Fig. 4) confirmed that coating the base materials with a TiN coating greatly increased their hardness values. For Dievar substrate, the hardness increased from about 10 GPa to well above 30 GPa following the TiN deposition. Likewise, in Vanadis 23, the hardness increased from around 14 GPa to about 28 GPa following the TiN coating deposition. This remarkable improvement can be attributed to the intrinsic high hardness of the TiN layer deposited by CAPVD, which contributes significantly to both base metals surface properties with very high effectiveness. Moreover, the greater relative improvement demonstrated in Dievar shows that the TiN coating affected this substrate more in comparison with Vanadis 23.

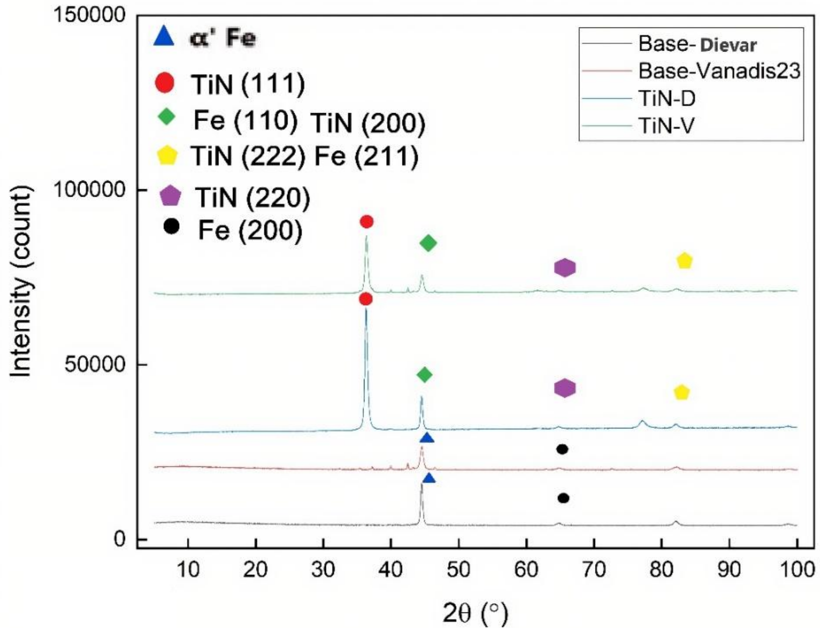

Fig. 3. The XRD patterns of the base metals and coated samples.

Table 2. EDS analyse Chemical composition of TiN coating (weight %).

Elements	Fe	Ti	N	O
Vanadis 23	7.91	57.95	33.39	0.75
Dievar	33.71	33.93	31.73	0.63

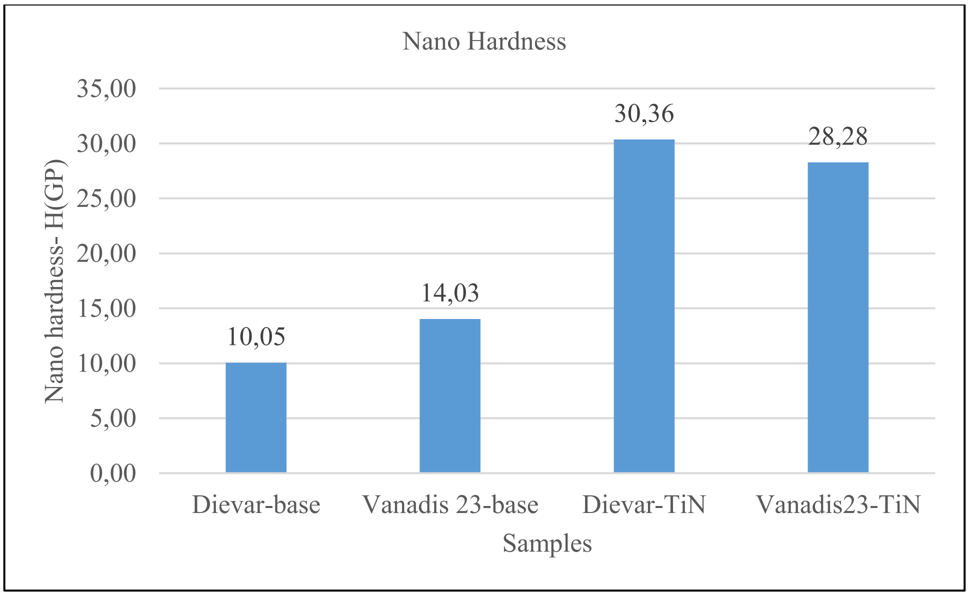

Fig. 4- The nano hardness results of base metals and coatings.

3.2 Adhesion strength analysis

Fig. 5 presents the scratch test results for the base metal samples coated with TiN, i.e., Dievar and Vanadis 23. The critical load (Lc_2), which indicates the beginning of coating failure, is considerably higher in the Vanadis 23-TiN sample (92.6 N) than that of the Dievar-TiN sample (62.2 N). This is indicative of better adhesion strength and mechanical properties of the TiN coating when deposited onto the Vanadis 23 substrate. In both samples, the scratch track images demonstrate the typical modes of failure of hard coatings, which include cohesive cracking of the coating and partial delamination. The Vanadis 23-TiN sample shows a smoother and more consistent scratch path with fewer severe defects and suggests a tougher substrate-coating bond.

3.3 Friction and wear properties

Fig. 6 illustrates the evolution of the friction coefficient as a function of time for base metals and their TiN-coated counterparts. In the initial testing stages, there is an abrupt increase in the friction coefficient in all specimens, which is typically attributed to the running-in period, where surface asperities interact and accommodate under load.

After this initial transition, the frictional behavior becomes stabilized, demonstrating marked differences between the TiN-coated and base material. Dievar's base metal (described by the red curve) presents the lowest and most stable friction coefficient throughout the experiment. In contrast, samples coated with TiN, particularly Vanadis23-TiN (blue), show steadily high friction coefficients. The observed effect is likely due to increased surface hardness and roughness provided by the TiN coating that enhances the resistance to sliding. In addition, there are minor variations in the friction coefficient curves observed in all the materials, which capture the dynamic character of surface interactions through extensive sliding.

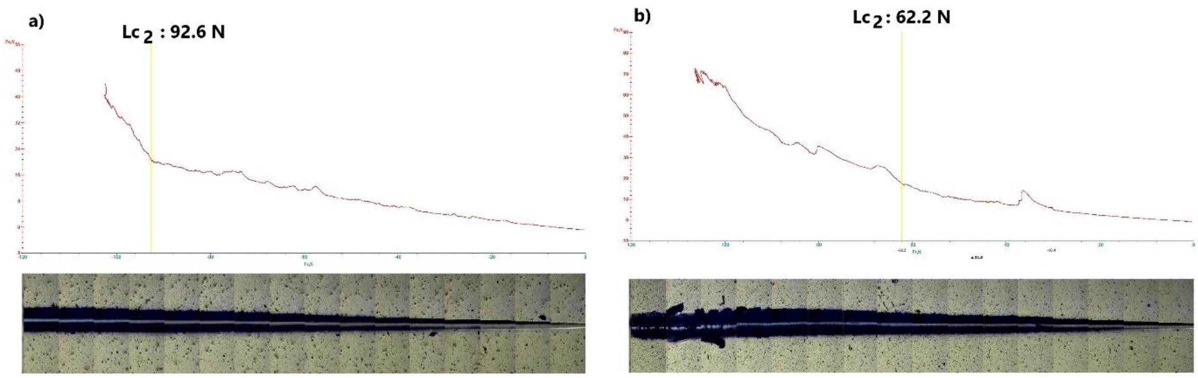

Fig. 5. The graphs of Scratch test on a) Vandis 23- TiN coating and b) Dievar- TiN coating

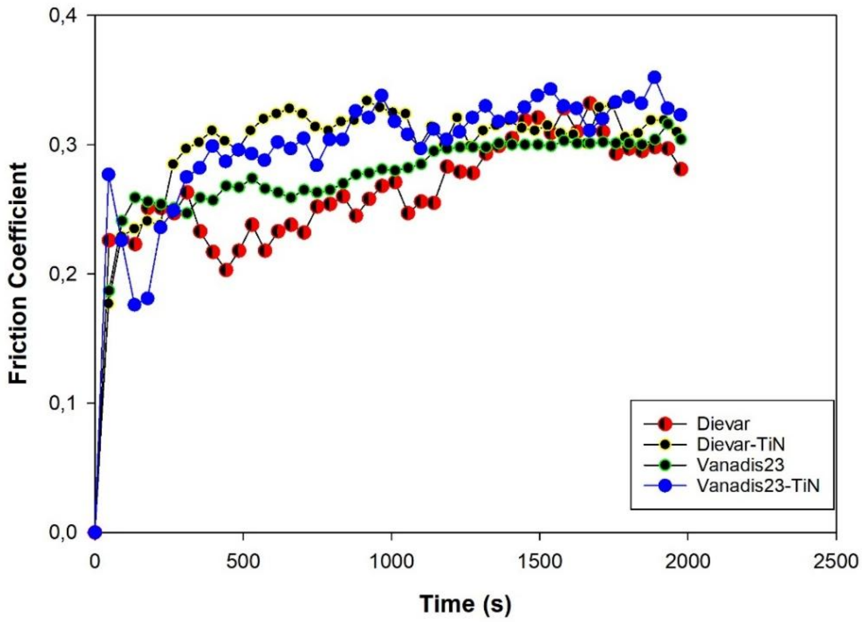

Fig. 6. The friction coefficient graphics of base metals and TiN coated materials.

Fig. 7 illustrates the Scanning Electron Microscope (SEM) micrographs of worn surfaces of Dievar and Vanadis 23 steels, tested under both uncoated and titanium nitride (TiN)-coated conditions, after an impact-sliding wear test. Every row of the figure designates a specific sample condition, while the three columns designate different positions along the wear track: (a) impact area, b) sliding area and c) final contact area.

For the Dievar-base sample (top row), the surface wear is dominated by severe plastic deformation and delamination features, particularly in the impact area, suggesting a strong initial mechanical response to cyclic loading. The wear track becomes progressively smoother towards the final contact area, but there are still recognizable grooves, which suggest continued abrasive interaction. The wear morphology of Vanadis 23-base (second row) is noticeably finer. The surface degradation is less severe than in the case of Dievar, with smaller debris particle size and less frequent microcracking events. This reflects the fact that the higher intrinsic hardness and microstructural stability of Vanadis 23 impart to it greater resistance to repeated mechanical loadings.
Moving to the coated samples, Dievar-TiN surface (third row) shows coating fracture and localized delamination, predominantly in the middle and end regions. Crack patterns spread over the coating layer, which may be attributed to lacking load-carrying capacity or interfacial strength under cyclic impact-sliding loading conditions. There is partial peeling away of the coating in some areas, revealing the substrate below.

In contrast, the Vanadis 23-TiN sample (bottom row) retains a well-intact coating over most of the wear track. Micro-cracks and ploughing scratches are apparent—particularly in the star and mid regions—however, the coating has enhanced adhesion and more regular interaction with the substrate. This enhanced performance can be attributed to the compatibility of the TiN coating with the harder Vanadis 23 matrix, which enhances the load transfer and crack deflection.

Collectively, these scanning electron microscope observations offer deep insight into wear mechanisms active and the influence of substrate nature and coating integrity on tribological performance in complex loading conditions.

Fig. 8 presents SEM images of the worn surfaces of base and TiN-coated samples. In Figure 8A, for the base material-Dievar specimen, there is pronounced abrasive wear with deep grooves and severe surface degradation. The inset, magnified further, exhibits massive plastic deformation and material removal, evidence of a vigorous sliding interaction.

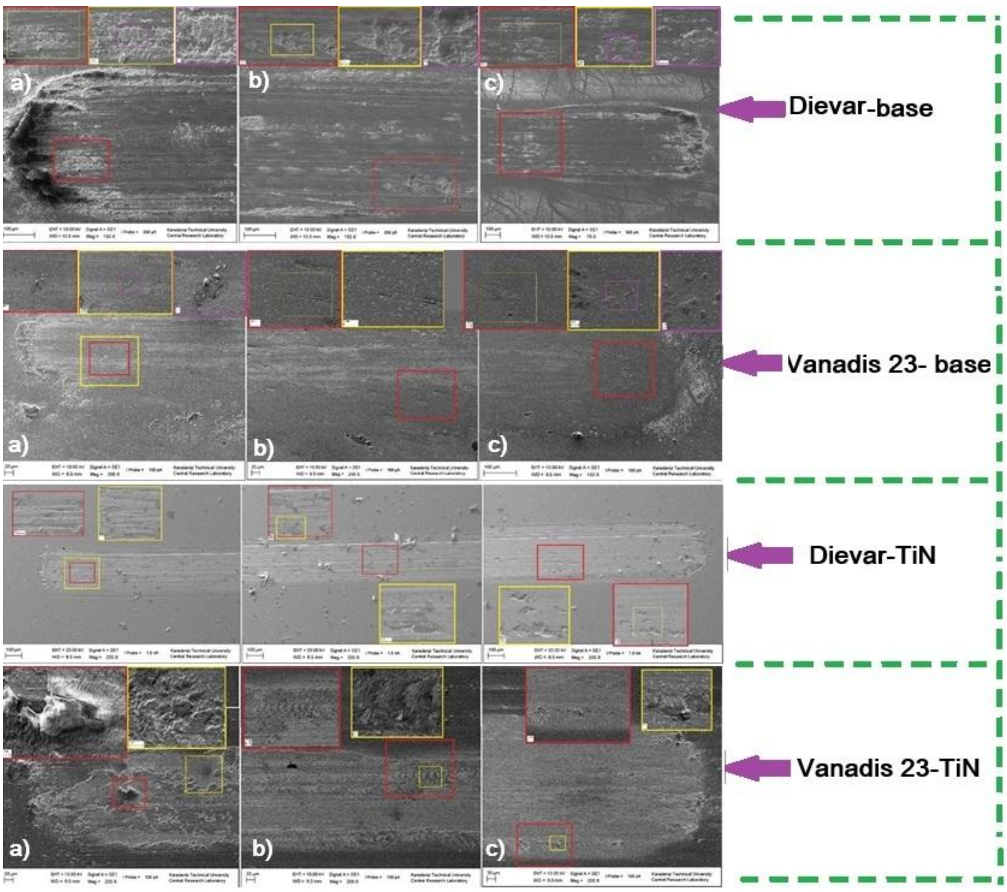

Fig. 7. The SEM images of worn surfaces by impact-sliding test. a) Impact area, b) Sliding area and c) Final contact area

Fig. 8(b) presents the worn surface of the base metal Vanadis 23 sample. In this case, the wear tracks are noticeably more pronounced than those observed in Dievar, and this is due to the greater hardness and wear resistance characteristics of the Vanadis 23 material. Accordingly, evidence of material delamination and micro-cracking is still evident in some localized areas.

Considering the coated samples, Fig. 8(c) (Dievar-TiN) reveals a more uniform wear pattern. The addition of TiN would seem to have had a profound impact on material degradation; however, small grooves can still be discerned.

Last, Fig.8(d) (Vanadis 23-TiN) manages to demonstrate the lowest amount of surface damage out of all of the samples. Wear tracks observed are relatively shallow in nature, and the coated surface seems to have maintained much of its structural integrity.

Fig. 9 illustrates the values of wear rate (mm³/N·m) for base and TiN-coated samples of Dievar and Vanadis 23 steels. As can be seen, the Dievar-base sample has the highest wear rate of all, whereas Vanadis23-base has a much smaller value. When coated with TiN, both materials are seen to significantly reduce their wear rate. The wear rate of Dievar-TiN is significantly less than that of its uncoated equivalent but remains higher than in the TiN-coated Vanadis23 sample. The Vanadis23-TiN sample has the lowest wear rate in this study. These wear behaviors are quantified very nicely by the bar chart to enable a ready comparison between all the conditions that were examined.

Fig. 10 shows the impact-sliding wear rate (mm³/N·m) of Dievar and Vanadis 23 steels in both uncoated and TiN-coated (by CAPVD) conditions. One can see a distinct difference in the wear behavior of the samples. The most pronounced wear rate among all the samples is that of the Dievar-TiN sample, showing a high sensitivity of the coated surface to the combined impact and sliding stresses.

Interestingly, though, the TiN coating affects the two substrate materials differently. On Vanadis 23, the TiN coating causes an increase in the wear rate in its coated compared to its uncoated sample; however, the increase is quite contained. In contrast, Dievar's wear rate rises substantially with TiN coating, indicating potential incompatibility or lack of adhesion performance in dynamic loading conditions for this material–coating combination.

4. Conclusions

This work investigated the microstructure, mechanical, and tribological characteristics of CAPVD-deposited TiN films on Vanadis 23 and Dievar steels in a systematic manner. SEM and XRD measurements attested successful crystallite growth of the TiN(200) orientation on both substrates with substrate-dependent morphology. Whereas the Dievar coating possessed a denser and more uniform microstructural content, Vanadis 23 exhibited a more columnar structure with a greater incidence of droplet defects.

Nanoindentation experiments revealed a remarkable surface hardening in both the materials being investigated, Dievar exhibiting a very strong increase. The result suggests that it is possible for the TiN coating to enhance surface properties. However, this benefit was not always transferred to performance enhancement under all circumstances. Scratch testing and wear measurements revealed that Vanadis 23 had much better adhesion and tribological performance than Dievar. Although having a lower hardness increment, Vanadis 23-TiN exhibited high critical load values and low wear rates under sliding and impact-sliding conditions.

These findings suggest that substrate-coating interaction is an equally important determinant of the functional behavior of PVD coatings. While TiN deposition increases hardness in general, the performance under multiplex loading and especially dynamic or impact conditions is very substrate-dependent. The much poorer wear behavior of Dievar-TiN under impact-sliding conditions is reflective of a suggested mechanical compatibility mismatch and needs further optimization of coating scheme or surface pretreatment.

In conclusion, Vanadis 23 displayed higher overall compatibility with TiN coatings in rigorous tribological environments and consequently established itself as the more durable alternative for high-wear and impact-resistant applications. The work accentuates the requirement to optimize coating-substrate systems not merely based on intrinsic material characteristics but also considering the ambient environment and complexities of loading conditions.

Abstract. One of the most efficient routes to decarbonising the cement industry is using supplementary cementitious materials to partially substitute Portland cement. Raw clays are the most abundant materials in the field and have promising pozzolanic properties. However, non-clay materials' impurities, such as calcite, dolomite, quartz, and feldspar, may influence their reactivity. Thus, this paper systematically explores, for the first time, the influence of calcite impurities on the physicochemical and pozzolanic properties of alternatively activated (MCA) 2:1 (montmorillonite) clays and their potential utilisation in the LC^3 system. Montmorillonite samples before or after MCA were blended with 35% calcite, equivalent to the optimum ratio (2:1 clay-to-calcite) for the LC^3 system. The results suggest that adding mechanochemically activated montmorillonite significantly improved the compressive strength, showing superior properties to their thermally activated counterpart in the LC^3 system. In particular, simply co-milling montmorillonite with calcite results in the best performance by achieving approximately 20% higher strength than its thermally activated counterpart. The superior strength of co-milled montmorillonite can be related to increasing MCA efficiency with calcite addition due to its shielding effect, where the harder component (limestone 3 Mohn hardness), compared with montmorillonite (1-2 Mohn hardness), stays coarser and abrades the softer one. It was also observed that a decrease in the crystallinity of calcite after MCA can be another reason for better performance.

Keywords: 2:1 Clays; Limestone calcined clay cement; Mechanochemical activation; Calcite impurities

1.Introduction

Using supplementary cementitious materials (SCMs) as a partial replacement for Portland cement is one of the most effective ways to decarbonise the cement and concrete industry. Due to their abundance, relatively good geographic distribution, and high pozzolanic reactivity, clay minerals show great potential to decarbonise the cement industry and a 50% reduction in the clinker factor when combined with limestone (Antoni, Rossen, Martirena, & Scrivener, 2012). Thermal treatment has been the standard activation method for aluminosilicate minerals, with high temperatures leading to the loss of lattice water of clays (dehydroxylation) and their subsequent transformation to amorphous aluminosilicate with a disordered structure, which has high reactivity potential (Monteiro, Miller, & Horvath, 2017). However, not all clays and minerals can be effectively activated thermally and might require relatively high-temperature treatment, generating considerable CO_2 emissions (Fernandez, Martirena, & Scrivener, 2011; Ilić, Radonjanin, Malešev, Zdujić, & Mitrović, 2016; Kumar, Kumar, & Mehrotra, 2007; Zhou, Wang, Tyrer, Wong, & Cheeseman, 2017). 2:1 Clays, such as illite and smectite-type minerals (e.g. montmorillonite), show minimal reactivity improvement after thermal activation. This limited reactivity can be attributed to the stable order of structural layers after complete dehydroxylation and the location of the Al groups trapped between silicate tetrahedral, limiting the reactivity of 2:1 clays (Fernandez et al., 2011; He, 2000). Sintering, formation of new crystalline phases (Mg-Al silicate) and partly amorphisation were also primary reasons for the limited reactivity of 2:1 clays (montmorillonite and illite) (Habert, Choupay, Escadeillas, Guillaume, & Montel, 2009). As for impure phases, the presence of impure phases, such as calcite, quartz, feldspar and sulfite, can impact the reactivity of clay minerals after thermal activation (Habert et al., 2009). Clay minerals reactivity is also reduced with thermal activation due to recrystallised products (feldspars) (Habert et al., 2009). Similar results were also reported by Zunino et al., where calcite impurities lead to the formation of a granular deposit on the surface of kaolin, which reduces specific surface area and results in slightly worsening clay reactivity (Zunino

* Corresponding author, E-mail: vbaki@ic.ac.uk

https://doi.org/10.31462/icearc2025_ce_mat_482

& Scrivener, 2019). Due to the disadvantages of thermal activation reported above, mechanochemical activation has gained significant interest in academia and industry.

Despite the abundant literature regarding the thermal-treated calcite–clay system, there is a lack of systematic studies exploring these interactions for alternative activation methods, such as mechanochemical activation, which gained interest within the academic research community and the industry as an alternative clean activation route to thermal treatment. This study explores the effect of 35% calcite impurities, which is determined by considering the optimum clay-calcite ratio for the LC^3 system.

2. Materials and experimental methods

2.1.Materials

This study used pure montmorillonite (MNT) and calcite from Sigma Aldrich. CEM I 52.5N type Ordinary Portland cement from CEMEX was used to prepare the blended cement paste and mortar.

2.2.Sample preparation

2.2.1.Mechanochemical and thermal treatments

The montmorillonite and calcite were collected in powder form from Sigma Aldrich. Mechanochemical treatment of 60 g montmorillonite and 40 g montmorillonite-20 g calcite for co-grinding was performed in a Fritsch pulverısette 6 with a Tungsten carbide jar. Fifteen tungsten balls of 20 mm diameter in a 250 ml volume jar were used for activation~~,~~ as the Fritsch pulverısette manual recommended for optimum grinding. The 15/1 ball-to-mass ratio, equivalent to 60 g of powder~~,~~ was chosen for 20 minutes of mechanochemical activation at a constant milling speed of 500 rpm, as was determined in previous research on parameters for optimal activation.

For the thermal treatment, montmorillonite powders were heated for three hours at 800°C with a 10°C heat-up ramp in a standard air atmosphere. The targeted temperatures for thermal activation were determined from thermogravimetric analysis and previous research (Baki et al., 2022). After the thermal activation (3 hours), the samples were immediately removed from the oven and spread on a steel plate at room temperature for natural cooling.

2.2.2.Preparation of LC^3 pastes and mortars

LC^3 pastes and mortars with fixed water/binder ratio of 0.5 were prepared by replacing 50% of cement with 35% mechanochemically or thermally treated montmorillonite and 15% limestone, in addition to reference (100% OPC) samples. The pastes were prepared by hand mixing and cured at room temperature (20±2°C) for 28 days. Table 1 summarises the mix proportions, wherein the first letter of the label, "M" denotes mortar samples, while "P" represents paste samples. The last letter of the label indicates the treatment type: "M" for hand mechanochemical treatment, "ML" for mechanochemical co-grinding, and "T" for thermal treatment.

Mortar cubes of LC^3 systems were prepared according to EN 196-1 ("BS EN 196-1:2016 - TC: Tracked Changes. Methods of testing cement: Determination of strength," 2020) using a one-part binder, half-part water, and three-part standard sand to follow the development of compressive strength. It is also essential to note that sulphate optimisation to avoid providing under- or super-sulphated to the system with gypsum addition is not in the scope of this study.

Table 1**.** LC^3 mix designs for pastes and mortars

Series	SCMs Type	Sample ID	CEM I (g)	Montmorillonite (g)	Limestone(g)	Water/Binder Ratio	Sand/Binder Ratio
R	-	P-OPC	100	0	0	0.5	0
	-	M-OPC	100	0	0	0.5	3
M	MNT	P-LC^3-M	50	35	15	0.5	0
		M-LC^3-M	50	35	15	0.5	3
ML	MNT	P-LC^3-ML	50	35	15	0.5	0
		M-LC^3-ML	50	35	15	0.5	3
T	MNT	P-LC^3-T	50	35	15	0.5	0
		M-LC^3-T	50	35	15	0.5	3

MNT refers to montmorillonite, R stands for reference, M refers to mechanochemical activation, ML for the co-grinding kaolin with limestone, and T stands for thermal activation.

2.3.Test methods

X-ray diffraction (XRD) was used to characterise the activated montmorillinite's mineralogy and chemical bonding. The pozzolanic reactivity of the raw and activated montmorillonite was determined with a bound water test reported in ASTM C 1897-20 (International, 2020). The compressive strength of the examined mix designs was determined on 28-day mortar cubes using the Instron 150 frame conforming to EN-196-1 ("BS EN 196-1:2016 - TC: Tracked Changes. Methods of testing cement: Determination of strength," 2020).

2.3.1.Particle size distribution and surface properties

The surface morphology of the activated montmorillonite was characterised using SEM. First, the powdered samples were mounted on conductive carbon tape and then coated with 99% pure gold (Au) for 150 s in an argon gas environment using a coating device (Quorum, SC-7620). The surface morphology of the coated samples was examined using the JEOL JSM 6610 SEM under vacuum with an acceleration voltage of 15 kV. The particle size distribution (PSD) of differently activated montmorillonite minerals before and after activation was determined with a Malvern Mastersizer 2000. Both mechanochemically (including co-grinding) and thermally treated montmorillonite minerals were dispersed in distilled water for characterisation. Five minutes of ultrasonication was used for montmorillonite powders before particle size measurement.

2.3.2. Spectroscopic analysis (XRD)

The XRD was performed on an STOE STADI P (Cu radiation, λ = 1.54 Å) instrument in transmission mode, operated at 40 kV and 40 mA. The diffraction results were recorded from 5° to 75° (2θ), with a step resolution of 0.015° (2θ) per step. A double Mythen detector was used, with each detector covering a range of 19° (2θ) and operating at 31.6 s per degree (2θ). Each XRD scan took around 20 minutes.

2.4.Pozzolanic reactivity measured by R^3 test

The reactivity of montmorillonite before and after activation was examined using bound water measurements as specified in the R^3 test method (International, 2020). For each SCM precursor, bound water content was determined by mixing the examined materials with $Ca(OH)_2$, $CaCO_3$, and a potassium solution, which was prepared by dissolving 4.0 g of potassium hydroxide and 20.0 g of potassium sulphate in 1.0 L of distilled water at 23±3°C. All parts were stored at 40°C overnight before casting. The solid part was gently mixed by hand for 2 minutes. Then, the solid and liquid components were mixed at 1600 rpm for 2 minutes using a propeller mixer. Immediately after mixing, 15 g of the R^3 pastes were kept in sealed containers at 40°C for seven days for the bound water test.

2.4.1.Bound water test

After seven days of reaction, the pastes are crushed into pieces smaller than 2 mm. Then, around 10 g of crushed hydrated samples were placed into a crucible and dried in an oven at 40°C until constant weight was reached. Finally, about 5 g of the dried samples were heated at 350°C for two hours, and then cooled in a desiccator for one hour. The bound water capacity was calculated according to Equation 1, given in ASTM C 1987-20 (International, 2020).

$$H_2O_{bound,dried} = \frac{w_0 - w_t}{w_0 - w_c} \times 100 \quad (1)$$

where w_c is the weight of the crucible, w_0 is the weight of the dried material and the crucible at 40°C, and w_t is the final weight of the cooled material after heating at 350°C.

3.Results and discussion

3.1. Physicochemical properties

Fig. 1. summarises the effects of different activation methodologies on the surface morphology of montmorillonite. The irregular and sheet type morphology of montmorillonite did coarsened while some level of sheet type remained unchanged after the thermal treatment at 800°C (MNT-T). Additionally, the agglomeration of platelets in irregular stacks became more apparent.

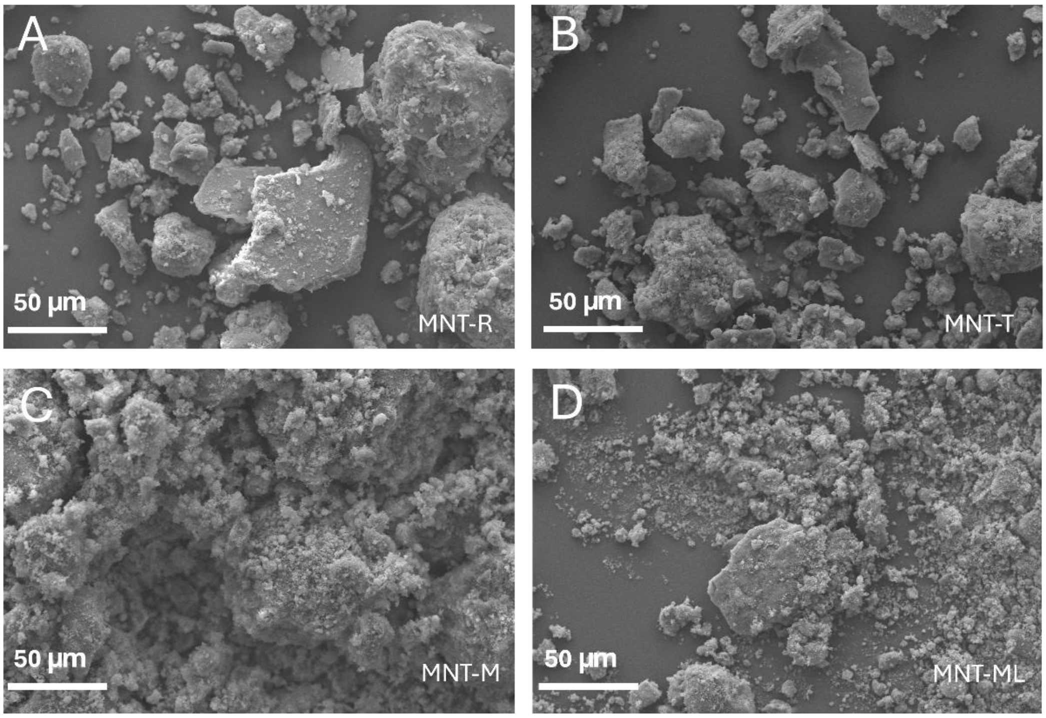

Fig. 1. Montmorillonite SEM images after different activations methodology

Table 2. D_{90}, D_{50} and D_{10} values of montmorillonite after different type of treatment

Sample ID	D90 (µm)	D50 (µm)	D10 (µm)
MNT-R	103.205	30.65	6.029
MNT-T	87.793	29.009	6.098
MNT-M	123.518	39.671	4.652
MNT-ML	111.066	35.287	4.229

The particle size reduction of montmorillonite after thermal treatment can be due to its relatively larger original particle size, where the contraction effect were observed due to heating and cooling likely surpassed the aggregation effect (Yanguatin, Ramírez, Tironi, & Tobón, 2019). For the mechanochemically treated montmorillonite, delaminated montmorillonite particles, which are small, close-to-spherical, and agglomerated into larger particles, were observed (Baki et al., 2022). Mechanochemical activation have increased the overall size distribution of the montmorillonite due to agglomeration as a result of mechanical effect. It is also important to note that co-grinding montmorillonite with limestone slightly shifts to particle size coarser areas than their mechanically activated counterpart, consistent with D_{90}, D_{50} and D_{10} values.

3.2. Phase assemblage (XRD)

The XRD measurements showed a loss in the structural ordering of the kaolinite by both mechanochemical and thermal treatment. The XRD pattern of as-received montmorillonite (Fig. 2) indicates that montmorillonite, muscovite, albite and quartz were observed from the XRD pattern of as-received kaolinite.

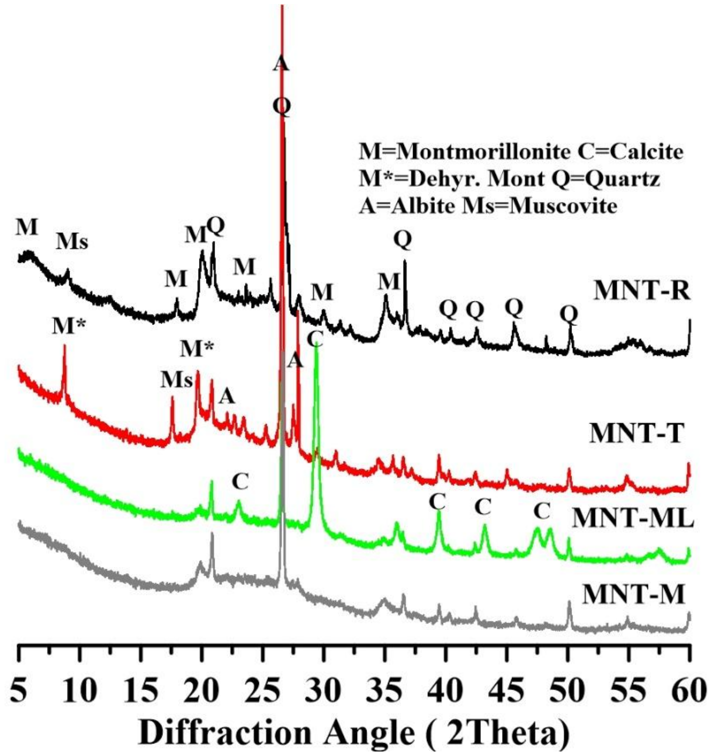

Fig. 2. X-ray diffractograms of the original and mechanically and thermally activated montmorillonite

The thermal treatment (800°C for 3 h) destroyed the crystal structure and dehydroxylate the montmorillonite but quartz peaks, on the other hand, remained unaffected, consistent with the reported literature (Baki et al., 2022). The montmorillonite reflection at about 6°2θ was reduced in intensity; however, the reflection close to 20°2θ was remained. The absence of montmorillonite peak at about 6° (2θ) and broad peak at 9° (2θ) after calcination can be related to the dehydrated structure of montmorillonite to a 10 Å TOT structure (Andrini et al., 2017; Dellisanti et al., 2018). These results are consistent with the literature, which indicates that the dehydroxylation of montmorillonite minerals disrupts the stacking of layers along the crystallographic c-axis (Garg & Skibsted, 2014; Heller-Kallai, 2006). In contrast, it does not affect the a- and b-axes within the layer plane (Garg & Skibsted, 2014; Heller-Kallai, 2006), supporting the view that dehydroxylation alone does not necessarily lead to amorphisation of montmorillonite clays (Marsh, Krishnan, & Bernal, 2024). Broadening and lowering montmorillonite peak intensities and areas after mechanochemical activation indicate a decrease in their crystalline sizes and amorphisation of the montmorillonite structure (Baki et al., 2022). Particularly, mechanochemical treatment was more efficient as it co-grinded with limestone. Also, it is important to note that the intensity of the quartz peak decreased with mechanochemical activation, can be attributed to the increase in lattice defects and degree of amorphisation.

3.3. Performance as SCM for LC^3 system

3.3.1. Fresh properties of LC^3 systems

Fig. 3 demonstrates the flowability results of different LC^3 systems, where the untreated and thermally activated montmorillonite-doped sample gives the lowest flow results. This can be related to the high fineness, specific surface area, and negative zeta potential (Py, Neto, Longhi, & Kirchheim, 2024; Sposito, Maier, Beuntner, & Thienel, 2022; Zunino, Martirena Hernandez, & Scrivener, 2021). Conversely, mechanochemically activated montmorillonite showed higher flowability, which can be related to the formation of small close-to-spherical particle agglomerate after intense milling, consistent with SEM results given Figure 1. The higher flowability values can be attributed to the phenomenon reported for fly ash addition, where the water demand decreases with fly ash addition due to their spherical particle shapes (Jiao, De Schryver, Shi, & De Schutter, 2021).

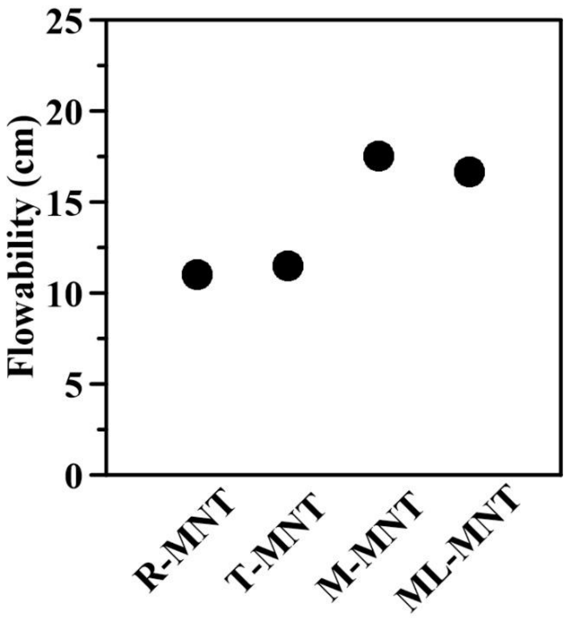

Fig. 3. Flowability results of LC^3 systems

3.4. Compressive strength and bound water test

Fig. 4 summarises the bound water percentages, which compare the pozzolanic reactivity of differently activated montmorillonite. The montmorillonite's bound water content increased after both thermal and mechanochemical treatment. The highest bound water was observed for the mechanochemically treated montmorillonite. It is also important to note that the bound water was further increased for the montmorillonite co-grinding with limestone. Bound water test results were also corroborated with strength results, where the mechanochemically activated sample (co-grinding with montmorillonite) using the LC^3 system showed the highest compressive strength, followed by the mechanically activated and thermally activated sample.

Compared with raw mechanical activation, the superior strength of co-milled montmorillonite can be related to increasing MCA efficiency with calcite addition due to its shielding effect, where the harder component (limestone 3 Mohn hardness), compared with montmorillonite (1-2 Mohn hardness), stays coarser and abrades the softer one. It was also observed that a decrease in the crystallinity of calcite after MCA can be another reason for better performance.

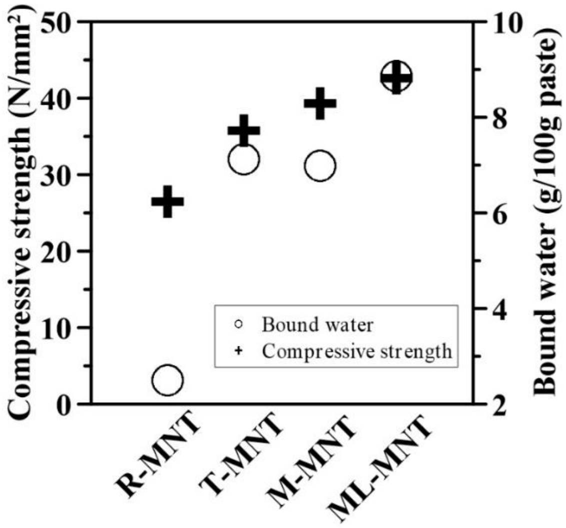

Fig. 4. Differently activated montmorillonite bound water test results and their LC^3 system compressive strength

4.Conclusion

The results show that mechanochemical activation can effectively promote the delamination, dehydroxylation and amorphisation of montmorillonite's original structures. Co-grinding montmorillonite with limestone further increases mechanochemical activation efficiency and improves strength performance. The superior strength of co-milled montmorillonite can be related to increasing MCA efficiency with calcite addition due to its shielding effect, where the component having higher hardness (limestone 3 Mohn hardness), compared with montmorillonite (1-2 Mohn hardness), stays coarser and abrades the softer one. It was also observed that a decrease in the crystallinity of calcite after MCA can be another reason for better performance.

This study presents the advantages of mechanochemical activation over thermal activation in montmorillonite for the first time by revealing higher flowability due to small close-to-spherical particle agglomerate formation after intense milling, which is a significant issue for LC^3 system particularly thermally treatment. Additionally, co-grinded montmorillonite blended LC^3 system showed 10% and 20% higher compressive strength compared with their mechanochemically and thermally activated counterpart, respectivelly.

Abstract. This paper discusses the usage of recycling concrete aggregate (RCA) as an environmental-friendly substitute for natural river sand in geopolymer mortars (GMs), considering the increasingly growing demand for such greener construction materials. In this study, GMs were designed with 50% ground granulated blast furnace slag (GGBFS) and 50% Ceramic Powder as binder compositions and replacing 100% of the natural river sand with ≤2 mm-sized RCAs. The influence of variations in the activator-to-binder ratio between 0.7 and 1.2, coupled with variations in NaOH molarity to 2M, 4M, 6M, and 8M, on geopolymerization and mechanical properties are analyzed. Ambient curing was carried out at 23±2°C with a relative humidity of 95%, thermal curing at 80°C for 24 hours, and electrical curing with an application of 20V to study the effects of all these curing methods on the compressive and flexural strengths at 7 and 28 days to provide details on short- and medium-term performances. The study also brings into focus how curing methods interact with a/b ratios and NaOH molarity in determining hydration and matrix behavior, while providing a practical and sustainable solution to construction waste management and contributing to the development of high-performance, eco-friendly materials. This study revealed that electrical curing at low molarity is more effective than curing under ambient conditions and that sample production is not always possible at the lowest molarity values.

Keywords: Geopolymer; Recyling concrete aggregate; Curing methods; Mechanical properties

1. Introduction

Traditional concrete and cement-based mortars are frequently preferred and have been used in the construction sector for a long time. These concretes and mortars also provide advantages such as high compressive strength, easy workability and long service life (Neville, 2012). However, the production stage of Portland cement from beginning to end causes significant environmental problems as it is responsible for approximately 8% of global carbon dioxide (CO_2) emissions (Mehta & Monteiro, 2014). In addition, despite all these positive effects, these concretes and mortars, which are frequently preferred, still have negative aspects. It is known that the products (e.g. calcium hydroxide) that emerge in cement-based materials as a result of hydration reactions are open to durability problems (chemical attack, carbonation) in the long term and at advanced ages depending on the environmental conditions. Therefore, the development of sustainable alternative binding systems in order to eliminate these negative effects has become very important both for the reduction of environmental impacts and the production of more durable and long-lasting building materials (Scrivener et al., 2018).

For this purpose, geopolymer mortars have gained a place in the sector as a remarkable option due to the recycling of industrial wastes, the reduction of carbon emissions and the high strength and durability properties. While the use of by-products such as fly ash, silica fume and granulated blast furnace slag (GGBFS) is common in geopolymer production, it has been observed that alternative aluminosilicate sources such as ceramic powder, glass powder, marble powder and aluminum sludge also provide successful and effective results (Torgal & Jalali, 2011; Pacheco-Torgal et al., 2008).

Among the activators used during the production of geopolymer mortars, sodium hydroxide (NaOH) and sodium silicate (Na_2SiO_3) solutions stand out and are widely preferred. The reason for this can be explained as NaOH ensures the dissolution of aluminosilicate structures and increases the amount of substance to interact, while sodium silicate solution increases the amount of silica in the system and contributes to the formation of a dense, durable matrix. (Duxson et al., 2007; García-Lodeiro et al., 2015). By using low molarity NaOH solutions (2M–6M), both environmentally friendly and low-cost production processes can be carried out, and in addition, occupational safety risks are less compared to high molarity productions (Veerappan et al., 2017; Inti et al., 2017).

In the curing process of geopolymer concrete and mortars, the use of innovative techniques such as electrical curing instead of traditional ambient and thermal methods increases both energy efficiency and easy applicability and provides a usable strength gain in a short time (Aygun, 2023).

Geopolymerization process is carried out by dissolution and repolymerization of aluminosilicate sources in an alkaline environment. Depending on the abundance of alkali activators such as sodium hydroxide in the mixture, the reaction rate and speed of the geopolymer and the mechanical properties of the obtained product are directly affected (Livi et al., 2017). When other studies are examined, high molarity solutions (10M-16M) provide faster strength results; however, both the cost and the risks to be encountered during production increase due to high molarity (Chithambaram et al., 2018). On the other hand, significant and acceptable strength values can be obtained on geopolymer mortars prepared using low molarity sodium hydroxide solutions (2M-6M). Especially mortars produced with 6M molarity provide sufficient strength and are an economical and safe option. After the production of mortars, geopolymer mortars and concretes also need curing, just like in the traditional way. Traditional curing methods have negative aspects such as high energy consumption and time loss compared to new alternatives (Livi et al., 2017). As an alternative option, the electrical curing method accelerates the hydration process and strength gain by directly applying low voltage to the fresh mortar, causing the internal temperature to increase (Aygun, 2023). Similarly, Halis Alakara (2022) has shown that electrical curing increases the mechanical strength in geopolymers containing alkali activator containing recycled asphalt dust-based aggregate and can be advantageous especially in applications where early age strength is required. In order to continue the low cost and sustainability targets within the scope of alternative concrete production and innovations, the reuse of concrete wastes is very important in terms of sustainable construction practices. The use of RCA in geopolymer mortars reduces the consumption of natural resources and raw materials, as well as allowing the evaluation and disposal of waste (Alakara, 2022). However, the surface roughness and porosity of RCA grains can affect the bonding mechanisms and cause strength losses. For this reason, it is necessary to work with low molarity alkaline solutions and effective curing methods in mortars using RCA (Inti et al., 2017).

In this study, geopolymer mortars were produced with a binder system consisting of 50% granulated blast furnace slag and 50% ceramic powder, and 100% standard sand or river sand replaced recycled concrete aggregate (RCA). Sodium hydroxide and sodium silicate were used as alkali activators, and low molarity NaOH solutions were preferred. Alkali activator/binder ratio was changed according to the changing low molarities, taking into account the appropriate workability. Mortar samples were cured with ambient curing, thermal curing and electrical curing methods, and the effects of these methods on compressive and flexural strengths were investigated. Thus, both the 100% usage potential of recycled aggregates in construction materials and the effectiveness of alternative curing methods were investigated and the results were presented.

2. Materials and methods

2.1. Materials

In order to understand the effectiveness and difference of low molarity and different curing conditions more clearly, two basic materials were used as binders: granulated blast furnace slag (GBFS) and ceramic powder (CP). Blast furnace slag was considered to be an effective choice for geopolymer mortars produced with low molarity due to its early and high strength. Ceramic powder was preferred for better interpretation of the results under different curing conditions due to its closeness to temperature levels and better observation of its interaction.

Blast furnace slag is a waste material formed as a by-product during the smelting of iron ore in blast furnaces. Its granulated form can be preferred as a binder in cement and concrete production. If the slag is cooled rapidly instead of slowly, it turns into an amorphous structure rich in silica and aluminum oxide and exhibits pozzolanic behavior due to these properties. When ground into fine grains, it reacts with cement hydration products, increasing strength and providing the majority of the strength to be produced. In addition, it contributes to environmental sustainability. They are generally light colored and have a glassy grain structure. Their density is around 2.9 g/cm^3.

Ceramic powder is a fine-grained material obtained by grinding waste generated during ceramic production and is generally light-colored, close to orange. Its density is around 2.5-2.7 g/cm^3. This powder has pozzolanic properties due to its high silica and alumina content and can be used in concrete and mortars as a substitute for cement. The use of ceramic powder, just like other pozzolanic materials, contributes to waste management and reduces environmental impacts. Table 1 shows the chemical components of granulated blast furnace slag and ceramic powder used in this study.

Sodium hydroxide (NaOH) and sodium silicate (Na_2SiO_3) were used to interact with the binders and their ratios are 1/2 units, respectively. Sodium hydroxide is a strong alkali with a pH value of approximately 13.4 and is used as an activator in geopolymer production. NaOH initiates the polymerization process by dissolving aluminosilicates. It has a salt-like appearance in the form of white and opaque crystals and must be dissolved in water according to the desired molarity before use. Its density can be expressed as 2.13 g/cm^3. Sodium silicate is the second activator used together with sodium hydroxide in geopolymer mortar production. Thanks to its silica content, it supports the formation of polymer chains and improves the mechanical properties of the mortar. In addition, the viscosity of sodium silicate affects the workability of the mixture. It has a colorless but slightly viscous, syrup-like appearance. Its density is 2.4 g/cm³. The SiO_2 content is around 24–26% and the Na_2O content is around 11.5–13.5%. The modulus (SiO_2/Na_2O ratio) is usually in the range of 1.90–2.25.

As aggregate, 100% recycled aggregate (RCA) with a grain size of ≤2 mm was used. Recycled aggregate is the material obtained by breaking demolished concrete structures or from old test samples. Since RCA has a more porous structure compared to natural aggregates, it also has a higher water absorption capacity. These properties can affect the strength and durability of geopolymer mortars. However, the negative effects of RCA can be minimized with appropriate mixture design and curing methods. The aggregates used in this study were obtained from the test laboratory within the university. Samples used have different strength classes and contents and are waste samples on which the relevant tests have been previously performed. The appearance of these aggregates is irregularly shaped, porous and gray. Its density is around 2.3–2.5 g/cm³. Its water absorption rate is higher than other aggregates, such as 5–10%. Table 2 includes the mixture calculation and recipe for mortars of different molarities produced in this study for 1 m³.

Table 1. Chemical composition of binders

Main Oxide (%)	GBFS	CP

*2M,4M,6M,8M - (50% GBFS + 50% CP + 100% RCA)

2.2. Methods

In the first stage, many different samples with different strength classes and components obtained from the building test laboratory were ground by rotating them in the Los Angeles device by means of balls. Then, a sieve with a 2 mm sieve opening was used to ensure that the aggregate grain size to be used was ≤2 mm. All the aggregates obtained below 2 mm were mixed in the mixer in dry form to be homogeneous and packaged in that way and made ready for use.

When it came to the production of samples, the production was carried out in accordance with the recipe and prismatic samples of 40x40x160 mm dimensions were produced in order to obtain 7-day compressive and flexural strength results in accordance with ASTM C349 and TS EN 196-1 standards. A total of six prismatic samples were produced for each series, two of which were exposed to ambient, two thermal and two electrical curing conditions.

While preparing the mortar, firstly granulated blast furnace slag and ceramic powder were mixed in dry form in the container of the mixer and made homogeneous. Then, 1 unit sodium hydroxide and 2 units sodium silicate solution was added to the binders as liquid phase according to the desired molarity and mixed. Finally, the determined amount of recycled aggregate was added to form the mortar and after mixing, the mortar was placed in the molds.

The samples to be exposed to ambient cure were removed from the mold after completing the 24-hour setting period and placed in a curing cabinet with a temperature of 23 ± 2 °C and a relative humidity of 95% to complete their 7-day waiting period. The samples to be exposed to thermal cure were removed from the mold after completing the 24-hour setting period and placed in an oven at 80 °C for 24 hours. Then, the samples removed from the oven were placed in the same curing cabinet after cooling to room temperature to complete the 7-day waiting period. Finally, the samples to be exposed to electrical cure were placed in wooden molds with copper plates at both ends while they were still fresh and fluid and were exposed to an alternating current effect corresponding to 20V for 24 hours. At the end of one day, the samples removed from these molds were placed in the curing cabinet to complete the 7 days.

After the 7 day waiting period, first bending and then compressive strength tests were performed on all prismatic samples in accordance with the previously specified standards. After determining the bending strengths, compressive strength tests were performed on two pieces of a single sample obtained from the prism and the average of the results of the two pieces was taken.

3. Results and discussion

Findings obtained from this study show that the mechanical strength performances of geopolymer mortars prepared with low molarity sodium hydroxide and sodium silicate solutions vary significantly depending on both the curing method differences and the molarity value. When the flexural and compressive strength values are examined together, it is seen that the highest strength values among all three curing methods are generally reached in the samples applied with thermal cure (T). This difference is more pronounced especially in the 6M and 8M molarity samples, and the compressive strength in the 6M-T series reached approximately 31.9 MPa, while the flexural strength resulted in a value of 4.47 MPa. This finding shows that the high temperature effect accelerates the geopolymerization process and supports the formation of a denser and stronger matrix (Livi et al., 2017; Duxson et al., 2007).

In addition to the thermal curing method, it is observed that the electrical curing (E) method, which is an alternative and new cure method, also has a remarkable effect. It has been observed that even at very low molarity values such as 2M and 4M, the samples cured with electrical cure have a positive effect and provide significant increases in both flexural and compressive strength compared to the cure under ambient conditions (A). For example, while the samples belonging to the 2M-A series showed a bending strength of approximately 1.1 MPa and a maximum compressive strength of 6.6 MPa, the 2M-E sample reached a maximum flexural strength of 2.1 MPa and an average compressive strength of approximately 10 MPa. This situation reveals that electrical cure is effective in activating the internal structure of the matrix in low molarity systems and that, as in electrical curing, other alternative curing techniques may be more advantageous in some cases compared to classical methods (Aygun, 2023; Alakara, 2022). Fig. 1 shows a graph showing the 7-day flexural and compressive strength results of samples with different molarity and curing conditions.

Table 3 shows the results of all compressive and flexural strength tests in MPa on samples with varying low molarity values and exposed to three different curing conditions.

Table 3. 7-day flexural and compressive strength results of geopolymer mortars with different molarity values and subjected to different curing conditions

Series	Strength Results			
	Sample 1		Sample 2	
	Flexural Strength (MPa)	Compressive Strength (MPa)	Flexural Strength (MPa)	Compressive Strength (MPa)
2M-A	1.08	6.15	1.10	6.63
2M-E	2.13	11.04	1.91	9.96
2M-T	3.15	14.60	3.61	14.53
4M-A	2.30	8.46	1.90	8.11
4M-E	3.35	19.23	3.36	20.11
4M-T	4.70	27.79	4.34	26.40
6M-A	3.32	11.39	3.30	11.87
6M-E	3.86	24.88	3.88	26.13

*2M,4M,6M,8M - (A- Ambiant curing, E- Electrical curing, T- Thermal curing)

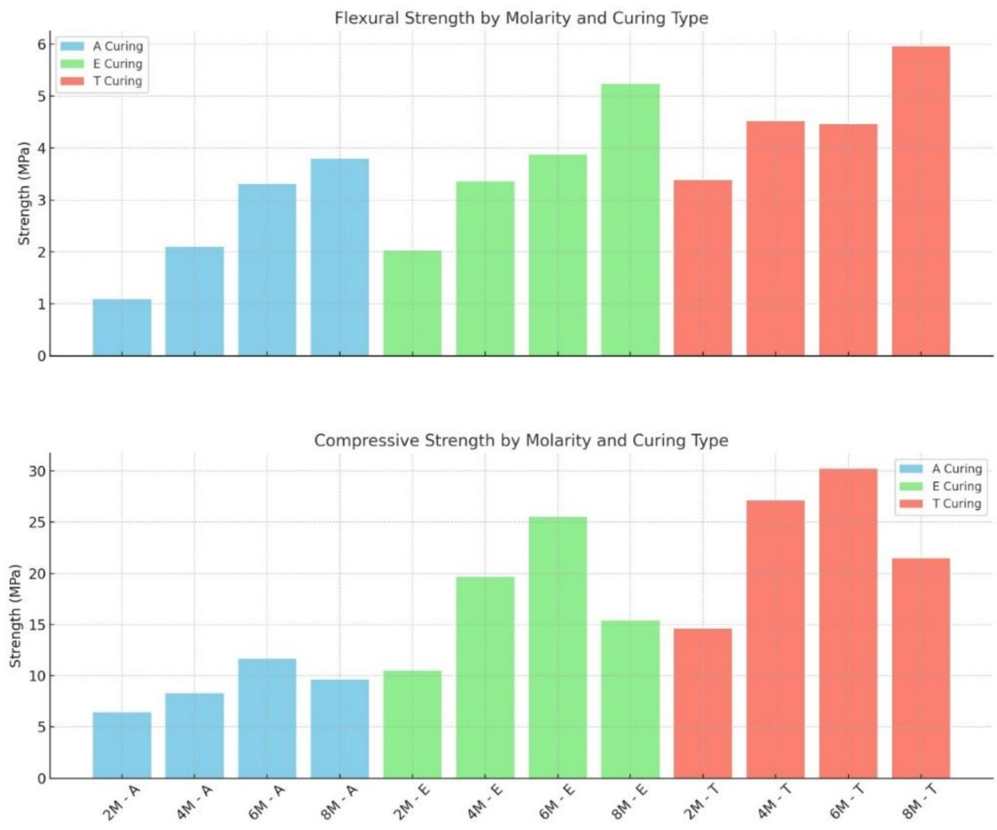

Fig. 1. 7-day flexural and compressive strength results of samples with different molarity and curing conditions

4. Conclusions

- In addition to the curing types, the molarity level has also been shown to have significant effects on mortar performance. As molarity increases, the strength values for each curing method increase significantly.
- In particular, there was a jump in both flexural and compressive strengths between 4M and 6M, which showed that the 6M value could be a threshold value that can provide high mechanical performance with low cost and environmental risks within the low molarity class.
- However, the fact that the strength values in 8M in some cure types (e.g. 8M-A) are not as high as 6M-E or 6M-T is the biggest indicator that high molarity does not guarantee the best result under all conditions.
- In general, despite the weakening effects of low molarity, electrical curing and the use of 100% recycled aggregates and the surface properties and porosity of the aggregate, acceptable strength levels were achieved in many samples.
- In addition, the binder system used in this study (50% GGBFS + 50% CP) and alternative curing techniques applied with low molarity solutions were found to support that geopolymer technology can become a more economical, environmentally friendly and applicable building material.

Comparative investigation of micro steel fiber effects on the electrical resistivity of PC and AAS composites

Ahsanollah Beglarigale*[1]

[1] Istanbul Okan University, Department of Civil Engineering, 34959 Tuzla, Istanbul, Türkiye

Abstract. This study investigates the influence of micro steel fiber incorporation on the electrical resistivity of two cementitious binder systems: Portland cement (PC) and alkali-activated slag (AAS). Eight mixtures, including reference mortars and fiber-reinforced compositions with 3%, 4%, and 5% fiber volume fractions, were prepared and evaluated. The uniaxial bulk electrical resistivity of each mixture was monitored over a 56-day curing period. The results demonstrated that fiber addition led to a reduction in resistivity in both systems, although the magnitude of improvement varied significantly depending on the matrix chemistry. AAS-based mortars exhibited substantially lower resistivity values compared to PC-based mortars, attributed to the superior ionic conductivity of the AAS matrix. The incorporation of fibers further enhanced conductivity, with 4% fiber volume identified as an effective threshold in both systems. As part of a comprehensive ongoing research project, this study focuses on optimizing the electrical conductivity of fiber-reinforced composites, laying an essential foundation for the subsequent fabrication of various smart construction materials such as self-sensing cementitious composites.

Keywords: Self-sensing mortars; Micro steel fibers; Electrical resistivity; Alkali-activated slag; Cementitious composites

1. Introduction

Cementitious composites endowed with intrinsic self-sensing capabilities are redefining the approach to structural health monitoring by enabling materials to autonomously detect and respond to internal changes such as stress, deformation, cracking, and damage accumulation. Through the integration of sensing functionality directly within the matrix, these composites eliminate the need for external devices and provide real-time, distributed monitoring based on variations in electrical properties, offering significant advantages in terms of system reliability, durability, and long-term infrastructure management. In piezoresistive systems, the introduction of conductive components, such as carbon fibers or conductive aggregates, enhances the electrical connectivity within the matrix, enabling measurable and repeatable changes in electrical resistivity under mechanical strain (Ma et al., 2020). This piezoresistive behavior depends not only on the establishment of conductive pathways but also on maintaining an appropriate balance between matrix resistivity and sensitivity to mechanical stimuli. On the other hand, for cementitious composites incorporating piezoelectric ceramics such as lead zirconate titanate (PZT), the electrical conductivity of the matrix and the composite as a whole plays a critical role: sufficient conductivity can make the poling process easier and more effective (Gong et al., 2011), which is essential for activating piezoelectric behavior. Therefore, the electrical resistivity of cementitious composites should be carefully optimized to enable efficient polarization and ensure a reliable piezoelectric response under practical conditions. In particular, achieving a relatively high matrix conductivity can be highly beneficial for the fabrication of various smart cementitious materials—an objective that constitutes the central focus of the present study.

Building upon the critical role of matrix optimization, recent studies have also highlighted the contribution of steel fiber incorporation to improving the electrical performance of cementitious composites. Cleven et al. (2021) demonstrated that increasing the steel fiber content in PC-based mixtures significantly decreased electrical resistivity, although parameters such as the water-to-binder ratio and binder content also influenced the overall conductivity. Extending these findings to alkali-activated systems, Piao et al. (2025) reported that fiber addition enhanced electrical conductivity, with more pronounced improvements observed at higher fiber concentrations. Similarly, Lu et al. (2025) investigated alkali-activated slag/fly ash mortars and found that steel fiber incorporation led to satisfactory conductivity and improved piezoresistive self-sensing behavior under cyclic loading. Although the self-sensing mechanisms differ between piezoresistive and piezoelectric composites, the formation of continuous conductive networks remains a common and essential requirement.

The sensing functionality of such materials depends significantly on the electrical continuity within the matrix. While conductive fibers or other conductive fillers can improve charge transport, the baseline electrical resistivity of the matrix remains a critical factor. Therefore, the selection and optimization of the binder system is essential. PC-based matrices typically exhibit relatively high resistivity due to limited ionic mobility in their pore solutions. In contrast, AAS systems, when properly designed, offer a chemically favorable environment for ionic conduction, making them a promising alternative for electrically functional composites (Rovnaník et al., 2019).

This study constitutes a part of an ongoing comprehensive research project. In the earlier phases of the project, binder systems with enhanced ionic conductivity were developed to achieve relatively low matrix resistivity—which, notably, remains a controllable and optimizable parameter depending on the composite's moisture content—thereby establishing a foundation for the subsequent development of smart cementitious composites. This property will be further optimized in later stages to enhance the functional performance of the composites. The present work reflects a portion of this phase, specifically addressing the evaluation of electrical resistivity in fiber-reinforced PC-based and AAS-based composites. This paper focuses on analyzing how micro steel fiber incorporation influences the electrical conductivity of these systems—a critical step toward the future development of smart cementitious composites.

2. Materials and methods

2.1. Materials

Two different binder systems were used in this study: Portland cement and alkali-activated slag. The Portland cement (CEM I 42.5R) was supplied by Nuh Cement (Kocaeli, Türkiye) and had a Blaine fineness of 3645 cm^2/g. The ground granulated blast furnace slag (GGBFS), employed as the primary binder in the AAS mixtures, was obtained from Kardemir (Karabük, Türkiye), with a Blaine fineness of approximately 4150 cm^2/g and a specific gravity of 2.88.

For alkali activation, a binary activation solution was prepared using sodium hydroxide (NaOH) and sodium silicate (SS) solution, both obtained from Merck-SigmaAldrich. Initially, NaOH pellets were dissolved directly in the total mixing water defined in the mix design, and the solution was allowed to cool to ambient temperature. Subsequently, the sodium silicate solution, which contained approximately 8% Na_2O and 27% SiO_2 by mass, was added to the NaOH solution.

Crushed limestone with a maximum particle size of 4 mm was used as the aggregate in all mixtures. Its specific gravity was measured as 2.65. A polycarboxylate ether (PCE)-based superplasticizer (MasterGlenium ACE 450, Sika Group) was used in all PC mixtures to ensure consistent and desired flowability.

The steel microfibers used in the study were brass-coated and straight. Each fiber was 6 mm long and 0.16 mm in diameter, with a nominal tensile strength of 2000 MPa. The fibers were incorporated into the mixtures at volume fractions of 3%, 4%, and 5%, depending on the test group.

2.2. Mix designs and specimen preparation

Eight mortar mixtures were prepared in this study to investigate the influence of steel micro-fiber content on the electrical resistivity of two binder systems: Portland cement (PC) and alkali-activated slag (AAS). Each binder system included a reference mixture without fibers (PC_REF and AAS_REF) and three fiber-reinforced mixtures containing 3%, 4%, and 5% steel fibers by volume (PC_3F, PC_4F, PC_5F; and AAS_3F, AAS_4F, AAS_5F, respectively).

The reference mixtures were not arbitrarily selected but were based on a comprehensive matrix optimization study conducted in the earlier stages of the same project. These mixtures were specifically designed to simultaneously meet three key performance criteria: (i) adequate flowability to ensure uniform fiber dispersion and facilitate the subsequent incorporation of PZT particles, (ii) low bulk electrical resistivity, and (iii) sufficient compressive strength to maintain mechanical stability. Following the selection of the reference mixtures, the impact of fiber volume on performance was investigated by adjusting the aggregate content in the mixtures.

All mixtures were proportioned with a constant water-to-binder (W/B) ratio of 0.47, and the paste volume was maintained identical across the PC and AAS series. In fiber-reinforced mixtures, the volume of steel fibers was deducted from the total aggregate content to preserve the overall volumetric balance and maintain the continuity of the paste phase. The PCE-based superplasticizer (SP) was incorporated into all PC mixtures at a fixed dosage of 2.0 kg/m^3 to stabilize workability regardless of fiber content.

In AAS mixtures, the binder consisted of ground granulated blast furnace slag (GGBFS) activated by a binary alkali solution composed of sodium hydroxide (NaOH) and sodium silicate (SS). The activator was formulated to deliver 10% Na_2O relative to the binder mass, with a silica modulus (SiO_2/Na_2O) of 1.2. During the proportioning process, the water content of the sodium silicate solution (approximately 65% by weight) was considered in calculating the net water content to maintain the targeted water-to-binder (W/B) ratio. All activation solutions were prepared in advance and cooled to ambient temperature prior to mixing.

The mixing procedure was carried out using a Hobart mixer. Initially, all dry components, including the binder, aggregate, and steel fibers, were combined to achieve a uniform dry blend. Subsequently, the liquid phase—comprising water and superplasticizer for PC mixtures, or the pre-prepared alkali activator solution for AAS mixtures—was added, and mixing was continued until a sufficiently homogeneous mixture exhibiting sufficient workability was achieved.

Cylindrical specimens with a diameter of 100 mm and a height of 200 mm were cast in three equal layers. After 24 hours, the specimens were demolded and transferred to standard water curing conditions, where they were maintained until testing. To ensure consistent electrical contact, the upper surfaces of AAS specimens were trimmed by approximately 1–2 mm prior to the initial UBER measurement. In PC specimens, surface trimming was performed after 14 days. The detailed mixture proportions for all PC and AAS compositions are summarized in Table 1 and Table 2, respectively.

Table 1. Mix design of PC mixtures (kg/m^3)

Mixture	PC	Water	SP	Limestone	Steel Fiber
PC_REF	764.0	359.08	2.0	1052.92	—
PC_3F	764.0	359.08	2.0	973.42	215.1
PC_4F	764.0	359.08	2.0	946.92	286.8
PC_5F	764.0	359.08	2.0	920.42	358.5

Table 2. Mix design of AAS mixtures (kg/m3)

Mixture	GGBFS	Water*	Limestone	Steel Fiber	NaOH	SS	Na_2O (%)
AAS_REF	670.0	121.34	1054.2	—	57.45	297.78	10%
AAS_3F	670.0	121.34	974.7	215.1	57.45	297.78	10%
AAS_4F	670.0	121.34	948.2	286.8	57.45	297.78	10%
AAS_5F	670.0	121.34	921.7	358.5	57.45	297.78	10%

** The water content listed for AAS mixtures excludes the water already present in the sodium silicate (SS) solution (~65% by weight). To obtain the actual total water content, 65% of the SS mass should be added to the listed water value.*

2.3. Electrical resistivity test

The bulk electrical resistivity of all mixtures was measured periodically over a 56-day curing period using the uniaxial bulk electrical resistivity (UBER) method. Measurements were conducted with a commercial resistivity device (Resipod, Proceq) featuring a 50 mm probe spacing, used in conjunction with a custom measurement setup compatible with Ø100 mm cylindrical specimens (Fig. 1). Prior to each measurement, the specimens were removed from standard water curing and immediately positioned between two moist sponges and stainless steel plate electrodes.

According to the manufacturer's guidelines (Proceq SA, 2017), moist sponges ensure sufficient electrical contact between the specimen and the electrodes, but they also introduce a certain level of internal resistance. Therefore, to accurately determine the true UBER values, the internal resistance of the sponges must be subtracted from the measured data. However, experimental observations indicated that fully saturating the sponges by immersing them in water prior to testing provided the most consistent results. Under such conditions, the internal resistance of the sponges—owing to their high moisture content—was found to be negligible. Furthermore, applying a constant load on the top electrode (e.g., by stacking additional cylindrical specimens) improved the electrode–specimen contact and further stabilized the readings.

In the test, the Resipod instrument displays a value (RD) in $k\Omega \cdot cm$. To obtain the "corrected" value (cRD) in $k\Omega$, the RD should be divided by $2\pi a$, where "a" is the probe spacing (5cm). The UBER , ρ, in $k\Omega \cdot cm$, can then be calculated using the following equation (Proceq SA, 2017):

$$\rho = K \cdot cRD \tag{1}$$

where $K = A / L$, with A and L representing the cross-sectional area (cm²) and the length (cm) of the cylindrical specimen, respectively.

Fig. 1. UBER test configuration with Resipod and sponge–electrode assembly

3. Results and discussion

The evolution of uniaxial bulk electrical resistivity (UBER) for all mixtures is presented in Fig. 2. The results clearly demonstrate that both the binder system and the fiber content significantly affect the electrical performance of the composites. Although the incorporation of steel micro-fibers reduced resistivity in all cases, the extent and efficiency of this reduction differed markedly between the PC and AAS systems.

In the PC series, the reference mixture (PC_REF) exhibited the highest UBER values throughout the 56-day period, increasing from 1.763 kΩ·cm on day 7 to 2.888 kΩ·cm by day 56. This increase is attributed to ongoing hydration and pore refinement, which progressively restrict ionic mobility. In contrast, the fiber-reinforced PC mixtures showed consistently lower resistivity values. The incorporation of 3%, 4%, and 5% steel micro-fibers resulted in 56-day UBER values of 2.651, 2.413, and 2.450 kΩ·cm, respectively. While the addition of fibers improved conductivity, the magnitude of this improvement remained relatively limited. For instance, the reduction between PC_REF and PC_5F at 56 days was only 0.440 kΩ·cm, underscoring the challenge of achieving high conductivity in an inherently resistive and ion-deficient matrix. Moreover, the resistivity curves for PC_4F and PC_5F were nearly convergent at all ages, suggesting that increasing the fiber content beyond 4% offers diminishing returns. This may be due to fiber interlocking or segregation at higher dosages, potentially disrupting the continuity of conductive pathways.

The time-dependent trend further supports this interpretation: all PC mixtures exhibited a pronounced increase in resistivity, particularly between days 14 and 56, with increasing divergence between the curves. Notably, PC_4F consistently demonstrated the lowest resistivity at all ages, suggesting that a 4% fiber volume may represent an optimal threshold for balancing homogeneity and electrical performance in PC-based composites.

In the AAS series, the resistivity values were significantly lower across all mixtures. The reference mixture (AAS_REF) remained as low as 1.888 kΩ·cm at 56 days, approximately 35% lower than PC_REF, highlighting the superior ionic conductivity of the AAS matrix due to its ionically enriched pore solution. This notable difference can be attributed to the distinct ionic composition and transport mechanisms within the AAS matrix. Whereas conductivity in PC-based mortars primarily depends on the mobility of Ca^{2+} and OH^- ions—both of which gradually diminish due to hydration and pore refinement—AAS mixtures benefit from the sustained presence of Na^+ ions and other residual species that do not fully participate in the reaction. These characteristics result in higher ionic concentration and mobility within the pore solution, thereby supporting enhanced electrical conduction throughout the matrix. As emphasized by Rovnaník et al. (2019), AAS systems can achieve low bulk resistivity even without the use of conductive additives, making them inherently suitable for self-sensing applications. Similarly, Di Mare and Ouellet-Plamondon (2023) highlighted the potential of one-part alkali-activated mortars in smart material technologies due to their favorable electrochemical environment. Furthermore, the incorporation of steel fibers led to a more substantial and immediate reduction in resistivity compared to the PC system.

The addition of 3%, 4%, and 5% steel micro-fibers reduced the 56-day UBER values to 0.720, 0.623, and 0.582 kΩ·cm, respectively. All AAS mixtures maintained resistivity values below 1.0 kΩ·cm throughout the 56-day period, demonstrating robust and stable conductive behavior. The sharp drop from AAS_REF to AAS_3F (~61.9% reduction) demonstrates the strong compatibility of steel fibers with the AAS matrix in forming interconnected conductive networks. This trend was consistently observed across all ages, with fiber-reinforced AAS mixtures exhibiting significantly lower resistivity, particularly in comparison to their PC-based counterparts. For instance, at 56 days, the best-performing PC mixture (PC_4F) showed a UBER value of 2.413 kΩ·cm, which is nearly four times higher than its AAS counterpart (AAS_4F, 0.623 kΩ·cm). While the inclusion of fibers in PC mixtures resulted in only moderate reductions (e.g., 15.9% from PC_REF to PC_4F), the improvements in AAS mortars were far more substantial. This contrast highlights the superior efficiency of conductive fiber networks formed within the highly ionic and chemically favorable AAS matrix. Moreover, the marginal difference between AAS_4F and AAS_5F after day 28 suggests that a 4% fiber volume is also sufficient in AAS systems to establish near-optimal conductivity. This plateauing behavior aligns with the trend observed in the PC series, although the absolute resistivity levels in AAS mortars were considerably lower.

The significantly enhanced performance observed in the AAS series upon fiber incorporation supports the presence of a synergistic mechanism between the steel fibers and the conductive matrix. This enhanced behavior likely results from the interplay between the high ionic conductivity of the AAS pore solution and the electronic pathways established by the embedded fibers. By comparison, PC mixtures—where fiber addition yielded relatively modest gains—demonstrated the limitations imposed by matrix chemistry on the effectiveness of conductive networks. These results underscore the pivotal role of binder composition and pore solution characteristics in supporting the formation of efficient charge transport pathways.

When evaluated across both systems, the findings clearly indicate that while steel fiber addition contributes to enhanced electrical conductivity, it is the intrinsic electrochemical nature of the matrix that fundamentally dictates the extent of improvement. In this regard, AAS mixtures consistently outperformed their PC counterparts, offering a more favorable environment for the development and continuity of conductive fiber networks. Furthermore, a fiber volume of 4% emerges as a practical and effective threshold in both systems, offering an optimal balance between conductivity enhancement, matrix integrity, and workability.

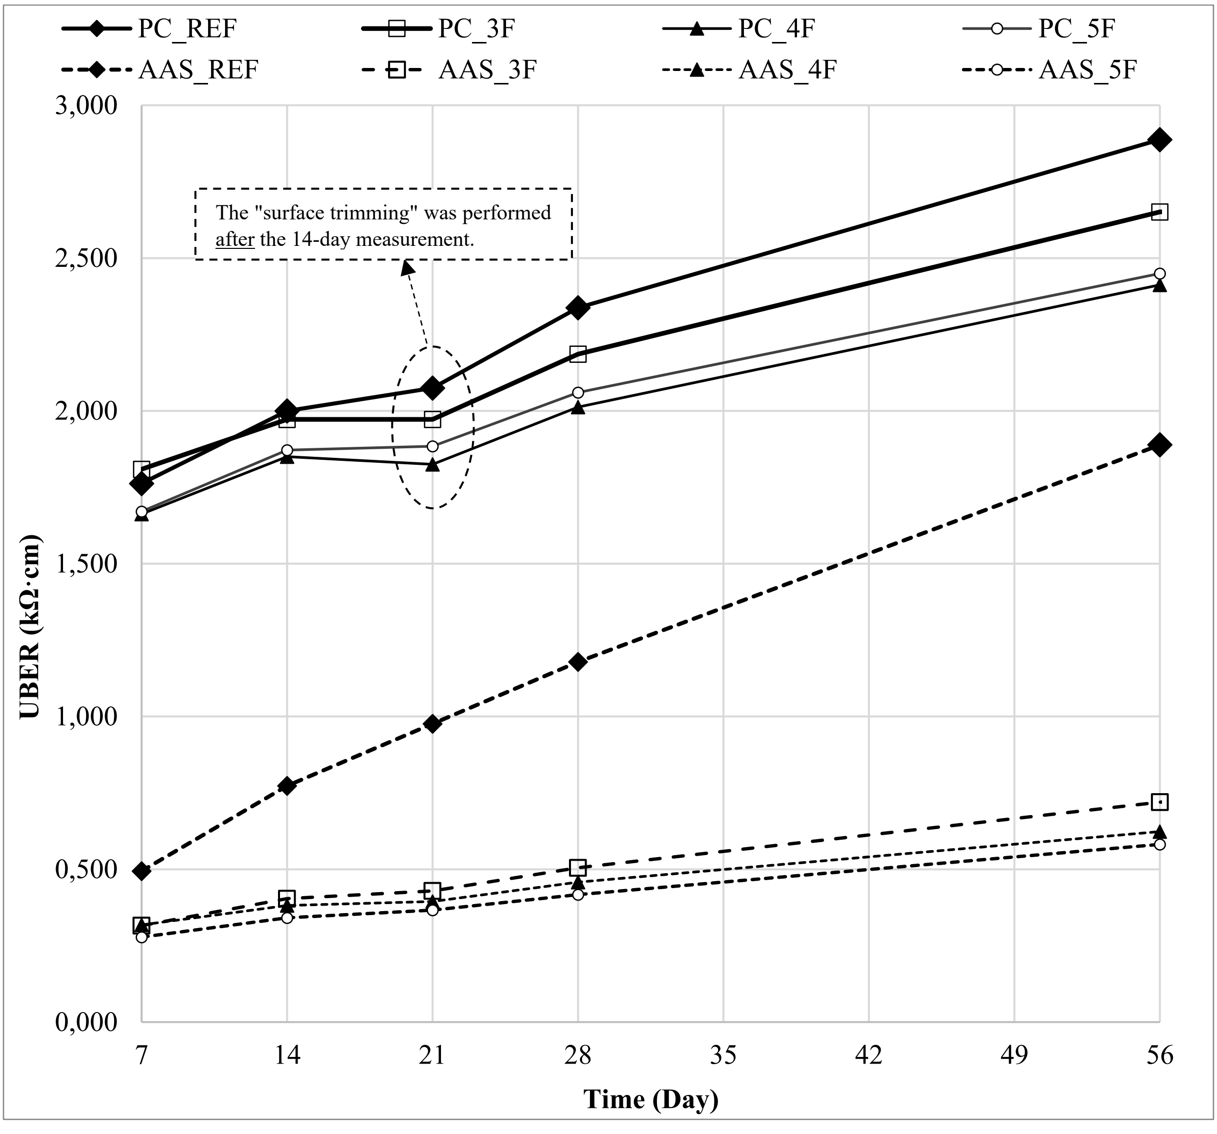

Fig. 2. Development of UBER in PC and AAS mortar mixtures incorporating different volumes of micro steel fibers over a 56-day curing period

4. Conclusions

This study provided a comparative evaluation of the influence of micro steel fiber incorporation on the electrical resistivity behavior of Portland cement and alkali-activated slag-based mortars. Based on the experimental findings, the following conclusions can be drawn:

- The inclusion of micro steel fibers improved the electrical conductivity of both binder systems, although the degree of enhancement was strongly influenced by the electrochemical nature of the matrix.
- AAS-based mortars exhibited superior performance due to their inherently higher ionic conductivity and stronger synergy with conductive additives, enabling more efficient charge transport
- In contrast, PC-based mortars showed only moderate improvements, constrained by limited ionic mobility and a more resistive microstructural environment.
- A fiber volume of 4% was found to be optimal across both systems, offering a favorable balance between conductivity enhancement and mix homogeneity, while rheological aspects were not considered in this study.
- These findings highlight the critical role of matrix chemistry in governing conductive network efficiency and support the potential of alkali-activated slag binders for use in self-sensing or smart cementitious applications.

Eco-friendly composite development using cement paste waste, hemicellulose, chitosan, and natural fibers

Ejazulhaq Rahimi*[1], Ayane Yui[1], Yuta Yamachi[1], Yuma Kawasaki[1]

[1]*Ritsumeikan University, Department of Civil and Environmental Engineering, 525-0058 Shiga, Japan*

Abstract. To reduce dependency on natural resources and mitigate the environmental impact associated with construction waste disposal, the adoption of waste valorization and environmentally friendly production techniques has become imperative. This study explores the development of a green composite incorporating cement paste waste and hemicellulose, with mechanical performance further enhanced through the partial substitution (50 wt%) of hemicellulose with chitosan. Additionally, natural fibers derived from bamboo and banana were introduced to assess their reinforcing effects on the composite. The composites were fabricated using a hot-pressing method and subjected to mechanical testing after a three-day curing period. The results demonstrated that heat pressing, fiber reinforcement, and chitosan incorporation each positively influenced the mechanical properties; however, the addition of chitosan exhibited the most pronounced effect. FTIR analysis further supported these findings, revealing slight shifts in peak intensities and positions attributable to chitosan incorporation. Notably, the characteristic peak at 1509 cm^{-1}, observed in composites containing cement paste waste and hemicellulose, was suppressed upon chitosan addition—suggesting potential chemical interactions. These results indicate that the impact of chitosan on mechanical enhancement surpasses that of heat treatment alone. This research contributes to the foundational development of sustainable, high-performance cement-free composites utilizing biopolymers, offering a viable alternative for environmentally conscious construction applications.

Keywords: Cement paste waste; Hemicellulose; Chitosan, recycle & reuse; Biopolymer; Banana fiber; Bamboo fiber; Hot-pressing; FTIR spectroscopy

1. Introduction

The rapid expansion of the cement and concrete industry has been accompanied by increasing exploitation of natural resources and significant waste generation. Globally, it is estimated that only in 40 countries, 3 billion tons of waste concrete is generated annually, until 2012 (Akhtar & Sarmah, 2018). This situation is further exacerbated by the industry's high carbon dioxide emissions, making the development of sustainable solutions a pressing concern. A multifaceted approach is required to address these challenges, balancing the need for construction materials with environmental preservation and waste management.

In recent years, researchers have turned to green composites as a promising alternative. These materials leverage recycled concrete waste and botanical substances, eliminating the need for traditional cement (Liang & Sakai, 2020). Our previous studies have demonstrated the potential of green composites made from recycled concrete powder and botanical components, such as hemicellulose, which offer advantages including reduced production time and enhanced flexural strength. However, the application of cement paste waste in green composites remains underexplored.

This study investigates the development of a green composite using cement paste waste and hemicellulose as primary components. The composite's properties are further enhanced by replacing 50% of the hemicellulose mass with chitosan, a biopolymer known for its mechanical strengthening capabilities. Additionally, bamboo and banana fibers, sourced from natural materials, are incorporated as reinforcements. The influence of pressing temperature on the composite's mechanical properties is also examined, with samples subjected to room-temperature and elevated-temperature press molding.

The findings aim to provide new insights into the use of recycled concrete powder and cement paste waste with biopolymers in construction material production. By addressing waste management challenges and reducing carbon emissions, this research contributes to the broader goal of advancing sustainable practices in the construction industry and aligning with the United Nations' Sustainable Development Goals (SDGs).

2. Materials and methods

2.1. Sample preparation

The raw materials utilized in this study include cement paste waste (CPW), hemicellulose, chitosan, bamboo fiber, and banana fiber. The cement paste waste was synthesized in the laboratory by preparing a cement paste using ordinary Portland cement and a water-to-cement (w/c) ratio of 0.5. This paste was cured for seven days in a standard curing chamber. After curing, the cement paste was crushed using a jaw crusher, sieved to obtain particles in the range of 0.15–0.30 mm, and subsequently oven-dried at 120 °C for 24 hours to ensure moisture elimination and particle consistency.

Hemicellulose (corn xylan) was procured from TCI Chemicals, while chitosan was purchased from a commercial online retailer (Amazon). Bamboo and banana fibers were sourced locally from suppliers in Shiga Prefecture, Japan, to support regional resource utilization and sustainability. All materials were stored in sealed plastic bags prior to use to preserve their quality and prevent contamination.

The composite samples were prepared through a four-step process: (1) Manual mixing of all components in a plastic container; (2) Casting into a steel mold; (3) Application of 25 MPa pressure using an AS ONE H400-15 hot press; and (4) Demolding and sample retrieval post-pressing.

The mix proportions and molding conditions for the samples are provided in Table 1.

Table 1. Mix proportion and experiment condition

	Materials (gr)						Molding condition		
	CPW	H	Ch	BF	BnF	Water	Temp.	Pressure (MPa)	Time (min)
CPW-H	34	17	0			5.1	Room Temp. & 60°C	25	5
CPW-H-BF	34	17	0	1		5.1		25	5
CPW-H-BnF	34	17	0		1	5.1		25	5
CPW-H-Ch	34	8.5	8.5			5.1		25	5
CPW-H- BF-Ch	34	8.5	8.5	1		5.1		25	5
CPW-H-BnF-Ch	34	8.5	8.5		1	5.1		25	5

*CPW: Cement Paste Waste; H: Hemicellulose; BF: Bamboo Fiber; BnF: Banana Fiber; Ch: Chitosan.

Due to the high hydrophilicity of hemicellulose, it tends to rapidly absorb water during mixing, resulting in clumping and reduced dispersibility. To overcome this issue, a modified mixing sequence was implemented:

1. *Initial dry mixing:* All dry components excluding hemicellulose were mixed for 1 minute to achieve uniformity.
2. *Water addition:* Water was then added and stirred for an additional minute.
3. *Hemicellulose incorporation:* Hemicellulose was added last and mixed thoroughly to ensure homogeneous distribution.

After molding, all samples were cured under laboratory conditions for three days before mechanical and chemical testing.

2.2. Experimental testing

2.2.1. Flexural strength test

Flexural strength tests were conducted in accordance with ISO 4013 standards using a Shimadzu AG-X autograph testing machine. Compressive strength was measured following ISO 4012 protocols using a Shimadzu UH-F2000kNXR universal testing machine.

2.2.2. Fourier-Transform Infrared (FTIR) spectroscopy

FTIR analysis was performed to investigate the chemical structure and functional group interactions in the composites. The spectra were collected using a PerkinElmer Spectrum 3 spectrometer over a wavenumber range of 4000–400 cm^{-1}, with a resolution of 4 cm^{-1}. The KBr pellet technique was used for sample preparation. For consistency in comparison, the spectra of all CPW-based samples were normalized to the absorption band at 875 cm^{-1}, corresponding to the out-of-plane vibration of the C–O bond typical of carbonate in the cement paste waste matrix.

3. Results and discussion

3.1. Flexural strength results

The flexural strength results of the composite materials are illustrated in Fig. 1 and Fig. 2. At 24 °C molding, the flexural strength of CPW-H—comprising only cement paste waste and hemicellulose—was found to be below 2

MPa. The incorporation of bamboo fibers (CPW-H-BF) and banana fibers (CPW-H-BnF) into this matrix significantly improved flexural performance, more than doubling the strength compared to the unreinforced composite. Among the two fiber types, banana fibers exhibited a more pronounced reinforcing effect. This observation aligns with the findings of Sales et al. (2024), who reported a 71.78% increase in flexural strength with banana fiber reinforcement, and Sanchez-Echeverri et al. (2020), who noted a 40% enhancement with bamboo fibers in cement-based systems (Sales et al., 2024; Sanchez-Echeverri et al., 2020).

Hot pressing at 60 °C resulted in further increases in flexural strength across all composite variants. The most substantial improvement was observed in the CPW-H composite, which lacked fiber reinforcement. This increase is attributed to the densification and improved polymeric chain interactions facilitated by thermal activation, which are especially beneficial in composites with initially low mechanical integrity.

Replacing 50% of the hemicellulose with chitosan further enhanced the flexural strength in all composite formulations. This enhancement is consistent with previous studies, which suggest that strong hydrogen bonding and chemical interactions between the hydroxyl groups of hemicellulose and the amine and hydroxyl groups of chitosan contribute to mechanical reinforcement through the formation of crosslinked structures (Karaaslan et al., 2012). In fiber-reinforced and chitosan-containing systems, the initial mechanical properties were already improved, thereby reducing the relative impact of heat pressing. These findings are in agreement with those of Akkus et al. (2014), who demonstrated that thermal treatment improves flexural strength by promoting densification and enhancing interactions between hemicellulose polymer chains (Akkus et al., 2014).

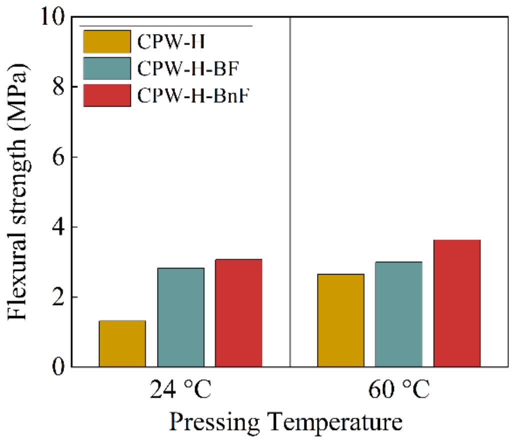

Fig. 1. The flexural strength of the composite made of CPW and hemicellulose

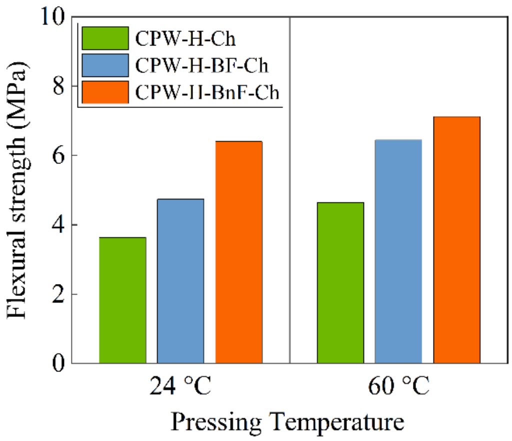

Fig. 2. The flexural strength of the composite made of CPW, hemicellulose, and chitosan

3.2. FTIR analysis results

Fig. 3 presents the FTIR spectra of composites prepared using cement paste waste (CPW), hemicellulose, and chitosan, subjected to pressing at 24 °C and 60 °C. The composite containing fibers are not consider for FTIR analysis.

In the CPW, the sharp band at 3640 cm^{-1} is attributed to O–H stretching vibrations in portlandite [$Ca(OH)_2$], a prominent hydration product in cementitious systems (Chen et al., 2025). The peak at 1422 cm^{-1} corresponds to the asymmetric stretching vibration of carbonate ions (CO_3^{2-}) (Gunn et al., 2024), while the 975 cm^{-1} peak is related to the symmetric stretching of Si–O and Al–O bonds, characteristic of silicate (SiO_4) and aluminate (AlO_4) tetrahedra (Dassekpo et al., 2022). The peak at 875 cm^{-1} is attributed to out-of-plane bending of the C–O bond in carbonate groups, indicating the presence of $CaCO_3$ (Huang et al., 2025), and the 470 cm^{-1} band corresponds to the bending vibrations of Si–O in silicate structures, typically observed in calcium silicate hydrate (C–S–H) and unhydrated residual phases (Hospodarova et al., 2018).

For hemicellulose, the broad absorption band between 3700–3000 cm^{-1} is assigned to O–H stretching vibrations, representing hydroxyl groups in lignocellulosic materials and potentially overlapping with hydration products such as C–S–H gel (Hawanis et al., 2025). The peak at ~2900 cm^{-1} corresponds to C–H stretching of –CH_3 and –CH_2– groups in the sugar units of hemicellulose (Raja, 2025). The 1660 cm^{-1} band can be attributed to H–O–H bending of adsorbed water or minor C=O stretching from conjugated carbonyl groups (Musule et al., 2016). The 1255 cm^{-1} band is indicative of C–O skeletal aromatic vibrations, which may arise from residual lignin or hemicellulose aromatic structures (Mohomane et al., 2017). A strong absorption at 1040 cm^{-1} corresponds to C–O stretching in the sugar units (Besserer et al., 2024), while the 897 cm^{-1} peak is associated with C–H rocking in the lignocellulosic backbone (Md Salim et al., 2021). The 558 cm^{-1} band, typically seen in hemicellulose, appears to shift toward 470 cm^{-1}, potentially overlapping with the silicate bending region in CPW.

golden light publishing®

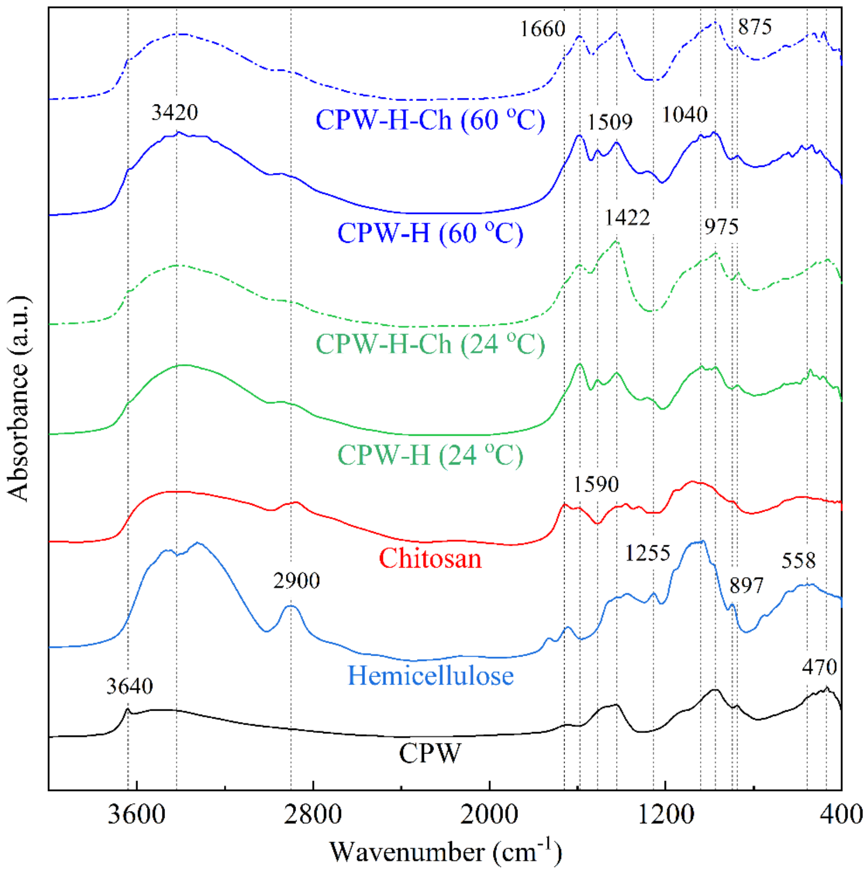

Fig. 3. The FTIR spectra of the composites and its raw materials

Chitosan, a deacetylated derivative of chitin, exhibits distinct bands due to its functional groups. The 2900 cm⁻¹ band is associated with C–H stretching of methyl and methylene groups (Daeialiakbar et al., 2025), while the 1660 cm⁻¹ peak corresponds to the Amide I band due to C=O stretching of the residual acetyl groups (Soufiani et al., 2025). A peak at 1590 cm⁻¹, not observed in the raw components, appears in all composite spectra, and is attributed to the Amide II band from N–H bending vibrations of primary amine groups (Bussiere et al., 2021), or possibly due to asymmetric stretching of carboxylate ions arising from hemicellulose degradation or interactions with cementitious phases.

The 3640 cm⁻¹ O–H band from portlandite persists in all cases, although with reduced intensity compared to the raw CPW. Meanwhile, the 2900 cm⁻¹ band from hemicellulose and chitosan exhibits diminished intensity in CPW–H and is further reduced in CPW–H–CH at both pressing temperatures, may indicate to interaction or partial degradation of aliphatic groups.

In the CPW–H composite, prepared at both 24 °C and 60 °C, a new peak emerges at 1509 cm⁻¹, suggesting additional molecular interactions or degradation byproducts. The intensity of 1590 cm-1 peak is higher in CPW–H cases compared to the CPW–H–Ch cases. The 1422 cm⁻¹ carbonate peak exhibits increased intensity in CPW–H–CH composites, which may indicate enhanced carbonation or stabilization. The 1255 cm⁻¹ peak from hemicellulose slightly shifts upward in CPW–H, but becomes indistinguishable in CPW–H–CH, suggesting possible structural disruption or masking due to chitosan incorporation.

In CPW–CH, the intensity of the 1040 cm⁻¹ hemicellulose peak have the same intensity as 975 cm⁻¹ from CPW, while in CPW–H–CH, the 975 cm⁻¹ peak dominates. The 875 cm⁻¹ peak, attributed to carbonate bending in CPW, remains consistent in position and intensity across all composite variants, suggesting its structural stability. The 558 cm⁻¹ peak, clearly present in CPW–H, appears suppressed in CPW–H–CH, with the 470 cm⁻¹ band becoming dominant—indicating possible peak overlap or shifting due to component interaction.

Table 1 shows a summary of the absorption peaks in the composite and its raw material.

Table 1. Summary of FTIR absorption peaks and their Assignments

Wavenumber [cm⁻¹]	Functional Bond	Assigned to	Reference
3700–3000	O–H stretching (broad)	Hemicellulose, C–S–H, lignocellulose	(Hawanis et al., 2025)
3640	O–H stretching	Portlandite ($Ca(OH)_2$)	(Chen et al., 2025)
2900	C–H stretching ($–CH_3$, $–CH_2–$)	Hemicellulose, Chitosan	(Daeialiakbar et al., 2025; Raja, 2025)
1660	H–O–H bending / C=O stretching	Hemicellulose, Chitosan (amide I)	(Musule et al., 2016; Soufiani et al., 2025)
1590	N–H bending (amide II)	Chitosan	(Bussiere et al., 2021)
1422	Asymmetric CO_3^{2-} stretching	$CaCO_3$	(Gunn et al., 2024)
1255	C–O aromatic skeletal vibration	Hemicellulose, lignin	(Mohomane et al., 2017)
1040	C–O stretching	Hemicellulose sugar units	(Besserer et al., 2024)
975	Si–O / Al–O stretching	Silicate and aluminate	(Dassekpo et al., 2022)
897	C–H rocking	Lignocellulosic materials	(Md Salim et al., 2021)
875	C–O out-of-plane bending	CO_3^{2-} in $CaCO_3$	(Huang et al., 2025)
470	Si–O bending	Silicate phases	(Hospodarova et al., 2018)

These spectral variations collectively indicate that the incorporation of chitosan significantly alters the chemical environment of the composite, as demonstrated by noticeable changes in the intensities and positions of key functional group bands. Such modifications may suggest the occurrence of chemical interactions or potential bond formation within the matrix, although further investigation is necessary to substantiate these assumptions. In contrast, the application of temperature during pressing showed negligible influence on the chemical structure, indicating that chitosan addition exerts a more pronounced effect on the composite's chemistry. This observation is further supported by the corresponding enhancement in flexural strength associated with chitosan incorporation.

4. Conclusion

This study focused on the development of a sustainable, cement-free composite using cement paste waste and hemicellulose, with the aim of minimizing environmental impact while enhancing mechanical performance through the inclusion of biopolymers and natural fibers. The composites were fabricated via press molding at two temperatures (24 °C and 60 °C), and their structural and chemical characteristics were thoroughly evaluated. Based on the experimental findings, the following conclusions can be drawn:

- Chitosan incorporation demonstrated the most substantial influence on both flexural and compressive strengths, surpassing the effects of both fiber reinforcement (bamboo and banana fibers) and thermal processing. This highlights chitosan's significant contribution to improving mechanical integrity through enhanced interfacial bonding and possible chemical interactions.
- Fourier-transform infrared (FTIR) analysis revealed that chitosan addition induced changes in the chemical structure of the composite, as evidenced by shifts in peak intensities and the emergence or suppression of specific functional group bands. In contrast, heat pressing at 60 °C did not result in notable chemical alterations, suggesting that the mechanical improvements due to heating are primarily physical (e.g., densification).
- Natural fibers contributed positively to the mechanical performance, with banana fibers exhibiting a more pronounced reinforcing effect than bamboo fibers. However, their influence was still secondary to that of chitosan.

These findings underscore the potential of integrating biopolymers such as chitosan with recycled cementitious waste to produce eco-friendly construction materials. The research provides foundational knowledge for further development of high-performance green composites and contributes to the broader goal of sustainable building practices, aligning with global environmental and circular economy objectives.

Abstract. Recycling and reuse of the demolition, which is emerging from the destruction of old concrete structures that have completed their service life, is becoming more important day by day. In this study, the effect of two different geopolymer slurries containing different proportions (0%, 0.5%, 0.8%, 1.2%, 1.5%) of water-proofing admixture (WPA) on the treatment of recycled aggregate (RCA) was investigated. In these slurries, two different aluminosilicate materials, class F fly ash (FA) and ground granulated blast furnace slag (GGBFS), were used as binders and a mixture of sodium silicate and sodium hydroxide was used as activator. The Na_2O ratio of the activator mixture used was 10% and the M_s ratio was selected as 1.25. The aluminosilicate content was 70% FA and 30% GBFS in the first mixture and 70% GBFS and 30% FA in the second mixture. RCAs were subjected to the impregnation process in the geopolymer slurry mixtures for 5±1 minutes, some under ambient conditions and some in a vacuum oven. In order to determine the effectiveness of WPA in the geopolymer slurry, SEM-EDS analysis was performed on the slurries with and without this admixture. The significance of the difference between the treatment ratios of RCAs was statistically investigated using the One-Way ANOVA test. It was observed that the water absorption capacity of RCAs not impregnated with slurry varied between 5.4% and 6.2%, while the water absorption capacity after treatment was between 3.6% and 5.6%.

Keywords: Geopolymer slurry; Water-proofing admixture; Recycled aggregate; Treatment of RCA

1. Introduction

Globally, 25 billion tons of concrete are produced annually, which can have a significant environmental impact (ACI CRC 18.517, 2019). The recycling and reuse of waste generated from the demolition of old concrete structures that have reached the end of their service life (Arısoy, 2016; Neville, 1995) are becoming increasingly important. According to Tosun (2022), the use of recycled concrete aggregates (RCA) instead of natural aggregates in concrete production can result in a cost savings of 10% to 20% in material costs (Zheng et al., 2017). The lack of a globally accepted common standard, potential issues with durability properties, and differences in the type of aggregate used in the source concrete have led to the limited adoption of RCA systems in concrete applications. Existing documents such as European RILEM standards, Japanese Industrial Standards, German standards, ASTM C33, and the ACI 555 report impose certain limitations on the properties of RCA suitable for use in concrete. However, most of these documents rely on small-scale studies and lack large data sources and their statistical analyses (ACI CRC 18.517, 2019). Additionally, a life cycle assessment of the environmental impacts of recycled aggregate in Hong Kong found that concrete prepared using coarse RCA can reduce greenhouse gas emissions by 65% and non-renewable energy consumption by 65% compared to traditional concrete with natural aggregate (Hossain et al., 2016).

Improving recycled aggregates can lead to fewer mechanical losses in traditional or geopolymer concrete. Some methods have been applied to eliminate the negative effect of mortar adhering to RCA on aggregate properties and to treat RCA (Katz, 2004; Dimitriou et al., 2018; Xiao, 2018; Tateyashiki et al., 2001; Bru et al., 2014; Purushothaman et al., 2014; Sui and Mueller, 2012; Ismail and Ramli, 2013; Katkhuda and Shatarat, 2017; Chen et al., 2017; Kim et al., 2018). Bui et al. (2018) conducted a study in which they treated RCA by immersing it in sodium silicate and then in silica fume. In this study, concrete mixtures containing treated and untreated aggregates were prepared. A 33–50% increase in compressive strength was observed in concrete mixtures containing treated coarse aggregates. Alqarni et al. (2021) used cement-silica fume slurry at different ratios (20%,

* Corresponding author, E-mail: gokhan.gurbuz@mail.ege.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_582

30%, 40%, and 50% of RCA) in their experimental study on RCA treatment. They found that using 40% cement-silica fume treated the water absorption ratio and abrasion resistance of RCAs. In the literature, researchers have generally attempted to strengthen the mortar layer of RCAs using pozzolans and cement (Kisku et al., 2017; Behera et al., 2014; Shi et al., 2016; Kou and Poon, 2012). Some researchers have also observed a decrease in permeability and an increase in compressive strength and elastic modulus in concrete mixtures containing RCA by using waterproofing additives (Pereira-de-Oliveira et al., 2014; Zhang et al., 2020; Zong et al., 2014).

In this study, geopolymer slurry mixtures containing two powder binders, F-type fly ash (FA) and ground granulated blast furnace slag, were prepared, and water permeability additives (WPA) were used in different proportions (0%, 0.5%, 0.8%, 1.2%, 1.5%) in these mixtures. The effect of these slurry mixtures on the treatment ratio of WPA was investigated by determining the water absorption capacity after impregnation with RCA.

2. Material and method

2.1 Material

The water absorption ratio and specific gravity (TS EN 1097-6), unit volume weight (TS 3529), abrasion resistance (TS 1097-2), flatness ratio (TS EN 933-3), and particle size distribution (TS EN 933-1) of the RCA have been determined. The analysis results are presented in Tables 1 and 2.

In the production of geopolymer slurry, sodium silicate (SS) and sodium hydroxide (SH) are used as activators, while GGBFS and F-class FA are used as aluminosilicate sources. To reduce the water absorption capacity of RCA, a water-proofing admixture with a crystalline structure (WPA) was used. The physical and chemical properties of the GGBFS, FA and WPA were determined through XRF and SEM analyses conducted at the Central Research Test and Analysis Laboratory Application and Research Center at Ege University. The chemical and physical properties of SS and SH were obtained from the manufacturer. The analysis results of the aluminosilicate materials and the values given in the relevant standards are presented in Tables 3 and 4, the physical and chemical results of the activator components and WPA are shown in Table 5. Additionally, the SEM-EDS analyses of the aluminosilicate materials are presented in Figs 1 and 2.

2.2 Method

2.2.1. Mix design

Geopolymer slurries were prepared using GGBFS and FA in different ratios as aluminosilicate material. In these mixtures, the water/binder (W/B) ratio was 1 and the silicate modulus (Ms) ratio was 1.25. The WPA was added to the slurry mixtures at ratios of 0%, 0.5%, 0.8%, 1.2%, and 1.5% by weight of the aluminosilicate materials. The mixture design is presented in Table 6, and the coding for the abbreviations used is given in Fig 3.

2.2.2. Determination of water absorption ratios

The water absorption ratios of RCAs before and after treatment and the slurry impregnation process were determined as follows.

- Recycled aggregates have been classified using 5 and 15mm sieves and kept in water for one day
- After extracting from the water, RCA surface was dried using a cloth, and 1,000-gram samples were weighed as required for three repetitions of each experiment.
- Pre-treatment water absorption ratios were calculated for all samples.
- The slurry prepared at the specified ratios was mixed with 30 kg of pre-treated RCA, of which 15 kg was left to rest in a vacuum oven (VO) environment at a pressure of 0.9 ± 0.1 bar and 15 kg under environmental conditions (EC) for 5 ± 2 minutes.
- After being sieved, the RCA was left to rest for 24 hours under environment conditions. Then, the aggregates were placed in containers and dried in an oven at 60°C for 48 hours.
- The RCAs taken out of the oven were weighed and left to stand in water for another 24 hours.
- Finally, the water absorption ratios of the treated RCA were recalculated.

The images related to the RCA treatment and water absorption ratio determination process are shown in Fig 4. Equation (1) was used to calculate the average treatment ratio.

$$Average\ treatment\ ratio = \frac{\text{Water absorbtion capacity before treatment} - \text{Water absorbtion capacity after treatment}}{Water\ absorbtion\ capacity\ before\ treatment} \quad (1)$$

Fig 4. RCA treatment and water absorption processes

2.2.3. Statistical analysis

To statistically evaluate the effects of the parameters within the prepared mixtures on the experimental outcomes, GraphPad Prism 9 software (GraphPad Software, San Diego, CA, USA) was used. The normality of the data distribution was assessed using the Shapiro-Wilk test. Depending on the distribution characteristics, either One-Way ANOVA or One-Sample t-test was conducted. A p-value of less than 0.05 was considered indicative of statistical significance.

2.2.4. SEM-EDS analysis

SEM-EDS analysis was performed on hardened slurry samples prepared in 1×1 cm^3 dimensions. To ensure electrical conductivity, the surfaces of the samples were coated with a 7 nm thick layer using a target plate containing 80% Au and 20% Pd in a Leica EM ACE600 coating device. SEM analysis of the samples was performed using a Thermo Scientific Apreo S device. The samples were analyzed in secondary electron mode under high vacuum conditions using an acceleration voltage of 7.5-20 kV and a spot size of 8-12. Energy-dispersive X-ray spectroscopy (EDS) was used to identify the elements present on the surface. Both point and area analyses were performed to determine the elemental composition and distribution.

3. Results and discussion

The water absorption ratios before and after RCA treatment with geopolymer slurries, the treatment ratios, and the statistical analysis results of these findings are presented in Tables 7, 8, 9, and 10. The graphs corresponding to these results are shown in Figs 5, 6, and 7. The significance of the difference in the treatment ratios of these mixtures was investigated statistically using a One-Way ANOVA test.

A decrease in water absorption ratios was observed in all mixtures, including the mixture without WPA, after the geopolymer slurry impregnation process (see Table 7 and Fig 5). The lowest water absorption capacity after treatment was observed in the 70S-30FA-1.5WPA-VO mixture. The greatest treatment ratio was observed in mixtures containing 0.8% WPA under both conditions.

Table 7. RCA treatment with 70S-30FA mixture

Mixture	Average Water Absorption Before Treatment (%)	Average Water Absorption After Treatment (%)	Average Treatment (%)

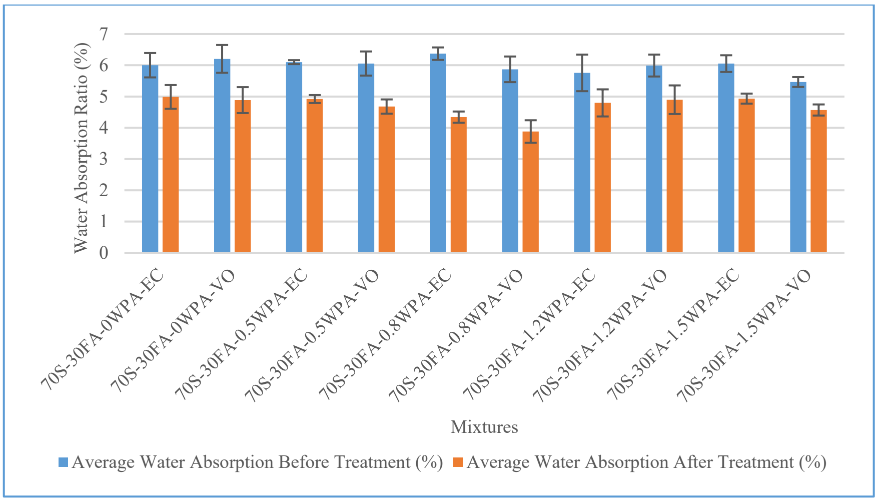

Fig 5. Average water absorption ratios before and after treatment for 70S-30FA with 5-15mm RCA

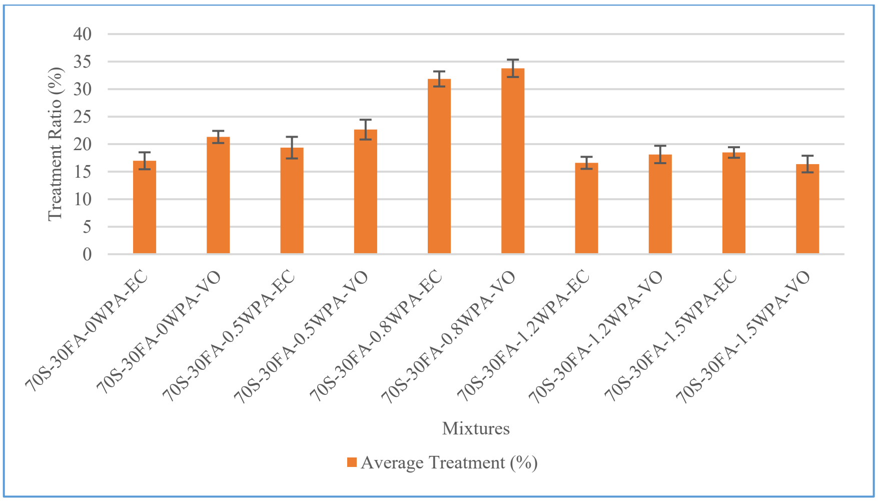

Fig 6. Average treatment response ratios of 5-15mm for 70S-30FA

As shown in Fig 6, treatment was observed when all geopolymer slurries were impregnated with RCA. The treatment ratios ranged from 16% to 33%. In both conditions, the highest treatment was observed in the 70S-30FA-0.8WPA mixtures.

A decrease in the water absorption ratio of all mixtures was observed after the treatment process (see Table 8 and Fig 7) . Prior to the treatment process, water absorption ratios ranged from 5.45% to 6.08%, while these values decreased to 4.05% to 4.76% after the treatment process. Considering the treatment ratios, the 30S-70FA-0.8WPA mixture showed the highest treatment in both conditions.

It is observed that treatment was detected in all mixtures containing different ratios of WPA (see Fig 8). Similar to the 70S-30FA mixtures, the highest treatments were found in the mixture containing 0.8% WPA, with 29.4% and 32.0%. The lowest treatments were found in mixtures without WPA, with 18.6% and 21.1%.

Regarding the treatment results at different WPA ratios in the 70S-30UK and 30C-70UK mixtures, the greatest treatment effect was observed in mixtures containing 0.8% WPA. Tables 9 and 10 present the statistical significance of the differences between 70S-30FA and 30S-70FA mixtures with varying WPA ratios.

The analysis of the 70S-30FA mixture revealed a statistically significant difference between the mixture containing 0.8% WPA and all other mixtures in terms of treatment under both curing conditions (Table 9). Additionally, a slight but meaningful difference was observed in the treatment values of the 0.8% WPA mixture between ambient and vacuum oven curing. Moreover, in the case of geopolymer slurry with 1.5% WPA under vacuum oven curing, a significant difference was identified between the 0WPA-EC and 0.5WPA-VO mixtures.

Examination of the 30S-70FA mixture results indicated a statistically significant difference between the mixture containing 0.8% WPA and all other mixtures in terms of treatment under both curing conditions (Table 10). For the 0.8% WPA mixture, no significant difference was found between the EC and VO curing environments.

Li et al. (2023) designed slurry mixtures containing two powdered binding materials, cement and fly ash, and conducted studies to treat recycled aggregates ranging from 2.35 to 26.5 mm using these mixtures. The results of the experiments showed that the water absorption ratio of RCA decreased by an average of 52.8%. When the treatment results were examined, it was observed that the slurry impregnation process reduced the water absorption ratio of RCA, consistent with our study.

Statistical analysis identified 0.8% as the optimal WPA ratio. Accordingly, SEM-EDS analysis was conducted to compare the microstructural properties of mixtures with 0% and 0.8% WPA. The SEM-EDS analyses of the geopolymer slurries are presented in Fig 8.

In the WPA-free sample, voids appear more open and irregular, whereas the WPA-containing sample shows a denser and more compact microstructure, suggesting that the admixture fills the internal spaces (Fig 8).

EDS results reveal a significant increase in Na content (from 13.47% to 22.46%) and a decrease in Si content. The reduction in silicon may be attributed to partial replacement or dilution of the original aluminosilicate network by the sodium-based components of the WP admixture. This indicates that the admixture not only fills the voids but also alters the gel structure in a way that enhances impermeability.

Shaban et al. (2019) conducted a study on treating recycled aggregates below 5 mm using a slurry mixture containing ordinary Portland cement, fly ash, silica fume and nano-silica fume. As a result of the SEM-EDS analysis, it was observed that the aggregates without the treatment process were more porous and had irregular surface texture, while the samples treated with slurry impregnation had less porosity and a homogeneous structure.

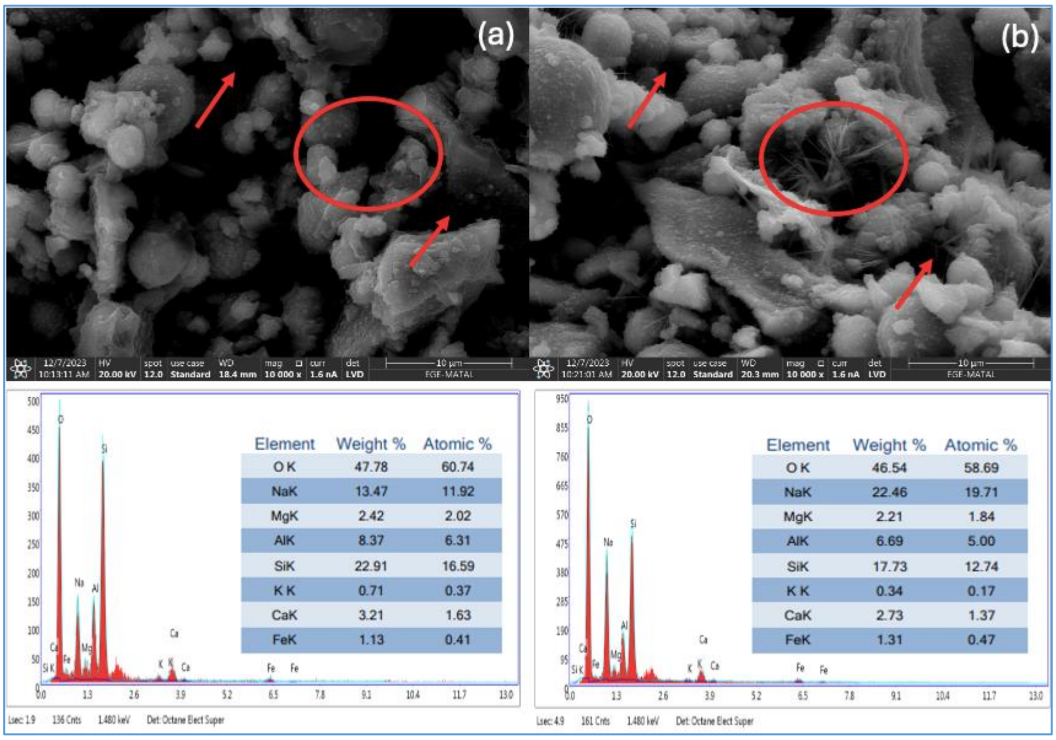

Fig. 9. SEM images and EDS analyses of geopolymer slurries: (a) without crystalline water-proofing admixture, (b) with crystalline water-proofing admixture.

Although no study was found in the literature on the use of WPA in RCA treatment studies, the results were consistent with our study, and it was observed that the slurry impregnation process treated the microstructure properties of RCA.

4. Conclusions

Within the scope of this study, investigations were conducted on treating the water absorption properties of recycled aggregate (RCA) using geopolymer slurry and water-proofing admixture (WPA). When the results of the study were evaluated;

- The best treatment results were obtained with the use of 0.8% WPA in both 70S-30FA and 30S-70FA geopolymer slurry mixtures. For the 70S-30FA-0.8WPA and 30S-70FA-0.8WPA mixtures, treatment ratios of 31.85% and 29.45% were determined under environmental conditions, and 33.78% and 32.05% under vacuum oven conditions, respectively.
- It has been determined that the treatment ratios in both 70S-30FA and 30S-70FA geopolymer slurry mixtures with 0.8% WPA use are statistically significantly different from all other mixtures.
- When SEM-EDS analysis results were examined, it was observed that the use of 0.8% WPA, which is the optimum ratio, in the geopolymer slurry filled the voids in the RCA and treated it.

Effect of shear span-depth ratio on recycled coarse aggregate concrete beams without stirrups

Nwzad Abduljabar Abdulla*[1]

[1] *University of Salahaddin, Erbil, Iraq*

Abstract. Recycling has emerged as a potent tactic to lessen the harm that concrete waste causes to the environment. It is possible to use recycled concrete as coarse aggregate in structural members. One such structural member is longitudinally reinforced concrete beam with no shear reinforcement. The shear span-effective depth ratio (a/d) affects how well such beams perform under shear stresses. In order to examine the effect of this parameter, a database was compiled for beams evaluated under one-point load, where the load was central or applied on one shear span only. The data-base was utilized to ascertain the impact of the a/d ratio on the shear capacity of recycled coarse aggregate concrete beams without shear reinforcement. Shear predictions using the old, the more modern and detailed, the recent, and the new updated ACI code models were compared with the experimental results from the database, which had an a/d ratio ranging from above (1) to 8. This comparative study provides proof for this problem and shows how variations in the a/d ratio impacted the four equations. For the beams tested for an a/d ratio of 6-7, the average projected shear values using the ACI code Eq. (1) and Eq.(3) were nearly identical to the corresponding average experimental values. This criterion holds true For Eq. (4). However, the assessd average shear values using the ACI code Eq. (2) for the specimens tested for an a/d ratio of 2-3, 3-4, 6-7, and 7-8 were considerably lower than the corresponding experimental averages.

Keywords: Concrete debris; Coarse recycled aggregate; Un-transversely reinforced beams; Shear-span-effective depth; Shear strength

1. Introduction

The shear span-to-effective depth ratio (a/d) is known to have a significant impact on the shear strength of reinf-orced concrete elements. The performance of reinforced concrete beams in the absence of shear reinforcement is more crucial to take into account. When recycled concrete coarse aggre-gate (RCCA) is substituted for the co-arse natural aggregate, this problem is made worse. One major challenge is the water absorption which is increa-sed because of the porous adhering mortar that is bound to the surface of the recycled aggregate (Abdulla, 2015).

For an a/d ratio of 2.5, comparable shear strengths were observed for NA beams and beams with 50% and 10 0% RCCA replacement ratio. For the same a/d ratio of 1.15, the shear capacity of RCCA beams was 27% lower than that of control beams, both without shear reinforcement. When the a/d ratio was reduced from 2.5 to 1.15, the shear capacity of beams with 50% and 100% RCCA replacement ratios increased by two to three times. Wh-en the main steel ratio was raised by 60%, the shear capacity of RCCAbeams increased by only 4 to 6%, where-as that of its corresponding beamswith NA increased by 17% (Sagheer & Tabsh, 2022).

The aggregate interlock mechanism of RCCA concrete is different from that of NA concrete because it cont-ains the old weak adherent mortar (Abdulla, 2024b). An experimental study found that changing the a/d ratio from 3.1 to 3.25 resulted in a small improvement in shear capacity of beams not reinforced for shear (Sayhood et al., 2019). The source of RCCA affects the shear performance (Abdulla, 2024a). average values of 0.92 and 0.87 were recorded for the v_{RCCA}/v_{NA} ratios for beams tested for a/d ≤2:5 and 2.5 <a/d ≤ 3.5. The same value was 1.02 for beams tested for a/d > 3.5. This showed that the shear span to depth ratio of ≤ 3.5 had an adverse effect on the shear resistance of RCCA. The weaker compressive strength of RCCA contributes to this perform-ance (Pradhan et al., 2018). For RCCA beams, with a 30% partial replacement of the RCCA, tested under shear span-to-depth ratio of 1, 2, and 3, the shear strengths dropped by roughly 2%, 14%, and 37%, respectively (Etm-an et al., 2018).

The RCCA beams with an a/d ratio of 0.9 showed significant increases in shear strength due to cooperation of the arch mechanism, compression strut forms in the shear span and the main steel contributes to this action by restraining the ends of strut from opening. Therefore direct strut action is employed and loads are transferred

* Corresponding author, E-mail: anwzad@yahoo.com

https://doi.org/10.31462/icearc2025_ce_mat_603

directly to supports. The arch mechanism becomes less powerful in beams with 1.8 a/d ratio, whereas it diminishes in shallow beams with 2.7 span to depth ratio. This mechanism reduces in shallow beams of span-to-depth ratio of 2.7 (Abdulla, 2024c).

1.1. Applicability of ACI Code

Because of inconsistencies, the current shear specifications cannot predict the shear capacity of RA beams without web reinforcement. The ACI 318 formulae (Knaack & Kurama, 2015) were used to conservatively predict the shear strength of RCCA beams, and the ACI 318 Code, Eurocode-2 Code, and AS3600 Code can be used for the shear design of 25% RCCA concrete beams; for slender beams, the code prediction becomes conserveative (Lian et al., 2013). The current standards do not include the parameters, beam action, and arch action, which affect the shear resisting ability; evaluating the shear capacity of RCCA concrete beams using the current specification equations in ACI 3182014 are a conservative design method(Choi & Yun, 2017).

The normalized shear stresses determined by ACI 318-19 was more conserveative than that of ACI 318-14 for RCCA beams with main steel ratio (ρw) equal to 1.16% (DB16series). When the ρw was increased to 1.81% (DB20 series), the ACI 318-9 shear strength equation prediction was slightly higher than the ACI 318-14 one. For RA replacement rates below 75%, the shear capability of beams was conservatively evaluated by the ACI 318-19 shear strength requirements. The ACI formula was modified to include a reduction factor of 0.75 for RA replacement ratios between 50 and100%. The adjusted algorithm yields conservative redictions for an RA replacement ratio of 100% or less (Setkit et al., 2021). The applicability of current design principles for NA beams to RCCA beams can be assessed by comparing code predictions with experimental test results (Sato et al., 2007). RCCA beams with a 50% RA replacement ratio and an a/d ratio of three can be designed using the current shear design approach (Choi et al., 2010). Previous research suggests that the shear models can evaluate the shear strength of the beams with shear reinforcement. The current work aims to fill the gap in the literature by doing quantitative research on the effect of a/d on the shear capacity of RA concrete.

1.2. ACI Code shear equations

1.2.1. Old and simple ACI Code 318-14

Takes into consideration the effect of compressive strength only.

$$Vc = 0.17\sqrt{fc}bd \tag{1}$$

where $f_c \le 70$MPa and λ a parameter for the normal concrete equal to 1.

1.2.2. More detailed ACI Code 318-14

This is the only model which considers the effect of shear-span-depth ratio (a/d).

$$Vc = \left[\sqrt{fc} + \frac{120\rho t}{\frac{a}{d}}\right]\frac{bd}{7} \le 0.3\lambda\sqrt{fc}bd, where: fc \le 70MPa \tag{2}$$

1.2.3. Recent ACI Code 318-19

This ACI code introduced the size effect parameter (λ_s) since the shear capacity don’t change proportionally with the change in effective depth of shear member.

$$Vc = \left[0.66\lambda s\lambda\left(\sqrt[1/3]{\rho}\right)\sqrt{fc} + \frac{Nu}{6Ag}\right]bd \tag{3}$$

Where $\lambda = \sqrt{\frac{2}{1+0.004d}} \le 1, fc \le 8.3MPa, V_{ACI} = 0.42\sqrt{fc}$

1.2.4. New ACI Code 318-25

The new ACI code is similar to the ACI code 318-19 but the size effect parameter is freed from the square root restrictions.

$$Vc = \left[0.66\lambda s\lambda\left(\sqrt[1/3]{\rho}\right)\sqrt{fc} + \frac{Nu}{6Ag}\right]bd \tag{4}$$

Where $\lambda = \frac{2}{1+0.004d} \le 1, fc \le 8.3MPa, V_{ACI} = 0.42\sqrt{fc}$

2. Database

The important test parameter of shear span-to-depth ratio (a/d) of stirrup-free beams and slabs, which varies from above1 to 8, is covered by the research in the collected database. From the literature that was available, thirty-four test beams and slabs with RCCA and without shear reinforcement were collected. The database contained seven papers (Michaud, 2015), (Sagher, 2016), (Tabsh, 2018), (Sayhood et al., 2019), (Cardoso et al., 2021), (Younis et al., 2022),(Sagheer & Tabsh, 2022). published between 2015 and 2023. Every beam or slab was tested with a point load, either in the center or on one of the shear spans. all the specimens had a rectangul-ar cross-section and were under reinforced.

3. Discussions

The performance of Eq. (1) in predicting the shear capacity of recycled coarse aggregate (RAC) concrete specimens without shear reinforcement in the database is plotted in Fig. (1) versus the a/d ratio. The simple and straightforward ACI code calculation produces conservative values (Hollow markers) compared to the experimental shear strength values (Solid markers). As the a/d values increases, there are noticeable differences between the mean projected value (dashed line) andthe experimental average value (solidline). This difference is significant between the two averages for the a/d ratios≤2. The disparity between the two averages narrows as the a/d ratio augments. This criterion holds true for the a/d ratio in the ranges 2-3, 3-4, 6-7, and 7-8. The best agreement between the experimental-predicted averages reached in the range 6-7. The number of specimens tested for ranges considered are equal except for the a/d ratio of 7-8.

The experimental and their equivalent predicted shear capacity using ACI code Eq. (2) versus the a/d ratio are depicted in Fig. 2. The second ACI code equation which takes into account the influence of a/d ratio yields more conservative values, underestimating the shear capacity for all the ranges of a/d ratio. However, the aver-age experimental and predicted shear values are similar for all the ranges of a/d ratio except the range 1-2. Mor-eover, despite including the a/d ratio in the model, the second equation predictions are more conservative compared to equation one.

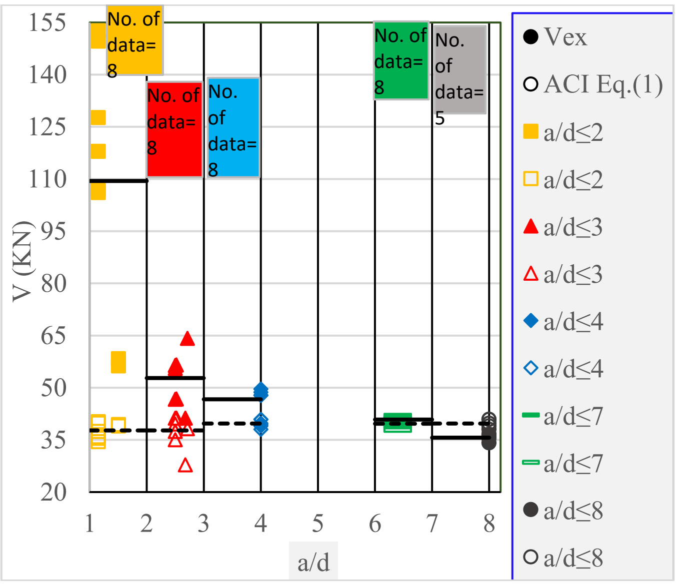

Fig. 1. Experimental and their equivalent predicted shear capacity using ACI code Eq. (1) versus the a/d ratio

The experimental and corresponding predicted values using Eq. (3) are plotted against the a/d ratio in Fig. 3. The conservatism of Eq. (3) holds true in consistence with the previous two equations. Compared to the experimental database values, the revised ACI code equation produces conservative results. However, the performance of Eq. (3) follows a similar pattern to that of Eq. (1), as the a/d ratio increase the gap between the two values diminish, except the a/d ratio of 7-8 with little increase.

There is a noticeable difference between the experimental average value (solid line) and the average expected value (dashed line) in the a/d ratio range of 1-2. This is ascribed to the effect of arch action, which results in considerable increase in the shear resistance of the specimen. The new ACI code 318-25 shear model also results in underestimation of the experimental results, as illustrated in Fig. (4). This equation includes a parameter which accounts for the size affect. The performance of Eq. (4) is very similar to that of Eq. (3). The predictions in the a/d ratio of 6-7 by the Eqs. (1), (3), and (4) are very similar. This shows the applicability of the three models to a/d ratio greater than three, especially the a/d ratio of 6 to 7.

Using the a/d ratio and the ACI code Eqs. (1) to (4), Fig. 5 displays the absolute average error (AAE) between the experimental and corresponding anticipated shear capacity. Employing equations (1) through (4), the AA error values change in accordance with the a/d ratio.

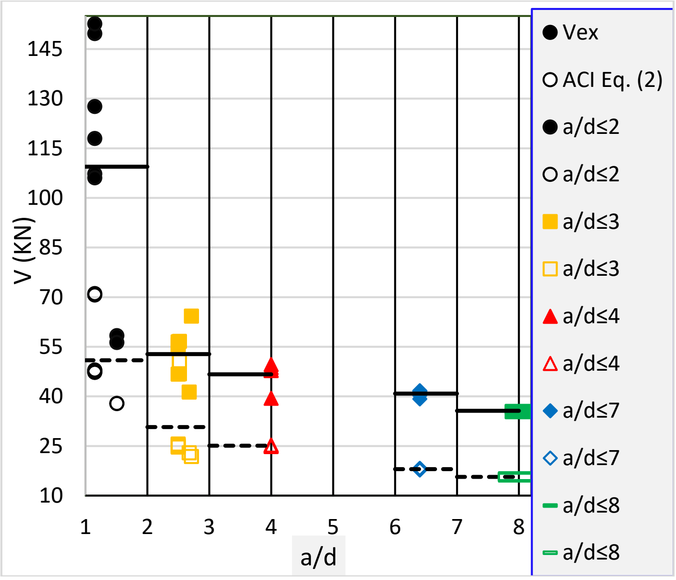

Fig. 2. Experimental and their equivalent predicted shear capacity using ACI code Eq. (2) versus the a/d ratio

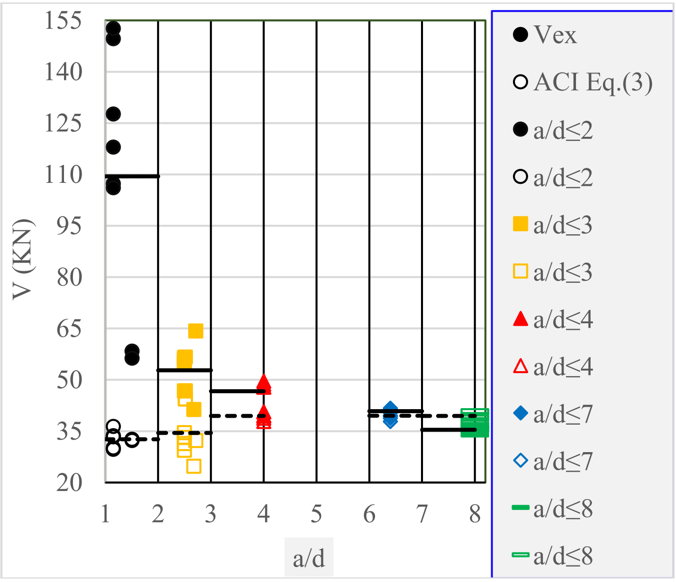

Fig. 3. Experimental and their equivalent predicted shear capacity using ACI code Eq. (3) versus the a/d ratio

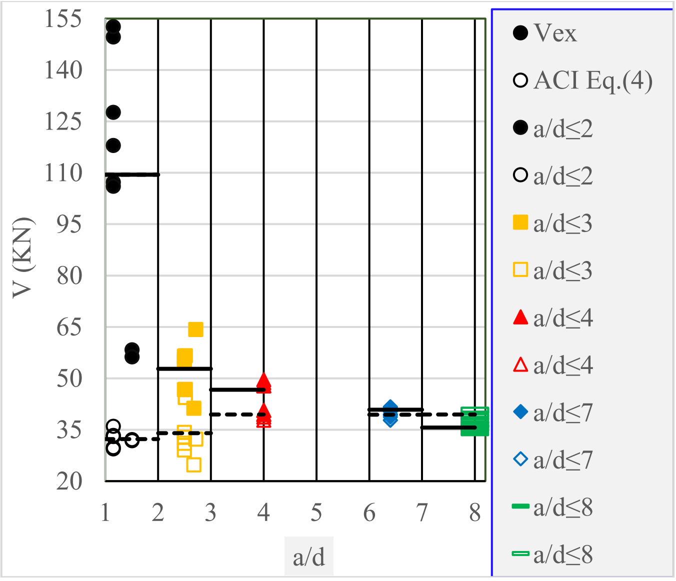

Fig. 4. Experimental and their equivalent predicted shear capacity using ACI code Eq. (4) versus the a/d ratio

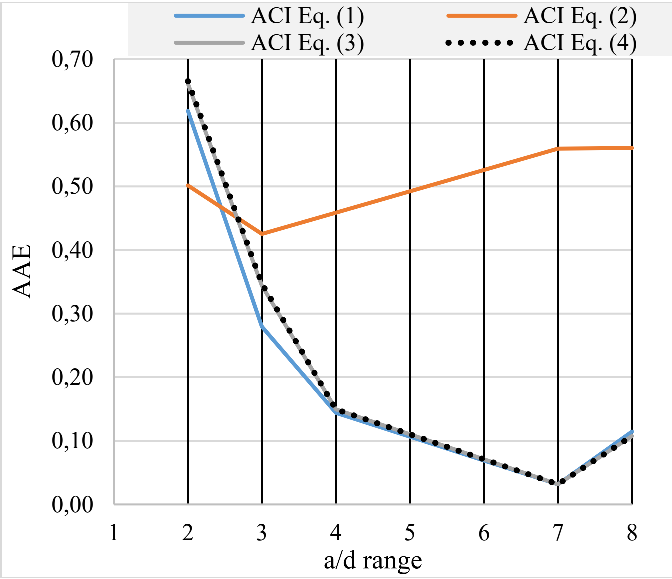

Fig. 5. Absolute average error between the experimental and their equivalent predicted shear capacity using ACI code Eqs. (1), (2), (3), and (4) versus the a/d ratio

Eq. (2) leads to the largest difference in AAE values compared with the other equations, especially for a/d ratio greater than 3. Eq. (1) yields the lowest AAE values for the a/d ratio of 6-7. This trend applicable to the Eqs. (3) and (4). Using the ACI code Eqs. (1) to (4), the a/d ratio is shown in Fig. 6 with the corresponding changes in the standard deviations for the experimental-anticipated shear capacity. Depending on the a/d ratios, different standard deviation values exist. For Eqs. (1), (3), and (4) the standard deviation (STD) values decrease with a/d ratio, except for the for a/d ratios of 7-8, which slightly increases. Moreover, the a/d ratio of 7 results in the lowest STD values. On the other hand, the Eq. (2) deviates from this trend, resulting in increment in STD with change in a/d ratio.

The two statistical indexes, AAE and STD are compared in Fig.7. For the RCA specimens assessed for the a/d range of 4 to 8 there is a close agreement between the two indexes, for all the equations, except Eq. (2). For the latter equation there is considerable difference between the two indexes. the largest deviation between the two indexes is observed for the a/d ratio of 1 to 3. The shear performance of RCA specimens tested under static three-point loads are affected by a number of factors, including the shear span-to-effective depth ratio (a/d). The two ACI codes 318-19 and 318-25 shear models use a modification factor, λs, for the size effect. The new upda-ted code equation, Eq. (4), results in a slightly more conservative estimation of the shear capacity of RCA concrete specimens without shear reinforcement compared with Eq. (3).

To analyze the impact of shear models on the experimental strength, a Z-test was executed. Table 1 illustrates the outcome of the Z-test on the database. The $Z_{Statistic}$ is above the $Z_{Critical}$ and all the β -values are below the p-value of 0.05. Therefore, the null hypothesis is rejected and it can be concluded that there is substantial statistically difference between the means of the experimental shear and the predicted means from the four ACI code shear equations in z-test.

The difference in the predicted means of Eq. (1) was compared with the average predicted shear strength of Eqs. (2) to (4) in Table 2. Compared with the mean of Eq. (1) the $Z_{Statistic}$ is higher than the $Z_{Critical}$ and all the β -values are below the p-value of 0.05 for the means of Eqs. (2) and (4) indicating a considerable difference between the predicted averages of the shear values for Eqs. (2) and (4) compared with Eq. (1). However, the $Z_{Statistic}$ is below the two-tail $Z_{Critical}$ and the β -value of 0.52 is greater than the P-value of 0.05, showing that there is no difference in the average predicted shear strength of Eq. (1) compar-ed with the average predicted shear strength of Eq. (3).

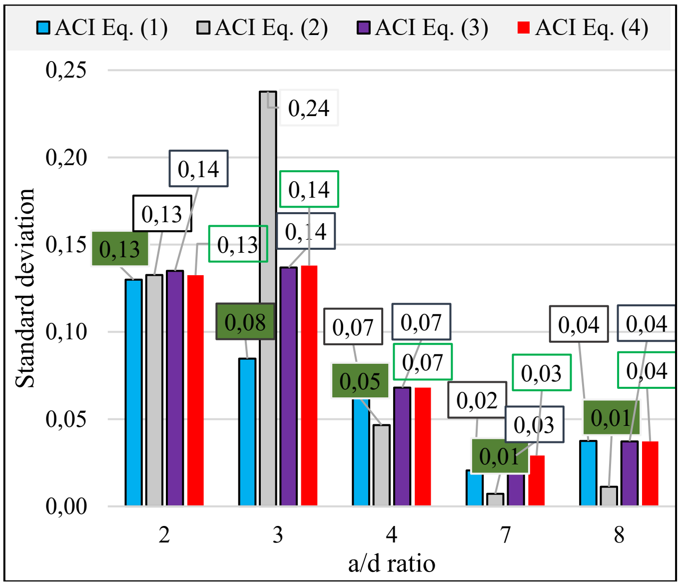

Fig. 6. The standard deviations between the experimental and their equivalent predicted shear capacity using ACI code Eqs. (1), (2), (3), and (4) versus the a/d ratio

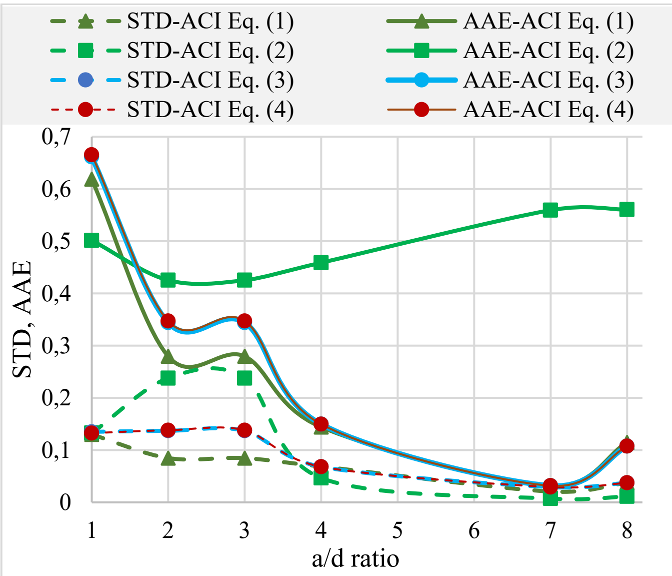

Fig. 7. AAE and or STD for the experimental-predicted shear capacity using ACI code Eqs. (1), (2), (3) and (4) versus the a/d ratio

The average predicted shear strength of Eq. (2) was compared with the average predict-ed shear of Eqs. (3) and (4) in Table 3. All β -value is lower than P-value of 0.05, which confirms the substantial difference in the predicted average shear strength of Eq. (2) compared with average predicted shear of Eqs. (3) and (4).

A direct comparison between the predicted average shear strength of Eq. (3) and Eq. (4) using the z-test is tabulated in Table 4. The $Z_{Statistic}$ is greater than two-tail $Z_{Critical}$ and all the β -value is smaller than the P-value of 0.05 therefore the null hypothesis is rejected therefore there is no enough evidence to conclude that the means of Eq. (3) and Eq. (4) are equal.

Table 1. Summary of Z-test for experimental-predicted shear strength using Eqs. (1)-(4)

Eq.	$Z_{Statistic}$	$Z_{Critical}$ two-tail	β -value	P-value	Is $Z_{Statistic} > Z_{Critical}$	Is P value > β-value
(1)	3.72	1.96			Yes	
(2)	4.67	1.96			Yes	
(3)	3.51	1.96			Yes	
(4)	4.09	1.96			Yes	
			0.0002	0.05		No
			0.0000	0.05		No
			0.0004	0.05		No
			0.0000	0.05		No

Table 2. Summary of Z-test for predicted Eq. (1) to Eqs. (2)-(4) shear strength

Eq.	$Z_{Statistic}$	$Z_{Critical}$ two-tail	β -value	P-value	Is $Z_{Statistic} > Z_{Critical}$	Is P value > β-value
(2)	3.01	1.96			Yes	
(3)	-0.64	1.96			No	
(4)	2.45	1.96			Yes	
			0.0026	0.05		No
			0.5221	0.05		yes
			0.0145	0.05		No

Table 3. Summary of Z-test for predicted Eq. (2) to Eqs. (3)-(4) shear strength

Eq.	$Z_{Statistic}$	$Z_{Critical}$ two-tail	β -value	P-value	Is $Z_{Statistic} > Z_{Critical}$	Is P value > β-value
(3)	-3.06	1.96			No	
(4)	-2.10	1.96			No	
			0.002	0.05		Yes
			0.035	0.05		Yes

Table 4. Summary of Z-test for predicted Eq. (3) to Eq. (4) shear strength

Eq.	$Z_{Statistic}$	$Z_{Critical}$ two-tail	β -value	P-value	Is $Z_{Statistic} > Z_{Critical}$	Is P value > β-value
(4)	2.15	1.96			Yes	
			0.031	0.05		Yes

4. Conclusions

- For the beams tested for an a/d ratio of 6-7, the average projected shear values using the ACI code Eq. (1) were nearly identical to the corresponding average experimental values.
- The evaluated average shear values using the ACI code Eq. (2) for the beams tested for an a/d ratio of 2-3, 3-4, 6-7, and 7-8 were similar and lower than the corresponding experimental averages.
- Good agreement was found between the predicted average shear values using the ACI code Eq. (3) its corresponding experimental shear values in a/d ratio of 6 to 7. This criterion holds true For Eq. (4).
- The a/d ratio affects the AA error values, between the experimental shear and the predicted shear using Eqs. (1) to (4). For a/d ratios of 7, the least amount of AAE is produced by Eqs. (1), (3) and (4). This error is less than 10% for the ranges 5-6, 6-7, and 7-8. The detailed Eq. (2) produces the highest errors for all the ranges of a/d ratio.

- The difference in standard deviation values between the four equations becomes less than 10% in the a/d ratios of 4, 7, and 8.

Evaluation of concrete paving block strength through ultrasonic pulse velocity (UPV) measurements

Bircan Arslannur [1], Muhammed A. Özdemir[*1]

[1] *Igdir University, Department of Civil Engineering, 76000 Iğdır, Türkiye*

Abstract. In Türkiye, the majority of rural village roads are being constructed using concrete paving blocks which must adhere to TS 2824 EN 1338 specifications. The conformity of these materials is generally evaluated through testing on samples obtained post-road pavement completion. Nevertheless, acquiring samples, dispatching them to laboratories, and awaiting results can lead to considerable time and labor inefficiencies. The main aim of this work is to facilitate real-time assessment of concrete paving blocks in situ via Ultrasonic Pulse Velocity (UPV) measurements, thus diminishing dependence on laborious laboratory testing methods. This strategy seeks to reduce potential labor and time inefficiencies linked to the production process during prolonged laboratory testing phases. This study entaile of 54 concrete paving block specimens from seven different villages' rural roads in Kars, Türkiye. Tensile strengthassessments were performed on samples to ascertain the relationship between tensile strengthand P-wave velocity. The flexibility of the concrete pavement blocks was also assessed. P and S-waves velocities were measured with a UPV device, while tensile strengthvalues were determined using a tensile testing machine. A regression analysis was conducted to correlate the UPV results with laboratory test outcomes, demonstrating a substantial association between the two datasets. The results indicate that performing thorough UPV and compression testing on concrete pavement blocks with varying compositions can yield empirical equations, enabling non-destructive strength evaluation in situ. The use of this method is anticipated to improve the efficiency and precision of quality control in the concrete paving block production and construction process.

Keywords: Ultrasonic pulse velocity; Concrete paving block; Strength assessment; Non-destructive testing; Engineering design; Road materials

1. Introduction

Concrete paving blocks are extensively used in rural road construction throughout Türkiye owing to their durability and ease of installation. These blocks must satisfy stringent quality and performance requirements as outlined in TS 2824 EN 1338:2005. Conventional quality control involves collecting samples after pavement completion and sending them to laboratories for destructive testing. However, this approach often introduces delays and additional labor costs in the production process.

The primary objective of this study is to explore the feasibility of using UPV measurements as an in situ, non-destructive method to predict the tensile strengthof concrete paving blocks. By establishing a robust correlation between UPV-derived elasticity measurements and laboratory-obtained tensile strengthdata, the study aims to develop a rapid quality assessment tool that can be applied directly in the field. The successful integration of UPV techniques into routine quality control could enhance project timelines, reduce material wastage, and promote more sustainable construction practices.

2. Literature review

2.1. Principles of UPV testing

Ultrasonic Pulse Velocity (UPV) testing is a well-established non-destructive evaluation (NDT) technique that measures the time an ultrasonic pulse takes to travel through a concrete specimen. Based on the fundamental equation This method provides valuable insights into the density, homogeneity, and elastic properties of the material.

$$Velocity = Distance/Time \tag{1}$$

In general, higher pulse velocities indicate a more homogeneous and structurally sound material, while lower velocities may suggest the existence of defects such as cracks or voids. UPV has been successfully applied to

[*] Corresponding author, E-mail: m.alperen.ozdemir@igdir.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_613

golden light publishing

assess reinforced concrete structures due to its non-invasive nature and its capacity for rapid evaluation (Popovics, 2005; Aggelis, 2013).

2.2. Applications in concrete structures and the literature gap

UPV testing is routinely employed in conventional concrete structures to evaluate quality, detect internal damage, and ensure overall structural integrity. While its use in reinforced concrete such as beams, columns, and slabs is well documented, the application of UPV for concrete paving blocks remains underexplored. The literature reveals a notable gap: few studies have directly correlated UPV measurements with tensile strengthin paving blocks, even though their loading mechanisms and failure behaviors differ from those of traditional reinforced concrete elements. In paving block production, UPV testing is particularly advantageous for real-time quality control; by measuring pulse velocity during manufacturing, the process can verify that blocks meet the required strength and durability standards. For instance, research has demonstrated that UPV can reliably assess concrete blended with recycled coarse aggregates and seashore sand (Al-Zuhairi, 2013; Rodríguez et al., 2017). Moreover, UPV's capability to detect internal cracks and voids is critical since such defects can severely compromise structural performance, enabling engineers to take corrective actions before premature failure occurs (Sharp & Ozyildirim, 2014; Hong, 2012). Additionally, because concrete paving blocks are exposed to harsh conditions including freeze-thaw cycles UPV can serve as an effective means of monitoring long-term degradation, facilitating early detection of deterioration and guiding maintenance efforts (Toutounchi et al., 2021). Finally, UPV data have been correlated with key material properties, such as compressive strength and elastic modulus, underscoring the technique's potential for comprehensive, non-destructive material characterization (Tang et al., 2007). Together, these applications not only underline UPV's versatility but also highlight the need for further dedicated research to bridge the existing literature gap in the field of concrete paving blocks.

2.3. Advantages and limitations of UPV testing

UPV testing offers several distinct advantages that make it an attractive method for quality control and material assessment. Its non-destructive nature allows repeated measurements without compromising the structural integrity of the material, which is particularly useful for both initial inspections and ongoing monitoring. Moreover, the technique is both rapid and cost-effective compared to traditional destructive methods, especially when used in conjunction with other NDT approaches such as sonic echo-impulse response for enhanced defect detection (Sharp & Ozyildirim, 2014). Additionally, UPV testing is versatile, having been applied successfully to a wide range of concrete structures, from newly manufactured paving blocks to aging infrastructure.

Despite these advantages, UPV testing is not without limitations. The accuracy of the results is highly dependent on proper surface preparation, as a clean and well-leveled surface is essential for optimal transducer contact. Furthermore, the choice of ultrasonic frequency plays a critical role; higher frequencies can provide improved resolution but may suffer from greater signal attenuation, whereas lower frequencies offer deeper penetration with reduced resolution. Finally, the interpretation of UPV data requires significant expertise to ensure that velocity measurements are correctly correlated with known material properties, thereby avoiding misinterpretation of the concrete's condition (Singh et al., 2022; Tang et al., 2007).

2.4. Case studies and practical examples

Several studies illustrate the practical application of UPV testing in the context of concrete paving blocks and related materials. Research on quality control has shown that UPV can effectively assess the strength and durability of concrete paving blocks produced with recycled aggregates and seashore sand, offering a reliable method for ensuring compliance with established standards (Singh et al., 2024). In cold regions, UPV has been used to monitor freeze-thaw damage in roller-compacted concrete, demonstrating its utility in long-term degradation monitoring (Toutounchi et al., 2021). Moreover, UPV testing has been applied to estimate crack depth in concrete structures, providing crucial information for evaluating defect severity and guiding maintenance decisions (Cho et al., 2012). These case studies underscore the technique's potential for expanding its application to concrete paving blocks—a research area that warrants further exploration.

3. Materials and methods

3.1. Sample collection

A total of 54 concrete paving block specimens were obtained from rural roads in seven villages within the Kars area of Türkiye. The sampling distribution was as detailed below: Çıplaklı (8 samples), Katrancı (6 samples), Kaynarlı (10 samples), Kilit Taşı (10 samples), Kümbetli (5 samples), Melikköy (5 samples), and Şenolköy (10 samples).

Despite the paving blocks being created in accordance with a uniform recipe and production criteria, it is probable that the material compositions differed among villages due to variations in sourcing, batching techniques, or local aggregate availability. Moreover, the sampling occurred at disparate times across the villages, indicating that the blocks experienced diverse environmental and climatic conditions—such as temperature variations, freeze-thaw cycles, and moisture levels—prior to testing. These factors may have substantially affected the mechanical properties of the specimens, especially their tensile strength.

Consequently, assessing the data on an individual village basis seems to be a more suitable method than consolidating the results. This will facilitate a fuller comprehension of localized differences in material performance and more effectively isolate the impact of production techniques and environmental exposure. This technique emphasizes the significance of context-specific quality control and the necessity for site-level monitoring to guarantee the consistent durability and performance of concrete paving blocks in rural infrastructure.

3.2. UPV measurement procedure

UPV measurements were conducted on all specimens using a calibrated ultrasonic pulse velocity device under controlled laboratory conditions. The procedure involved:

- Device Calibration: The UPV device was calibrated following the manufacturer’s specifications to ensure accurate readings.
- Measurement Conditions: Prior to testing, the surface of each concrete paving block was cleaned and leveled. All measurements were performed at a stable ambient temperature and humidity.
- Data Collection: For each specimen, P-wave and S-wave velocities were measured at three distinct points. The average UPV value for each block was then determined for subsequent analysis. The UPV results, illustrated in Fig. 1, represent the values documented during the experimental process.

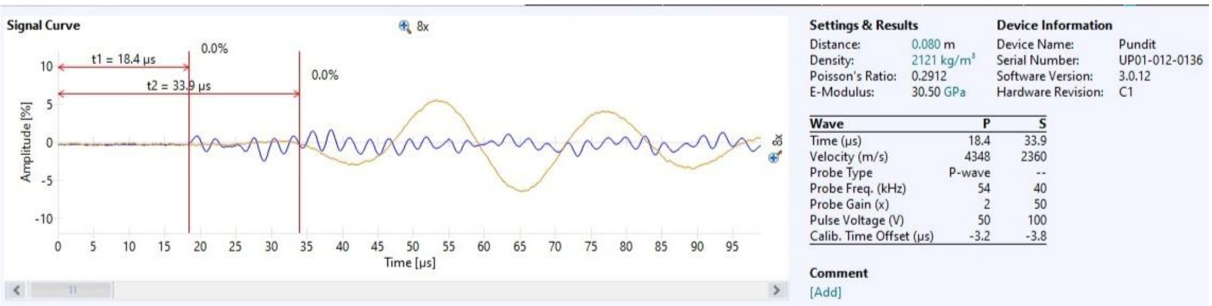

Fig. 1. Sample UPV Test Result

3.3. Laboratory tensile splitting strength test

Immediately after UPV measurements, the same specimens underwent tensile strengthtesting:

- Standards Compliance: Tensile testing was carried out following TS 2824 EN 1338:2005, which provides the required procedures for evaluating concrete paving blocks.
- Test Setup: Each block was subjected to a tensile test using an appropriate testing machine. The bending behavior and fracture characteristics were recorded.
- Data Documentation: Results, including precise tensile strengthvalues and observations of failure modes, were systematically documented for further statistical analysis.

3.4. Statistical analysis

Data derived from UPV measurements and tensile strengthtests were subjected to Pearson’s correlation analysis to assess the strength and direction of the association between the two variables. The analysis was performed utilizing Microsoft Excel. A correlation coefficient (R) was computed to assess the extent of linear relationship between UPV values and tensile strength. As no regression model was constructed in this study, no prediction equation was established. The correlation results offer preliminary insights into the viability of UPV measurements as markers of tensile performance.

4. Results

4.1. Test results

The test results for each village were compiled, and the P-wave and S-wave velocities, elasticity values derived from these waves, saturated unit weight, breaking force, and tensile splitting strength values were documented in a table. Table 1 displays the tensile test and UPV measurement findings for the samples from each village.

Table 1. Test results

	Non Destructive Method			Tensile Splitting Strength Test (EN 1338:2003)

4.2. Correlation analysis

The statistical analysis demonstrated a robust positive association between UPV readings and the tensile strengthof concrete paving blocks. The Pearson correlation coefficient, computed via Microsoft Excel, was between 0.80 and 0.96, suggesting a positive association between elevated UPV levels and increased tensile strength. This indicates that UPV measurements can yield significant insights into the mechanical performance of concrete paving blocks.

Nonetheless, as demonstrated in Fig. 2, while the specimens from each village displayed a significant level of internal correlation, aggregating the results from all villages did not produce a coherent or consistent trend. This suggests that assessing all samples together may not constitute a reliable analytical method. Although all tested specimens conform to the pertinent standard standards, the observed diversity is probably due to discrepancies in manufacturing conditions among villages. This encompasses aspects such as varying manufacturers, curing techniques, water-to-cement ratios, aggregate gradation, and types of aggregates in the concrete mix design. These discrepancies highlight the necessity of localized analysis in interpreting mechanical performance and underscore the requirement for consistent production and quality control techniques across locations.

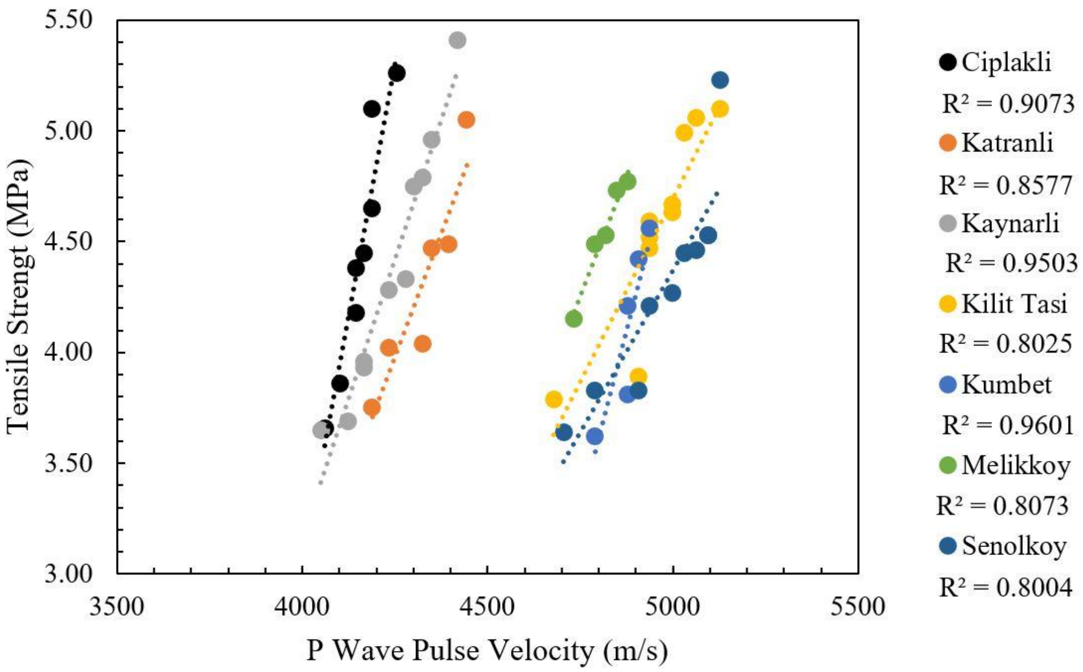

Fig. 2. Correlation Results

5. Conclusion

This study illustrates that Ultrasonic Pulse Velocity (UPV) testing is an excellent non-destructive method for assessing the tensile strength of concrete paving blocks. A strong positive correlation between UPV measurements and laboratory tensile strength values validates the viability of UPV as a practical and effective substitute for traditional destructive testing methods. This non-destructive method facilitates swift in situ evaluations, therefore reducing the time, labor, and material expenses often linked to quality control in rural road construction.

The results endorse the proposal that UPV testing methodologies should be standardized and integrated into regular quality control practices, especially in projects requiring extensive sampling and swift decision-making. Simultaneously, it is imperative that laboratory tensile strength evaluations comply with TS 2824 EN 1338:2005 standards to guarantee uniform benchmarking and result comparability.

Notwithstanding the encouraging results, the study possesses inherent limitations. The constrained sample size—limited to 54 specimens from seven villages—may impede the generalizability of the findings. Subsequent research should focus on augmenting the dataset to enhance statistical rigor and investigate regional disparities in material composition and craftsmanship. Moreover, environmental variables including surface wetness, ambient temperature, and the quality of contact between transducers and specimen surfaces might affect UPV measurements. These characteristics must be methodically examined to improve the reliability of field applications.

A significant avenue for future research entails the amalgamation of Ultrasonic Pulse Velocity (UPV) with alternative non-destructive testing (NDT) techniques, like rebound hammer tests, impact-echo, or ground-penetrating radar, to yield more thorough assessments of concrete quality. Multimodal NDT methodologies may address the shortcomings of singular techniques and offer a more comprehensive insight into internal flaws, material consistency, and long-term efficacy.

In conclusion, incorporating UPV testing as an adjunct method for assessing concrete paving blocks offers significant potential for enhancing construction processes, increasing the precision and efficacy of quality assurance measures, and fostering more sustainable practices by minimizing the necessity for destructive sampling and testing. With more validation and methodological enhancement, UPV could emerge as a crucial element of contemporary, field-ready infrastructure evaluation methodologies.

Reinforcement of unreinforced masonry buildings with carbon emission reduced cement

Pınar Usta Evci[1], Bilge Arslan[*2]

[1] Isparta University of Applied Sciences, Department of Civil Engineering,32260 Isparta, Türkiye
[2] Sinop University, Department of Architecture and Urban Planning, 57200 Sinop, Türkiye

Abstract. Buildings made of masonry pose serious safety issues due to their insufficient load-bearing capacity, especially in areas with high earthquake risk. The traditional methods of reinforcement often have a high carbon footprint and contradict with sustainability goals. This study investigates the use of carbon emission-reduced cement for sustainable strengthening of unreinforced masonry buildings, aiming to both increase structural safety and reduce environmental impacts. Geopolymer cement, cements enhanced with industrial by-products such as Calcined Clay and Limestone Cement (LC3) and fly ash and slag provide significantly lower carbon emissions compared to conventional Portland cement. These innovative Cements can be applied in reinforcement techniques such as grouting mortar, cementitious coatings, textile reinforced mortars (TRM) and sustainable grouting, effectively improving the structural integrity and earthquake performance of masonry walls. The study highlights the environmental benefits of these methods, such as reducing CO_2 emissions, utilizing industrial solid waste and ensuring the long-lasting durability of reinforced structures. These results reveal that reinforcement methods with carbon-reduced cement contribute to sustainable construction practices while improving the earthquake performance of the masonry buildings. This study aims to fill an important gap in terms of both building safety and environmental sustainability and provides direction for future studies in the related field.

Keywords: Reinforced masonry building, Carbon emission reduced cement, Earthquake performance, Geopolymer cement, Environmental sustainability

1. Introduction

Masonry structures, as a product of architectural traditions extending from the past to the present, have been widely constructed for centuries, particularly in regions such as the Mediterranean basin, the Middle East, and Southern Europe. These systems still constitute a significant portion of the current building stock. The historical continuity of this building typology has been made possible by the ease of material procurement in both rural and urban areas, low-cost construction processes, and the reliance on local labor. However, since the load-bearing system of such structures depends solely on wall elements working in compression, they exhibit brittle behavior under lateral loads such as earthquakes and often lack structural integrity (Lagomarsino & Cattari, 2015; Milani et al., 2021). In countries like Turkey, which are located in high seismic risk zones, the prevalence of these structural systems poses serious engineering challenges in terms of life and property safety, necessitating the performance-based retrofitting of the existing building stock.

Conventional techniques for retrofitting unreinforced masonry structures include interventions such as external cement-based plastering, steel confinement systems, reinforced concrete frames, and pressure grouting (Triantafillou, 2001; Benedetti & Petrini, 2004). Although these methods can provide short-term gains in stiffness and ductility, they typically involve high energy consumption and carbon emissions due to the materials and processes used, making them incompatible with principles of sustainability. Particularly, Portland cement-based retrofitting applications contribute significantly to global CO_2 emissions—approximately 7–8%—not only due to chemical clinker transformations but also because of high-temperature manufacturing processes (Andrew, 2018; Scrivener et al., 2018). This indicates a dual challenge where structural enhancement is accompanied by considerable environmental burden.

Recent advancements in materials science and sustainable construction technologies have enabled the development of more eco-friendly and performance-oriented alternatives for the strengthening of masonry structures. Low-carbon and highly reactive alternative binders such as geopolymer binders, limestone calcined clay cements (LC3), fly ash, ground granulated blast furnace slag (GGBFS), metakaolin, and natural pozzolans not only improve mechanical strength but also significantly reduce carbon emissions during production, thereby

* Corresponding author, E-mail: barslan@sinop.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_640

contributing to sustainable construction practices (Gartner & Sui, 2018; Provis, 2022). For instance, LC3 systems can be manufactured at lower temperatures compared to Portland cement and offer a 30–50% reduction in CO_2 emissions due to a reduced clinker content (Gluth et al., 2020). Similarly, geopolymer binders—activated by fly ash and alkaline solutions—can decrease environmental impacts by up to 60%, aligning structural engineering practices with environmental responsibility.

Moreover, the formulation of these alternative binders using industrial by-products and waste materials reflects strong compatibility with circular economy principles and sustainable development goals, offering multi-dimensional benefits in terms of waste management and resource efficiency. The use of locally available additives can also reduce implementation costs in low-income and rural areas, increasing the applicability and scalability of these systems. In this context, low-carbon binder systems hold not only engineering relevance but also strategic importance for sustainable urban planning, climate policy, and disaster risk management.

Particularly in advanced retrofitting methods such as Textile Reinforced Mortar (TRM) systems, geopolymer-based binders demonstrate high adhesion, crack control, and rheological stability, significantly enhancing the performance of such applications and marking a qualitative transformation in the paradigm of masonry strengthening (Micelli et al., 2020; Asteris et al., 2023). However, engineering-oriented studies that comprehensively examine the integration of alternative binders with masonry strengthening systems remain limited.

Accordingly, the present study aims to explore the integration of low-carbon binder systems into the retrofitting of unreinforced masonry structures, with the dual objective of enhancing structural performance and reducing environmental impact. The findings obtained through laboratory evaluation of geopolymer cements, LC3, and fly ash-blended binder systems offer a novel contribution toward the sustainable strengthening of existing building stock and address a significant gap in the literature.

2. Materials and methods

2.1. Materials used

In this experimental study, a new type of blended cement mortar with reduced carbon dioxide emissions was developed using pozzolanic additives such as fly ash, microsilica, metakaolin, and hydrated lime. The components used include Class F fly ash, microsilica with a particle size ranging between 0.1–0.2 µm, and CEM IV 42.5 cement.

As shown in Table 1, the mixture composition consists of 40% CEM IV-B 42.5 cement, 20% metakaolin, 20% hydrated lime, 10% microsilica, and 10% Class F fly ash. These components were selected with the dual objective of achieving high mechanical strength and a reduced carbon footprint. The mortar consistency was adjusted to a water-to-binder ratio of 0.30, and cubic specimens with dimensions of 40 × 40 × 40 mm^3 were prepared. After 24 hours, the specimens were demolded and transferred to a curing tank. Uniaxial compressive strength tests were then conducted on days 2, 7, and 28.

2.2. Materials used

Uniaxial compressive strength tests were conducted on the specimens at 2, 7, and 28 days, and the resulting data were evaluated in accordance with the TS EN 196-1 standard. Additionally, physical properties such as initial setting time and water demand were determined and compared against the threshold values specified in the EN 197-1 standard.

The initial setting time was measured between 180 and 220 minutes, which is significantly above the minimum requirement of 75 minutes set by EN 197-1. As shown in Table 2, the 2-day compressive strength of the specimens was recorded as 14.5 MPa, while the 28-day strength reached 33 MPa. These results demonstrate equivalent or even superior performance when compared to standard CEM IV-B 32.5N class cements under EN 197-1 specifications.

The incorporation of alternative components contributed to a notable environmental advantage, achieving an average reduction of approximately 40% in carbon emissions during the production phase, compared to conventional Portland cement.

Table 1. Mix proportions (%)

Microsilica	Fly Ash (Class F)	Metakaolin	Hydrated Lime	CEM IV 42.5
10%	10%	20%	20%	40%

Table 2. Physical properties of the novel blended cement

Property	CEM IV-B 32.5N Reference	Measured Value	Standard limiti	
			Min.	Max.
Initial Setting Time	180-220	115	75	-
Water Demand (%)	%31-33	%20-30	-	-
2-day Compressive Strength (MPa)	9,5 -10 MPa	14,5 MPa	10,0	-
2-day Compressive Strength (MPa)	-	22 MPa		
2-day Compressive Strength (MPa)	32,5-38 MPa	33 MPa	32,5	52,5

3. Evaluation of findings

The experimental findings demonstrate that the low-carbon binder system exhibits high suitability for the strengthening of unreinforced masonry structures in terms of both structural performance and environmental sustainability. The inclusion of highly pozzolanic components such as metakaolin and microsilica enriched the hydration products of the binder matrix, resulting in a more compact structure that limits crack propagation and enhances microstructural integrity. This, in turn, significantly improved the ductility capacity and energy dissipation ability of the masonry walls.

Furthermore, the integration of chemically active and fine-grained materials such as fly ash and hydrated lime into the binder composition promoted high adhesion at the mortar-to-masonry interface. This led to notable improvements in shear strength, which is of critical importance for limiting shear cracks under lateral loading.

The binder's initial setting time of approximately 180 minutes provides operators with sufficient working time for large-scale applications, thereby helping to minimize workmanship errors. This characteristic is particularly valuable in rural areas or low-tech application environments, where extended workability directly contributes to the success of material implementation.

Another key advantage of the developed binder system is its high level of compatibility with existing retrofitting techniques. The system demonstrates rheological and chemical properties suitable for external plaster applications, injection grouts, cement-based overlays, and especially textile-reinforced mortar (TRM) systems. In TRM applications, the binder's strong adhesion and microstructure, which effectively limits crack propagation, enhance both the durability and efficiency of the overall strengthening system (Micelli et al., 2020; Asteris et al., 2023). In injection-type applications, the binder maintains low viscosity and high penetration capacity, allowing it to infiltrate micro-voids and offering intrinsic crack-healing potential.

From an environmental sustainability perspective, the binder system also offers significant advantages. According to existing literature, LC3 and geopolymer-based binders can reduce carbon emissions by 30% to 80% compared to traditional Portland cement (Gartner & Sui, 2018; Scrivener et al., 2018; Gluth et al., 2020). The use of industrial by-products such as microsilica and fly ash in the formulation of the developed system contributes to waste recovery and aligns with the principles of the circular economy. Moreover, the local availability of these components enhances the feasibility of sustainable retrofitting in low-income regions and increases the system's scalability.

4. Conclusions

This study was conducted to evaluate the structural and environmental performance of a low-carbon cement-based binder system designed for the strengthening of unreinforced masonry structures. The binder system, developed with the objective of reducing the environmental burden of conventional Portland cement and promoting sustainable construction materials, consisted of 40% CEM IV-B cement, 20% metakaolin, 20% hydrated lime, 10% microsilica, and 10% fly ash.

The experimental findings revealed that this system not only achieved high mechanical performance in compliance with EN 197-1 and TS EN 196-1 standards, but also significantly enhanced critical performance parameters such as stiffness, ductility, and shear strength in unreinforced masonry structures. The binder's high pozzolanic reactivity contributed to microstructural densification, effectively limiting crack propagation and providing a material behavior characterized by strong surface adhesion and controlled setting time.

These properties enabled high compatibility with widely used retrofitting techniques such as external plastering, injection grouting, and Textile Reinforced Mortar (TRM) systems, thereby improving its applicability in real-world construction scenarios. Moreover, due to the use of industrial by-products and naturally available additives in the formulation, the binder system achieved an approximate 40% reduction in carbon emissions compared to conventional Portland cement, offering a solution fully aligned with sustainable development goals.

The results clearly demonstrate that the developed binder system is a viable, scalable, and environmentally responsible alternative for the sustainable strengthening of existing building stock, especially in low-income and high seismic risk regions. In this regard, the study offers an interdisciplinary contribution by simultaneously addressing the concepts of structural safety and environmental sustainability.

Investigation of P-M interaction for rRC columns confined with CFRP sheets under uniaxial bending

Ali J. Noorzad*[1], Hakan Dilmaç[2]

[1]Suleyman Demirel University, Graduate School of Natural and Applied Sciences, Çünür, 32260 Isparta, Türkiye
[2]Suleyman Demirel University, Faculty of Engineering and Natural Sciences, Çünür, 32260 Isparta, Türkiye

Abstract. The retrofitting of reinforced concrete (RC) columns with carbon fiber-reinforced polymer (CFRP) sheets is recognized as a highly efficient technique for substantially enhancing structural performance, particularly with respect to axial load strength and flexural capacity. Although extensive research has been conducted on CFRP-confined columns, a significant gap persists in the detailed understanding of the axial-flexural (P–M) interaction behavior of rectangular RC (rRC) columns subjected to eccentric loading. This study presents a rigorous analytical investigation of CFRP-strengthened rRC columns, focusing on the development of P–M interaction diagrams based on three prominent stress–strain models: Lam and Teng, Rami and Paultre, and Wei and Wu. A sectional analysis framework was employed, incorporating variations in material properties, eccentricity levels, corner radii, CFRP volumetric ratios, and aspect ratios. The parametric analysis revealed that CFRP confinement significantly enhances both axial and flexural capacities, particularly at lower eccentricities, although its effectiveness diminishes with increasing eccentricity. Columns with larger corner radii and lower-grade concrete exhibited superior confinement performance due to improved stress distribution and increased deformability. Furthermore, increasing the number of CFRP layers substantially elevated the axial strength and resulted in moderate improvements in flexural resistance. Experimental validation confirmed the reliability of the analytical models, highlighting their high predictive accuracy and affirming their ability to reliably forecast outcomes in similar situations. CFRP confinement proves to be a highly effective technique for enhancing the structural resilience of rectangular RC columns; however, its efficacy is profoundly influenced by cross-sectional geometry, material properties, and loading conditions.

Keywords: CFRP confinement; P-M interaction diagram; Rectangular RC columns; Eccentric loading; Axial-flexural behavior

1. Introduction

The utilization of CFRP composites for retrofitting RC columns has become a popular technique to enhance both strength and deformability (Abid et al., 2021; H. S. Al-Nimry & Al-Rabadi, 2019; Fan et al., 2023). CFRP wraps, typically applied transversely to confined RC columns, provide lateral confinement, preventing outward expansion of the concrete core and increasing load-bearing capacity and ductility (Ahmed et al., 2021; Cao et al., 2018). The widespread use of FRP in structural industry is due to its mechanical properties, including high tensile strength, corrosion resistance, and ease of installation (Koksal et al., 2009; Liao et al., 2023). Most studies have focused on RC columns under axial compression (Harajli, 2006; Harajli & Hantouche, 2006), with fewer addressing columns subjected to combined axial and flexural loads (Abid et al., 2021). Eccentrically loaded FRP-confined columns are of particular interest, as many structural columns face both axial compression and bending moments.

Although much research has been conducted on the compressive stress-strain behavior of FRP-confined rectangular RC columns, existing models are often designed for circular columns (Eid et al., 2017; Harajli, 2006). Some analytical models for rectangular columns under axial load have been proposed, but the influence of factors like loading eccentricity and column shape remains significant (Ahmed et al., 2021). Most research has focused on circular sections, but rectangular columns, commonly used in practice, are also subject to eccentric loads. Therefore, more research is needed on the mechanical behavior of rectangular RC columns retrofitted with FRP wraps.

While FRP wraps provide sufficient confinement for circular columns, the enhancement in strength and ductility for rectangular cross-sections is less pronounced due to the non-uniform lateral confining pressure (Abdallah et al., 2018; Harajli, 2006). For rectangular columns, sharp corners concentrate lateral pressure, leading

https://doi.org/10.31462/icearc2025_ce_mat_643

to early failure of FRP jackets at low deformation (Noorzad & Dilmaç, 2025). This has led to further investigation into techniques for improving fiber efficiency in retrofitted rectangular RC columns. Studies have also explored the behavior of eccentric RC columns confined with FRP jackets, focusing on the (P-M) interaction curve (Mai et al., 2020). These studies emphasize the role of material properties, loading eccentricities, and column dimensions in determining the effectiveness of FRP confinement.This study analytically evaluates the (P-M) interaction curves of FRP-confined rectangular RC columns under eccentric loads, evaluating factors like material properties, confinement ratio, and load eccentricities to better understand the advantages of FRP fibers in enhancing axial and flexural load strength.

2. Materials and methods

2.1. Material properties

A comprehensive understanding of the materials' mechanical properties in FRP-RC columns is essential for evaluating their structural performance. Concrete, the core material, has high compressive strength but low tensile strength, making its tensile resistance always neglected in structural design (Rasheed, 2014). Under axial compression, concrete exhibits nonlinear elastic-plastic behavior followed by brittle failure, highlighting the importance of knowing its properties for assessing confinement efficiency. In this study, various grades of unconfined normal-strength concrete were used, with three shown in the compressive stress-strain curves in Fig. 1a. Steel reinforcement bars, which provide tensile resistance, behave elastic-plastic behavior and high ductility under tensile loading. Steel with a yield strength of f_y=420MPa was used, with its stress-strain characteristics shown in Fig. 1b. CFRP composites, recognized for their high tensile strength and corrosion resistance, are commonly used in retrofitting RC columns. CFRP has a linear-elastic behavior and brittle failure mode, with a modulus of elasticity of E_f=250GPa and an ultimate tensile strain of 1.5%, as shown in Fig. 1b.

2.2. Methodology

This study evaluates the axial-flexural behavior of rectangular RC columns confined with CFRP sheets under eccentric loading. Axial load–flexural moment (P–M) interaction diagrams were developed by integrating internal stresses across the column's cross-section. The compressive behavior of confined concrete was modeled using three established stress–strain models: Lam and Teng (Lam & Teng, 2003), Rami and Paultre (2017), and Wei and Wu (Wu & Wei, 2016), which accurately predict the response of both circular and rectangular columns. An Excel-based tool was used for iterative calculations, ensuring equilibrium and strain compatibility. Fifteen rectangular specimens with varying geometries and material properties were analyzed under eccentric loading to determine axial-flexural capacities. The methods used for calculating axial load and bending moment strength included both the equivalent rectangular stress block approach and full stress–strain integration. The influence of load eccentricity (e/h) on confinement efficiency and stress distribution was also considered. The results, shown through normalized P–M interaction curves, demonstrated improvements in load capacity and ductility from CFRP confinement. The study also assessed various confinement parameters, providing insights for retrofitting non-circular RC columns.

3. Stress-strain models for confinement

Three FRP-confined concrete stress–strain models were used to determine the (P–M) interaction diagrams of eccentrically loaded RC columns strengthened with FRP composites. These models include Lam and Teng (Lam & Teng, 2003), Rami and Paultre (Eid & Paultre, 2017), and Wei and Wu (Wu & Wei, 2016), with corresponding equations shown in Table 2. Additionally, ACI 440.2R(ACI, 2008) was evaluated to determine column strength under eccentric load and generate the interaction curves.

The Lam and Teng (Lam & Teng, 2003) model was mainly used due to its accuracy for FRP-confined rectangular RC columns, as adopted by ACI 440.2R(ACI, 2008). Rami and Paultre (Eid & Paultre, 2017) proposed a unified stress–strain model for FRP-confined RC columns with transverse steel reinforcement, applicable to both circular and rectangular sections. This model features two branches, with corresponding equations in Table 2 and Fig. 2a. Wei and Wu's model uses a two-branch curve, with a parabolic first segment and a straight line in the second, applicable to circular, rectangular, and square sections, with expressions provided in Table 2.

3.1. Effect of eccentricity on the confinement of concrete

The influence of load eccentricities on the compressive behavior and stress-strain response of FRP-confined concrete in RC columns is a critical factor in evaluating the strength and ductility of these columns under eccentric loading conditions. Hayder Rasheed (Rasheed, 2014) proposed a relationship between the maximum confined compressive strength of concrete under pure axial load and that under eccentric loading. For eccentrically loaded rectangular RC columns, a factor known as the compression zone ratio (CR) is calculated; this factor depends on the column's dimensions and the magnitude of the load eccentricity and is illustrated in the following equation. Ultimately, the confined compressive strength of concrete in RC columns strengthened with FRP jackets is determined based on the following expression:

$$CR = \frac{0.2\frac{e}{\sqrt{bh}} + 0.1}{\frac{e}{\sqrt{bh}}} \tag{1}$$

$$f_{ce} = \frac{1}{1 + \frac{1}{CR - 0.2}} f_{cc} + \frac{1}{0.8 + CR} f_{co} \tag{2}$$

where f_{ce} is the confined compressive strength of concrete under eccentric loading at an eccentricity of e/h; f_{co} is the confined compressive strength of concrete under pure axial load; CR is the compression zone ratio; e is the magnitude of the load eccentricity; and b and h are the cross-sectional dimensions of the rectangular column.

Table 2. Stress-strain models used in this study.

Lam and Teng model (Lam & Teng, 2003)	Rami and Paultre model (Eid & Paultre, 2017)	Wei and Wu model (Wu & Wei, 2016)

4. Nominal strength of FRP-confined RC column

4.1. Axially loaded RC columns

In practical applications, perfectly axially loaded columns rarely exist; however, analyzing such idealized members serves as a foundational approach to understanding the underlying principles in the design of real columns subjected to eccentric loading. At the point of failure, the theoretical or nominal axial load-bearing capacity of short RC columns strengthened with externally bonded FRP wraps under pure axial compression can be reliably estimated using the equation recommended by ACI 440.2R (ACI, 2008).

$$P_n = P_{nc} + P_{ns} = 0.85 f_{cc}(A_g - A_{st}) + f_y A_{st} \tag{3}$$

Where P_n represents the ultimate axial compressive load; f_{cc} denotes the maximum confined compressive strength of concrete, determined through analytical modeling; A_g is the gross cross-sectional area of the column, calculated as $A_g = b \times h - (4-\pi) r_c^2$ for rectangular cross sections ; f_y and A_s refer to the tensile yield strength and the total cross-sectional area of the longitudinal steel reinforcement, respectively; and r_c indicates the corner radius of the column cross-section.

4.2. Eccentrically loaded RC columns

All structural columns are exposed to both axial forces and bending moments, necessitating their design to effectively withstand the combined effects. Columns experience bending under flexural moments, resulting in compressive stress on one side and tensile stress on the opposite side. The distribution and intensity of these stresses depend on the interplay between the applied axial load and bending moment. An FRP-confined column is considered to reach its ultimate strength when the strain in the confined concrete reaches the ultimate confined strain, denoted as ε_{ccu}. When such columns are subjected to eccentric loading, their nominal axial capacities and flexural moments are evaluated using two analytical approaches: one involves integrating the stress-strain response of the compression zone, while the other utilizes an equivalent rectangular stress block method(Mai et al., 2024).

4.2.1. Rectangular stress-block approximation method

The simplified rectangular stress block method, originally proposed by Whitney(Mai et al., 2024) and later incorporated into ACI 318(ACI, 2011), employs an idealized stress distribution—depicted in Fig.3—to estimate the nominal axial load and bending moment. This technique assumes a uniform compressive stress of $0.85F_{cc}$ within the confined concrete, applied over an equivalent compression zone. This zone is delineated by the boundaries of the cross section and a line drawn parallel to the neutral axis, located at a depth a=βc from the most compressed concrete fiber where the peak confined strain ε_{ccu} is observed. The corresponding compressive force in the concrete, represented as P_{nc}, can be determined using the following formula:

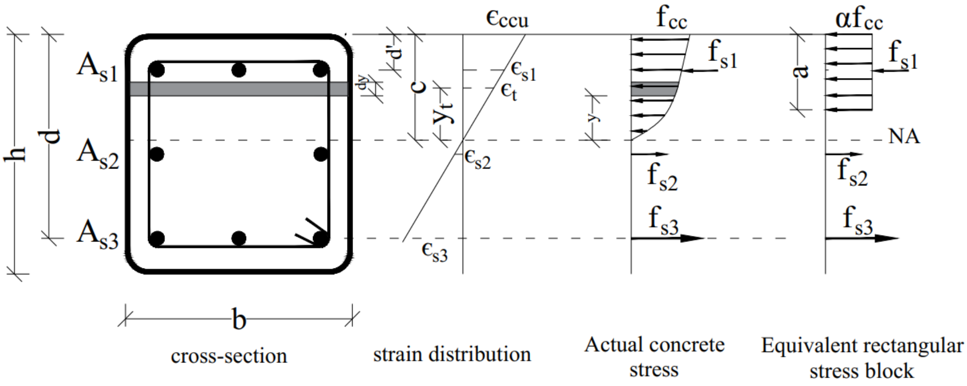

Fig.3. Stress and strain distribution at ultimate conditions.

$$P_n = P_{nc} + P_{ns} = \alpha f_{cc} ab + \sum_{i=1}^{n} f_{si} A_{si} \tag{4}$$

$$P_{nc} = 0.85 f_{cc} ab = \alpha f_{cc} \beta_1 cb \tag{5}$$

Where is c is the distance to the neutral axis from the extreme compression, a is depth of equivalent rectangular stress block, α and β_1 are the reduction factor of equivalent compressive stress block and deph, b is the width of cross section.

The strain in the longitudinal steel reinforcement is determined using the strain compatibility principle. Specifically, the strain in the i-th layer of reinforcement bars (ε_{si}) is derived through geometric similarity, based on similar triangles. Subsequently, the internal forces within the i-th layer of the primary reinforcement bars and ultimate nominal flexural moment are computed using the following expressions:

$$P_n \times e' = \mathrm{C} \times \left(d - \frac{a}{2} \right) + \sum_{i=1}^{n} p_{si} \times \left(d - d_i \right) \tag{6}$$

$$M_n = P_n \times e \tag{7}$$

4.2.2. Integration using stress–strain models

This method provides greater accuracy than the equivalent rectangular stress block approach, as it captures the distinct stress distribution behavior of FRP-confined concrete, which differs markedly from that of unconfined concrete. To determine the nominal axial compressive load and flexural moment capacity within the compression zone of a column cross-section, the analytical stress–strain relationship is integrated over the confined area(Rasheed, 2014). The proposed stress–strain model comprises two segments: an initial parabolic branch that shows the same slope as unconfined concrete, followed by a linear branch with a slope equal to E_2. Integration is carried out continuously across both segments. The detailed steps of this integration process for confined concrete are illustrated in Fig.4.

$$w = w_1 + w_2 = \int_0^{x_t} f_{c1} dx + \int_{x_t}^{c} f_{c2} dx \tag{8}$$

$$P_{nc} = w \times b = b \left[\int_0^{x_t} f_{c1} dx + \int_{x_t}^{c} f_{c2} dx \right] \tag{9}$$

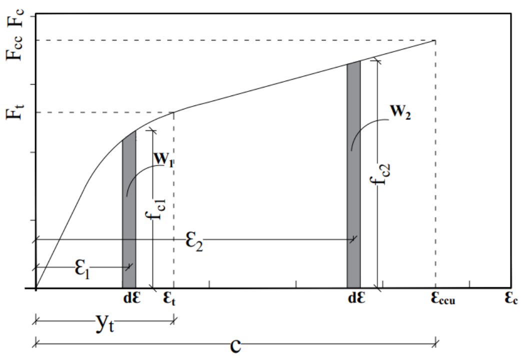

Fig. 4. Integration from the stress–strain curve of confined concrete.

Based on Lam and Teng model (Lam & Teng, 2003):

$$P_{nc} = b\left[\int_{0}^{x_t}\left(E_c\varepsilon_c - \frac{(E_c - E_2)^2}{4f_c^{'}}\varepsilon_c^2\right)dx + \int_{x_t}^{c}\left(f_{co} + E_2\varepsilon_c\right)dx\right] \tag{10}$$

Based on Rami and paultre (Eid & Paultre, 2017):

$$P_{nc} = b\left[\int_{0}^{x_t}\left(\frac{a\varepsilon_c}{1 + b\varepsilon_c + z\varepsilon_c^2}\right)dx + \int_{x_t}^{c}\left(f_{cc} \times e^{\left(k_1(\varepsilon_c - \varepsilon_{cc})^{k_2}\right)} + E_{cu}(\varepsilon_c - \varepsilon_{cc})\right)dx\right] \tag{11}$$

Here,P_{nc} denotes the nominal axial compressive strength of the confined concrete; f_{c1} and f_{c2} represent the compressive stress functions corresponding to the confined concrete in the parabolic and linear regions, respectively. The variables x_t and f_t indicate the coordinates of the transition point on the stress–strain curve, while w denotes the distributed compressive force within the concrete section.

4.2.3 (P–M) interaction diagrams

The interaction curve of an RC column evaluates the combined effects of axial load and bending moment in eccentrically loaded columns (H. S. Al-Nimry & Al-Rabadi, 2019). It shows the relationship between axial force and flexural moment at the ultimate limit state of the concrete section, helping assess the strength of confined RC columns under varying load combinations. The curve is developed under the assumptions that the tensile strength of concrete is neglected in flexural strength calculations and that cross-sections remain plane after bending. The nominal axial load (P_n) and flexural moment (M_n) are determined relative to the geometric centroidal axis. The P–M interaction diagram consists of three regions: pure axial compression, combined axial-flexural loading, and pure bending (Ahmed et al., 2021) and illustrated in fig.5.

The shape of the P–M interaction diagram for FRP-confined RC columns is influenced by factors such as cross-sectional geometry, confinement level, unconfined concrete strength, and the volumetric ratio of transverse steel reinforcement. The Lam and Teng stress–strain model (Lam & Teng, 2003) is adopted for its high accuracy in predicting the response of FRP-confined columns. The nominal axial load and flexural moment contributions of longitudinal steel reinforcement are determined based on the neutral axis and internal stress–strain distribution in the confined concrete. The interaction diagram is often normalized using dimensionless parameters, K_n (normalized nominal axial load) and R_n (normalized ultimate flexural moment), to facilitate comparisons across various configurations and material properties (ACI 318, 2011).

The P–M interaction diagram is defined by four critical points. Point A represents pure axial compression with no flexural moment. As the moment increases, the axial load capacity decreases. Point B shows the strain distribution where the longitudinal steel furthest from the compression face experiences zero strain. Point C indicates balanced failure, with the compression face at ultimate strain and the tension steel yielding. Point D represents pure bending with no axial force, where the compressive strain and tensile strain exceed the yield strain. The strain distribution used for the diagram is shown in Fig. 6.

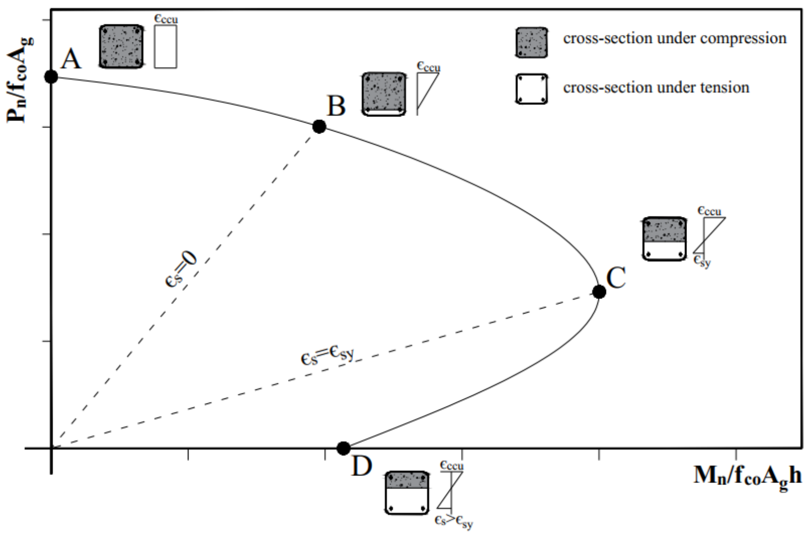

Fig.5. Simplified interaction diagram for rectangular RC column.

According to the Lam and Teng(Lam & Teng, 2003) model and the principles of static equilibrium, the values of the nominal axial load (P_n) and nominal moment (M_n) for a given FRP-confined column, subjected to a specified strain distribution, can be accurately determined using the following expressions(Rasheed, 2014):

$$P_{nA} = 0.85 f_{cc}\left(A_g - A_{st}\right) + f_y A_{st} \tag{12}$$

$$P_{n(\mathrm{B,C,D})} = P_{nc} + P_{ns} = \int_0^{y_t} (bf_{c1})dy + \int_{y_t}^{c} (bf_{c2})dy + \sum_{i=1}^{n} (\mathrm{f}_{si} - \mathrm{f}_c) A_{si} \tag{13}$$

$$M_{n(B,C,D)} = M_{nc} + M_{ns} = \int_0^{y_t} (bf_{c1})(\mathrm{y} + \frac{h}{2} - \mathrm{c})dy + \int_{y_t}^{c} (bf_{c2})(\mathrm{y} + \frac{h}{2} - \mathrm{c})dy + \sum_{i=1}^{n} (\mathrm{f}_{si} - \mathrm{f}_c) A_{si} \tag{14}$$

4.2.4. ACI 440.2R-08 proposed P–M interaction diagram

The ACI 440.2R-08(ACI, 2008) guidelines present simplified equations for estimating the axial compressive capacity and corresponding flexural moment strength of FRP-confined RC columns. These formulations are derived from the confinement model developed by Lam and Teng(Lam & Teng, 2003). The axial load capacity (P_n) and the corresponding bending moment (M_n) at three critical performance points are calculated using the following expressions:

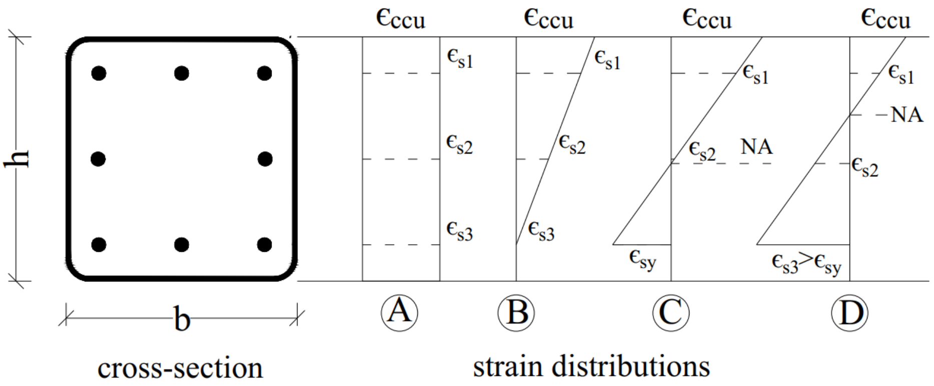

Fig.6. Strain distributions for developing of interaction diagram.

$$P_{nA} = 0.85 f_{cc}\left(A_g - A_{st}\right) + f_y A_{st} \tag{15}$$

$$P_{n(\mathrm{B,C})} = \left[A(y_t)^3 + B(y_t)^2 + C(y_t) + D\right] + \sum f_{si} A_{si} \tag{16}$$

$$M_{n(\mathrm{B,C})} = \left[E(y_t)^4 + F(y_t)^3 + G(y_t)^2 + H(y_t) + I\right] + \sum f_{si} A_{si} d_{si} \tag{17}$$

In this approach, the maximum confined compressive strength of concrete (f_{cc}) is determined using the Lam and Teng (Lam & Teng, 2003) confinement model. The parameters fy and Ast represent the yield strength in tension and the cross-sectional area of the longitudinal steel reinforcement. The variable yt refers to the vertical distance from the neutral axis to the transition strain εt. Additionally, f_{si} and A_{si} denote the normal stress and cross-sectional area of the i-th layer of longitudinal reinforcement, while dsi represents the distance from the centroid to the i-th reinforcement layer. The coefficients A through I, used in the equations from ACI 440.2R (ACI, 2008), are calculated, but their specific formulations are not provided here.

5. Results of parametric study

5.1. Compressive stress-strain curves

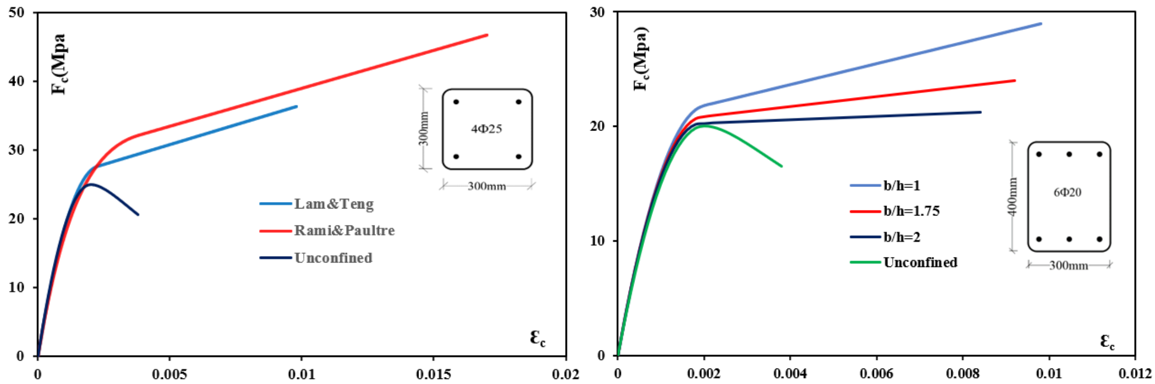
Fig. 7a shows the axial compressive stress-strain response of a rectangular RC column confined with FRP wraps, compared to an unconfined column. The curves, based on Lam & Teng (Lam & Teng, 2003) and Rami & Paultre (Eid & Paultre, 2017) models, show significant improvements in both compressive strength and strain capacity due to FRP confinement. Unconfined concrete has lower peak stress and a more brittle failure mode. The Lam & Teng model predicts a moderate strength increase and enhanced ductility, while the Rami & Paultre model (Eid & Paultre, 2017) forecasts a greater rise in peak compressive stress and a more gradual plateau. Both models emphasize FRP wraps' ability to delay concrete failure and improve deformability.

Fig. 7b illustrates the behavior of FRP-confined columns with different aspect ratios (b/h = 1, 1.75, 2), showing that aspect ratio significantly impacts confinement efficacy. The square column (b/h = 1) shows the greatest enhancement, while the improvement decreases as the aspect ratio increases (b/h = 1.75 and 2). This suggests that

FRP wraps are more effective in compact sections, with slender columns experiencing less uniform confinement pressure, reducing the overall improvement in compressive performance.

5.2. Effect of eccentricity on confinement efficiency

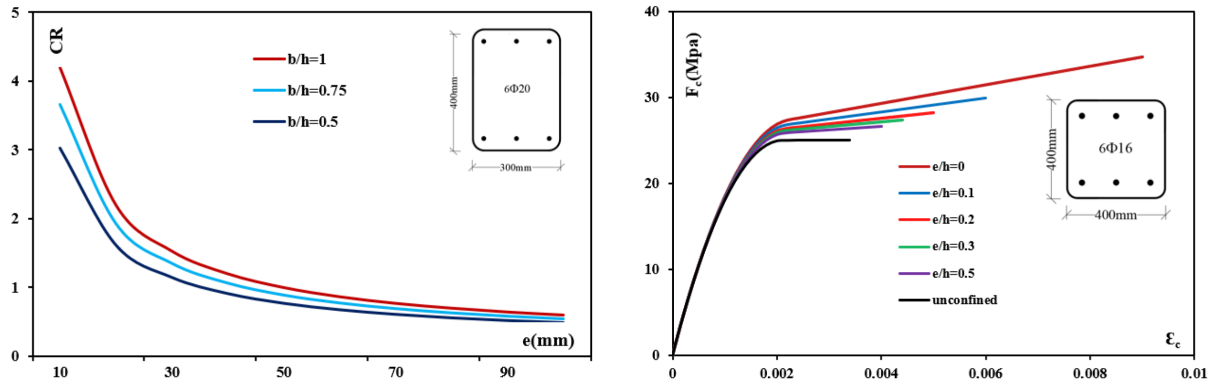
The relationship between Compression Zone Ratio (CR) and load eccentricity (e) for eccentrically loaded FRP-confined RC columns is shown in Fig. 8a. The vertical axis represents CR, indicating the effective compression zone size, while the horizontal axis measures eccentricity (e) in millimeters from the column's centroid. Three curves are presented for aspect ratios (b/h) of 1.0, 0.75, and 0.5. The results show a remarkable decrease in CR with increasing eccentricity, particularly at lower eccentricities, with a gradual reduction at higher values. The square column (b/h = 1) consistently has the highest CR, followed by b/h = 0.75 and 0.5. This indicates that as columns become more elongated, CR decreases faster. The graph emphasizes the influence of load eccentricity and aspect ratio on stress distribution in FRP-confined columns.



(a) (b)

Fig.7. Stress–strain curves of concrete: (a) comparison of models, (b) based on aspect ratios.

Fig. 8b shows the compressive stress-strain responses of a square RC column confined with CFRP wraps under varying load eccentricities. The legend identifies eccentricity ratios (e/h) from 0 to 0.5, along with the response of unconfined concrete. The curves indicate that as eccentricity increases, both compressive strength and strain at peak stress decrease for confined concrete. The concentrically loaded column (e/h = 0) shows the highest peak compressive stress and improved strain capacity compared to the unconfined concrete. As eccentricity increases (e/h = 0.1, 0.2, 0.3, 0.5), peak stress and ultimate strain decrease. This highlights that CFRP confinement improves compressive performance but becomes less effective as load eccentricity increases, reducing strength and ductility enhancements.

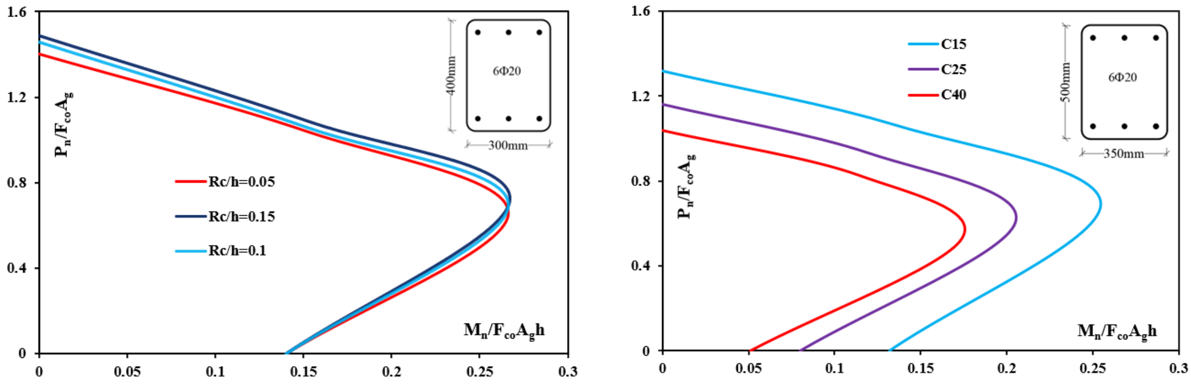


(a) (b)

Fig.8. (a) Compression zone ratio based on eccentricity, (b) Stress–strain curve under eccentric loads.

5.3. Effect of corner radius

Fig. 9a shows the effect of corner radius on the axial and flexural capacity of rectangular columns fully wrapped with FRP, with a 300 × 400 mm cross-section. Three corner radii (20 mm, 40 mm, and 60 mm) were investigated with a constant FRP volumetric ratio of 0.85% and a confinement ratio of 0.22, using three layers of 0.25 mm thick FRP. The interaction curves reveal that increasing the corner radius improves both normalized axial load (K_n) and bending moment (R_n) capacities, primarily due to the shape factor increase. The effect of corner radius becomes less significant as load eccentricity increases, being more noticeable at lower eccentricities. Compared to the baseline column with a 20 mm radius, the 40 mm radius showed a 2.4% increase in axial strength, and the 60 mm radius showed a 4.5% improvement.



(a)   (b)

Fig.9. Interaction diagrams: (a) Influence of corner radius, (b) Effect of concrete strength.

5.4. Effect of unconfined compressive strength of concrete

The influence of unconfined concrete strength on the behavior of FRP-confined, eccentrically loaded RC columns was analyzed. A rectangular column (350 × 500 mm) retrofitted with three layers of CFRP sheets and reinforced with 6ϕ20 mm longitudinal steel bars was subjected to uniaxial eccentric loading, following ACI 440.2R(ACI, 2008) guidelines. Three concrete strengths—15 MPa, 25 MPa, and 40 MPa—were evaluated, and the axial load–flexural moment (P–M) interaction diagrams were developed (Fig. 9b). The results show that low-strength concrete (15 MPa) benefits the most from CFRP confinement, with significant improvements in both axial load and flexural strength. As concrete strength increases (25 MPa and 40 MPa), the confinement's effectiveness decreases due to reduced lateral deformability and energy absorption in stronger concrete. The interaction curve for the 15 MPa specimen expands outward, while those for 25 MPa and 40 MPa contract inward, indicating reduced confinement efficiency at higher concrete strengths. These findings highlight the importance of concrete strength in optimizing the performance of FRP-retrofitted columns for improved strength and ductility.

$$\Delta K_n(\%) = \frac{K_{ni} - K_{no}}{K_{no}} \times 100 \tag{18}$$

where ΔK_n represents the increase in axial load capacity, K_{ni} is the axial strength at the specified point, and K_{no} is the reference axial load.

5.5. Effect of volumetric ratio on confinement efficiency

The FRP volumetric ratio in RC columns is defined by the number of CFRP plies applied to the column surface. This ratio represents the proportion of the total volume of CFRP relative to the volume of concrete enclosed within the column's perimeter. In rectangular RC columns, the volumetric ratio is typically calculated based on the total thickness of CFRP layers and the perimeter of the cross-section, and it can be determined using the following equation(Mai et al., 2020).

$$\rho_f = \frac{V_f}{V_c} = \frac{\left[2(\mathrm{b}-2\,\mathrm{r_c}) + 2(\mathrm{h}-2\,\mathrm{r_c}) + 2\pi\,\mathrm{r_c}\right]\times t_f}{\left[bh - (4-\pi)\,\mathrm{r_c}^2\right]} \tag{19}$$

The influence of FRP plies, represented by the volumetric ratio, on the axial and flexural capacity of RC columns has been investigated, and the corresponding P–M interaction diagrams are illustrated in Fig.11a and table 3. The study was conducted on a rectangular column with dimensions of 150 × 200 mm and a single FRP ply thickness of 0.25 mm, under three volumetric ratio conditions: 0%, 1.1%, and 1.7%.

5.6. Effect of aspec ratios

The aspect ratio (b/h) of rectangular cross-sections significantly affects the behavior and load-carrying capacity of eccentrically loaded RC columns strengthened with CFRP jackets. It plays a key role in the efficiency of FRP confinement and the shape of the interaction curve. The normalized axial load–bending moment (P–M) interaction diagrams in Fig. 10b were obtained for columns with aspect ratios of 0.5, 0.6, and 1.0. Columns with an aspect ratio of 1.0 (square cross-sections) show higher axial strength and flexural moment capacity, especially at low eccentricities. In contrast, columns with lower aspect ratios (0.5 and 0.6) have reduced confinement efficiency and smaller strength improvements. As the aspect ratio decreases, confinement becomes less uniform, reducing the confined core area. For example, a column with an aspect ratio of 0.5 shows normalized values of (1.03, 0.14), while one with a 0.6 aspect ratio shows a 7% increase in axial strength and 21% in flexural capacity. A square column (aspect ratio 1.0) shows a 25% improvement in axial load and 71% in bending moment compared to the 0.5 aspect ratio column as shown in table 3. These results emphasize the importance of cross-sectional geometry in optimizing CFRP-confined RC columns under eccentric loading.

Table 3. Normalized Axial and Flexural Strength

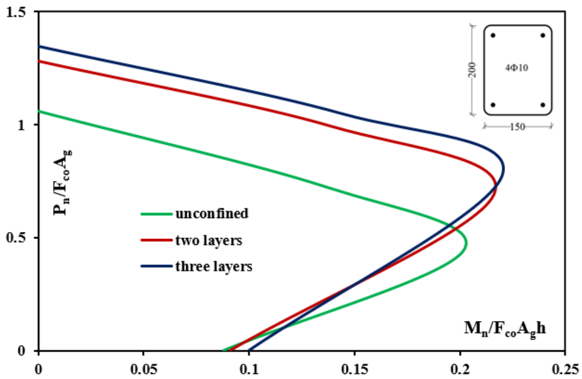
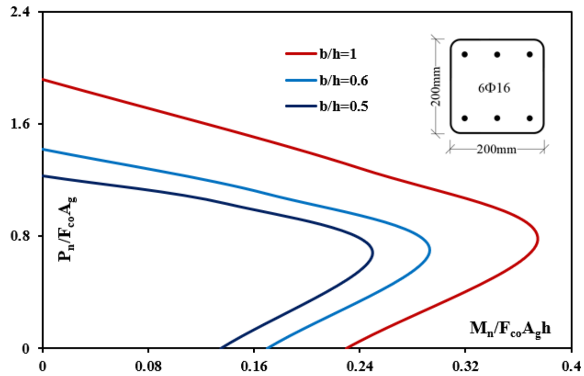
5.7. Comparison of analyticl models with experimental results

The interaction diagrams in Fig. 11a show the axial load–flexural moment relationship from two analytical models—ACI 440.2R(ACI, 2008) and Lam & Teng (Lam & Teng, 2003) —compared with experimental results by Darby et al. (2011) for FRP-confined square RC columns with larger cross-sections. The comparison reveals that experimental data consistently show slightly higher axial compression and flexural strengths than the analytical models. Both the Lam & Teng (Lam & Teng, 2003) and ACI 440.2R(ACI, 2008) models provide nearly identical predictions for axial load and bending moment capacities. The interaction curves indicate a strong correlation with experimental results, especially in the compression-dominated region, where RC columns exhibit compression-controlled behavior. This alignment highlights the accuracy and reliability of these models in predicting the performance of FRP-confined RC columns under axial loading.



(a)



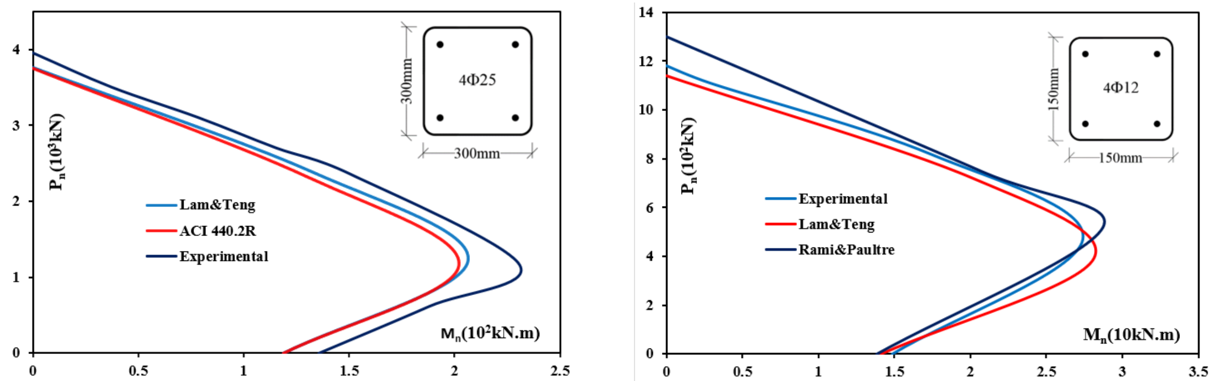
(b)

Fig.10. Interaction diagrams: (a) Influence of volumetric ratio, (b) Effect of aspect ratios.

The interaction curves illustrate the effects of different confinement levels. A volumetric ratio of ρf = 0% represents an unconfined concrete column, while ρf = 1.1% and ρf = 1.7% correspond to columns confined with two and three layers of FRP, respectively. The results show that increasing the volumetric ratio significantly improves the axial and flexural capacities of eccentrically loaded RC columns. For example, at point B, the unconfined column achieves (434 kN, 16.4 kN·m), while the confined columns show (595 kN, 16.7 kN·m) for ρf = 1.1% and (631 kN, 17.3 kN·m) for ρ_f = 1.7%. The column with one FRP layer shows a 37% increase in axial load and a 2% increase in flexural moment, while two layers improve axial load by 45% and bending moment by 5%. These results demonstrate that higher volumetric ratios significantly enhance axial strength, slightly improve flexural capacity, but confinement efficiency decreases with increasing load eccentricity.

The interaction diagrams in Fig. 11b compare the analytical models of Lam & Teng (Lam & Teng, 2003) and Rami & Paultre with experimental data for FRP-confined RC columns with smaller cross-sections. The Rami &

Paultre model tends to overestimate the axial compression capacity compared to both the Lam & Teng model and experimental results, although it aligns well at higher eccentricities. The Lam & Teng model (Lam & Teng, 2003), however, shows excellent agreement with experimental results across the full interaction range, especially at low eccentricities. These comparisons underscore the importance of the selected stress–strain model in accurately capturing the behavior of eccentrically loaded RC columns confined with CFRP sheets.



(a) (b)

Fig.11**.** Comparison of analytical models with experimental data.

6. Conclusion

This study analyzed the axial–flexural (P–M) behavior of rectangular reinforced concrete (rRC) columns confined with CFRP wraps under eccentric loading. The results show that CFRP confinement significantly improves both axial load-bearing capacity and flexural strength, with improvements influenced by load eccentricity, cross-sectional shape, concrete compressive strength, and CFRP volumetric ratio. Using three stress–strain models (Lam & Teng (Lam & Teng, 2003); Rami & Paultre (Eid & Paultre, 2017); Wei & Wu (Wu & Wei, 2016)), P–M interaction diagrams were developed to assess how CFRP wrapping affects column performance under combined loads. Key findings include: confinement effectiveness decreases with higher eccentricities; square sections (b/h = 1) show the greatest improvements, while elongated sections are less effective due to uneven stress distribution; rounding column corners enhances confinement by reducing stress concentrations; and lower-strength concrete benefits more from CFRP confinement than higher-strength concrete. Additionally, increasing the CFRP volumetric ratio boosts axial capacity, though flexural strength gains are more modest, and the benefits diminish with higher eccentricities. Comparisons with experimental data confirmed the accuracy of the selected models, with the Lam & Teng (Lam & Teng, 2003) model showing the best agreement across eccentricities and geometries. The Rami & Paultre (Eid & Paultre, 2017) model slightly overestimated axial capacity under pure axial loading. In conclusion, CFRP confinement enhances rRC column performance, but its effectiveness depends on various design factors, including loading conditions, sectional geometry, and concrete strength, offering valuable insights for optimizing retrofitting strategies.

The effect of ohmic heating on alkali-activated blast furnace slag-fly ash concrete with marble powder replacement

Mazem Yılmaz*[1], Mücteba Uysal[2]

[1] *Istanbul Aydin University, Depertment of Civil Engineering, 34295 İstanbul, Türkiye*
[2] *Yildiz Technical University, Department of Civil Engineering, 34220 İstanbul, Türkiye*

Abstract. Ohmic heating is a green curing method that provides the heat required for the geopolymerization of alkali-activated concrete through direct electric curing, resulting in early rapid strength development. Marble powder is a by-product produced during marble processing, and proper disposal of these wastes is important. This study focuses on analyzing the influence of ohmic heating on early strength in the geopolymerization of alkali-activated concrete and the effect of marble powder on this concrete. In this study, marble powder was replaced as fine aggregate in sodium silicate-hydroxide activated blast furnace slag-fly ash-based concrete at various proportions (by weight 10%, 20%, and 30%). The effects of various curing conditions (room temperature curing, thermal curing at 60°C and 80°C, and direct electrical curing at 15V and 25V) on the physical-mechanical properties were investigated. Compressive and flexural strength tests were performed at 3 and 28 days to evaluate early and late strength for the series under different curing conditions. Additionally, unit weight and water absorption test were performed on the samples. The results show that direct electrical curing enhances early-age strength and has a positive effect on the final strength. In the replacement of fine aggregates with marble powder in alkali-activated blast furnace slag-fly ash concrete, the lowest water absorption value was observed at a 10% replacement, while the highest strength values were achieved at a 20% replacement ratio. The findings encourage the utilization of waste materials as aggregate replacements in the building sector and provide curing solutions that will promote the widespread use of alkali-activated materials.

Keywords: Direct electring curing; Ohmik heating; Alkali-activated concrete; Marble powder

1. Introduction

In construction practices, environmental preservation and the use of sustainable materials have become key priorities. The significant carbon emissions linked to the manufacture of of Portland cement have raised serious environmental concerns, thereby driving the need for alternative binder systems (Di Filippo et al., 2019). In this regard, geopolymers have emerged as a promising and environmentally friendly alternative, owing to their low carbon footprint and the potential for incorporating industrial by-products (Pavitra et al., 2016; Alahmari et al., 2023).

Alkali-activated concrete (AAC) are inorganic polymeric materials synthesized through the alkali activation of aluminosilicate-rich precursors. Common sources of these precursors include industrial by-products like fly ash (FA), blast furnace slag (GBFS), and metakaolin (Slaty et al., 2013; Huseien, 2019; Kuranlı et al., 2022. The utilization of such materials not only contributes to waste valorization but also results in binders with high mechanical strength and long-term durability (Zhang et al., 2025). Despite these advantages, the widespread adoption of AAC is hindered by certain technical limitations. Notably, low-calcium systems often require elevated curing temperatures (typically between 60-80 °C) to achieve sufficient mechanical performance (Bakharev, 2005; Saludung et al., 2023). This requirement poses a challenge compared to conventional Portland cement, which hardens at ambient conditions. Therefore, the development of more efficient curing solutions is of great importance to promote the wider use of AAC in production.

Ohmic heating, also referred to as Joule heating, is a rapid curing technique that supplies the thermal energy required for the geopolymerization process through the direct application of electrical current (Anvari et al., 2020). This method enables localized heating of the material, resulting in higher energy efficiency compared to conventional thermal curing techniques such as ovens or steam curing (Wang et al., 2023). It is particularly effective in promoting early-age strength development in low-calcium geopolymer systems (Wang et al., 2024). Aygün et al. (2025) investigated the effect of electric curing on GBFS –FA-based AAC. In their study, they

* Corresponding author, E-mail: mazembalaban@aydin.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_667

reported that electric curing increased the compressive strength (CS) by 148% compared to conventional thermal curing at 80 °C.

Marble has been extensively used throughout history; however, its processing generates large amounts of waste. The proper utilization of this waste is crucial for the conservation of natural resources, the prevention of waste disposal, and the development of sustainable construction materials (Demirel & Alyamaç, 2018). As Turkey is among the countries with the largest marble reserves in the world, it faces a significant opportunity to manage this waste effectively (Singh et al., 2019). Marble powder (MP) consists of fine particles with a high inorganic mineral content, with calcium carbonate (calcite) being its primary component. Research in recent years has centered on the application of MP in the construction industry emphasizing its potential as an important resource for creating more sustainable building materials. (Corinaldesi et al., 2010; Gameiro et al., 2014; Khyaliya et al., 2017; Danish, et al., 2023; Meera & Gupta, 2024).

Tunc (2019) carried out a review study regarding the use of MP in concrete. In his study, the author emphasized that the utilization of waste marble is advantageous for producing cost-effective and durable concrete. It was demonstrated that replacing aggregate, cement, and other waste materials with MP enhances the strength of concrete. Moreover, the author highlighted that the substitution of marble powder as aggregate yielded more satisfactory results compared to its use as a cement replacement. Rashad et al. (2025) incorporated waste MP into alkali-activated GBFS cement at replacement levels ranging from 5% to 50%. They reported that incorporating WMP at levels between 5% and 20% enhanced the mechanical strength and durability properties of the material. The authors recommended an optimal replacement level of 10% for MP.

In this study, the potential use of waste MP as an aggregate replacement in AAC produced by ohmic heating curing is investigated, and its effects on the physical and mechanical properties of the material are examined.

2. Materials and methods

In this study, GBFS and FA were employed as binder materials in equal proportions by weight. Natural river sand, possessing a maximum particle diameter of 5 mm and a specific gravity of 2.80, was utilized as the fine aggregate. MP was used as a partial replacement for the fine aggregate at substitution levels of 10%, 20%, and 30% by weight. The The images of MP, FA, and GGBS are presented in Fig. 1.The chemical compositions of GBFS, FA, and MP are presented in Table 1. Sodium silicate (modulus 3) and sodium hydroxide (with 99% purity) were utilized as alkaline activators, with chemical properties of sodium silicate also detailed in Table 2. The molarity of the sodium silicate solution was fixed at 12 M.

The mix proportions of the AAC series are presented in Table 3. In this study, the alkali activator-to-binder ratio was set at 0.7, the fine aggregate-to-binder ratio at 2.5, and the sodium silicate-to-sodium hydroxide (SS/SH) ratio at 2. The series are designated based on the amount of MP incorporated, with the numerical values indicating the replacement ratios by weight (%). The AAC series were cast in prismatic molds with dimensions of 40 mm × 40 mm × 160 mm and were subjected to various curing conditions as presented in Table 4.

MP10	225	225	1013	112.5	210	105
MP20	225	225	900	225	210	105
MP30	225	225	787.5	337.5	210	105

Table 4. Applied curing conditions for AAC series.

Curing Type	Curing Condition	Temperature / Voltage	Curing Duration
Ambient Curing	Room Temperature	~22 °C	24 hours
Thermal Curing	Oven Curing	60 °C	24 hours
Thermal Curing	Oven Curing	80 °C	24 hours
Ohmic Heating Curing	Direct Electric Current (DEC)	15 V	24 hours
Ohmic Heating Curing	Direct Electric Current (DEC)	25 V	24 hours

Copper plates were attached to the 40 mm × 40 mm faces of the prismatic molds with dimensions of 40 mm × 40 mm × 160 mm. These conductive plates were connected to an alternating current (AC) power supply to allow the flow of electric current through the AAC mixture. Ohmic heating was achieved by applying a constant voltage, resulting in internal heat generation due to the electrical conductivity of the material. This method enabled temperature increase within the specimen, facilitating effective curing through ohmic heating.

To determine the physical properties of the AAC samples, unit weight and water absorption (WA) tests were carried out in accordance with ASTM C642 standard. The unit weight of the AAC was determined by weighing the specimens after drying them in an oven at 105 °C for 24 hours. The unit weight (ρ) was obtained using the Equation 1. In this formula, M_d represents the dry mass of the sample (g), and V denotes the volume of the sample (cm^3).

$$\rho = \frac{M_d}{V} \tag{1}$$

WA tests were conducted by immersing the oven-dried specimens in water for 24 hours. The WA rate was obtained as the percentage increase in mass, based on the difference between the saturated mass and the dry mass of the sample, using the Equation 2. In this formula, M_s represents the mass of the sample after immersion in water (g), and WA denotes the water absorption percentage (%).

$$WA = \frac{M_s - M_d}{V} x100 \tag{2}$$

Specimens in the form of prisms, sized 40 mm × 40 mm × 160 mm were prepared to evaluate the CS and flexural strength (FS) of the series. Initially, the samples underwent a FS test in accordance with the TS EN 196-1 standard, after which the fractured halves were used for CS testing. The CS tests were performed using a testing machine equipped with appropriate capacity and a loading surface area of 40 mm × 40 mm.

3. Result and discussion

3.1 Unit weigth

The unit weight values of the MP10, MP20, and MP30 series under different curing conditions are presented in Fig. 2. Under all curing conditions, the highest unit weight value was generally observed under ambient curing conditions. This trend may have resulted from higher curing temperatures or electric fields accelerating water loss and microstructural densification, leading to minor reductions in density. Among all the series, MP30 exhibited the lowest unit weight, while MP10 and MP20 remained relatively stable under different conditions.

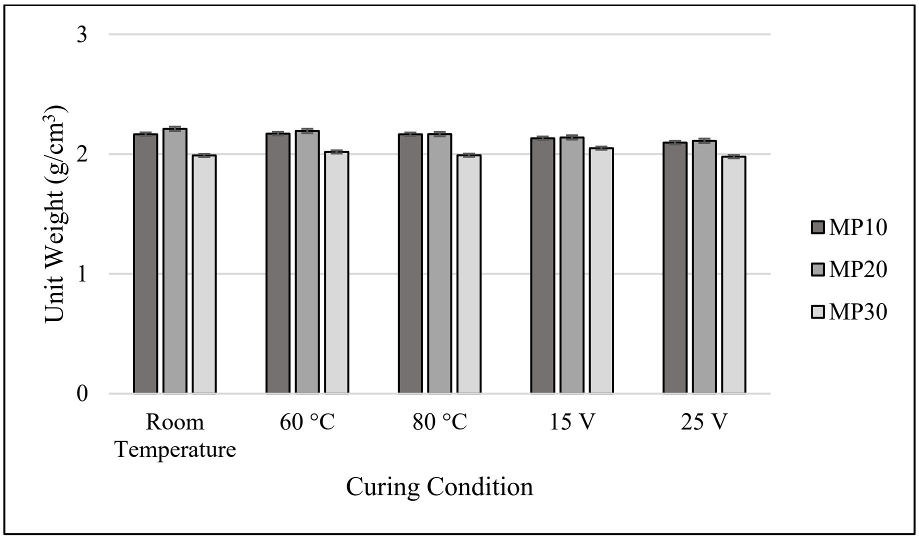

Fig. 2. Unit weight results (g/cm^3)

3.2 Water absorption

The WA results (Fig. 3) show a minor increase in WA values for all series under thermal curing and direct electric curing compared to ambient curing conditions. Among all the series, MP10 exhibited the lowest WA value under all conditions, whereas MP30 exhibited the highest WA value.

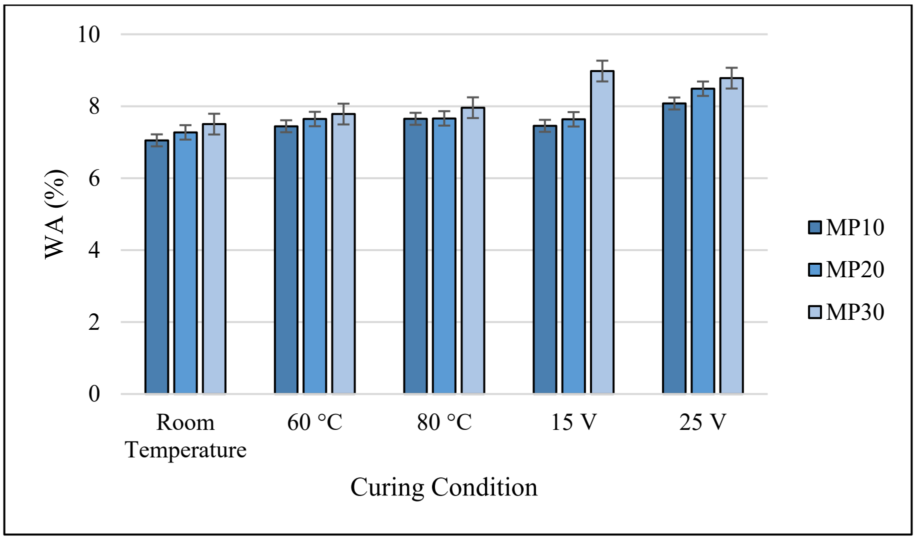

Fig. 3. WA results (%)

3.3 Compressive strength

The compressive strength results of the MP10, MP20, and MP30 series under various curing conditions are presented in Fig. 4. In general, for all series, the 28-day CS were higher than the 3-day values, indicating the continued progress of the geopolymerization process over time. Notably, under room temperature and ohmic heating conditions at 15 V, a significant increase in strength was observed between 3 and 28 days. This increase may be attributed to the fact that the heat generated by the 15 V electric field was insufficient to accelerate the geopolymerization reaction at early ages. On the other hand, both thermal curing (at 60 °C and 80 °C) and ohmic heating curing effectively enhanced the early-age strength development. The highest CS was recorded for the MP20 series under ohmic heating curing, reaching 51.4 MPa. In contrast, the MP30 series exhibited lower CS values under all curing conditions compared to the other series. The obtained CS results are consistent with the study conducted by Rashad et al. (2025), which reported a negative impact on strength values when the replacement ratio of MP in alkali-activated GBFS cement exceeded 20% (Rashad et al., 2025).

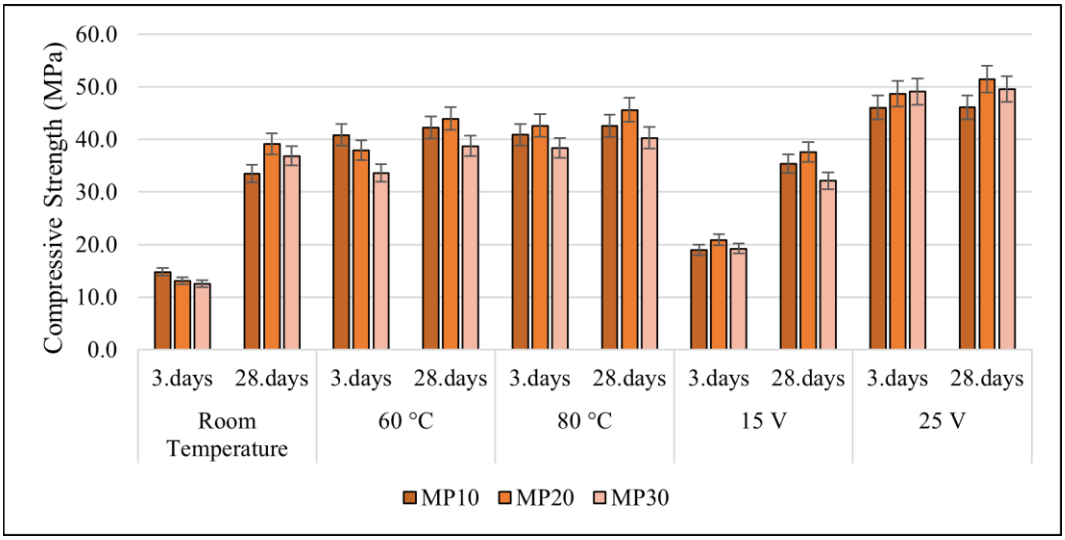

Fig. 4. CS results (MPa)

3.4 Flexural strength

The FS results of the MP10, MP20, and MP30 series under various curing conditions are presented in Fig. 5. The findings demonstrate that both curing conditions and the MP replacement ratio have a significant effect on FS. Specimens cured at room temperature exhibited relatively lower FS, with only a limited increase observed from 3 to 28 days. In contrast, thermal and ohmic heating curing methods significantly enhanced early-age strength compared to ambient curing. According to the 28-day strength results, the MP20 series cured at 80 °C exhibited the highest FS with a value of 5.22 MPa. The ohmic heating method also improved FS in all series at both early and later ages. Specifically, the MP20 series cured under 25 V achieved the highest FS, reaching 9.37 MPa at 3 days and 9.91 MPa at 28 days. These results indicate that curing under both thermal and ohmic heating conditions accelerates the polymerization reaction, thereby enhancing the mechanical properties of the matrix. Moreover, the consistent superior performance of the MP20 series under all curing regimes suggests that a 20% MP replacement represents the optimum substitution ratio for fine sand in GBFS and FA-based AAC systems.

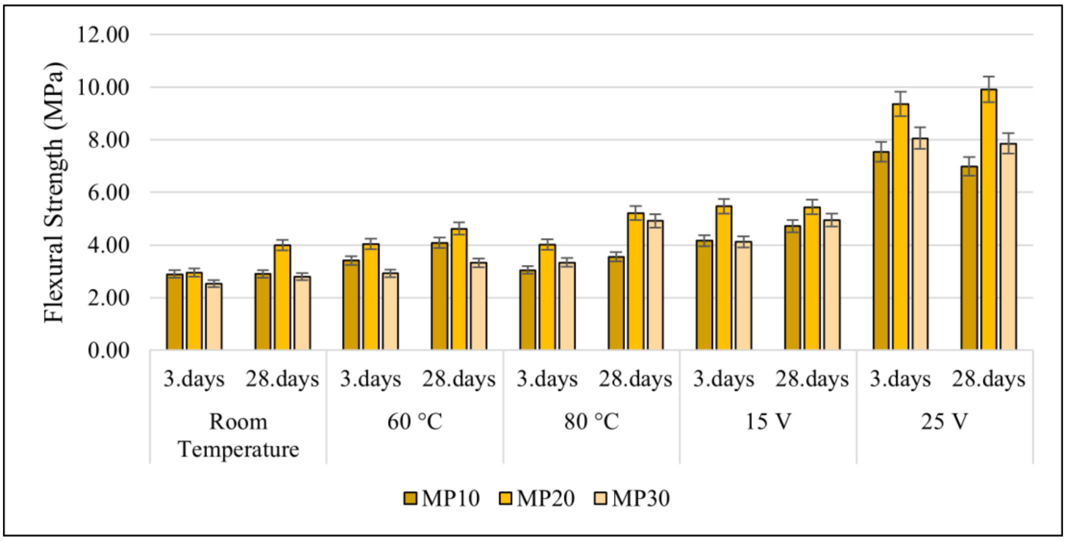

Fig. 5. FS results (MPa)

4. Conclusions

In this study, the effects of various curing conditions—ambient curing, thermal curing at 60 °C and 80 °C, and ohmic heating at 15 V and 25 V—on the physical and mechanical properties of alkali-activated GBFS –FA-based concrete incorporating MP were investigated. The following conclusions were drawn:

- Ambient curing generally resulted in the highest unit weight, while thermal and ohmic heating slightly reduced density due to accelerated moisture loss.

- WA slightly increased under thermal and electric curing. Among all mixtures, MP10 exhibited the lowest WA, indicating a denser and less porous matrix.
- CS increased over time across all series, with thermal curing and ohmic heating promoting early strength development. The highest CS (51.4 MPa) was obtained from the MP20 series cured with 25 V ohmic heating.
- FS was also significantly improved by both thermal and ohmic curing. MP20 achieved the highest values, especially under 80 °C thermal curing (5.22 MPa) and 25 V ohmic heating (9.91 MPa), suggesting that 20% MP replacement is optimal for enhancing performance in GBFS-FA-based AAC.

Abstract. The use of composite materials in the field of civil engineering has grown in recent years, and this is due to their performance. Marine infrastructures (ports, bridges, offshore, etc.) are subject to the effects of seawater and deteriorate rapidly if they are not properly protected. To this end, two glass-epoxy and aramid-epoxy composites have been the subject of a scientific study to propose solutions to this type of problem. The glass-epoxy material must resist the aggressiveness of seawater, to which it is exposed, and the aramid-epoxy material, in the internal layer, must resist shocks. To test these two materials, we carried out static tensile and tensile fatigue tests and aging in salt water under acoustic monitoring. The aim of this work is not to compare these two materials, but to prove that they are resistant to the aggressiveness of salt water. The results of the static tests show good behavior of both materials. On the other hand, tensile fatigue tests at 1000000 cycles show that the aramid-epoxy material resists better than the glass-epoxy material. Aging at 1000 hours in salt water shows that both materials resist the effect of seawater. They show little loss of strength. The acoustic tool confirms that both materials perform well in salt water and can therefore be safely used in civil engineering.

Keywords: Glass-epoxy; Aramid-epoxy; Seawater; Acoustic; Aging

1.Introduction

The use of composite materials in the field of civil engineering, as protection for reinforced concrete structures, is experiencing significant growth (Ghaib et al., 2024; Akter Hosen et al., 2017). These materials have characteristics and performances unmatched by other materials. The cost, lightness, resistance to corrosion and especially the method of obtaining them by different molding processes, make composite materials become the materials of the 21st century par excellence. Due to their characteristics and especially their cost, glass fibers are the most used fibers in the field of civil engineering (Rami et al., 2017; D'Antino & Pisani, 2019; Kychkin et al., 2025). On the other hand, aramid fibers (Kevlar) are less used (Wang & Xia, 1999; Sabu Sebastian et al., 2008; Guo et al., 2010; Eslava-Hernández et al., 2024; Ursache et al.,, 2024 ; Bandaru et al., 2025). Our study will contribute to a better understanding of these. The exposure of these materials to seawater, which is an aggressive environment due to its physicochemical composition, puts them to the test (Devine et al., 2023; Danijela Stankovic et al., 2024). Despite the large number of studies on the influence of salt water on these materials, the effect of humidity on the modification of the behavior of composites remains poorly determined (Bunsell, 1989). Various studies have shown that the complexity of the phenomenon of salt water absorption by composites remains an issue. These studies have shown that, depending on the case, the absorption of water by these materials can generally slightly increase the mass of the reinforced concrete structure, while in other cases, it is the opposite, i.e. a decrease in weight due to the destruction of the resin following washing out (Perreux et al., 1992). This degradation of composites is initiated by a phenomenon of plasticization or physical aging, resulting from the diffusion of salt water within the polymer matrix at the fiber-matrix interface (Vigier & Tatibouet 1993). Subsequently, hydrolysis or chemical aging of the micromolecular chains takes place, ultimately generating damage by osmotic cracking (Gautier et al., 2000). Thanks to the various investigation techniques and scientific means that have been developed, it is now possible to predict the durability of a composite more or less reliably (Gaumet et al., 1996) . In order to better understand the effect of this salt water absorption phenomenon by glass-epoxy and aramid-epoxy composites, we used the acoustic tool to complete our investigations (Nimdum

*Corresponding author E-mail: menailyounes43@gmail.com

golden light publishing

et Renard, 2012; Bentahar, 2005; Ben khalifa, 2013; Tan Duong, 1995; Ghaib et al., 2024) . The objective of our study is to show that both materials are resistant to the effect of salt water. The glass-epoxy material is intended to resist salt water by serving as protection for the reinforced concrete structure (placed in the outer layers) and the aramid-epoxy material is intended to resist shocks generated by the external environment and salt water (in case of infiltration) and is placed in the inner layers. Figure 1.

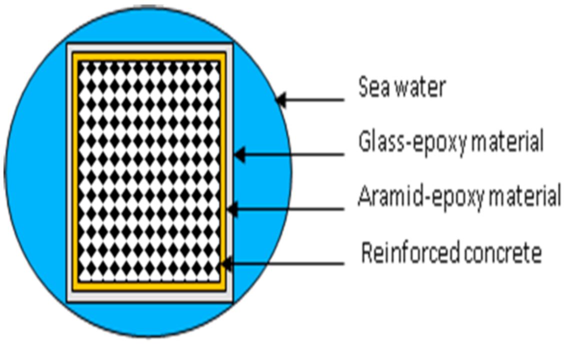

Fig. 1. Protection against sea water

2. Experimental

The experimental study is conducted by a destructive quasi-static tensile and tensile fatigue method, under acoustic monitoring. An INSTRON model 8516 universal hydraulic tensile machine equipped with a 100 kN force cell was used for these tests, Figure 2.

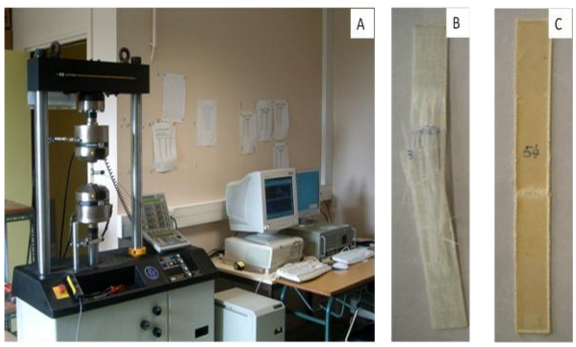

Fig. 2. Tensile test (a)Tensile machine with acoustic acquisition (b) Glass specimen (c) Kevlar specimen

Tensile fatigue of both materials at 1000000 cycles is followed by natural ageing in synthetic seawater at 37‰, at 1000h immersion. This is to determine the evolution of the mechanical properties of the studied glass-epoxy and aramid-epoxy laminates. 2.

The two materials used are laminates based on the same SR 1500 epoxy resin combined with an SD 2505 amine hardener. The reinforcements consist of 4 plies of UD glass weave, with a mass per unit area of 300 g/m2 and 6 plies of aramid taffeta weave with a mass per unit area of 170 g/m2. The percentage of reinforcement is 67% for the glass and 42% for the aramid (Table 1). The processing was done by contact moulding under vacuum, at a pressure of 0.3 bar for 6 hours. Polymerisation was carried out in an oven at 80°C for 8 hours. The specimens were then cut to the same dimensions: 200x20x1 mm3.

2.1. Materials

Table 1. Material

Fiber	Glass E	Kevlar
weaving	UD	Taffeta
Surfacedensity [g/m2]	300	170
mass fraction [%]	67	42
Resin	Epoxy SR 1500 /Hardner glass	
Layer	4	6
Weight[g]	7.2	4.4
Dimensions [mm3]	220x30x1	
supplier	Sicomin France	

2.2. Fatigue

Tensile fatigue was carried out under loading at a constant rate of 1mm/min, under controlled displacement up to 50% of the static failure displacement. Fatigue amplitude of 10% of the displacement at failure was imposed on the materials (Table 2).

Table 2. Experimental data

Fiber	Glass		Kevlar
Breaking Force [N]	10292		6124
Breaking deformation [mm]	1.76		1.34
Amplitude [mm]	0.35		0.27
Speed [mm/mn]		1	
Frequency [Hz]		10	
Number of cycles		1000000	
Immersion [h]		1000	

2.3. Natural ageing

The specimens were immersed in synthetic seawater at 37‰, for 1000h, after fatigue at 1000000 cycles. Composite materials have been the subject of several studies and acoustic monitoring has provided a good understanding of the different types of damage caused by the external environment (Roundi et al., 2019; Refahi & Milad Hajikhani, 2009; Ben Ammar, 2014; Nechad, 2004). The tensile test manifests itself as surface vibrations in the form of elastic waves that are amplified and collected by three piezoelectric sensors and recorded by an acquisition system, to give the acoustic emission signal, Figure 3. The interpretation of these signals, based on the work of some researchers who have exploited this niche, allows us to understand the different degradations and their origins.

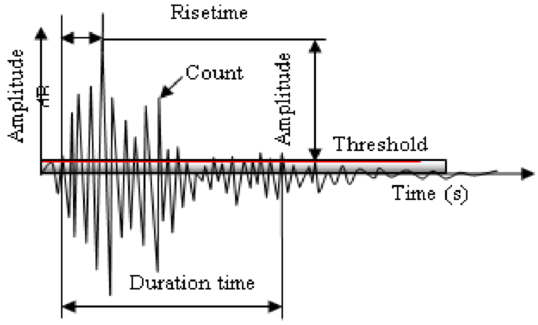

Fig. 3. Acoustic emission signal

Some authors, among many others (Rolando Rios-Soberanis et al., 2017; Kline et al., 1981) specializing in the field of acoustic emission for composite materials, have developed a quantitative approach to the technique dedicated to this niche. They have determined the relationship between the event resulting from a source and the signal detected by the acoustic sensors, connected to the processed material (Wadley et al., 1981).

In order to exploit the results of the acoustic emission in a rational way, we have based ourselves on the work of several authors, pioneers in the field (Ceausescu-Ersen, 2004; Åberg & Gudmundson, 2000; De Groot et al., 1995; Chen et al., 1992; Kim & LEE, 1997) to interpret the results of our work. These authors observed that the acoustic signals associated with matrix cracks correspond to low frequency signals, whereas those associated with fiber breakage have higher frequencies (Kocsis et al., 1995; Kotsikos et al., 1999; Kotsikos et al., 2000; Benzeggagh et al., 1992). They classified the amplitudes into three or four groups, from the lowest to the highest, to associate them with matrix cracking, then with decohesions and delaminations and finally with fiber breakage. We have opted for an acoustic map, given in Table 3, following the synthesis of the results given by the practical tests and the results of the bibliography.

Table 3. Acoustic map

N°	Damage mechanism	Nb of dB
0	Threshold (Parasite noises)	0-40
1	Matrix cracking	40-60
2	Interlaminar delamination	60-70
3	Debonding	60-70
4	Fiber breakage	70-90

3. Result and discussion

3.1 Static tests

In order to characterize the two materials, static tensile tests were carried out to determine the corresponding stresses and strains. For this purpose, a batch of five specimens of each type was statically tested. Figures 4 and 8, obtained from the previous tests, give us an idea of these materials. They represent the evolution of the stress as a function of the deformation. We observe a quasi-linear behavior until failure of the glass fiber and Kevlar fiber specimens, which are of the brittle type. The results of the static tests for both materials are given in Table4.

Table 4. Physical and mechanical properties of GFRP and KFRP

Fiber	Glass	Kevlar
Maximal stress [MPa]	438	305
Maximal strain[%]	3.92	2.7
Longitudinal module[GPa]	18	16.5
Transversal Module [GPa]	---	16.5

3.2 Epoxy composite plates

The interpretation of the fracture progression of the glass-epoxy composite specimen in static tension is based on four zones.

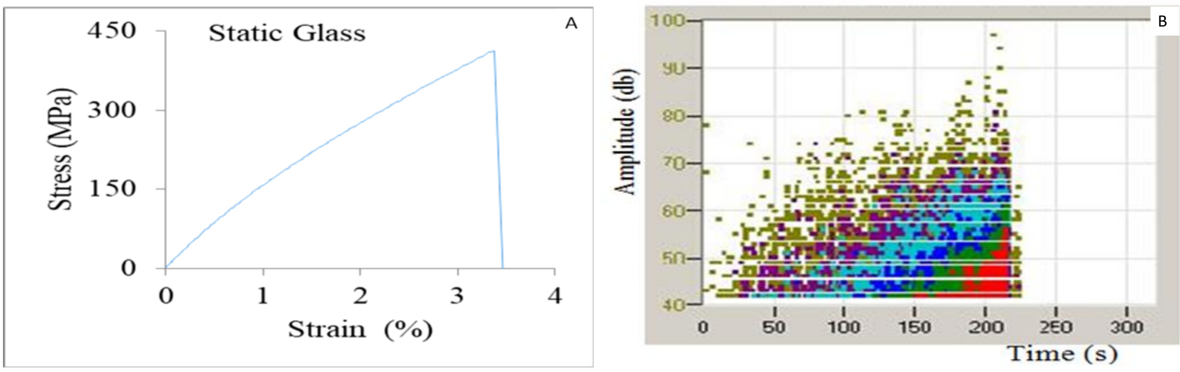

Fig. 4. Stress-strain curves for glass-epoxy specimens (A) Mechanical curve (B) Acoustic curve

Zone 1: Resin failure (Acoustic signal amplitudes between 40 and 60 dB), Figure (5:A). During the static tensile test, the resin degrades progressively, following the appearance of micro-cracks, which form preferred crack paths (Barre & Benzeggagh, 1994). These micro-cracks correspond to events that are captured by the three piezoelectric sensors and appear as dots on the screen of the acoustic event acquisition system. Each point corresponds to a degradation of the composite material. Depending on the location of the point on the acoustic acquisition screen, between the amplitude axis and the time axis, we will know if it is a matrix fracture (40-60 dB), decohesion or delamination (60-70 dB) and fiber fracture (70-90 dB).

Matrix failure is the longest period of material degradation. It starts from the beginning of the load until the specimen breaks. This proves that the matrix is the most affected by the static load and is the one that initiates the material failure.

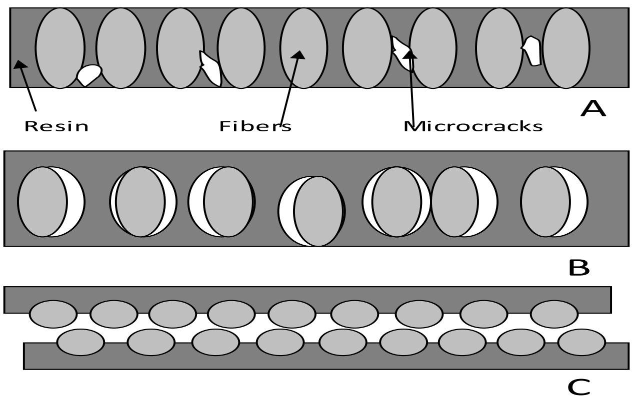

Fig. 5. (A)Initiation of matrix rupture, (B) Fiber delamination of the resin, (C) Interlaminar delamination

Zone 2-3: Decohesion and delamination (Acoustic signal amplitudes between 60 and 70 dB): Figure (5:B) decohesion, (5:C) delamination:Decohesion is the loosening of the fibers in the resin Figure (5:B). This delamination of the fibres from their matrix is due to the difference in strength of the two components of the composite material. This degradation weakens the material and usually leads to delamination.

When delamination occurs between the plies of the material we have interlaminar delamination, when it occurs within the same ply we have intralaminar delamination, Figure (5:C).The acoustic tool does not allow us to distinguish decohesion from delamination. We have the same phenomenon, either a delamination of the fibre from the resin, or the separation of one ply from another. We have the same amplitudes for both types of degradation. These events are less numerous than those of the matrix rupture. Zone 4: (Amplitudes of the acoustic signal between 70 and 90 dB), Figure 6:Fiber breakage is the final event that corresponds to the breakage of the specimen and the end of the material's life. It is the shortest and fastest stage. It corresponds to the least eventful area. Fibre breakage starts with the progressive degradation of the resin, then decohesion begins followed by delamination.

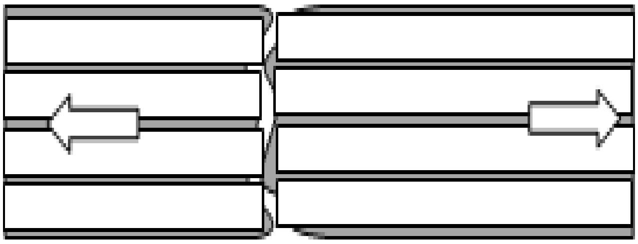

Fig. 6. Fiber breakage

3.3 Aramid-epoxy specimens
Aramid-epoxy specimens show fewer events than glass fibres. This is due to the nature of the fibres. The matrix is the first to be subjected to the effects of the tensile stress and this throughout the duration of the stress. The number of impacts due to decohesion and delamination is small compared to the tensile impact on glass fibres. This again shows that the wetting and fibre-matrix cohesion are good. The last fibre failure to appear has few impacts, indicating an abrupt failure of the specimen, shown as a straight line failure perpendicular to the tensile axis, Figure 7.

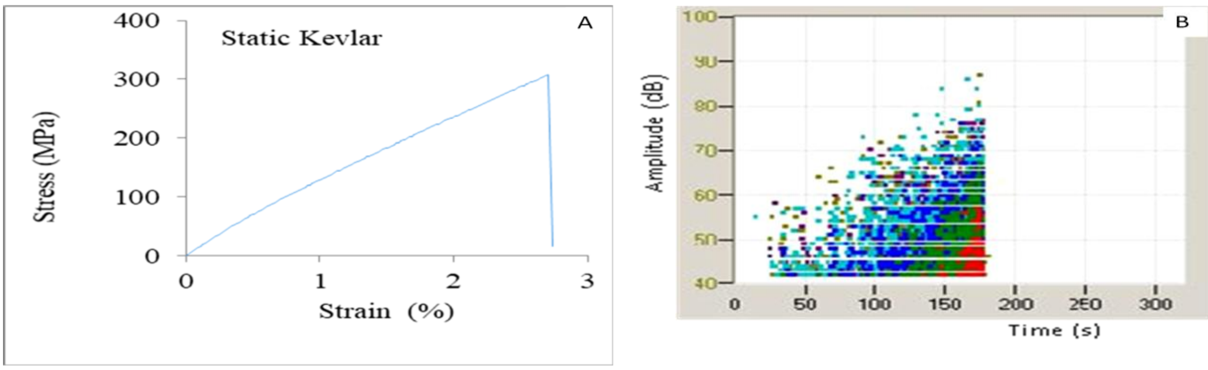

Fig. 7. Stress-strain curves for Kevlar specimens, mechanical curve and Acoustic curve

3.4 Fatigue tests
The curves of the fatigue test results for both materials are shown in Figure 8. The results obtained show that the loss of stiffness, measured by the Fmax/F0max ratio until the specimen breaks, takes place in three phases. Initially, it manifests itself by a sudden decrease in the Fmax/F0max ratio from the first cycles (on the figure, it is not clearly visible because of the scale). The decrease then becomes very slow in the second phase, which corresponds to the stable propagation of the latter, as well as the initiation of decohesion and delamination, corresponding to almost the entire life of the specimen. The third phase corresponds to the end of the material's life; it is very short and corresponds to the loss of rigidity, which accelerates brutally until the specimen breaks. It should be noted that the first phase constitutes only 10% of the lifetime whereas it corresponds to 80% of the damage rate.In our case, the glass fiber specimen failed after more than 10,000 cycles, whereas the aramid fiber specimen did not fail after 10,000 cycles. We find that both types of specimens have the same fracture profile, but the aramid specimen has higher fatigue strength. Since both types of specimens have the same resin, we can deduce that aramid fibers have better tensile fatigue resistance than glass fibers.

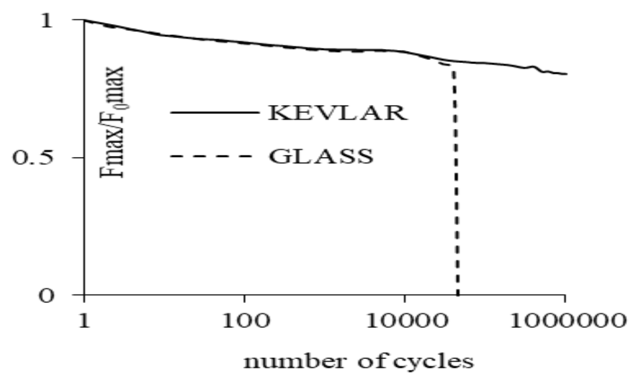

Fig.8. Fatigue test results

3.5. Acoustic results

The acoustic tool allows us to better understand the effect of tensile fatigue on the two materials. From the different studies and from Table 3, we divide the material degradation mechanisms into three groups. It should be noted that the group between 0 and 40 dB corresponds to the safety threshold generated by the parasitic noises due to the squeaking of the machines and other noises, and is not taken into consideration.

3.5.1. Fatigue of glass-epoxy specimens

Figure 9A shows the different degradations caused by tensile fatigue on a glass-epoxy material. Zone (1) between 40 and 60 dB represents the degradation of the resin during the tensile fatigue period. We note that this area is very eventful and the number of impacts is very high and therefore the resin undergoes a lot of degradation. The resin undergoes degradation from the beginning of the fatigue to the failure of the material, it is the component most exposed to degradation. The zone (2-3) between 60 and 70 dB represents decohesion and delamination. This zone represents the separation between the resin and the fibers. It weakens the material and contributes to the propagation of cracks within the material, in different forms, from decohesions that contribute to interlaminar and intralaminar cracks. The various cracks form in mode I at the onset of delamination and then transform into mode II when the specimens break. The zone (4) between 70 and 90 dB represents the degradation of the glass fibers during fatigue. The fiber breakage time is very low during fatigue compared to the resin breakage time in zone 1, indicating that the resin is most affected by fatigue. The only area of fiber breakage occurs at the beginning of the fatigue, during the first few cycles. Figure 10a shows overall consistent high resin failure, decreasing decohesions and delaminations and low fiber failure throughout the fatigue period.

3.5.2. Fatigue of aramid-epoxy specimens

The experimental study is conducted by a destructive quasi-static tensile and tensile fatigue method, under Figure 9B shows the impact of tensile fatigue on an aramid-epoxy specimen under acoustic monitoring. It can be seen that the number of impacts is less than that of the glass-epoxy specimen 9A. Since we have the same epoxy resin for both types of specimens, we can make a comparison of the wetting and the matrix fiber cohesion for both materials. The aramid-epoxy specimen shows better cohesion and wetting than the glass-epoxy specimen. This is due to the nature of the aramid fibers. The breakage zone of the resin is less important because there is better adhesion of the resin on the fibers. Decohesion, delamination and fiber breakage are represented by smaller areas than for the glass-epoxy specimen. This can be seen in Figure 2b and 2c, where we see the different effects of failure of the two specimens. The glass-fiber specimen is ruptured by extensive interlaminar delamination, whereas the aramid-epoxy specimen is ruptured cleanly in a straight line, perpendicular to the axis of the stress. This is also explained in Figure 8, where we see the glass fiber specimen breaking after about 300,000 cycles, whereas the aramid fiber specimen withstands more than one million cycles.

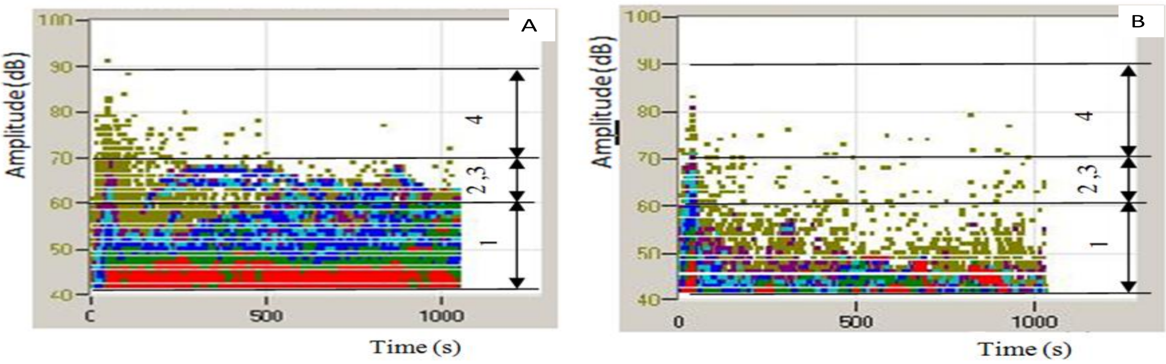

Fig.9. Acoustic results of fatigue tests (a) Acoustic results for the glass-epoxy material (b) Acoustic results for the aramid-epoxymaterial

3.6. Effects of ageing

The various studies referred to (Malpot, 2017; Mercier, 2006; Gellert & Turley, 1999; Heman, 2008; Hao et al., 2020) have shown that the osmotic origin of the degradation process of composite materials has been confirmed by previous tests in sea water and distilled water (Kececi & Asmatulu 2014). The progressive drop in mechanical properties is attributed to the plasticisation of the structural resin by water, when the material is saturated (Pal et al., 2012; Behera et al., 2020). Then the attack of the resin in the laminate occurs between two plies and leads to a further decline in mechanical properties (Gellert & Turley, 1999).

Osmotic cracking damage due to significant water uptake has been identified beyond 120h of aging. This value is far lower than our protocol of 1000h, which implies a maximum ageing. These results therefore confirm the state of damage of the materials (Castaing et al., 1992). At 20°C, the specimens quickly reach equilibrium (35 days, i.e. 840h), at 0.35% absorption and a Frick model allows the absorption kinetics to be described correctly (Chateauminois et al., 1990). At a temperature of 23°C, interactions between moisture and fatigue damage can only occur at the local scale, after capillary diffusion of moisture at the bottom of the crack (Vautier et al., 1996).

Glass-epoxy and aramid-epoxy composites undergo a progressive loss of strength as a function of the number of fatigue cycles and as a function of the immersion time. If we compare the ageing effects of both materials at 0h immersion with those immersed at 1000h, we find that the materials lose strength and acquire a certain ductility characterised by a higher elongation during tensile stress (ΔlG, ΔlK), Figure 10.

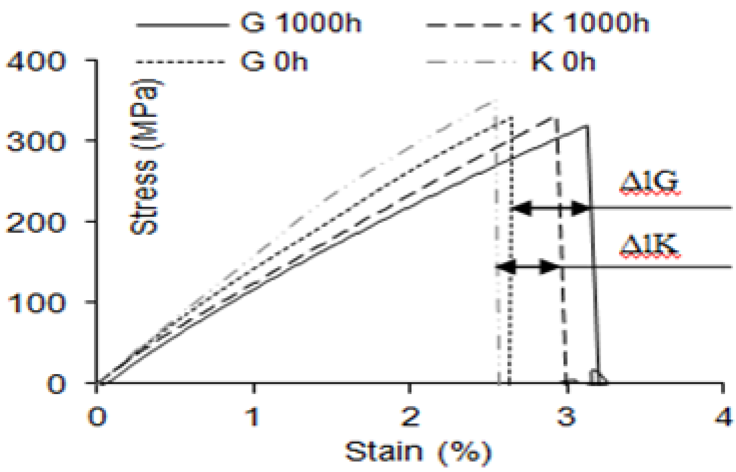

Fig. 10. Effects of ageing after fatigue for epoxy glass and epoxy aramid

Salt water permeates the interfaces and micro-cracks left by fatigue de-coating and delamination. This infiltration reduces the stiffness of the resin and gives the material a certain flexibility which allows it to stretch a little more before breaking. The relaxation of internal stresses developed during the cooling of the samples after curing may be responsible for this improvement. This demonstrates that the resin is well adapted to the effect of moisture. A similar phenomenon was observed by F. Dal Maso et al (Dal Maso et al., 1996). Since we have the same resin, for both materials we should have the same elongation at break. We find that the % elongation is higher in the glass-epoxy material than in the aramid-epoxy (ΔlG, ΔlK), which shows that the wetting and bonding of the resin on the aramid fibres is higher than on the glass fibres. This is due to the nature of the fibres in both materials. Aramid fibres are more fluffy than glass fibres. Therefore the resin adheres more and better to the aramid fibers, figure 11 (A) and (B).

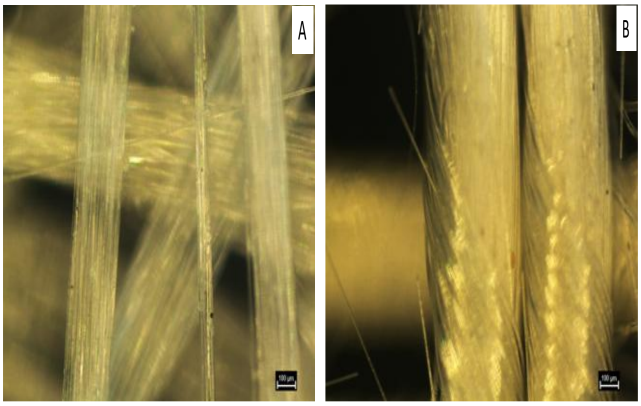

Fig. 11. Microscopy of glass fibres (a) and aramid fibres (b)

4. Conclusion

The glass-epoxy and aramid-epoxy composites were subjected to static tensile tests. Another set of specimens were subjected to tensile fatigue tests and then aged in synthetic seawater at 37‰. All specimens showed losses in strength and a gain in elongation. This loss in mechanical characteristics is in proportion to the increase in fatigue time and ageing time. The progressive drop in mechanical properties is attributed to the effects of fatigue and plasticisation of the resin by seawater, when the material is saturated. Subsequently, resin attack in the laminate occurs more readily between the glass-epoxy plies than between the aramid-epoxy plies and leads to a greater decline in mechanical properties (Gellert & Turley, 1999). When the specimens fail, we find significant delamination in the glass-epoxy material and not in the aramid-epoxy material. This is due to the nature of the fibers. Both materials can withstand the effects of seawater. Acoustic monitoring shows various degradations caused by static traction and fatigue over 10000 cycles. These different degradations lead to internal fractures which facilitate the diffusion of seawater in both composites and lead to leaching. This leaching results in a loss of strength and flexibility of the materials, without affecting their integrity.

Based on the mechanical, acoustic and microscopic results obtained, we can conclude that both materials are resistant to seawater and can be safely used in civil engineering.

Acknowledgments

The authors would like to thank the managers of the LAUM acoustics laboratory, CNRS UMR 6613 of the University of Maine, France, for providing them with the necessary equipment to carry out the various tests.

Abstract. Concrete curing is a critical process for achieving the design-stage strength in concrete and for maintaining its durability throughout its service life. In current construction practices, curing operations typically involve methods such as wet curing, membrane forming curing, and temperature controlled curing, most of which rely heavily on human supervision and labor. To optimize the concrete curing process and reduce the need for manual oversight, this study proposes an automation-based "Smart Curing Blanket". The proposed smart curing blanket consists of modular curing panels that include three functional layers: a hydrophobic top layer for water retention, a TPU-based intermediate water reservoir, and a hydrophilic textile base in direct contact with the concrete. These layers operate synergistically to absorb, store, and redistribute water as needed. The smart blanket is embedded with humidity and temperature sensors that monitor the concrete's hydration process. The data collected from sensors is wirelessly transmitted to a centralized external ESP32-based controller unit via Wi-Fi or Bluetooth, enabling off-site supervision and data logging. The designation of the blanket as 'smart' is attributed to its integrated system capable of real-time monitoring and data transmission. By automating the water distribution process and minimizing manual involvement, the smart curing blanket significantly improves curing consistency, reduces water waste, and enhances the structural performance of the concrete. This innovative approach presents a sustainable and scalable alternative to conventional methods, addressing both environmental and operational challenges in the construction industry.

Keywords: Concrete curing; Strength; Durability; Smart curing blanket; Sustainability

1. Introduction

Concrete is one of the most widely used construction materials worldwide, primarily due to its high compressive strength, formability, and durability. Among the many factors that influence concrete quality, the curing process plays a particularly critical role. After mixing its components, concrete gradually loses its plasticity and begins to harden, forming a rigid structure within a few hours. This transformation is driven by a chemical reaction between water and cement, known as hydration (Engin, 2014). To ensure complete hydration, concrete must retain sufficient moisture after placement. Curing helps maintain this internal moisture, allowing hydration to proceed and enabling the concrete to reach its designed strength. In essence, curing aims to slow the evaporation of water from the surface. When this process is not properly managed, rapid moisture loss can occur, leading to surface cracks due to shrinkage and compromising the concrete's long-term strength and durability (Neville, 2011).

Concrete curing methods generally fall into three main categories: moist curing, membrane forming curing, and temperature controlled curing. Moist curing involves keeping the surface wet to sustain hydration, which can be done by spraying water, submerging the concrete, creating water ponds, or covering the surface with wet materials like burlap or fabric. Membrane forming methods aim to trap moisture within the concrete by forming a protective layer on the surface, using plastic sheeting or applying thin coatings of polymer based or wax containing compounds. On the other hand, temperature controlled curing accelerates hydration by increasing the concrete's temperature, often through insulating blankets or embedded heating cables, especially in cold weather conditions (Kosmatka et al., 2002). Among these conventional methods, placing wet coverings or spraying water are widely used. However, these techniques require continuous supervision and frequent water application throughout the curing period. Materials like burlap release water gradually but must be regularly re-wetted, while water spraying via hoses or sprinklers demands consistent manual intervention. Concisely, these and other similar manual curing methods are generally difficult to control, require considerable labor, and often lead to excessive water use.

golden light publishing

Therefore, to reduce both labor demands and water consumption, the need for automated curing systems has become increasingly evident.

A review of the literature on automated curing systems indicates an increasing trend toward enhancing concrete curing processes through automation, sensor technologies, and remote monitoring methods. An early notable contribution by Barroca et al. (2013) involved developing a cost-effective wireless sensor network designed to remotely monitor internal temperature and relative humidity within reinforced concrete elements during the setting and curing phases. Due to the alkaline environment causing early sensor failure, the sensors were encapsulated with polypropylene sleeves to enable prolonged operational stability. Building upon this sensor-based monitoring concept, Yang et al. (2018) developed a PLC-controlled mist-spraying system designed to regulate surface temperature and relative humidity automatically. This system significantly reduced early-age cracking and provided notable reductions in water, energy, and labor costs compared to manual methods. Advancing further with IoT technology, Lo et al. (2021) introduced a system designed to control moisture loss by calculating instantaneous evaporation rates and automatically activating mist spraying. This approach effectively maintained moisture balance and significantly mitigated crack formation during concrete setting. Further innovating IoT applications, Baek et al. (2023) developed a system combining real-time flow rate sensors and image processing techniques to monitor curing compound applications on concrete pavements. This approach ensured consistent application quality and homogeneity, thus improving quality control and labor efficiency. Finally, Taffese and Nigussie (2023) conceptualized an integrated IoT system that continuously monitors internal humidity and temperature, automatically activating smart valves and spraying mechanisms based on real-time data. This system utilizes maturity methods to predict early-age strength development, optimizing concrete strength gains while minimizing water usage and labor costs. Collectively, these studies underscore the effectiveness of automation and sensor technologies in optimizing concrete curing processes.

Similarly, this study aims to develop an innovative approach that could serve as an alternative solution to existing automated curing methods. In this context, the research proposes an automation-based smart curing blanket designed to optimize the concrete curing process. Currently at the prototype stage, the proposed smart curing blanket will be further refined through laboratory testing. The smart curing blanket introduced in this research represents a simple, modular, energy-efficient, and fully automated system capable of actively monitoring both surface and internal humidity levels of concrete, precisely controlling water application, and being reusable across multiple projects. The system comprises modular panels with integrated low-pressure water distribution mechanisms, wireless humidity sensors, and battery-operated valve controls. The proposed smart curing blanket system aims to optimize concrete curing by ensuring continuous moisture availability while minimizing labor, water usage, and system complexity.

2. Material and methods

The proposed smart curing blanket will be technically presented in detail, including its design specifications and key functional components. The blanket system, composed of three distinct layers, is elaborated with respect to the water distribution mechanism, sensor and control infrastructure, power supply and maintenance considerations, as well as the overall system workflow and software logic. The components to be employed in the design of the smart curing blanket are illustrated in Fig. 1.

e) DHT22 sensor | f) HIH humidity sensor | g) ESP32 module | h) Battery pack

Fig. 1. System components of the smart curing blanket

2.1. Smart curing blanket design
In this subsection, the mechanical configuration of the smart curing blanket is presented. The proposed system is designed as modular panels measuring 1m x 2m, enabling ease of on-site assembly, scalability, and efficient curing over expansive surfaces such as foundations and floor slabs.

Each panel consists of three primary functional layers:

- Top Layer: A 3 cm thick hydrophobic high-density polyethylene (HDPE) sheet (Fig. 1a), which provides ultraviolet (UV) protection, reduces moisture loss due to evaporation, and offers a walkable surface suitable for construction site conditions.
- Middle Layer: A 5 cm deep thermoplastic polyurethane (TPU) welded reservoir (Fig. 1b) that functions as a temporary water storage unit, allowing for gravity-assisted water distribution when required.
- Bottom Layer: A 5 cm thick polyester-viscose hydrophilic textile (Fig. 1c) exhibiting capillary action, capable of absorbing water from the middle layer and releasing it gradually to the concrete surface, thereby maintaining consistent moisture contact.

The integration of these three layers ensures effective water retention and controlled delivery to the curing surface, promoting uniform and continuous hydration throughout the curing period. To support the practical deployment of this multilayer configuration in the field, the system has been further developed with modular connection features that enhance both structural integrity and installation efficiency. To facilitate modularity, each panel incorporates interlocking tongue-and-groove edge connections, allowing for horizontal and vertical integration without overlapping. This puzzle-type connection system enables the formation of a seamless and continuous curing surface, minimizing the risk of gaps or air pockets that may cause uneven hydration. Furthermore, the design eliminates the need for adhesives or external fastening components, thus streamlining installation and enhancing field applicability.

Fig. 2 presents a schematic cross-sectional and plan view illustrating the described multilayer configuration and modular connections of the smart curing blanket, along with the integrated water distribution components.

b)

Fig. 2. Cross-sectional (a) and plan (b) view of the smart curing blanket configuration and modular connections

2.2. Water distribution system
In this subsection, the operational workflow of the pool, valve, and microtube components within the water distribution system is described in detail. Initially, water is introduced into the intermediate pool layer of each panel via external hose connections. Each reservoir incorporates a 12V DC mini solenoid valve (Fig. 1d), which is integrated into a compact, gravity-fed distribution mechanism. Rather than employing conventional sprinkler

systems, the design utilizes four 4 mm internal microtubes connected to the valve outlet, enabling uniform water delivery to the four corners of the underlying hydrophilic textile layer. Upon receiving an activation signal from the control system, the solenoid valve opens, allowing water to flow by gravity through the microtubes and reach the textile interface at evenly distributed locations. This approach eliminates the need for pressurized plumbing infrastructure, thereby reducing mechanical complexity and ensuring minimal energy consumption.

Each valve is housed within a waterproof enclosure embedded in the hydrophobic top layer of the blanket. The microtubes are routed through sealed channels, ensuring uninterrupted delivery of water to the hydrophilic textile below. This fully enclosed configuration safeguards the water distribution process from external contaminants, physical impacts, and adverse environmental conditions.

Between activation cycles, the pool remains in a static state, maintaining a low water level of approximately 2–3 cm. Water is only dispensed when required, through controlled operation of the valve, ensuring both resource efficiency and system responsiveness.

A schematic cross-section and plan view illustrating the described multilayer configuration, modular connections, and integrated water distribution components of the smart curing blanket are provided in Fig. 2.

2.3. Sensor and control infrastructure

In this subsection, the sensor infrastructure of the proposed smart curing blanket is described in detail. To enable intelligent, adaptive, and efficient operation, each smart curing blanket panel is equipped with a dual-sensor configuration that facilitates real-time environmental monitoring and targeted water application. The first sensing unit consists of a DHT22 digital temperature and humidity sensor (Fig. 1e), positioned on the outer surface of the hydrophilic textile layer in direct contact with the concrete. This sensor measures surface relative humidity (RH) and connects to the panel via jumper wires terminated at a waterproof pin connector embedded in the side of the unit. These connectors are designed to support quick disconnection and reusability, allowing the system to be easily redeployed across multiple construction sites. Complementing the sensor network, the second component is a Honeywell HIH-5030 analog humidity sensor (Fig. 1f), which is embedded directly within the concrete mass. This sensor continuously monitors the internal relative humidity of the concrete, thereby enabling the assessment of long-term hydration progress. A key operational threshold is defined such that, once the internal RH reaches and maintains 100% for a specified duration (e.g., 48 hours), the system automatically and permanently terminates water delivery to the corresponding panel. This mechanism prevents over-curing and avoids unnecessary water consumption, ensuring both resource efficiency and performance reliability.

Sensor wiring from each panel is routed through waterproof side-mounted connectors, which facilitate rapid field connections via jumper cables. These cables extend from individual panels to a centralized control unit positioned outside the curing zone, typically housed in a weather-resistant enclosure mounted on a nearby structure or pole.

The centralized control unit is built on a single ESP32 development board (Fig. 1g), selected for its integrated Wi-Fi and Bluetooth capabilities, low energy consumption, and robust wireless communication support. The ESP32 controller continuously collects data from all connected panels via hardwired sensor inputs, with optional support for wireless low-power communication modules such as nRF24L01 or LoRa in large-scale implementations. This centralized architecture enables real-time monitoring, streamlined system coordination, and unified control through a single management interface.

Valve actuation is likewise coordinated by the central controller. Each panel's 12V DC solenoid valve is connected either through low-voltage relay lines or wireless relay modules. Based on panel-specific RH data, the ESP32 transmits individual actuation commands to open or close the valves, ensuring that water is supplied exclusively to panels requiring additional curing. This targeted control strategy enhances overall system efficiency and ensures optimal hydration conditions throughout the curing process.

2.4. Power system and maintenance design

In this subsection, the operational mechanism through which the proposed smart curing blanket is powered is presented. To ensure the independent functioning of each curing panel while minimizing wiring complexity and enhancing modularity, each unit is equipped with its own detachable power module. This module comprises a rechargeable 12V lithium-ion battery pack -typically configured as a 3S1P 18650 arrangement with a capacity of 2600–3000 mAh (Fig. 1h)- which is enclosed within a clip-in waterproof capsule mounted on the interior wall of the pool layer.

The battery pack is connected to the panel's solenoid valve through a plug-in connector such as JST or XT60, with the wiring routed via sealed channels embedded within the hydrophobic top layer. The design prioritizes field accessibility; batteries can be easily removed and replaced without dismantling the panel. For this purpose, a side flap or a silicone-sealed access port is integrated into each panel, allowing technicians to service or swap power units rapidly and with minimal disruption.

The system is engineered for energy efficiency, as the solenoid valves are activated only during short-duration watering cycles, typically drawing 200 mA of current for 30 to 60 seconds per activation. Under standard curing conditions, a fully charged battery is capable of powering the system for several consecutive days, thereby supporting operational continuity without frequent maintenance.

For extended use scenarios or off-grid applications, the system offers an optional upgrade: a 20W thin-film solar patch can be laminated into the surface of the hydrophobic top layer. This solar module is connected to a compact maximum power point tracking (MPPT) charge controller, enabling continuous passive recharging of the battery without interfering with the positioning or usability of the panel. Depending on regional solar irradiance, a single solar unit can sustain up to two to four panels simultaneously. By decoupling the battery unit from fixed internal wiring and providing accessible external interfaces, the system not only improves maintainability but also maximizes operational uptime, ensuring reliable and uninterrupted curing performance under various site conditions.

2.5. System workflow and software logic

The operational logic of the smart curing blanket system is governed by a centralized control framework implemented on the ESP32 microcontroller, which serves as the core computational unit responsible for real-time data acquisition, decision-making, and actuation. Upon system initialization, the ESP32 performs a comprehensive scan of all connected curing panels, identifying and registering each unit through unique panel-specific identifiers. Simultaneously, it begins collecting environmental data from the embedded sensors -namely, the DHT22 digital sensor for surface RH and the Honeywell HIH-5030 analog sensor for internal concrete humidity.

The system operates on a periodic data evaluation cycle, typically executed every ten minutes. During each cycle, the controller analyzes both surface and internal RH readings to determine the necessity of water application. If the surface RH falls below 70% and the internal RH is measured below 100%, the controller issues an actuation command to open the corresponding solenoid valve, thereby initiating water delivery. Conversely, if the surface RH is greater than or equal to 70%, no water is dispensed, as the ambient moisture is deemed sufficient. Furthermore, to prevent over-saturation, the system is programmed to permanently deactivate a panel's valve if the internal RH remains consistently at 100% for a continuous period of 48 hours. Valve actuation is facilitated by the ESP32 via either a wired relay connection or wireless communication modules, depending on the system configuration. Upon activation, water stored in the panel's reservoir is released through the microtube distribution system and uniformly delivered to the hydrophilic textile layer, ensuring even moisture absorption across the concrete surface.

All system activities, including sensor readings, time stamps, and actuation events, are meticulously logged and stored locally on an SD card. Additionally, data can be transmitted to cloud-based platforms such as Firebase or ThingSpeak for long-term storage, remote monitoring, and further analysis. An optional user interface, accessible through mobile or desktop applications, enhances user interaction by enabling real-time visualization, manual override of system functions, and over-the-air firmware updates.

This algorithmic control structure enables precise and responsive water management, minimizing manual intervention and promoting sustainable resource use. By ensuring that hydration is delivered only when needed, the system supports consistent curing conditions, reduces the risk of cracking, and contributes to the long-term durability and quality of the concrete structure.

3. Results and discussion

Although the prototype development and field-testing phases will be undertaken in future stages of research, this paper provides an assessment of the system's theoretical performance and the expected benefits it may offer to concrete curing practices. The proposed smart concrete curing blanket presents an innovative approach to moisture management during concrete hydration by integrating modular water distribution, automated valve control, and real-time sensor monitoring within a scalable system architecture. In this section, the theoretical concept and anticipated functionality of the smart curing blanket are discussed, alongside an evaluation of its comparative advantages and limitations in relation to conventional curing techniques. In this context, the system's strengths and potential drawbacks are analyzed through comparison with conventional curing methods, particularly in terms of resource efficiency, consistency of hydration, and ease of implementation.

The proposed smart curing blanket demonstrates significant improvements in resource efficiency when compared to conventional curing methods. By utilizing automated, sensor driven water management, the system optimizes water usage, applying precise amounts of moisture only where necessary, thereby minimizing waste. Furthermore, automation significantly reduces labor intensity and associated costs by removing the need for constant manual intervention. Regarding the consistency of hydration, the embedded humidity sensors ensure continuous monitoring and responsive adjustments in real time, leading to uniform moisture distribution across the entire curing surface. This uniformity directly contributes to improved concrete quality by preventing localized drying or over-wetting, common issues in manual curing practices. Additionally, the modular panel design significantly enhances ease of implementation; the interlocking puzzle-joint edges allow quick, seamless installation and reconfiguration without specialized tools, adhesives, or extensive manual effort. This ease of deployment is particularly beneficial for large-scale construction projects involving extensive concrete surfaces, such as slabs and foundations.

Despite these notable advantages, the system does present certain limitations in relation to conventional curing approaches. Concerning resource efficiency, although the system significantly reduces water usage and labor demands, the initial capital investment associated with sensor integration, electronic components, and modular fabrication is considerably higher than traditional methods. This may create financial constraints for smaller-scale projects or for contractors with limited budgets. In terms of consistency of hydration, reliance on advanced sensor technology introduces the need for routine sensor calibration and maintenance to ensure accurate measurements, thus potentially impacting operational continuity and introducing additional complexity. Finally, regarding ease of implementation, although the modular design simplifies field deployment, the requirement for battery management, waterproof sealing, and potential wiring complexity (in large-scale, wired installations) might pose additional logistical challenges. These factors could necessitate specialized training or increased planning efforts during the initial deployment phase.

4. Conclusions

Concrete curing is a critical phase in construction projects, significantly influencing the long-term durability, strength, and overall performance of structures. Conventional and semi-automatic curing approaches exhibit several key limitations, including inconsistent moisture distribution, inefficient labor utilization, and a lack of real-time feedback on hydration progress. Although recent smart curing methodologies have been introduced to mitigate these challenges, persistent issues such as elevated energy consumption, complexity of installation, and insufficient modularity continue to impede their widespread adoption in practical construction environments.

This study proposes an innovative Smart Concrete Curing Blanket System designed to address these limitations by integrating modular mechanical configurations, centralized sensor-driven automation, and efficient water management strategies. The system comprises modular panels measuring 1m x 2m, each featuring distinct layers: an upper hydrophobic protective sheet, a middle reservoir pool layer, and a lower hydrophilic textile layer directly contacting the concrete surface. This layered structure provides a robust and reusable platform that ensures uniform moisture retention. A gravity-driven internal water delivery mechanism, actuated by low-energy 12V solenoid valves and regulated by a centralized ESP32 microcontroller, precisely applies water according to real-time surface and internal humidity measurements. The proposed design emphasizes modularity, energy efficiency, operational simplicity, and scalability, facilitating seamless deployment across expansive concrete surfaces such as slabs and foundations, with minimal disruption at the construction site. Additionally, the centralized control system simplifies overall maintenance and reduces complexity while enabling adaptive curing strategies through continuous real-time monitoring.

While the proposed system remains theoretical at this stage, initial analytical evaluations suggest substantial improvements in curing performance, water usage efficiency, and labor optimization compared to existing methods. Future research will involve the fabrication of physical prototypes, implementation of comprehensive field experiments to validate moisture management and strength development, and further enhancement of wireless communication technologies to improve scalability. The smart concrete curing blanket introduced in this study signifies a meaningful advancement toward intelligent, resource-efficient construction methodologies, offering considerable potential for enhancing the quality and longevity of contemporary concrete infrastructure.

Abstract. Lime, whose origin dates back to 7000 BCE, has always been the backbone of construction across civilizations-from the plastered floors of ancient Jordan to architectural marvels consisting of aqueducts and amphitheaters in the Roman Empire. Whereas Portland cement, which appeared at the beginning of the 19th century, was synonymous with high carbon emissions, lime continued to play its role as a sustainable and versatile binder with immense potential for reducing environmental impact. On the other hand, with ecological footprint considerations driving cement alternatives, lime, especially supplemented with pozzolanic additives, presents an extraordinary solution in the light of sustainable construction. Following study adds to the historical importance and ecological benefits of lime using natural hydraulic lime as the main binder (NHL 3.5 and NHL 5) with marble powder to replace fine aggregate at 10%, 20%, and 30% by wt. Hemp stalks and sunflower husks replace aggregate 20%, 40%, and 60% by weight to study further new material combinations. Mixtures designed with a water/binder (W/B) ratio 1.0 and a sand/binder (S/B) ratio 0.47 will be tested for water absorption and void ratio, compressive strength, flexural strength, and thermal conductivity at 28 days.

Keywords: Natural hydraulic lime; Hemp stalks; Sunflower husks; Thermal conductivity

1. Introduction

Partition wall components in current building practices have taken a more critical role in separating and organizing inner spaces without hosting any load-bearing actions. This has been most significant since the latter part of the 20th century with the use of industrialized construction methods and the prevalence of reinforced concrete systems. In the past, internal and external partitions used to be made with load-carrying materials such as stone, adobe, timber framing, or lime-based mortars. But in the current building paradigm, most of these walls remain in the role of internal, non-structural applications. While traditional masonry has been replaced by reinforced concrete in carrying loads, the focus has shifted towards the use of light-weight and efficient partition systems. These include clay bricks and autoclaved aerated concrete (AAC) since these come with lesser end-masses and ease of construction and operate in harmony with internal spaces. Clay bricks, though with higher weights, get prioritized on account of superior inertia against heat and sound and cultural acceptance. In contrast, AAC with 70-80% closed pores has a highly minimized density and hence is most suited to be used in non-structural internal partitions. Both materials are also accompanied by significant environmental disadvantages, however. Production of clay bricks requires firing at temperatures over 1000°C and has large energy and carbon footprint implications. AAC production is also challenging because of the use of cement in creating it—an element that is associated with some 8% of the world's total anthropogenic CO_2 emissions—consequently sparking sustainability issues. These ecological repercussions mean that it is now of great importance to evolve alternatives with lower carbon footprint that utilize renewable energy and industrial and farming wastes. A current area of innovation in sustainable material design is the revaluation of lignocellulosic crop residues, in particular in the design of biocomposite partition wall components. In that regard, sunflower seed husk and the stalks of the hemp plant—both of which are readily available and underused crop residues in places like Turkey—show great potential. Cultivation of the sunflower is particularly common in the Marmara region and is associated with large volumes of resulting husk residues. These by-products comprise 21–30% of seed weight from oil-type varieties and up to 50% of snack-type varieties, and differences in machine performance correlate mainly with fiber composition. Historically, sunflower husk has been wasted, combusted to regenerate energy, or downgraded to animal bed filling material. Nevertheless,

golden light publishing

recent studies have shown them to be capable of being used as reinforcement in pressed composite panels that can be successfully employed in the manufacture of interior furniture such as coffee tables, with surface treatments improving both visual attraction and durability against abrasion (Zencirkiran, 2018).

Equally so, post-harvest sunflower stalks, which commonly are considered to be disposal biomass, have been tested to be useful in thermal insulation purposes and serve as a natural replacement to fossil-derived insulators (Efe, 2011). This strategic re-allocation of agro-residue not only facilitates circular economy policies but also reduces open-field biomass burning-induced pollution. Interest in the use of hemp stalks is also revived. By their cellulose richness and mechanical strength, these fibrous residues that usually burn or pulp can be transformed into construction materials. Industrial partners have already assessed them to be part of medium-density fiberboards (MDF) and also biodegradable polymer composites like PLA where the use of hemp adds toughness and delivers a renewable resource of raw material (Celik, 2023). Both hemp stalks and sunflower husks share multifunctional properties in applications ranging from insulation and panelling to animal bedding. Specifically, the lightweight fibrous composition of sunflower husks is most useful in internal partition systems where low mass, sound absorption, and modularity need to be emphasized over compressive strength. In addition, their biosafety has been tested and certified in food industry pigment extraction applications proving them to be nontoxi (Republic of Türkiye Ministry of Agriculture and Forestry, 2025).

Based on these properties, the current research seeks to design a lightweight and eco-friendly partition wall element composed of sunflower husk and hemp fibers reinforced in a natural hydraulic lime (NHL) matrix and fine aggregate. It was selected because of its eco-friendly properties and compatibility with plant reinforcement. In contrast to Portland cement, NHL has lower calcination temperatures and interacts with surrounding CO_2 to pursue continuous carbonation reactions that also impart it with inherent healing properties. Composite paste was developed by mixing the biomass fibers with calibrated water percentage, sand, and NHL to semi-dry consistency. Mixture was subsequently pressed into molds and cured in the surrounding environment. Samples were demolded after two days and left to mature further to achieve mechanistic stability. Subsequent tests further involved bulk density, thermal conductivity, compressive and flexural strength, and water absorption to establish indoor partition suitability. This energy-efficient manufacturing method in the absence of kiln firing or autoclaving also makes it highly adaptable to decentralized and low-scale production systems, particularly in rural areas. In keeping with earlier studies utilizing vine prunings in interior panels (Gencel, 2010) and cotton stalks in making MDF (Gencer, 1998; Guler, 2001), the study adds to the expanding evidence base supporting the construction applicability of agricultural residues in the form of strength properties. The incorporation of such agri-waste streams into mineral-bound composites supports the development of circular and climatic construction solutions. Such products are also backed by inherent aesthetic and sensation properties to meet visual and sensory expectations in the aesthetics of architecture and design and may eliminate the use of supplementary surface treatments and use of additional raw material and energy inputs with associated costs. Being developed in strict life cycle assessment (LCA) protocols that include carbon sequestration, such products can achieve carbon-negative classification. Taken together, conversion of sunflower husk and cannabis stalk to usable partitioning systems is a nature-friendly and cost-effective approach to next-generation green architecture solutions (Acar et al., 2025).

2. Materials and methods

2.1. Materials

Natural hydraulic lime (NHL 3.5) was used as the major binder material and natural river sand in a 0–5 mm particle size was used as the fine aggregate with good gradation to achieve mortar workability and compatibility with the structure. This research is innovative in that two particular agriculture wastes (sunflower seed husks and hemp stalk fibers) were used in association with the mortar matrix in part to replace some of the mortar constituents with wastes that are widely available in Turkey and with good ecocompatibility as per raw material properties and recycling potential to decrease partition wall material density and carbon footprint. Sample preparation was a sequential procedure to optimize homogeneity and reproducibility of the results in the specimens. Each organic additive (the hemp stalks or the sunflower seed husk) was poured into the water of the mixing at 60% of dry weight and was subjected to a 120-s premix to allow water absorption and partial softening of the fibers before gradually adding natural hydraulic lime to the wet fiber blend and further hand-stirring the blend of material for 60 seconds in a laboratory mortar mixer with regular shape and size blades to achieve maximum homogeneity of the paste and avoidance of air entrapments in the mold space during compaction of the mold space with light vibration with a symmetrical motion of the mold swing. Molded specimens were kept in undisturbed conditions (about 20°C and 60 % RH) during 48 hours to set and were subsequently demoulded and stored in room temperature to allow air curing before being subjected to the corresponding tests.

2.2. Mix Design

Experimental mixture formulations are listed in Table 1 and reflect biomass proportions with constant lime and sand proportions to isolate additive effects. Five base mix designs were produced with a reference mixture containing no organic component and four progressively modified mixes containing hemp stalks or sunflower seed husk in increasing proportions. Lime was maintained constant at 4488 grams in all mixes to compare them meaningfully, with sand and water proportions altered slightly to maintain workability. Equal mix designs of each additive group were produced and mirrored to permit direct comparison of performance between the samples based on hemp and sunflower. All materials were weighed with precise digital scales and mixed together in a standard cement mixer to encourage uniform dispersion. Optimal proportions of the selected proportions were determined through initial exploratory tests to prevent segregation, porosity exceeding desirable limits, and lack of adequate binding. This organised strategy allowed optimal fiber proportions to be determined that affect physical and mechanical behaviour and maximise dosage in lightweight partition wall applications.

Table 1. Material quantities used in each mix.

Mix No	Lime (g)	Water (g)	Sand (g)	Hemp Stalk (g)	Sunflower Husk (g)
1	4488	3140	6078	-	-
2	4488	3200	4588	585	585
3	4488	3200	4588	1170	1170
4	4488	3200	4588	1755	1755
5	4488	3200	4588	2340	2340

2.3. Methods

2.3.1. Compressive strength test

Compressive strength was tested in cubic samples of size 135 × 135 × 135 mm that were manufactured and cured in standardized laboratory conditions. Testing was conducted according to TS EN 12390-3 (2010) using a fully automated compression testing machine of 3000 kN capacity. Before testing, specimens were checked for surface defects and weighed. Loading was performed perpendicular to the surface at a constant rate of 0.6 ± 0.2 MPa/s up to failure. Compressive strength was calculated by using the maximum applied load at failure. Statistical accuracy was provided by a minimum of three replicate samples per series tested. Average compressive strength was calculated and analyzed from the data to determine the trends of compressive strength with various biomass proportions and fiber composition.

2.3.2. Flexural strength test

Flexural strength was determined from prismatic specimens with sizes of 67 × 67 × 265 mm through tests carried out under a three-point loading setup with the help of a universal testing machine and at a constant loading speed of 50 ± 10 N/s. 200 mm was kept constant between the support spans. Flexural strength was determined from the maximum load supported by individual specimens before fracture with the help of sample size and the loading span. This test was important to determine the material tensile properties that play an important role in resistance to cracking and durability in the case of applications in interior partition walls. Replications were conducted for each of the mixtures so that reliable and constant results were achieved.

2.3.3. Ultrasonic pulse velocity

Ultrasonic Pulse Velocity (UPV) tests were also performed to assess the internal compactness and structure of the composites. UPV tests were performed on the same cubic specimens used to determine compressive strength to assess internal compactness and structure of the composites. Testing was done by applying a digital ultrasonic tester with 54 kHz transducers on opposite faces of the sample. Coupling gel was employed to achieve good transmission of the signal. Travel time of the ultrasound pulse through the material was determined and velocity was calculated.

3. Results and discussion

3.1. Physical properties

Sunflower seed husk of bulk density around 1.10 kg/m³ was added to the study in the form of 1 cm pieces to allow even dispersal. These husks are dry and fibrous and have high surface areas with water absorption of up to 120%, according to earlier literature and gravimetric analysis. On the other hand, the hemp stalks employed were of the same length and had even higher absorption of around 140–150%, according to their hollow nature and sponge-like cellular structure with high porosity. Both the materials contain irregular surface and rough texture to enhance their bond with the matrix of lime and also enhance internal porosity of the composite at the same time. These physical properties—specifically water absorption and fiber surface morphology—have a direct bearing on internal microstructure of set mortar and affect density, water retention, and shrinkage behavior.

3.2. Mechanical properties

3.2.1. Compressive strength

Control mix had a compressive strength of 3.85 MPa. With the addition of 585 g of fibers, 49.3% of this strength was maintained by sunflower husk (1.90 MPa) and merely 18.2% (0.70 MPa) was maintained by hemp. At 1170 g, sunflower husk was reduced to 0.58 MPa—84.9% less than control—while hemp fell to 0.30 MPa (92.2% less). For Mix 4, the decline was steeper yet, with the use of sunflower husk dropping strength to 0.13 MPa (96.6% decrease) and hemp to 0.21 MPa (94.5% decrease). In Mix 5, the lowest compressive strength was achieved: 0.11 MPa with sunflower husk (97.1% loss) and 0.19 MPa with hemp (95.1% loss). These measures verify that at lower dosages, sunflower husk offers superior mechanics, but that the use of hemp is slightly less dramatic in its degradation curve with increasing dosage. Under high fiber levels, however, both additives drastically erode load-bearing capacity because of weakening of cohesive binder structure, increased porosity, and inefficient transfer of stress.

Table 2. Compressive strength results.

Mix No	Biomass Additive (g)	Hemp	Sunflower Husk
1	0	3.85	3.85
2	585	0.70	1.90
3	1170	0.30	0.58
4	1755	0.21	0.13
5	2340	0.19	0.11

3.2.2. Flexural strength

Flexural strength showed a similar decreasing trend to compressive strength but with a more pronounced benefit to sunflower husk. Compared with the control, Mix 2 sunflower husk samples maintained 40.1% of flexural strength (0.2998 MPa), compared with hemp at only 13.3% (0.0995 MPa). For Mix 3, the maximum of sunflower husk was 0.1670 MPa, 3.4 times that of hemp (0.0796 MPa). In Mix 4, the gap remained with more than double that of the flexural strength of hemp (0.0812 MPa compared with 0.0344 MPa), and in Mix 5 the gap increased further to 0.0617 MPa vs. 0.0249 MPa of hemp. This repeated differential performance indicates that sunflower husk is better to integrate with the matrix under flexural loading and that improved dispersibility of the finer and flatter geometry of the husk may be the reason. Enhanced specific surface area of the husk may also permit improved distribution of stresses and energy release upon bending loads. However, both materials suffer rapid loss of strength with higher content, with losses greater than 91% in the case of sunflower and 96.6% in the case of hemp in Mix 5. These results reinforce that biomass content should be confined to below 20% by weight to achieve mechanical viability in useful applications.

Table 3. Flexural strength results.

Mix No	Biomass Additive (g)	Hemp	Sunflower Husk
1	0	0.7477	0.7477
2	585	0.0995	0.2998
3	1170	0.0796	0.1670
4	1755	0.0344	0.0812
5	2340	0.0249	0.0617

Based on the results, the control sample (Mix 1) registered the highest UPVs (2882 m/s), verifying its good bonding and low porosity. Both 585 g of additive reduced UPV by 6.32% with hemp and by 29.6% with sunflower husk. This indicates that hemp at low levels maintains internal connectivity better compared to sunflower husk. For Mix 3, the decrease with sunflower husk was to 1332 m/s (53.7% from the original) and with hemp was 7.8% from the original (Mix 2). Further degradation was observed in Mixes 4 and 5. In the case of Mix 5, the specimen of sunflower husk fell to 1038 m/s (64% down from the control) with hemp remaining constant at 1283 m/s. In general, sunflower husk caused more drastic deterioration in wave velocity and hence greater internal discontinuity. The higher the levels of the two materials' contents, the larger is the performance gap observed here with the relatively higher retention of structural cohesion in the case of hemp.

Table 4. UPV test results (m/s).

Mix No	Biomass Additive (g)	Hemp	Sunflower Husk
1	0	2882	2882
2	585	2700	2030
3	1170	2657	1332
4	1755	1289	1250
5	2340	1283	1038

4. Conclusions

- UPVs were such that hemp stalk-strengthened specimens performed consistently better than those with sunflower seed husk, to imply higher internal continuity and matrix integration.
- Hemp composite samples revealed slightly improved performance in compressive strength evaluations than their counterparts from sunflower husk, particularly at increased dosage levels.
- As the proportions of husk in the mixture reduced, compressive strengths increased, which reflected a corresponding inverse relationship between the percentage of husk and mechanical integrity.
- The same was noticed in the case of hemp stalks: with decreased fiber content, compressive strength was higher, which again underscores the necessity of optimal dosage limits.
- Relative to conventional brick production, the composites developed consumed much less energy since there was no kiln firing required. Ambient temperature curing was undertaken with carbonation assisted with atmospheric CO_2, thus resulting in less air pollution.
- Lightness of the developed specimens—thanks to the use of low-density biomass—has benefits in structural design through minimization of dead loads and enhancement of general static efficiency in buildings.
- Incorporating sunflower seed husk in partition wall components helps promote recycling efforts and turns agro-industrial wastes into higher value-added construction products.
- Flexural strength tests revealed that decreases in the content of sunflower husk caused proportional increases in MPa values that signify that high levels negatively impact tensile performance.
- Also, reducing the concentration of the hemp stalks in the composite enhanced flexural strength, which suggests that both of these materials impede tensile action when in high concentration.
- Compared to their counterparts containing hemp in comparative flexural tests, sunflower husk specimens always had higher MPa values irrespective of dosage.
- Sunflower husk blends also performed better than hemp samples in compressive tests at lower additive proportions, with the advantage of their performance lessening with higher fiber concentration.
- Although environmentally friendly, neither of the composites tested fulfilled the structural requirements of load-bearing applications because of their dramatically lower strength profiles. Still, the developed materials can be applied to be used as non-load-bearing wall partitions where the strength is low in the internal environments.

Abstract. The cement industry uses energy resources intensively, resulting in significant carbon emissions. Magnesium-based binders, including the use of reactive MgO cement (RMC), are considered a promising alternative to cement. Three-dimensional (3D) printing technology has the advantages of unlimited flexibility, reduced cycle time, low labor cost and minimal waste. In this study, the improvement of 3D printing properties (rheological and mechanical) of MgO-derived binders by CO_2 curing in hardened state was investigated. Rheological measurements (yield stress and viscosity) and compressive tests have been performed. The yield stress and viscosity of the reference sample were 173 Pa and 3.9 Pa.s, respectively, and 12.5%, 18.75%, 25% and 31.25% rMgO substitution increased the yield stress by 156%, 157%, 174%, and 224%, and viscosity by 105%, 156%, 269%, and 610%, respectively, compared to the reference sample. The reason for these increases is the improvement of hydration kinetics with the increase in the amount of rMgO with higher purity. As the rMgO ratio increases, the compressive strength also increases. CO_2 curing has increased compressive strength compared to the curing with room conditions. The increase in rMgO, which acts as a hydration agent, and the carbonation of RMC have led to the formation of HMC by forming continuous networks, filling pores, densifying the matrix microstructure, and thus facilitating strength development. The rMgO substitution ratio with optimum properties in terms of 3D printability is 31.25% and the compressive strength, yield stress and viscosity are 11.8 MPa, 561 Pa and 27.7 Pa.s, respectively.

Keywords: Sustainability; Carbon capture storage/utilization (CCS/CCU); RMC; Compressive strength; Rheology

1. Introduction

Concrete is a widely preferred building material worldwide due to its mechanical properties, durability and adaptability to various shapes, and its primary binder is cement (Gartner, 2004). Cement and concrete production is increasing significantly due to rapid population growth, urbanization and high demand for better infrastructure (Meng et al., 2023). High cement demand has negative implications for the global environment. The cement industry uses energy, limestone and clay resources intensively, resulting in significant carbon emissions (Gartner, 2004). The cement industry is responsible for about 8% of global CO_2 emissions (Preston & Lehne, 2018).

Carbon capture and storage/utilization (CCS/U) techniques play an important role in reducing CO_2 emissions (Lena, 2018). While CCS technique stores CO_2 emissions in deep geological formations or deep in the ocean, CCU technique converts CO_2 emissions into valuable products (Quarton & Samsatli, 2020). Although CCS can store large amounts of CO_2, the process is expensive and there are potential risks such as leakage (Ajayi et al., 2019; Cunningham et al., 2009). Mineralization of cement-based materials, one of the CCU techniques, is considered as a low-risk and ecologically sensitive alternative for CO_2 sequestration (Li et al., 2022).

Carbonation of cementitious systems has received increasing attention over the past few years. Among these, magnesium-based binders, including the use of reactive MgO cement (RMC), are considered a promising alternative to PC (Hay & Celik, 2020a; Ünlüer, 2018; Al-Tabbaa, 2013). RMC is typically composed of 90% MgO and also contains SiO_2, CaO and Fe_2O_3. Magnesium oxide (MgO) is obtained by calcining magnesite deposits (dry route) or from seawater or waste brine (wet route) (Walling & Provis, 2016; Hay & Çelik 2020b). For the main production route (dry route), the calcination temperature required to produce RMC (700-1000°C) is much lower than for PC (up to 1450°C) (Shand, 2006). RMC is able to permanently sequester CO_2 in the magnesium carbonates produced, leading to a simultaneous power gain in relation to the degree of carbonation. Theoretically, the

* Corresponding author, E-mail: yeavsar@nku.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_726

maximum carbon sequestration capacity of RMC is 110% (Ruan et al., 2021), which is significantly higher than that of PC (46-58%) (Fang et al., 2017). Given the carbonation capacity of RMC, net CO_2 emissions can be significantly reduced. It has been reported that the net CO_2-e emissions of RMC after fully carbonized is only 264 kg CO_2-eq (Ruan & Ünlüer, 2016).

Carbonation of RMC offers a pathway for the long-term retention of CO_2 in concrete components. Carbonation of RMC leads to the formation of hydrated magnesium carbonates (HMCs) that form continuous networks, filling pores, densifying the matrix microstructure and thus facilitating strength development (Dung et al., 2019). The typical compressive strength range of carbonated RMC specimens is 20-85 MPa (Soares & Castro-Gomes, 2021). It exhibits better durability than PC in terms of freeze-thaw cycling, chloride and sulfate attack (Pu & Ünlüer, 2018; Kumar et al., 2021; Muthu et al., 2020). The full recyclability of RMC-based materials further enhances their sustainability at the end of their life cycle (Sonat et al., 2017). The hydration products of RMC (brucite) are a mechanically weak phase and the gain of higher strength depends on the carbonation process. Typical hydrated magnesium carbonate (HMC) phases include artinite, neskehonite, hydromagnesite and dipinjite (Ünlüer, 2018). The hydration and carbonation reactions of RMC samples are shown in Equations 1-5 (Ünlüer, 2018; Dung et al., 2019).

$$\mathrm{MgO} + \mathrm{H_2O} \rightarrow \mathrm{Mg(OH)_2}\ \text{(Brucite)} \tag{1}$$

$$2\mathrm{Mg(OH)_2} + \mathrm{CO_2} + 2\mathrm{H_2O} \rightarrow \mathrm{MgCO_3} \cdot \mathrm{Mg(OH)_2} \cdot 3\mathrm{H_2O}\ \text{(Artinite)} \tag{2}$$

$$\mathrm{Mg(OH)_2} + \mathrm{CO_2} + 2\mathrm{H_2O} \rightarrow \mathrm{MgCO_3} \cdot 3\mathrm{H_2O}\ \text{(Nesquehonite)} \tag{3}$$

$$5\mathrm{Mg(OH)_2} + 4\mathrm{CO_2} \rightarrow 4\mathrm{MgCO_3} \cdot \mathrm{Mg(OH)_2} \cdot 4\mathrm{H_2O}\ \text{(Hydromagnesite)} \tag{4}$$

$$5\mathrm{Mg(OH)_2} + 4\mathrm{CO_2} + \mathrm{H_2O} \rightarrow 4\mathrm{MgCO_3} \cdot \mathrm{Mg(OH)_2} \cdot 5\mathrm{H_2O}\ \text{(Dypingite)} \tag{5}$$

The degree of hydration and carbonation are critical factors affecting the microstructural development and strength gain of RMC specimens (Dung et al., 2019). Extensive research has been conducted focusing on mix design (water/binder and sand/binder ratio), curing conditions (CO_2 concentration/pressure, relative humidity and temperature) and the use of admixtures (hydration agent, carbonation agent and nucleation seeding) to enhance the carbonation of RMC-based concrete (Meng et al., 2023).

The choice of water content is critical as water provides the medium for hydration and carbonation reactions (Ünlüer & Al-Tabbaa, 2015). A low s/b ratio may result in poor compaction, comminution and insufficient formation of hydration products required for the subsequent carbonation reaction (Ruan & Ünlüer, 2017; Ünlüer & Al Tabbaa, 2011). On the other hand, high water content may inhibit CO_2 diffusion in the pore system. This is because the diffusion of CO_2 in water (0.0016 mm^2/s) is much slower than in air (16 mm^2/s) (Lide, 2004). The effect of s/b ratio on hydration and carbonation of RMC-based concrete was investigated by Ruan and Ünlüer (2017). Among the mixtures with three different s/b ratios (0.55, 0.6 and 0.65), RMC specimens with 0.55 s/b ratio exhibited the lowest porosity and the highest density increase after carbonation and achieved the highest strength (62 MPa), which was comparable to water-cured PC specimens (68 MPa).

Since the CO_2 concentration in the atmosphere is 0.041%, the carbonation process of RMC-based concrete is very slow under ambient conditions (Weber, 2021). Optimum curing conditions have been investigated in many studies, including the evaluation of factors such as CO_2 concentration/pressure, relative humidity, temperature and curing time to accelerate the carbonation process. Although the carbonation reaction can be enhanced by increasing the CO_2 concentration, there seems to be a critical point where other factors can limit CO_2 diffusion in RMC samples (Pu & Ünlüer, 2016). Studies have shown that RMC-based composites subjected to CO_2 concentrations of 5-20% can reach full strength development within 14 days (Pu & Ünlüer, 2016, Liska & Al-Tabbaa, 2009). In the studies of Ünlüer and Al-Tabbaa (2014) and Dung et al. (2021), the optimum CO_2 concentration in terms of strength development was determined as 10% among the tested CO_2 concentrations (5-20%).

Accelerated carbonation of RMC requires high levels of humidity due to the high water consumption of the carbonation reaction (Vandeperre & Al-Tabbaa, 2007). Although high relative humidity is beneficial for hydration and carbonation reactions, strength development does not increase linearly with relative humidity. Because CO_2 decomposes faster in drier environments (Meng et al., 2023). Ünlüer and Al-Tabbaa (2014) investigated the effect of different RH ratios ranging from 55-98% and found that 78% RH provided the most favorable carbonation condition and 24-34 MPa compressive strength was obtained after curing for 18 days. It was reported that the degree of hydration of RMC under ambient conditions was limited to 80% (Dung & Ünlüer, 2017a; Ünlüer & Al-Tabbaa, 2014).

Curing time is another important factor that ensures adequate carbonation of RMC samples. Determining the optimum curing time can reduce time and cost (Meng et al., 2023). Hay and Celik (2020b) investigated the strength development and carbonation of RMC-based composite under 20% CO_2, 30°C and 80% relative humidity. It was found that the compressive strength increased up to 14 days (23.9 MPa), but decreased by about 11.1% at 28 days (21.3 MPa). It was explained that excessive carbonation leads to volume expansion, which causes internal stress and cracking. In addition, a negligible increase in carbon sequestration rate was observed (Hay & Çelik, 2020b).

In this study, the improvement of 3D printing properties (rheological and mechanical) of MgO-derived binders by CO_2 curing in hardened state was investigated. This study is based on two main objectives. The first objective of the study is to produce a new binder system that can be used in the field at low cost by reducing CO_2 emission, high energy requirement and high production temperature caused by cement production. The second aim is to save time and cost in field applications by realizing the production of this material with sufficient strength and durability with an extrusion type 3D printer.

2. Materials and methods

In this study, the improvement of 3D printing properties (rheological and mechanical) of MgO-derived binders by CO_2 curing in hardened state was investigated. MgO, rMgO, PC, chemical additives, distilled water and aggregate were used in the production of the mixtures. Within the scope of compressive test and rheological measurement, rMgO substitution rate was 12.5%, 18.75%, 25% and 31.25%. 2 series were produced and the 1st serial was subjected to carbonation curing in an incubator and the 2nd serial was cured under room conditions. 24 mortar specimens (5×5×5 cm cube) were produced for compressive test and 12 paste specimens were produced for rheology measurements. The cube specimens were subjected to carbonation curing (10% CO_2, 50-70% humidity, 25°C) in an incubator until the compressive test (1, 3, and 7 days). Based on the rheological data and compressive test results, the optimum test point was determined. Test points with rMgO substitution ratio higher than 31.25% could not be produced because they were too dense and subject to rapid setting due to high reactivity.

While the primary binder matrix used in this study was MgO, rMgO (98% purity) was used to improve the hydration kinetics and buildability of the RMC mortar. Standard sand was also added to improve workability. Table 1 summarizes the properties of the MgO and rMgO components used in the study. 0.1M magnesium acetate aqueous solution was used as the primary liquid medium with a water/binder (s/b) ratio of 0.45. Magnesium acetate acts as a strong hydration agent in RMC and therefore it is recommended to add it in small concentrations to achieve a higher degree of hydration in RMC (Matabola et al., 2010). Polycarboxylate ether was added as a 'superplasticizer' to reduce the plastic viscosity of the RMC mortar and maintain its flow consistency over a long period of time. Hydroxyethyl cellulose was added as a 'suspending additive' to maintain the homogeneity of the mixture during extrusion. Finally, a non-ionic surfactant, also called 'defoamer', was added to prevent air entrapment in the modified mortar (Khalil et al., 2020). To produce a homogeneous 3D printable mixture, the solid components were mixed as a uniform dry powder mixture while the liquid components were mixed in a beaker to obtain a homogeneous solution. This solution was poured into the container containing the solid mixture and stirred for about 5 minutes. By applying this procedure, a homogeneous 3D printable RMC-based mortar was obtained. Table 2 summarizes the mixture composition.

A rotational rheometer was used to measure the rheological properties of the freshly prepared material. A measuring system with four blades and a measuring cup were used for the measurements. In order to ensure uniform distribution and to generate the same shear history for all mixtures, a constant shear rate of 50 s^{-1} was applied for 1 min for pre-shearing the mixtures and then rested for 1 min. Then, the shear rate was increased linearly from 0 s^{-1} to 100 s^{-1} for 1 min, followed by a decrease from 100 s^{-1} to 0 s^{-1} within 1 min (Wang et al., 2024).

Modified Bingham, Stress-Plateau, Herschel-Bulkley, De Kee and Casson methods were applied on the data sets of the test points to determine the yield stress and viscosity. In the Modified Bingham method, the coefficient of x in the equation represents the viscosity and the constant value represents the yield stress (Ebrahimi et al., 2022). In the Stress-Plateau method, the average of the shear stress values of the 2 points with the lowest shear rate representing the plateau region expresses the yield stress, and the coefficient of x in the equation of the 3 points with the highest shear rate representing the plastic viscosity region expresses the viscosity (Dinç Şengönül et al., 2020). The formulas of Herschel-Bulkley, De Kee and Casson methods are given Equations 6-8 respectively.

$$\tau = \tau_0 + K \cdot \gamma^n \tag{6}$$

$$\tau = \tau_0 + \mu \cdot \gamma \cdot e^{-\tau_0 \cdot \gamma} \tag{7}$$

$$\sqrt{\tau} = \sqrt{\tau_0} + \sqrt{\mu \cdot \gamma} \tag{8}$$

In these formulas τ, ϒ, τ0, and μ are shear stress, shear rate, yield stress, and viscosity, respectively.

The compressive test was carried out on 5×5×5 cm cube specimens at 1, 4 and 7 days in accordance with ASTM C109 (2020). The compressive strength was calculated using Equation 9. f_c is the compressive strength (N/mm^2), P is the maximum load at fracture (N) and A is the surface area of the square section of the prism (mm^2).

$$f_c = P/A \tag{9}$$

3. Results and discussion

3.1. Rheological measurements

The viscosity-shear rate graph for the test points is shown in Fig. 1. It can be seen that viscosity increases as the rMgO ratio increases. This is due to the increase in the amount of rMgO with higher purity and the development of hydration kinetics (Khalil et al., 2020). The produced mortars exhibited shear thinning behavior similar to cement-based mortars and slurries (Bras et al., 2010; Jorne et al., 2015; Gökyiğit-Arpacı et al., 2019). Shear thinning behavior is defined as a decrease in viscosity resulting from the breakage of flocs due to an increase in shear rate (Jorne et al., 2015). Low yield stress and plastic viscosity ensure easy injection of the mortars (Dinç-Şengönül et al., 2020).

The shear stress-shear rate graph for the test points is shown in Fig. 2. It can be seen that the shear stress increases as the rMgO ratio increases. This is due to the increase in the hydration kinetics with the increase in the amount of rMgO with higher purity (Khalil et al., 2020).

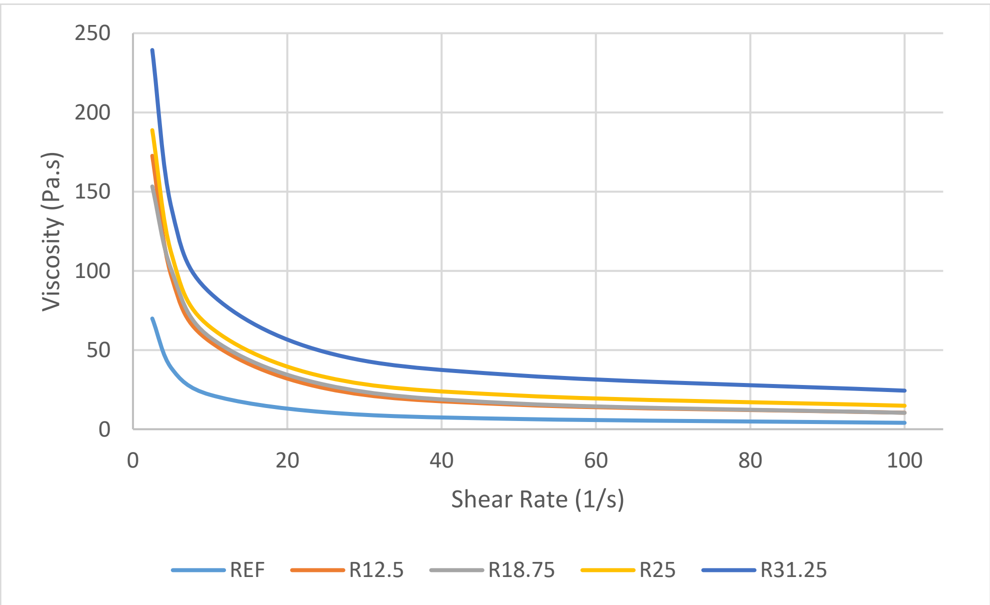

Fig. 1. The viscosity-shear rate graph for the test points

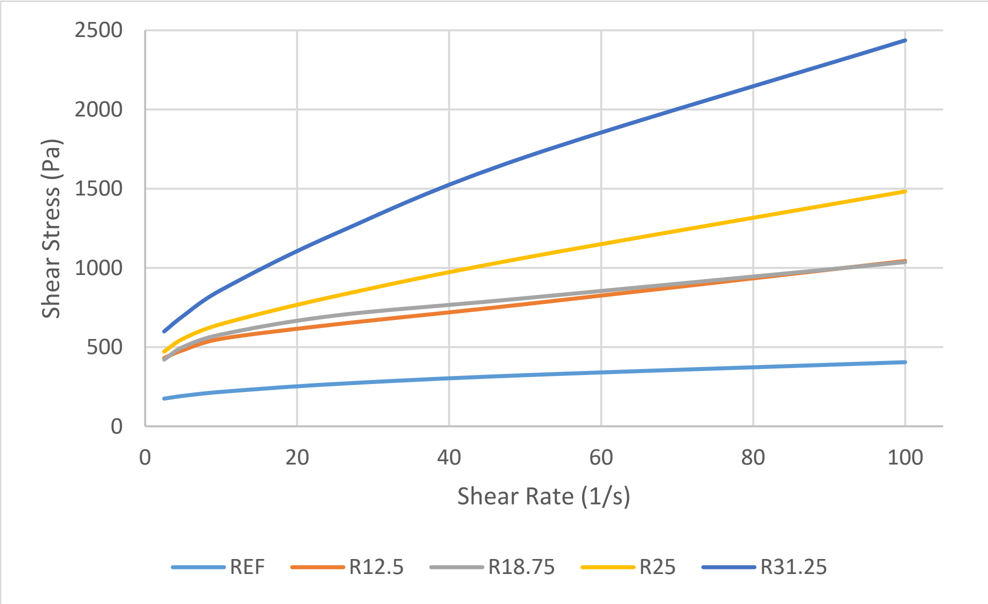

Fig. 2. The shear stress-shear rate graph for the test points

The Modified Bingham, Stress-Plateau, Herschel-Bulkley, De Kee, and Casson methods were applied to the data sets obtained from the test points to determine the yield stress and viscosity. The results of the Stress-Plateau method to reference, 12.5%, 18.75%, 25%, and 31.25% rMgO samples are presented in Figs. 3, 4, 5, 6, and 7, respectively. Upon examination of the figures, it is observed that no plateau formation occurs at any test point.

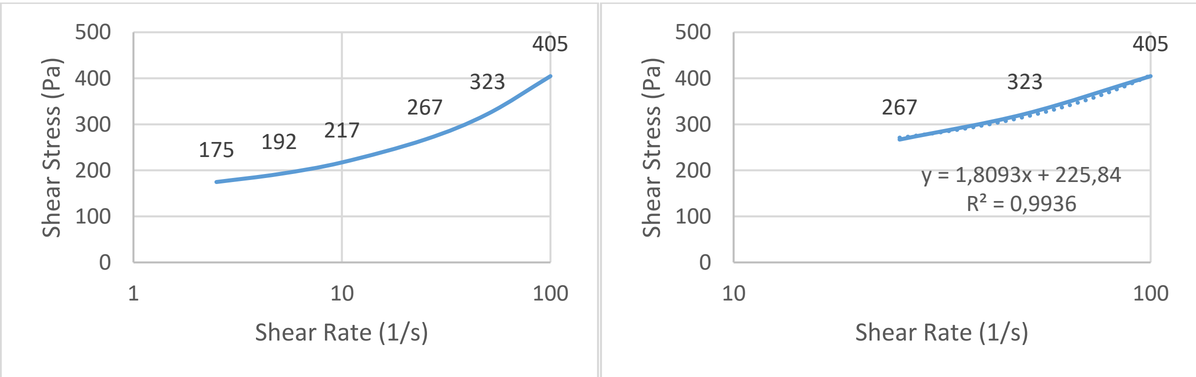

Fig. 3. The results of the Stress-Plateau method to Ref

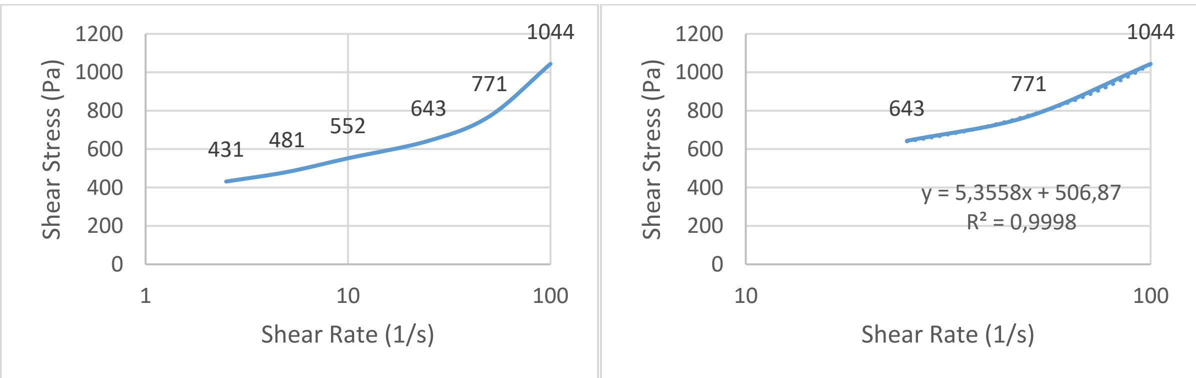

Fig. 4. The results of the Stress-Plateau method to 12.5% rMgO

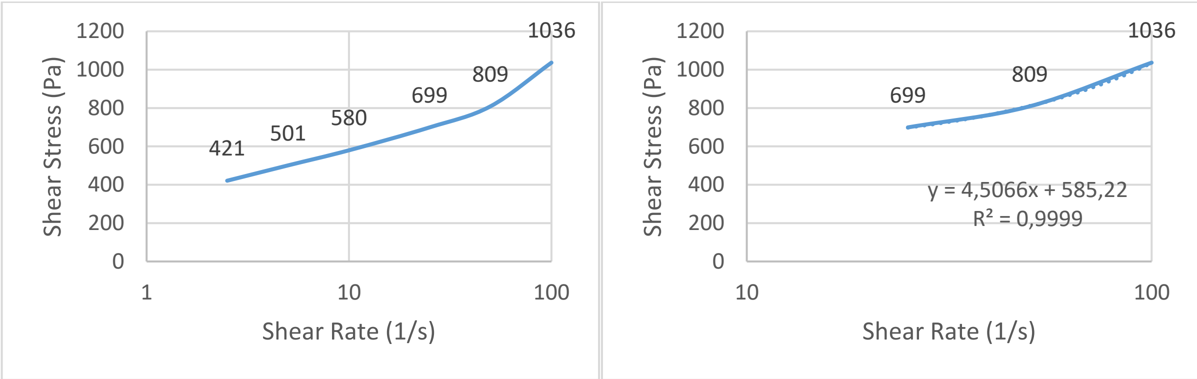

Fig. 5. The results of the Stress-Plateau method to 18.75% rMgO

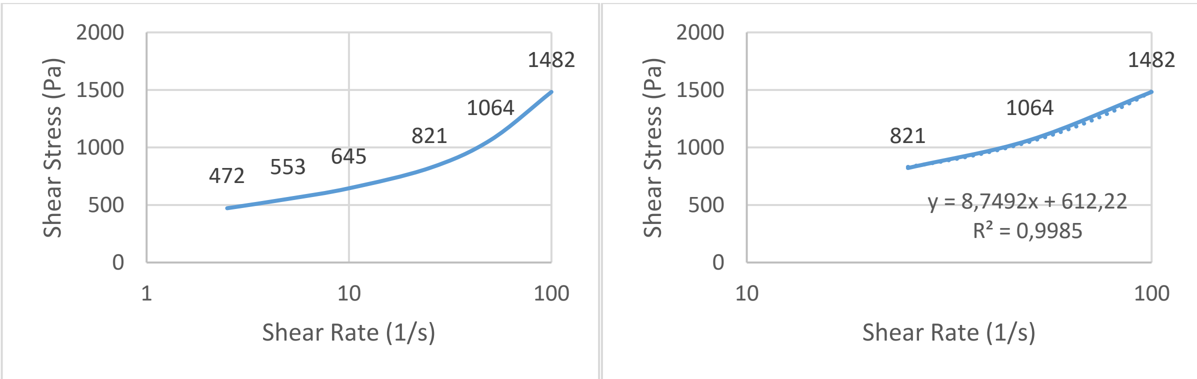

Fig. 6. The results of the Stress-Plateau method to 25% rMgO

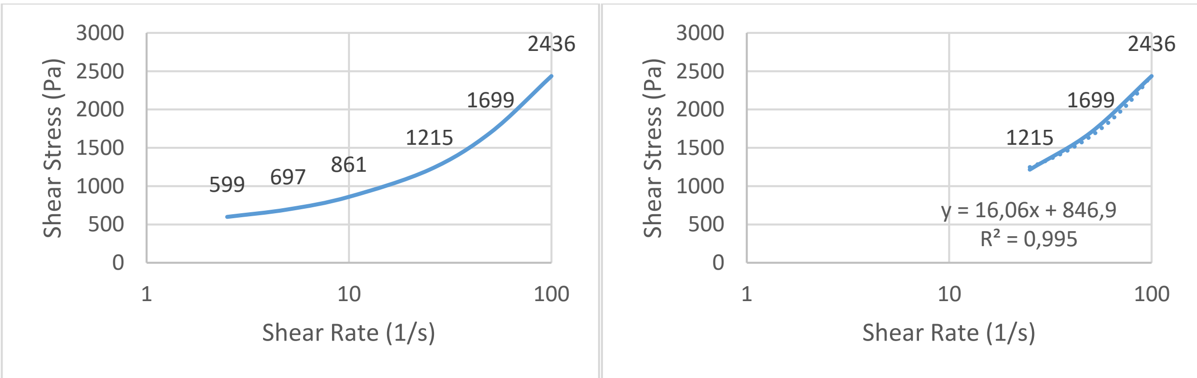

Fig. 7. The results of the Stress-Plateau method to 31.25% rMgO

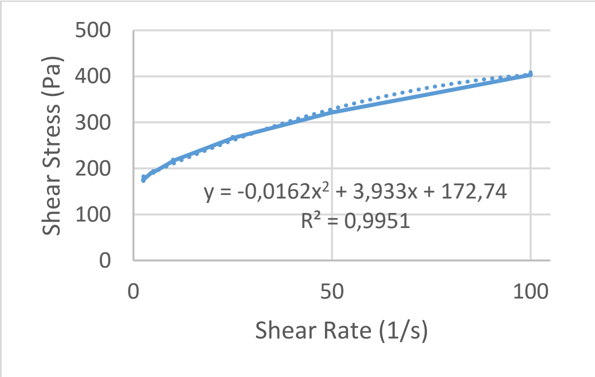
The results of the Modified Bingham method to reference, 12.5%, 18.75%, 25%, and 31.25% rMgO samples are presented in Figs. 8, 9, and 10, respectively. When the data sets were fitted to the Bingham model, a good linear fit was obtained between shear stress and shear rate.



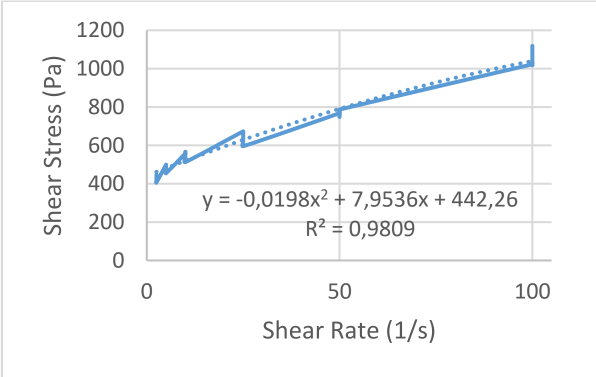


Fig. 8. The results of the Modified Bingham method to Ref (left) and 12.5% rMgO (right)

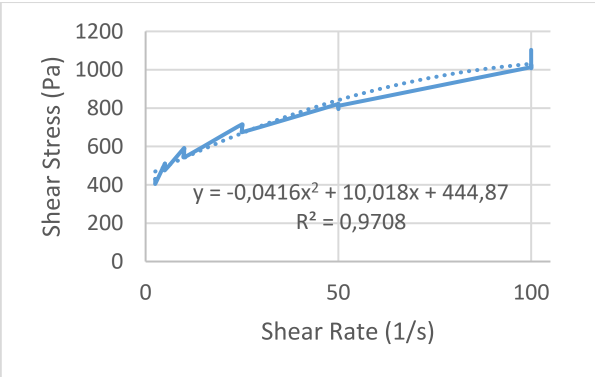

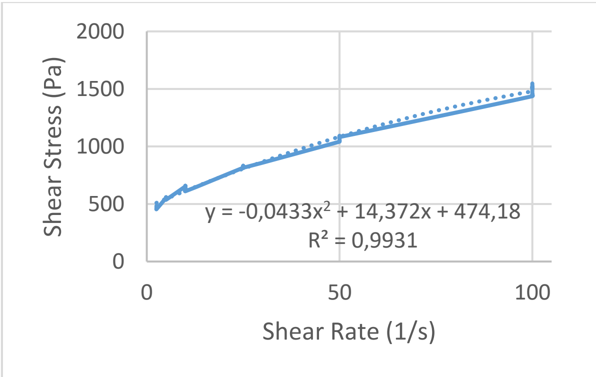

Fig. 9. The results of the Modified Bingham method to 18.75% rMgO (left) and 25% rMgO (right)

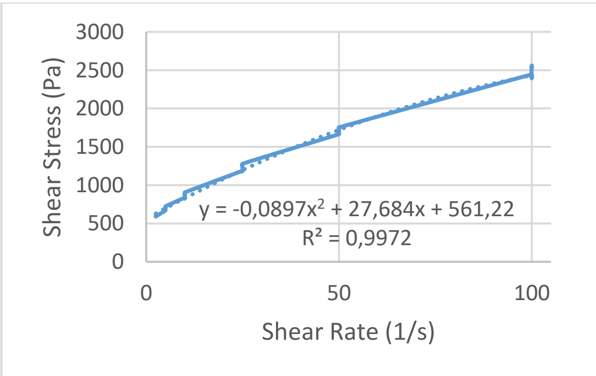

Fig. 10. The results of the Modified Bingham method to 31.25% rMgO

For Modified Bingham method, a replacement of rMgO at 12.5%, 18.75%, 25%, and 31.25% increased the yield stress by 156%, 157%, 174%, and 224%, respectively, while increasing viscosity by 105%, 156%, 269%, and 610%, respectively. The reason for these increases is the improvement in hydration kinetics due to the increased amount of rMgO with higher purity (Khalil et al., 2020).

The yield stress and viscosity values obtained by applying the Modified Bingham, Stress-Plateau, Herschel-Bulkley, De Kee, and Casson methods on the data sets of the test points are given in Table 3. In Table 3 TP, YS, and V are test point, yield stress, and viscosity, respectively. It can be seen that the R^2 values of the different methods are quite close. When the Modified Bingham and De Kee methods are applied, the yield stress and viscosity values are found to be quite similar. When the Casson method is applied, the R^2 value and viscosity value of the reference sample could not be calculated. Additionally, viscosity calculations cannot be performed using the Herschel-Bulkley method.

The comparisons of R^2, yield stress, and viscosity values obtained from different methods are shown in Fig. 11, Fig. 12, and Fig. 13, respectively.

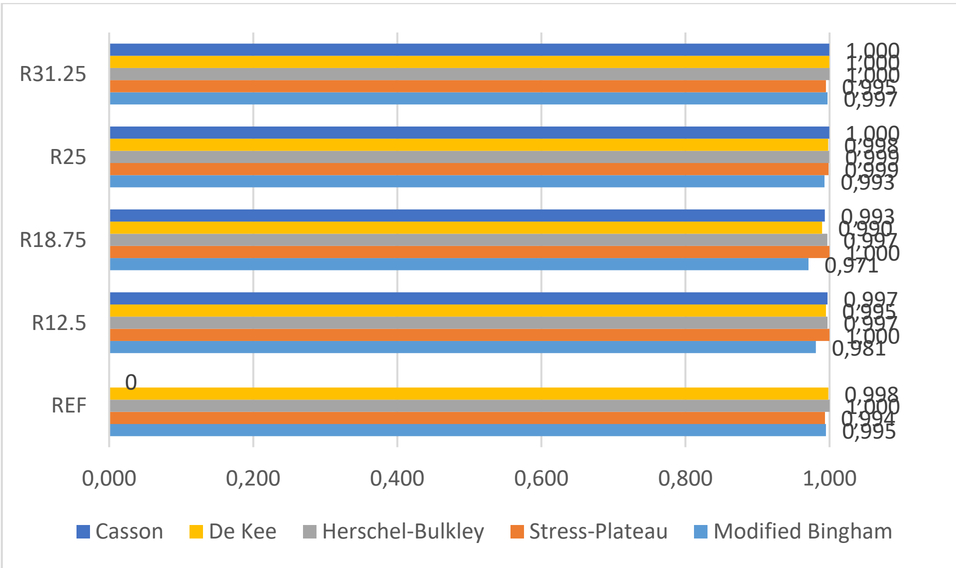

Fig. 11. The comparison of R^2 values obtained from different methods

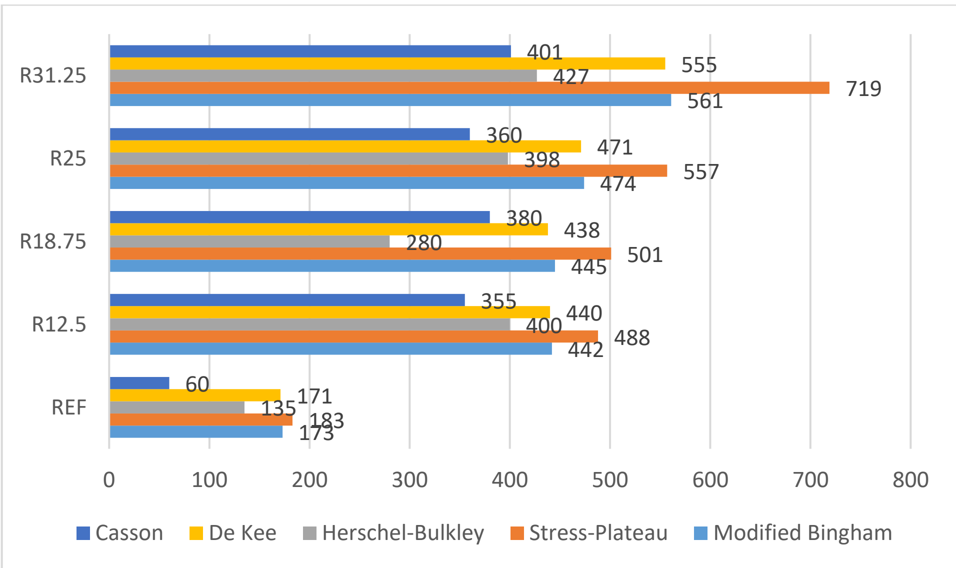

Fig. 12. The comparison of yield stress values obtained from different methods

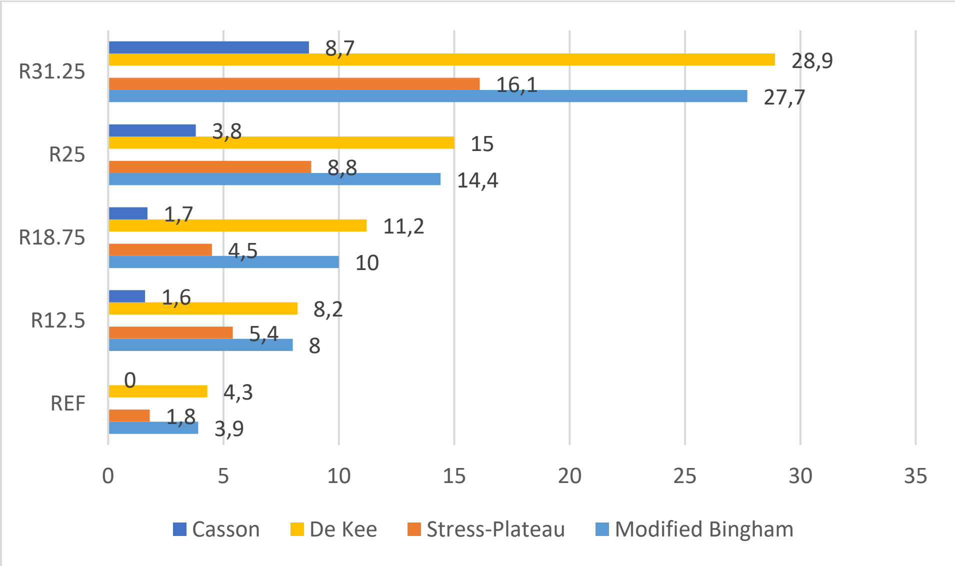

Fig. 13. The comparison of viscosity values obtained from different methods

A review of the literature reveals that the shear stress of 100% PC-based, PC-based with pozzolan replacement, and geopolymer mixtures is 180-3800, 14-6000, and 500-11000 Pa, respectively; while their viscosity is 4-46, 1.3-33, and 0.5-15 Pa, respectively (Zhong & Zhang, 2022; Paritala et al., 2023). In a study investigating whether the activation of 3D printing using additives such as nanocellulose (NC) and methyl cellulose (MC) improves the carbonation of MgO paste and has a positive effect on physical/mechanical properties (Douba et al., 2022). The addition of NC increased the static yield stress of MgO paste by 120 and 184 Pa per 1% NC by weight for 1.1 and 0.9 w/b ratios, respectively, while the addition of MC increased it by 1.3 and 9 Pa per 1% MC by weight, respectively. The addition of NC increased the plastic viscosity of the MgO paste by 0.2 Pa·s per 1% NC, while the addition of MC increased it by 0.27 and 0.38 Pa·s per 1% MC for 1.1 and 0.9 w/b, respectively.

3.2. Compressive test

The compressive strength values of 12.5%, 18.75%, 25%, and 31.25% rMgO mortar samples are given in the Table 4 and Fig. 14. In Table 4, CS means compressive strength.

In general, it has been observed that as the rMgO ratio increases, the compressive strength also increases. At all substitution ratios, CO_2 curing has increased compressive strength compared to the curing with room conditions, independent of sample age. The increase in rMgO, which acts as a hydration agent, and the carbonation of RMC have led to the formation of hydrated magnesium carbonates (HMC) by forming continuous networks, filling pores, densifying the matrix microstructure, and thus facilitating strength development (Dung et al., 2019). When 1-day samples cured with CO_2 were analyzed, the replacement of rMgO at 31.25% increased compressive strength by 70%, 115%, and 152% compared to replacements of 25%, 18.75%, and 12.5%, respectively. This is attributed to the improvement in hydration kinetics resulting from the increase in rMgO content (Meng et al., 2023). However, it was observed that the increase in strength decreases as the CO_2 curing time increases. This indicates that carbonation occurs more efficiently and effectively at the initial stage. The 4-day strengths of the samples with 12.5%, 18.75%, 25%, and 31.25% rMgO replacement, which were subjected to CO_2 curing, were 95%, 70%, 28%, and 4% higher than their 1-day strengths, respectively. As seen, the increase in strength decreases as the rMgO replacement ratio increases. This may be due to the hydration kinetics occurring abruptly and intensely at high rMgO ratios, leading to pore blockage and a reduction in the effect of the CO_2 curing (Meng et al., 2023). In general, it can be stated that an increase in the CO_2 curing time increases the compressive strength. However, there is no significant increase in compressive strength values between 4 and 7 days for all rMgO replacement ratios. This can be explained by excessive carbonation causing expansion, leading to internal stress and cracking (Hay & Çelik 2020b). The highest compressive strength (11.8 MPa) was obtained from a 7-day sample with 31.5% rMgO replacement treated with CO_2 curing.

Studies have been conducted on the use of hydration agents to increase carbon sequestration in RMC systems (Meng et al., 2023). The hydration of MgO in the presence of sodium acetate ($(CH_3COO)_2Mg$) promotes the precipitation of brusite in the slurry solution, thereby increasing the available space for continuous hydration (Dung & Ünlüer, 2017a). Additionally, it provides additional magnesium ions (Mg^{2+}) for brusite formation (Dung & Ünlüer, 2017b). Hydrochloric acid (HCl) increases the H^+ concentration and the solubility of MgO (Dung & Ünlüer, 2016). A comparative study was conducted to investigate the effectiveness of hydration agents ($(CH_3COO)_2Mg$, $MgCl_2$, and HCl) in RMC-based mixtures (w/b: 0.6). The addition of $(CH_3COO)_2Mg$, HCl, and

$MgCl_2$ increased the 14-day compressive strength by 273%, 160%, and 93%, respectively, compared to the control mixture (Dung & Ünlüer, 2017b). Sodium bicarbonate ($NaHCO_3$) has been applied in RMC systems to increase pH and thereby enhance CO_2 solubility. Additionally, $NaHCO_3$ provides additional bicarbonate ions that enable continuous carbonation reactions (Dung & Ünlüer, 2019; Dung & Ünlüer, 2018). Dung and Ünlüer (2018) investigated the enhancement of carbonation in RMC-based concrete using $NaHCO_3$ and NaCl. Chloride ions from NaCl can accelerate MgO dissolution by weakening its bonds. The combination of these additives (50 MPa) improved the morphology of the formed carbonate phases and increased the 28-day compressive strength by 110% compared to the control sample (Dung & Ünlüer, 2018).

Table 4. The compressive test results

Curing	1-day		4-day		7-day	
Type	Test Point	CS (MPa)	Test Point	CS (MPa)	Test Point	CS (MPa)
CO_2 curing	C12.5-1	4	C12.5-4	7.8	C12.5-7	7.9
	C18.75-1	4.7	C18.75-4	8	C18.75-7	8.2
	C25-1	6.8	C25-4	8.7	C25-7	9.8
	C31.25-1	10.1	C31.25-4	10.5	C31.25-7	11.8

4. Conclusions

In this study, the improvement of 3D printing properties (rheological and mechanical) of MgO-derived binders by CO_2 curing in hardened state was investigated. The main findings of the study are presented below.

- The viscosity and shear stress increases as the rMgO ratio increases. This is due to the increase in the amount of rMgO with higher purity and the development of hydration kinetics. The produced mortars exhibited shear thinning behavior similar to cement-based mortars and slurries.
- When the data sets were fitted to the Stress-Plateau method, it is observed that no plateau formation occurs at any test point.
- When the data sets were fitted to the Bingham model, a good linear fit was obtained between shear stress and shear rate. A replacement of rMgO at 12.5%, 18.75%, 25%, and 31.25% increased the yield stress by 156%, 157%, 174%, and 224%, respectively, while increasing viscosity by 105%, 156%, 269%, and 610%, respectively. The reason for these increases is the improvement in hydration kinetics due to the increased amount of rMgO with higher purity.
- The R^2 values of the different methods (Modified Bingham, Stress-Plateau, Herschel-Bulkley, De Kee, and Casson) are quite close. When the Modified Bingham and De Kee methods are applied, the yield stress and

viscosity values are found to be quite similar. When the Casson method is applied, the R^2 and viscosity value of the reference sample could not be calculated. Viscosity calculations cannot be performed using the Herschel-Bulkley method.
- The highest compressive strength (11.8 MPa) was obtained from a CO_2 cured 7-day sample with 31.5% rMgO.
- As the rMgO ratio increases, the compressive strength also increases. CO_2 curing has increased compressive strength compared to the curing with room conditions. The increase in rMgO, which acts as a hydration agent, and the carbonation of RMC have led to the formation of HMC by forming continuous networks, filling pores, densifying the matrix microstructure, and thus facilitating strength development.
- In CO_2 cured 1-day samples, 31.25% rMgO increased compressive strength by 70%, 115%, and 152% compared to 25%, 18.75%, and 12.5% rMgO, respectively. This is attributed to the improvement in hydration kinetics resulting from the increase in rMgO content. However, the increase in strength decreases as the CO_2 curing time increases. This indicates that carbonation occurs more efficiently and effectively at the initial stage.
- The CO_2 cured 4-day strengths of the samples (12.5%, 18.75%, 25%, and 31.25% rMgO) were 95%, 70%, 28%, and 4% higher than their 1-day strengths, respectively. The increase in strength decreases as the rMgO replacement ratio increases. This may be due to the hydration kinetics occurring abruptly and intensely at high rMgO ratios, leading to pore blockage and a reduction in the effect of the CO_2 curing.
- An increase in the CO_2 curing time increases the compressive strength. However, there is no significant increase in compressive strength values between 4 and 7 days for all rMgO replacement ratios. This can be explained by excessive carbonation causing expansion, leading to internal stress and cracking.

Abstract

In recent years, 3D concrete printing has emerged as an innovative construction technology, enhancing efficiency by enabling the creation of complex geometries, reducing labor costs, and minimizing construction waste compared to traditional construction methods. 3D-printed concrete is a tailored concrete that can be deposited layer by layer through a 3D printer without the need for formwork or vibration. However, despite extensive research on printable materials, the absence of specific design regulations for 3D-printed structures has limited the development of comprehensive assessments of their structural behavior. The layered structure and lack of conventional reinforcement in 3D-printed concrete further distinguish its structural behavior from that of conventionally constructed concrete. This study evaluates the structural performance of an unreinforced 3D-printed wall element subjected to in-plane lateral loading through numerical simulation. The wall is modeled in SAP2000 using the mechanical properties of cement-based printable materials. A nonlinear pushover analysis is conducted to assess the lateral load-bearing capacity and deformation characteristics of the wall under loading conditions representative of seismic demand. The developed model provides insights into the behavior of 3D-printed structures under lateral loading. The findings aim to contribute to the future integration of additive manufacturing into performance-based structural design and enhance understanding of the lateral performance of 3D-printed concrete.

1. Introduction

Three-dimensional concrete printing (3DCP) is rapidly transforming the construction industry by enabling automated, layer-by-layer fabrication of structural elements directly from digital models. Compared to traditional construction methods, 3DCP offers faster construction, reduced labor costs, improved on-site safety, and the ability to produce complex geometries without the need for formwork. As a result, it is increasingly being adopted in a range of applications, including single-story residential buildings, modular tiny homes, and infrastructure components like pedestrian bridges (Buswell et al., 2018; Khoshnevis et al., 2020). Despite its growing use, the structural reliability of 3D-printed elements under lateral and seismic loading remains a major research gap. While several studies have investigated the fresh and hardened properties of printable cement-based materials, limited research has focused on their structural performance. This gap is largely due to the lack of design standards and proper characterization of 3D-printed structures. In addition, the layered construction process, anisotropic material behavior, weak interlayer bonding, and lack of conventional reinforcement result in a different structural response from that of traditionally cast concrete (Pan et al., 2023).

Understanding the seismic behavior of 3D-printed elements is essential for the broader adoption of this technology in seismically active regions. Current experimental studies and numerical models remain limited in capturing the effects of key parameters such as layer orientation, interfacial bond strength, and geometric irregularities on the lateral load response of 3D-printed concrete (Feng et al., 2015). This highlights the growing need for research that integrates material characterization with structural analysis to assess the lateral load-bearing capacity (Mader et al., 2023). To address this gap, the present study evaluates the structural performance of a cement-based 3D-printed wall element. A numerical model is developed in SAP2000 using mechanical properties of printable cement-based materials reported in the literature, and a nonlinear pushover analysis is conducted to assess lateral load-bearing capacity, stiffness degradation, and potential failure mechanisms. The wall is loaded in-plane to simulate realistic seismic conditions, and crack formation is predicted based on the stress and strain

* Corresponding author, E-mail: kerem.sarikaya@ozu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_736

distributions obtained from the analysis. This approach aims to improve understanding of the failure mechanisms in 3D-printed walls and contribute to the development of performance-based seismic design strategies for printed concrete structures.

2. Materials and methods

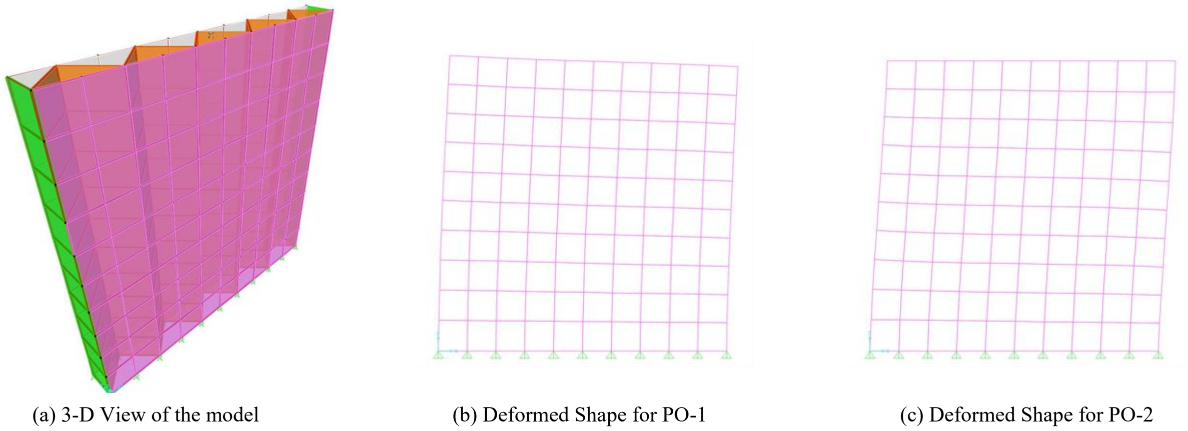
2.1. Materials and mechanical properties

The material properties and modeling parameters used in this study are based on a previously developed cement-based mortar formulated for 3D printing applications (Bayrak, 2023). The cement type used was CEM II/A-M (S-L) 42.5R, combined with silica sand at a sand-to-binder ratio of 1.5. The water-to-cement (w/c) ratio was 0.32. Mechanical properties were obtained through laboratory testing of core samples extracted from printed wall specimens. The study also noted measurable differences in mechanical behavior between the lower and upper wall segments, attributed to variations in material quality and layer consolidation during the printing process, with the upper part exhibiting lower mechanical properties. In this study, the mechanical properties of the upper part were used, as this region is more susceptible to defects caused by the extended duration of the printing process, reduced compaction, and environmental exposure during material deposition. Using these values ensures that the structural performance is evaluated under conditions that reflect the potential vulnerabilities of the printed element. Mechanical testing of 10 cm diameter cylindrical specimens at 90 days yielded an average compressive strength of 37.8 ± 3.2 MPa. In comparison, printed samples tested under loading perpendicular to the layer direction, showed compressive strengths approximately 80% of the cast specimens. The elastic modulus of the cast specimens was measured at approximately 18.5 GPa, while the modulus of printed samples tested in the same orientation was about 25% of that value.

Building on this foundation, the present study develops a numerical model to understand the mechanical response of a 3D-printed wall. The evaluation was done solely using the model without additional experimental tests on a printed wall. Therefore, the material properties were directly incorporated from the data obtained from the literature. The modeled wall has a uniform thickness of 20 mm, an in-plane length of 3000 mm, and a height of 3000 mm, representing a large-scale, unreinforced concrete panel. The material is treated as isotropic, with a compressive strength of 30 MPa and an elastic modulus of 14,400 MPa, values selected to reflect high-performance printable mortar while supporting simplified modeling. No internal reinforcement is included, allowing the analysis to focus solely on the matrix material response under seismic conditions.

2.2. Numerical modeling of the wall element

The finite element model of a representative 3D-printed wall element is developed using the structural analysis software SAP2000 (Dere, 2012 et. al). The geometry and dimensions of this wall are determined to reflect the use of such walls in actual 3-D printed concrete houses. The wall dimensions are 3 meters in length, 3 meters in height, and 300 mm in depth. The wall also has truss-like segments between the two outer faces, which are intended to enhance the stability and reliability of the wall during the extrusion process. As shown in the finite element model in Fig. 1a, shell elements are used to model all wall parts, including the outer surfaces and the inner truss-like segments. The outer surface shell elements are divided into a mesh size of 30 cm × 30 cm, and inner truss-like elements are connected with the resulting corner nodes of the outer surfaces. The thickness of the shell elements is taken as 2 cm for all surfaces. Each node at the bottom of the wall is pinned to prevent translation in all three directions.



(a) 3-D View of the model (b) Deformed Shape for PO-1 (c) Deformed Shape for PO-2

Fig. 1. Finite element model of the wall element in SAP 2000.

In the numerical model of the wall, nonlinear material behavior is considered to capture the progression of cracking and redistribution of stresses according to the employed material model for the 3-D printed concrete. Therefore, the outer surfaces and inner truss-like segment of the wall are modeled with layered shell elements, and nonlinear material properties are assigned to these elements to account for the inelastic behavior of concrete. The orthogonal surfaces at the edges are modeled using standard thin-shell elements with linear elastic material properties, as inelastic behavior is not expected on these elements due to the lateral direction of the loading acting along the other wall surfaces. Although anisotropic behavior is typically observed in 3-D printed concrete walls for several reasons, including printing layer orientation, the height of the layer in the structural element, isotropic material behavior is accepted for material definitions in the present study.

In a similar approach as presented in this study, Bayrak (2024) used the finite element analysis software ABAQUS to model a 3-D printed concrete wall specimen using six different material models, aiming to capture the effect of the variation of the material properties along the height of the wall. In that study, experiments were conducted to determine the lateral load capacity of several 3D-printed concrete wall specimens, and the results of the finite element model for one of the specimens were compared with the experimental results. As employed in that study, the stress-strain relationship of the 3D-printed concrete material is generated based on the material properties provided in Section 2.1 and is presented in Fig. 2. In this material model, stress-strain relationship as defined in Thorenfeldt et al. 1987 is considered for compression, while a linear relation is assumed up to the tensile strength and the exponential function is used as specified in Dere [2012]. However, to have a computational stability stress-strain relationship given for concrete in SAP 2000 is modified and used for the material model assigned to nonlinear shell elements. This material model is also plotted on the same figure in Fig. 2. A Poisson's ratio of 0.20 is assumed, in line with conventional cementitious materials (Mader et al., 2023; Pan et al., 2023). The unit weight of the material is taken as 22 kN/m^3. No reinforcement is assigned to the model, allowing for a focused evaluation of the unreinforced material.

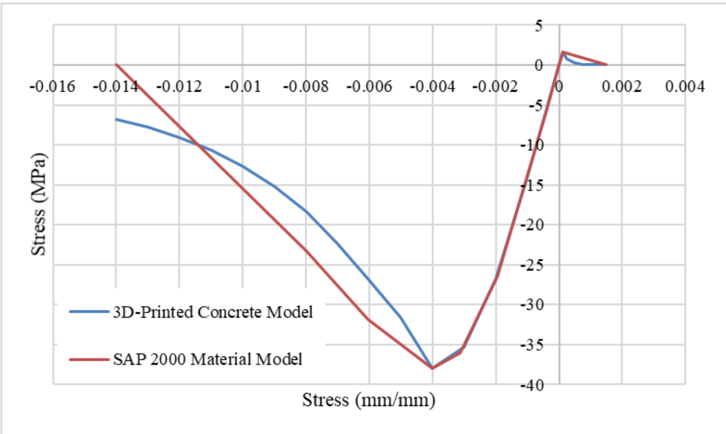


Fig. 2. Material model for the 3D-printed concrete

2.3. Pushover analysis

The main objective in this study is to estimate the in-plane lateral capacity of a full-size 3D-printed concrete wall. For this purpose, a lateral pushover analysis is performed, where increasing levels of lateral load is gradually applied on the master node at the top of the wall, and a displacement-controlled loading strategy is used to push the wall until failure. The resulting top displacement is plotted against the total pushing force (or base shear force) to obtain the lateral capacity curve of the wall. The program automatically terminates the analyses when the failure is achieved due to numerical instability, until the targeted top displacement.

Two pushover analyses are conducted in the present study, based on the boundary conditions assigned at the top of the wall. In the first analysis (PO-1), the master node at the top is constrained to have the same translational displacements. In the second analysis (PO-2), this constraint is extended to include rotational degrees of freedom as well. The deformed shapes of the wall for these two analyses are displayed in Fig. 1b and Fig. 1c.

3. Results and discussions

3.1 Lateral capacity of the wall

Fig. 3 shows the load-displacement curve of the wall resulting from the two pushover analyses, PO-1 and PO-2. The pushover analysis PO-1 is terminated when the target displacement of 20 mm is reached, while the analysis PO-2 automatically stops at around 15 mm before the target displacement when the wall no longer carries loading. The resulting pushover curve from the analysis PO-2 is assessed to be more realistic and compatible with the lateral behavior as would occur under a seismic loading scenario. A lateral force capacity of 1537 kN is obtained from the pushover curve resulting from PO-2.

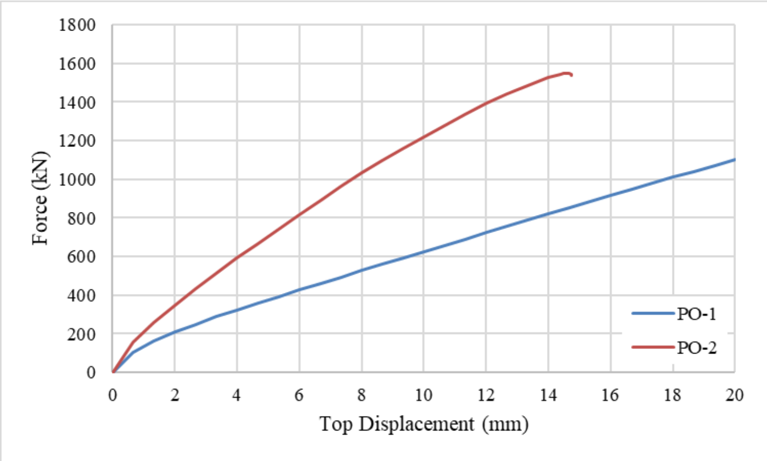

Fig. 3. Pushover curves

3.2 Progression of crack formation

Although no physical crack observation is conducted, crack formation is predicted based on tensile strain concentration and stiffness reduction observed in the analysis outputs. This approach supports the identification of likely failure zones and the overall lateral resistance capacity of the wall under simulated seismic action.

The modeling approach draws conceptually from Bayrak's (2023) work, which employed ABAQUS and a Continuum Damage Plasticity Model (CDPM) to simulate the cyclic behavior of unreinforced 3D-printed concrete walls. The onset of damage and failure was evaluated based on critical tensile strains and overall lateral drift beyond acceptable limits.

4. Conclusions

This study investigates the seismic performance of an unreinforced, cement-based 3D-printed wall element through numerical analysis. Drawing from the material characterization and modelling approach presented in the MSc thesis by Bayrak (2023), the study develops a simplified isotropic model in SAP2000 to simulate the in-plane lateral response of a full-scale wall panel. The wall is modelled without reinforcement and subjected to a nonlinear pushover analysis to evaluate its lateral load-bearing capacity, stiffness degradation, and failure mechanisms under seismic loading.

Using consistent mechanical properties and large-scale geometry, the model provides insight into the structural behaviour of 3D-printed concrete under monotonic lateral displacement. Although the wall is not physically printed or tested, the strain distribution and stress concentrations observed in the simulation enable the prediction of likely crack initiation zones and potential failure modes. These results highlight the vulnerability of unreinforced printed walls to in-plane seismic forces and reinforce the importance of considering interfacial behaviour, material quality, and geometric scaling in future structural assessments of 3D-printed systems.

The outcomes of this study contribute to the growing body of research aimed at understanding how layered cementitious structures respond under seismic demands. While simplified in scope, the findings support the development of performance-based evaluation methods for 3D-printed concrete walls and underline the need for further experimental validation and code development to guide their safe application in structural engineering.

[1] *Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye*

Abstract. Plastic waste, which is consumed in significant amounts today, by using it in building materials such as concrete or mortar stands out as an effective solution as it offers significant advantages both economically and ecologically. In addition, basalt fiber (BF) are generally used in engineering structures in order to minimize the negative effects that may be caused by other factors. In this scope, in this study, some properties of mortars containing basalt fiber and different proportions of plastic waste aggregate (PWA) were investigated exposed to high temperatures. The mixtures were varied according to two basic parameters: plastic PWA replacement ratio by volume (0%, 10% and 20%) and BF addition amount (0%, 0.25% and 0.50%). In the experimental study, 40x40x40 mm and 40x40x160 mm mortar specimens produced. The specimens exposed to 400°C, 600°C and 800°C. Residual compressive strength, flexural strength, mass loss, crack width-image processing relationship analysis tests performed on the specimens. The results showed that the use of PWA decreased both compressive strength and weight loss. In all mixtures, the flexural strength tended to decrease as the plastic aggregate ratio increased, regardless of basalt fiber. BF additive limited strength losses and maintained structural integrity, especially at elevated temperatures. Crack widths reached approximately 0.15 mm at 600°C and increased up to 0.25 mm at 800°C, which caused serious deterioration in the microstructural integrity of the material and accelerated strength loss.

Keywords: Plastic aggregate; Basalt fiber; High temperature; Crack; Image processing

1. Introduction

Nowadays, plastics have been used all over the world for a long time due to their very advantageous properties such as low density, low costs, etc. Plastics are generally used in packaging materials, shopping and garbage bags, toys, industrial and building materials, etc. (PlasticsEurope 2013; Sarma & Bansal, 2016). However, such an increase in plastic consumption leads to a significant amount of plastic waste. In a study, it is stated that approximately 300 million tons of plastic waste is generated annually (Wang et al., 2019). Many different types of plastics are produced every year and the most common types of plastics used are polyester (PET), polyethylene (PE) and polyvinylchloride (PVC). In addition, polycarbonate (PC), high density polyethylene (HDPE), polyvinylchloride (PVC), low density polyethylene/linear low density polyethylene (LDPE/LLDPE), polylactic acid (PLA), polypropylene (PP), polystyrene (PS) and others are used in many fields (Khairul et al., 2022). However, the use of plastic waste as construction material or concrete aggregate (coarse or fine aggregate) is not yet very common. Although there are various applications, the use and adaptation of plastic waste in the construction sector remains limited (da Silva et al., 2021). In this scope, the use and application of plastic waste in the construction industry can be improved due to its promising role in sustainability, environmental contribution and various economies.

Plastic consumption can be processed in 3 different ways such as landfilling, incineration and recycling (Gertsakis & Lewis, 2003). In this context, plastic waste is considered to be disposed of in landfills as a last resort because it takes up too much space and causes environmental problems. Incineration method is adopted in some countries due to the complete elimination of waste. This in particular releases large amounts of carbon dioxide and toxic chemicals. For this reason, recycling is the best solution in terms of reducing environmental impact, natural resource and energy efficiency. The reuse of waste and recycled plastic materials (aggregate or fiber) in the construction industry is considered an ideal method for waste disposal (Gu & Ozbakkaloglu, 2016). Plastic waste is used in mortar or concrete in two different ways. One of these is the substitution of plastic aggregate to replace

[*] Corresponding author, E-mail: safanayir@ktu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_738

normal aggregate (NA). This can be in the form of coarse and fine aggregates or both combinations (used together). The second option is the use of plastic as fiber (Gu & Ozbakkaloglu, 2016). There are many studies in the literature investigating the fresh, hardened and durability properties of plastic material. Kou et al. (2009) reported that concretes prepared using PVC have lower density, more ductile (larger Poisson's ratios and reduced modulus of elasticity) and higher resistance to chloride ion penetration. However, their study revealed that the workability, compressive strength and tensile strength of concretes prepared using PVC decreased. Mohammed et al. (2019), in a study on some properties of concretes containing plastic aggregates, stated that the use of high levels of PVC in concrete reduces the workability of concrete. It is stated that the water absorption and unit weight of concrete do not change significantly when PVC aggregate is replaced with fine aggregate, but this is not the case for high proportions of PVC. Ahmed et al. (2024), in their study on concrete properties using recycled aggregate and recycled plastic fine aggregate, reported that for 40% waste plastic content, the reduction in maximum compressive strength for concretes containing 0% and 10% silica fume was 29% and 28%, respectively. Hamada et al. (2024) conducted a study on the use of plastic waste as aggregate in concrete. In their study, they found that the addition of certain plastic wastes improves the workability of concrete while increasing the unit weight, compressive, flexural and tensile strengths.

Like the environmental benefits that waste plastics will provide, basalt fibers are also an environmentally friendly and sustainable material both during the production phase and after their lifespan. Basalt fibers have many superior properties such as resistance to many chemicals, good performance at high temperatures, low moisture properties (Selçuk et al., 2023). Basalt fibers are used to strengthen structural integrity in mortars. In a study on the effectiveness of basalt fiber on mortar, it was stated that while it had a negative effect on fluidity in the fresh state, it improved the flexural strength, toughness, and ductility of cement matrix composites (Ralegaonkar et al., 2018). In a another study, it is stated that the mechanical properties of mortar and concrete decrease with the increase in plastic waste. It is stated that the reason for this situation can be attributed to its hydrophobic structure, lack of bond between cement paste and plastic waste, and high porous properties (Rathore et al., 2021).

Experimental studies on the fresh, mechanical, durability and dynamic properties and possible crack behaviors of mortars produced using different proportions of waste PVC and basalt fiber contribute to the practical use of these composite materials in civil engineering applications. In this scope, this study include some properties of mortars containing different proportions of PVC aggregate (0%, 10% and 20%) and basalt fiber (%0, 0.25% and 0.50%) exposed to high temperature. The specimens exposed to temperatures of 400°C, 600°C and 800°C. Residual compressive strength, flexural strength, mass loss test performed on the specimens. In addition, the crack width-image processing relationship on the specimens after exposed to high temperature was evaluated.

2. Material and method

2.1. Mortar specimens

In this study, a total of nine different mortar mixtures containing different proportions of plastic waste aggregate (PWA) and basalt fiber (BF) were designed to contribute to the development of eco-friendly, durable and sustainable building materials. The mixtures were varied according to two basic parameters: PWA replacement ratio by volume (0%, 10% and 20%) and basalt fiber addition amount (0%, 0.25% and 0.50%). In this scope, in addition to partial replacement of natural aggregate with PWA in certain proportions, BF reinforcement was used to increase the resistance of the matrix against crack propagation. The amount of cement was kept constant in all mixtures and the water/cement ratio was selected as 0.60. The design of the prepared mixtures are given in Table 1. The expression 10PWA25PW is an example coding that defines a composite mixture prepared with the addition of 10% plastic aggregate and 2.5% basalt fiber.

Table 1. Mixture design

Mixtures	Cement	NA	PWA	BF	Water
0PWA0BF		1350	0	0	
10PWA0BF		1215	71.32	0	
20PWA0BF		1080	142.64	0	
0PWA25BF		1350	0	6.16	
10PWA25BF	450	1215	71.32	6.16	270
20PWA25BF		1080	142.64	6.16	
0PWA50BF		1350	0	12.33	
10PWA50BF		1215	71.32	12.33	
20PWA50BF		1080	142.64	12.33	

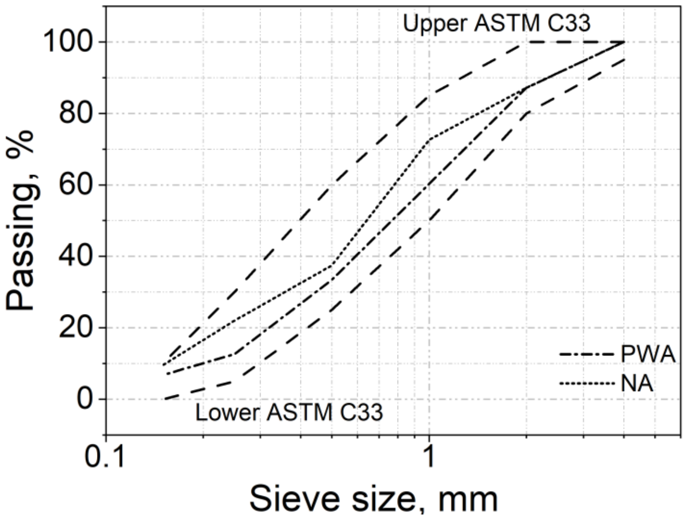

Fig. 1. Aggregate sieve analysis

The cement is CEM I 42.5 R type Portland cement conforming to EN 197-1 standard. Its chemical composition was determined as 18.80% SiO_2, 59.88% CaO, 1.67% MgO, 3.34% Fe_2O_3, 4.53% Al_2O_3 and 3.12% SO_3. The 28-day compressive strength of the cement was determined as 51.40 MPa, specific surface area as 3263 cm^2/g and specific gravity as 3.10 g/cm^3.

The natural sand used as NA was obtained from the stream deposits in Trabzon province and has a silica-based and round-grained structure. PWA was obtained from PVC waste left over from the production process of infrastructure pipes and made ready for use without any additional treatment. The grain distribution of the aggregates given in Fig. 1 was made in accordance with ASTM C33 (2023) standard.

The BF added to the blends has a length of 12 mm and a diameter range of 9-23 µm. The tensile strength of the fibers is 4840 MPa and the modulus of elasticity is 89 GPa. A special surface modification was applied on the fiber surface to improve adherence with the matrix. A polycarboxylate-based, highly effective superplasticizer (Sika® ViscoCrete® ACE 450) was used to maintain workability properties and achieve homogeneous mixing.

2.2. Test procedures

For each of the nine different mortar mixtures, 40×40×40 mm cube specimens were produced. After casting, the specimens were kept in their molds for 24 hours, then removed from the mold, placed in a water curing tank and kept in water curing for 28 days.

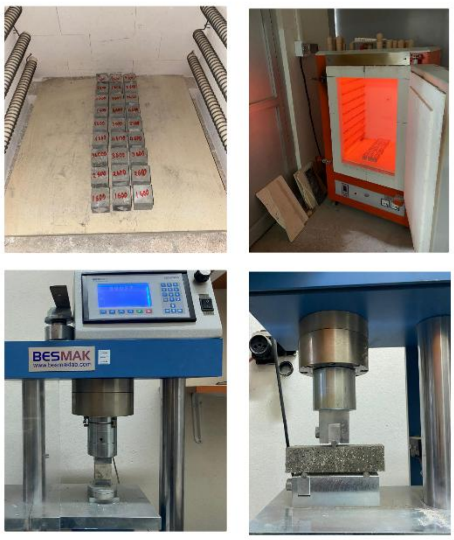

Fig. 2. Samples exposed to high temperatures, determination of compressive and flexural strengths of samples

In order to examine the strength properties, the specimens were exposed to high temperature levels after the cur ng period was completed. For this purpose, the specimens were subjected to temperatures of 400°C, 600°C and 800°C. For each temperature, the furnace temperature was increased at a rate of 2.5°C/minute to reach the desired peak temperature and kept at this temperature for 60 minutes. After completion of the heat treatment process, the specimens were allowed to cool at room temperature and then subjected to mechanical tests. The compressive strength tests were carried out in accordance with EN 1015-11 (2019) so that the residual strength properties of the different blends after high temperature were evaluated in a systematic way. Images of the experimental study are presented in Fig. 2.The total time for heat treatment and testing was approximately 220, 300 and 380 minutes for temperatures of 400°C, 600°C and 800°C, respectively.

3. Result and disccussion

Fig. 3 shows the 28-day compressive strength results. 0PWA0BF showed the highest strength with 41.56 MPa. The 10PWA0BF and 20PWA0BF mixtures showed a 17.9% and 26.3% decrease compared to 0PWA0BF with strength values of 34.10 MPa and 30.62 MPa, respectively. The 0PWA25BF mixture showed a strength of 37.02 MPa, 10.9% lower than 0PWA0BF, indicating the limited curative effect of BF alone. However, this effect was further reduced as the PWA ratio increased with BF admixture; 10PWA25BF showed a 17.4% decrease compared to the reference at 34.35 MPa and 20PWA25BF suffered a significant loss of 50.9% at 20.42 MPa. Similarly, the 0PWA50BF mix provided a strength of 40.89 MPa, very close to that of 0PWA0BF (1.6% decrease), but the 10PWA50BF and 20PWA50BF mixes lost 23.1% and 52.9% respectively, indicating that BF is not highly effective when used in combination with PWA. The main reason for the decrease in strength is the low workability and hollow structure caused by the combination of PWA and BF (Siddique et al., 2008; Safi et al., 2013; Ralegaonkar et al., 2018; John & Dharmar, 2021).

28-day flexural strength results are shown in Fig. 4. 0PWA0BF showed a flexural strength of 5.58 MPa. The 10PWA0BF mix with an increase in PWA ratio to 10% showed slightly increased compared to the 0PWA0BF with 6.83 MPa. However, when the PWA ratio was increased to 20% (20PWA0BF), the flexural strength decreased to 6.61 MPa. The strength rates for these three mixtures are quite close to each other and can be considered to remain at the same level. In addition, the 0PWA25BF mix containing only BF admixture presented a flexural strength of 7.23 MPa, 29.6% higher than the reference, demonstrating the improving effect of BF on this property. The 10PWA25BF mixture showed a similarly strong performance with 7.05 MPa. However, in the 20PWA25BF mix, the strength decreased to 5.80 MPa with a limited increase of only 3.9%, indicating that the effectiveness of BF admixture decreases at higher PWA levels. The highest flexural strength of 7.77 MPa was obtained in the 0PWA50BF mix; this mix showed an improvement of about 39.3% compared to the reference. However, the value decreased to 7.03 MPa in the 10PWA50BF mix, while 20PWA50BF was even lower than 0PWA0BF with 5.13 MPa.

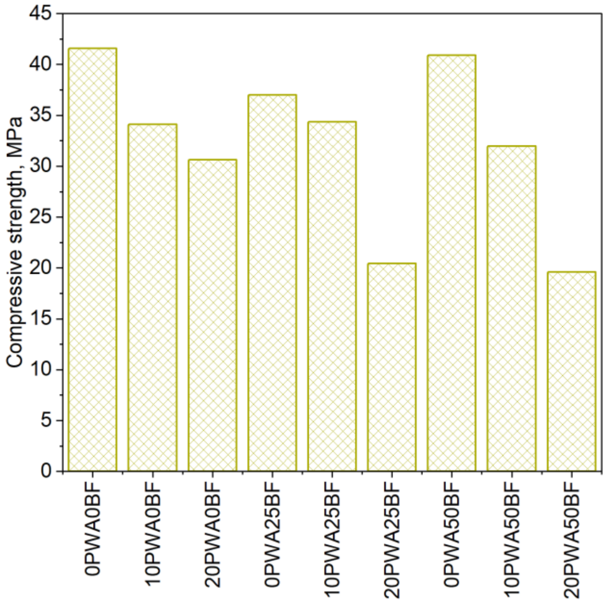

Fig. 3. Compressive strength results

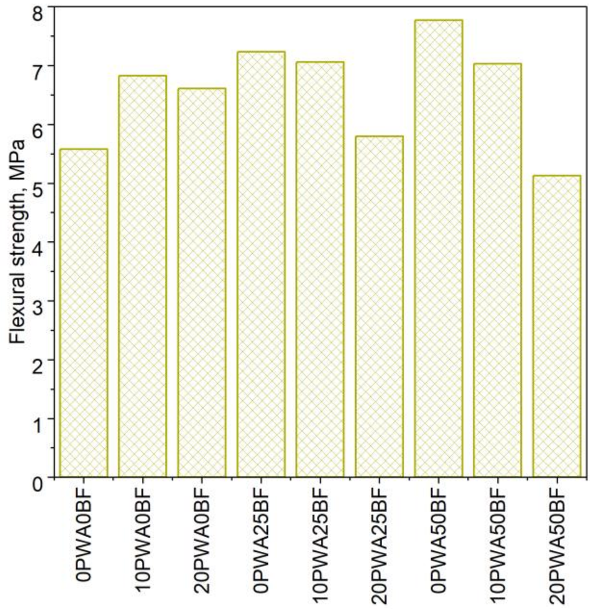

Fig. 4. Flexural strength results

The effect of elevated temperatures on the mechanical properties of concrete mixtures leads to significant changes, especially in terms of compressive strength. Compressive strengths of mortars exposed to 400°, 600°C and 800°C are presented in Fig. 5. The 0PWA0BF mix experiences a significant loss of strength with increasing temperature, with compressive strength values of 19.21 MPa at 400°C, 16.06 MPa at 600°C and 7.84 MPa at 800°C. This decrease indicates that the overall strength of concrete against thermal effects decreases and that heat impairs structural integrity, especially by weakening the chemical interaction between the binder and aggregate (Ma et al., 2015; Bao et al., 2023). Similarly, it is also observed in the mixtures 10PWA0BF and 20PWA0BF. In particular, the 20PWA0BF mix showed a strength of only 0.5 MPa at 800°C, indicating that the high PWA content has adverse effects on the mechanical properties of concrete at elevated temperatures.

This result supported that the use of PWA in structural concrete mixtures is limited in terms of structural performance under elevated temperatures. On the other hand, BF admixture has significant potential to improve the mechanical strength of concrete, especially exposed high temperature conditions. The 0PWA25BF mix exhibits a strength of 21.88 MPa at 400°C, showing a significant increase compared to the reference mix. However,

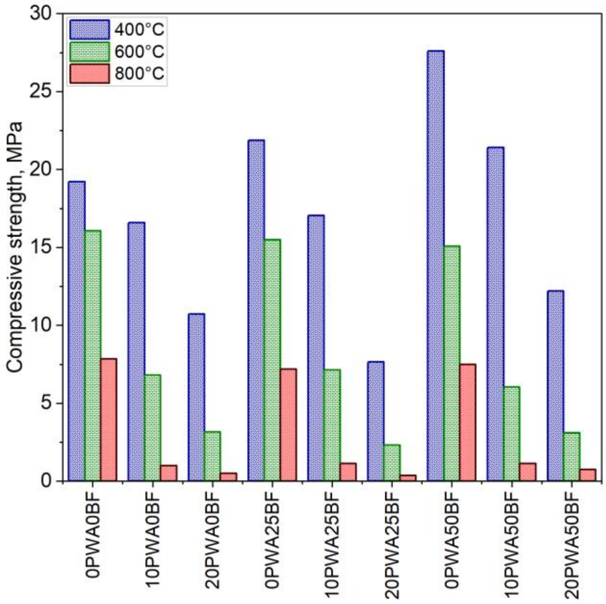

Fig. 5. Compressive strength results for 400°C, 600°C and 800°C

Similarly, the 10PWA25BF mix exhibited a lower strength compared to 0PWA25BF, showing a value of 17.04 MPa at 400°C and weakened more at higher temperatures. This indicated that BF provided a limited ameliorative effect on thermal strength, but this effect decreased when the PWA ratio increased. The 0PWA50BF mix desing exhibited the highest strength among all the blends with 27.60 MPa at 400°C, indicating that the BF additive greatly improved the high temperature strength. Although a decrease to 15.06 MPa and 7.50 MPa was observed at 600°C and 800°C, respectively, this mix design still exhibited a stronger performance at elevated temperatures than the other mixtures. The 10PWA50BF and 20PWA50BF blends showed a noticeable loss of strength at 800°C with strength values of 1.13 MPa and 0.75 MPa, respectively.

Fig. 6 shows the weight loss percentages of the mixtures at 400°C, 600°C and 800°C. The 0PWA0BF mixture showed weight loss of 2.93%, 3.85% and 6.30% respectively. The weight losses at 400°C, 600°C and 800°C for the 10PWA0BF mixture were 3.56%, 4.81% and 10.33%, respectively, indicating that the use of PWA increased the weight loss especially at higher temperatures. In the 20PWA0BF mixture, higher losses were observed at 4.67%, 6.80% and 11.12%, indicating that increasing the PWA content significantly increases the weight loss trend. The 0PWA25BF mixture containing only BF additive showed 3.09%, 3.68% and 6.44% weight loss, which were close to the reference. In the 10PWA25BF mixture, 3.63%, 5.09% and 8.54% weight loss were measured, where it was determined that the low PWA additive weakened the weight loss reducing effect of BF to a limited extent. The 20PWA25BF mixture showed weight losses of 4.45%, 6.46% and 10.27%, indicating that the high PWA ratio increased the weight loss despite the addition of BF. The 0PWA50BF mixture exhibited one of the lowest values with 2.79%, 3.46% and 6.18% weight loss, indicating that the use of high BF content can improve thermal stability. However, the weight losses increased to 4.83%, 5.18% and 7.51% in the 10PWA50BF mixture, while these values were 5.42%, 6.03% and 12.33% in the 20PWA50BF mixture. Especially at 800°C, the 12.33% loss in the 20PWA50BF mixture was the highest weight reduction among all mixtures.

When the images of the 0PWA0BF specimen are examined, it is seen that there is a significant deterioration in the microstructure of the material with increasing temperature. At 22°C, the surface has a very compact and homogeneous structure. When 400°C was reached, porosity on the surface increased, but crack formation was still limited and crack widths were small in the range of 0.02-0.03 mm; this temperature level indicates that the mechanical integrity of the sample was largely preserved. At 600°C, due to the complete evaporation of free water and the effect of calcium hydroxide degradation, wider and more widespread cracks were formed, with crack widths reaching up to 0.15 mm, indicating a decrease in structural strength. At 800°C, on the other hand, the crack network intensified significantly, the crack widths increased to 0.25 mm and the surface was completely decomposed, turning the specimen into a highly porous, brittle and weak structure, clearly indicating that the binder phases (especially the C-S-H gel) were severely degraded and the bearing capacity of the concrete was largely lost (Rao & Tadepalli, 2024; Tanash et al., 2024).

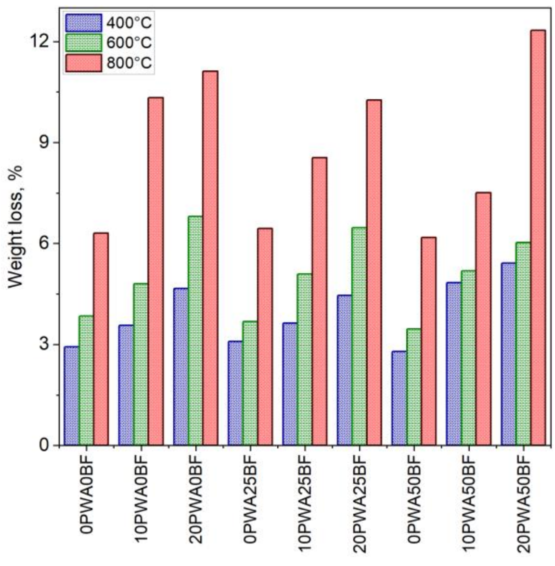

Fig. 6. Weight losses for 400°C, 600°C and 800°C

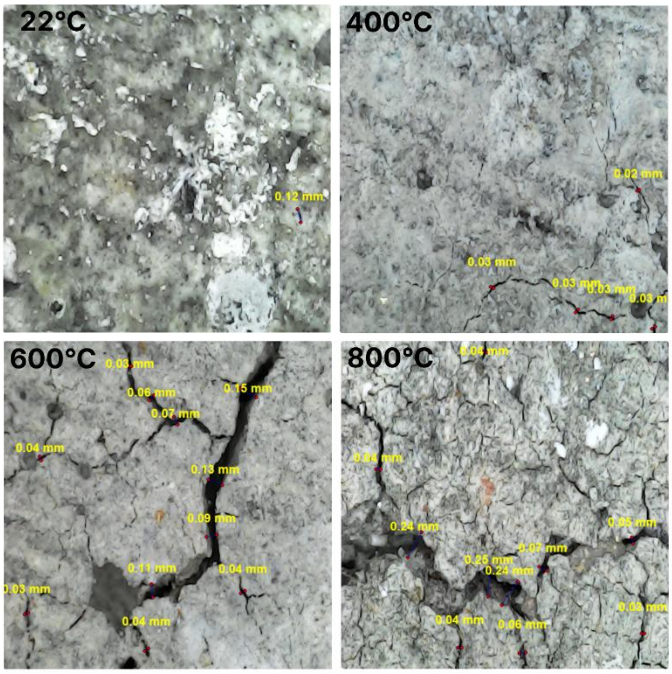

Fig. 7. Crack width and distribution relationship in mortar exposed to high temperature

4. Conclusions

In this study, the effects of PWA and BF admixtures on the mechanical and elevated temperature performance of mortars were investigated. The results showed that the use of PWA at low ratios increased the flexural strength, but at high ratios it had negative effects on both compressive strength and weight loss. BF additive limited strength losses and maintained structural integrity, especially at elevated temperatures. Significant strength losses were observed in all mixtures at high temperature exposure. The important results obtained from the study are given below:

- In the 20PWA0BF mixture, the addition of 20% PWA resulted in a 26% decrease in compressive strength and the strength decreased to 30.62 MPa.
- The 0PWA50BF mixture exhibited the highest flexural strength. In all mixtures, the flexural strength tended to decrease as the plastic aggregate ratio increased, regardless of basalt fiber.
- The 0PWA50BF mixture exhibited the highest temperature resistance among all mixtures, showing a compressive strength of 27.6 MPa after 400°C.
- In the 20PWA50BF mix design, 12.3% weight loss occurred after 800°C temperature exposure, and the negative effect of PWA content on the high temperature effect became evident.
- Crack widths reached approximately 0.15 mm at 600°C and increased up to 0.25 mm at 800°C, which caused serious deterioration in the microstructural integrity of the material and accelerated strength loss.

In line with the results of this study, it is recommended that the use of plastic waste aggregate be evaluated comparatively with different types of fibers (e.g. polypropylene, polyethylene, etc.) in future research. In addition, examining the effects of different fiber types such as steel, polypropylene and carbon fiber, not only basalt fiber, will contribute to a more comprehensive understanding of fiber-matrix interactions. In particular, a detailed investigation of the effects of fiber length, amount and distribution on elevated temperature performance offers an important field of study. In addition, it is thought that systems modified with nano-silica or different mineral additives can be improved in terms of both mechanical strength and thermal stability.

Effects of different types of fibers on the mechanical properties and shrinkage of one-part sodium carbonate-activated slag-based mortars

Busra Akturk*[1]

[1] *Istanbul Bilgi University, Department of Civil Engineering, Istanbul, Türkiye.*

Abstract. Alkali-activated materials present a sustainable and efficient alternative to traditional cement-based systems by incorporating industrial by-products such as slag, fly ash, and metakaolin as precursors. This innovation significantly reduces CO_2 emissions compared to conventional cement production, which contributes approximately 8% of global CO_2 emissions. This study examines the mechanical properties and shrinkage behavior of sodium carbonate-activated, fiber-reinforced mortars made with ground-granulated blast furnace slag. The one-part mixing method was selected for its ease of use and compatibility with conventional cement production practices. Steel, polypropylene, and hybrid fibers (a combination of steel and polypropylene) were incorporated at 1% by volume in the mortar mixes. Mechanical properties, including compressive strength at 7 and 28 days and flexural strength at 28 days, were assessed on mortar specimens. A three-point bending test was performed on beam samples. The results demonstrated that steel fibers significantly improved the flexural strength of the mortars, while polypropylene fibers were more effective in reducing shrinkage. The hybrid fiber combination exhibited a balanced performance, leveraging the strengths of both fiber types.

Keywords: Alkali-activated materials; sodium carbonate; slag; fibers; mechanical properties.

1. Introduction

Ordinary Portland Cement (OPC) remains the most widely used binder in construction engineering. However, its production is associated with significant environmental concerns, including high carbon dioxide emissions and substantial energy consumption. In response, researchers have been actively exploring sustainable alternatives that offer lower environmental impact and energy demands. Among these, alkali-activated materials (AAMs) have emerged as promising cementitious binders. These materials have gained attention primarily due to their reduced CO_2 emissions, improved mechanical performance, and superior durability compared to OPC (Komljenović et al., 2013; Zhang et al., 2017; Mithun & Narasimhan, 2016; Bilim & Atis, 2012).

The environmental advantages of AAMs are notable: their production can cut CO_2 emissions by 25–50% and reduce energy consumption by over 40% relative to OPC (Thomas et al., 2016; Jiang et al., 2014a). Moreover, most AAMs are derived from industrial by-products, such as blast furnace slag and fly ash, promoting waste valorization and resource conservation. As a result, AAMs are increasingly viewed as eco-friendly alternatives to conventional cement. Among AAMs, alkali-activated slag (AAS) stands out as a particularly viable candidate. However, its broader application in the construction industry has been limited due to challenges such as excessive drying shrinkage and the development of microcracks, which can negatively affect long-term durability and structural integrity (Neto et al., 20008). Research by Shen et al. (2011) demonstrated that the drying shrinkage of AAS mortars could be up to three times higher than that of OPC mortars. Similarly, Atiş et al. (2009) reported that the drying shrinkage of AAS mortars activated with sodium hydroxide and sodium carbonate solutions could be three to six times greater than OPC counterparts after six months. To mitigate these shrinkage-related issues, the incorporation of fibers has been proposed as an effective strategy. Studies have shown that adding fibers not only reduces drying shrinkage but can also enhance the mechanical performance of AAS-based materials (Aydn & Baradan, 2013; Xu et al., 2021). Fiber-reinforced alkali-activated slag composites are gaining attention for their unique properties, including high deformation capacity, self-healing capability, and environmental benefits (Nguyễn et al., 2018).

Fibers are known to improve various mechanical properties of cementitious composites, such as tensile strength, fracture toughness, abrasion resistance, and ductility (Arslan, 2016; Kizilkanat et al., 2015). When used

*Corresponding author, E-mail: busra.akturk@bilgi.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_803

in AAS systems, fibers contribute to the material's ductility by enhancing its deformation tolerance and controlling the development and propagation of cracks (Jiang et al., 2014b; Shaikh, 2013; Tassew & Lubell, 2014). This crack-bridging capability helps transform inherently brittle matrices into more resilient and damage-tolerant composites. Several experimental studies confirm that fiber reinforcement is a viable method for improving both the mechanical and shrinkage properties of alkali-activated mortars and concretes. For instance, Akturk (2023) investigated the fracture behavior of fiber-reinforced AAS mortars containing basalt and hybrid fibers, reporting that while compressive strength slightly decreased, flexural strength and fracture energy improved significantly.

The present study focuses on evaluating the effects of different fiber types on the mechanical performance and drying shrinkage behavior of one-part sodium carbonate-activated slag-based mortars. Experimental tests including flow diameter, compressive and flexural strength, and drying shrinkage were conducted, with the results discussed in the subsequent sections.

2. Experimental study

2.1 Materials

Slag was used as the binding material in this study, obtained from the KARDEMIR Iron and Steel Plant. The chemical composition of slag was determined by *X-ray fluorescence* analyses and presented in Table 1. The median particle size (d_{50}) of slag was found to be 8.8 µm.

Table 1. Chemical composition of slag

Chemical composition (% by weight)	Slag
SiO_2	39.0
Al_2O_3	12.4
Fe_2O_3	1.2
CaO	33.7
MgO	7.5
K_2O	0.6
TiO_2	0.9
Loss of ignition (%)	0.4
Specific surface area (cm^2/g)	4670
Relative grain density	2.88

To explore the effects of different types of fibers, polypropylene (PP) and straight steel fiber (ST) (Fig. 1) on the mechanical properties of one-part NC-activated slag-based mixes, they were used in the mortar mixes with a volume fraction of 1%. The properties of fibers are given in Table 2. Their preferred lengths were 12 mm and 13 mm for PP and ST, respectively.

Table 2. Properties of fibers

Fiber type	Length [mm]	Diameter [µm]	Aspect ratio	Tensile strength [MPa]	Specific gravity
Polypropylene	12	30–40	300–400	570–660	0.91
Steel	13	150	87	3000	7.85

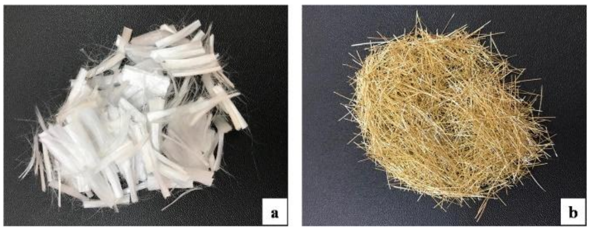

Fig. 1. Images of (a) polypropylene and (b) steel fibers

2.2 Mix design of one-part NC-activated slag-based mixes

A total of four mixes were prepared in this study. Reference is the plain mix, which does not contain any fiber, PP is the polypropylene fiber-reinforced mix, ST is the steel fiber reinforced mix and HYB contains both PP and ST at the same amount, each 0.5% by volume. The mixes are named according to the type of fiber used. Solid sodium carbonate (NC) serves as the alkaline activator in all formulations, maintained at 10% of the binder weight. The water/binder ratio was consistently set at 0.40 for mortar mixes. Silica-based fine aggregate with a maximum particle size of 2 mm was incorporated at a volume ratio of 50%. The fine aggregate gradation adhered to the standards outlined in the CEN standard sand.

Table 3. Mixing ratios of mortar mixes

Mix	Slag (%)	Water/binder ratio	Fiber [% by volume]	
			PP	ST
Reference	100	0.4	-	-
PP			1	-
ST			-	1
HYB			0.5	0.5

2.3 Testing methods

2.3.1 Flow diameter

The flow diameter of fresh mortar specimens was assessed per ASTM C1437, utilizing a mini-slump cone with standard dimensions: 70 mm upper diameter, 100 mm lower diameter, and 60 mm height. This test was conducted immediately following the mixing process. The base diameter of the sample, as distributed on the flow table, serves as an indicator of workability. Two perpendicular readings are recorded, and the final flow amount of the mortar samples is determined by calculating the average value of these readings.

2.3.2 Mechanical properties

The compressive strength test was performed on mortar samples according to the ASTM C109. The mortar specimens were produced as cubic samples of 50×50×50 mm dimensions and cured in a humidity cabinet maintained at (23±2) °C and ~65% relative humidity until the testing days. The specimens were tested on the 7th and 28th days and the corresponding strength values were recorded for each respective day.

The flexural strength and fracture properties of beam specimens were investigated via three-point bending tests conducted according to ASTM C293 - *Standard Test Method for Flexural Strength of Concrete (Using Simple Beam with Center-Point Loading)*. The tests were performed on the mortar samples on 28 days of curing. Rectangular beams with dimensions of 160 mm (length) × 40 mm (depth) × 40 mm (width) were used. Before a test, the dimensions of the beam sample were recorded, and the flexural strength was calculated by Equation (1).

$$f = \frac{3PS}{2b(d-a_0)^2} \tag{1}$$

where P is the maximum load, S [mm] is the span length, and b and d [mm] are the width and depth, and a_0 [mm] is the depth of pre-cutting crack of the sample, respectively.

2.3.3 Shrinkage

Shrinkage measurement was measured on mortar prisms with dimensions of 40×40×160 mm. Three identical prisms were used for each mix. All samples were kept at 23±2 C and relative humidity of 65±5%. The length change measurements were taken up to 28 days.

3. Results and discussions

3.1 Flow diameter

The flow diameters of the plain and fiber-reinforced mortar mixes are presented in Fig. 2. The reference mix exhibited the highest flow diameter at 170 mm. Fiber incorporation led to a reduction in flowability. While the steel fiber-reinforced mix (ST) showed a slight decrease to 160 mm, both the polypropylene (PP) and hybrid (HYB) mixes recorded a more pronounced reduction, with flow diameters of 140 mm. The decreased flowability in the PP and HYB mixes can be attributed to several factors. First, the addition of polypropylene fibers increases interparticle friction between sand and paste, as reported by Altalabani et al. (2020). Second, the potential formation of fiber clumps or balls disrupts uniform flow, further hindering workability, as noted by Mardani-Aghabaglou et al. (2018). Akturk (2023) also observed a reduction in flowability when incorporating basalt and polypropylene fibers into slag/basalt powder-based alkali-activated materials. The reduction was attributed to the hydrophilic nature of polypropylene fibers, which tend to wind around aggregates and trap paste, thereby impeding free movement and reducing flow diameter.

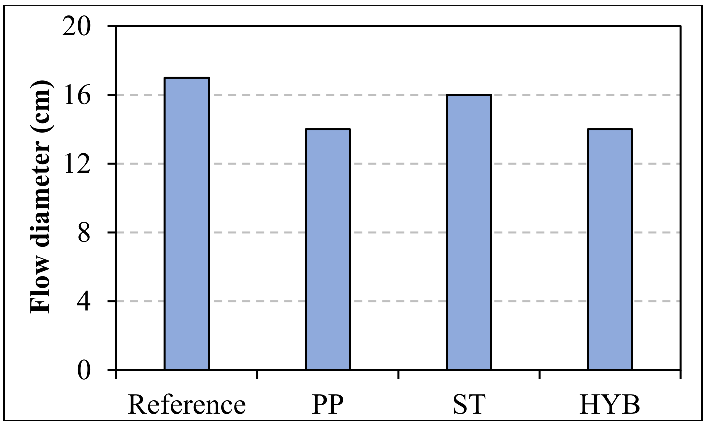

Fig. 2. Flow diameter results of the mixes

2.2 Mechanical properties

The compressive strengths of both plain and fiber-reinforced mixes were measured at 7 and 28 days, as presented in Fig. 3. At 7 days, the reference mix reached a strength of 7.0 MPa, while the addition of polypropylene (PP) fibers led to a slight increase to 7.6 MPa. The steel fiber-reinforced mix (ST) exhibited the highest strength at this age, achieving 7.9 MPa, followed by the hybrid mix (HYB) with 7.7 MPa. The notable improvement in the ST mix can be attributed to the superior mechanical properties of steel fibers, as detailed in Table 2. At 28 days, a significant increase in compressive strength was observed across all mixes, with the same trend continuing. The ST mix again showed the highest strength at 19.5 MPa, while the reference mix reached 16.3 MPa. The inclusion of either PP or ST fibers caused a slight increase in the compressive strength might be due to the delayed formation of the initial crack in the paste phase (Hilles & Ziara, 2019; Dawood & Ramli, 2011).

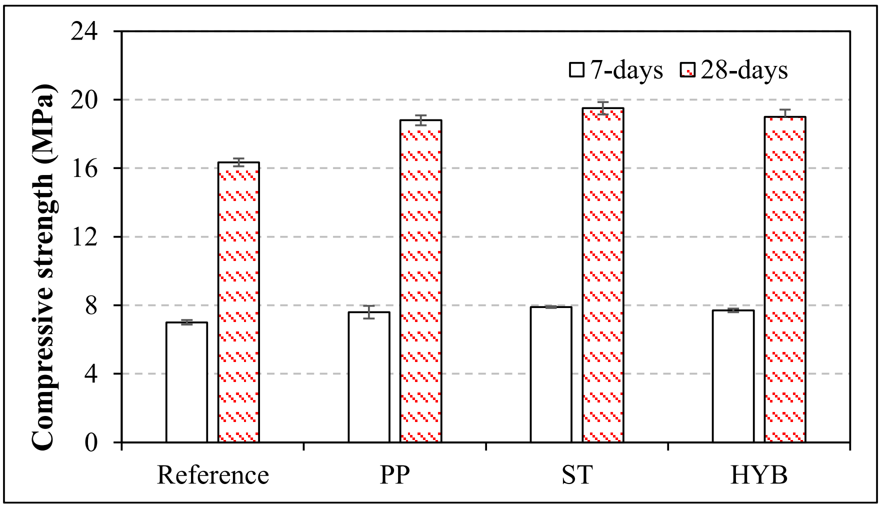

Fig. 3. Compressive strength results of the mixes

The influence of fiber incorporation on the flexural strength of mortars is illustrated in Fig. 4. As expected, the inclusion of fibers enhanced the flexural strength of all mixes. The Reference mix exhibited the lowest strength at 1.6 MPa, while the steel fiber-reinforced mix (ST) achieved the highest value of 2.3 MPa. The addition of polypropylene (PP) and hybrid (HYB) fibers also led to slight improvements in flexural strength compared to the reference mix. Specifically, the flexural strength increased by 13% with PP fibers, and by 44% and 25% for the ST and HYB mixes, respectively. The more pronounced enhancement in the ST mix can be attributed to the superior mechanical properties and bridging capability of steel fibers.

Similar improvements in flexural strength due to fiber reinforcement have been reported in the literature. Akturk et al. (2020) found that both steel and polypropylene fibers enhanced the flexural strength of sodium carbonate-activated slag mortars. Zhou et al. (2021) observed a gradual increase in flexural and splitting tensile strengths with increasing basalt fiber content. Similarly, Abdollahnejad et al. (2021) reported that various fiber types increased the flexural strength of alkali-activated slag mortars, although compressive strength varied depending on fiber type. In contrast, other studies have reported adverse effects of polypropylene fibers on flexural strength. Puertas et al. (2003) and Ranjbar et al. (2016) found that PP fibers reduced the flexural strength of alkali-activated slag mortars. This discrepancy may be attributed to casting and compaction challenges during mixing, leading to poor fiber dispersion and weak fiber–matrix bonding. Wang et al. (2012) noted that inadequate fiber dispersion during fresh-state processing can compromise the interfacial bond and overall mechanical performance.

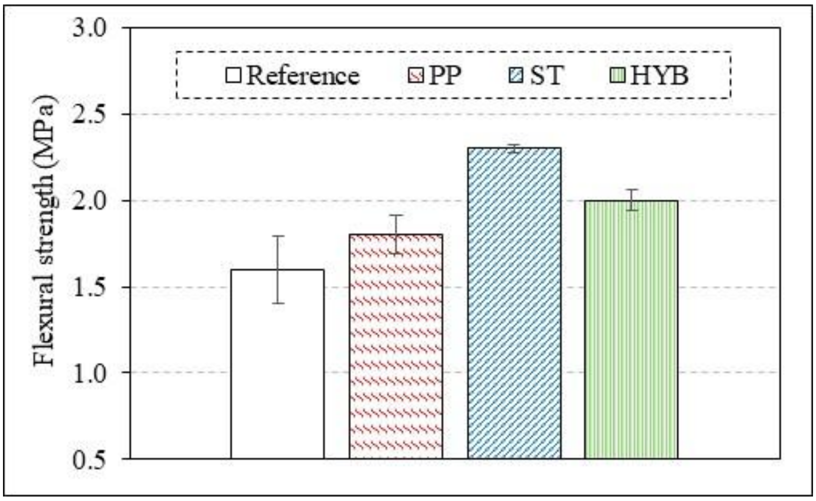

Fig. 4. Flexural strength results of the mixes

3.3 Shrinkage
Time-dependent drying shrinkage values of both plain and fiber-reinforced mixes were measured up to 35 days, as shown in Fig. 5. Among all mixes, the reference mix exhibited the highest shrinkage, whereas the polypropylene fiber-reinforced mix (PP) showed the lowest. For most mixes, the shrinkage rate was relatively high during the early ages, particularly up to 14 days, and tended to stabilize thereafter. The hybrid (HYB) and steel fiber-reinforced (ST) mixes exhibited similar shrinkage behavior at all ages. The PP mix recorded 52% and 46% lower ultimate shrinkage compared to the Reference and ST/HYB mixes, respectively. The superior shrinkage performance of the PP mix can be attributed to its ability to reduce bleeding, promote more uniform internal moisture distribution, and enhance the cohesiveness of the mortar matrix.

Xu et al. (2021) reported that increasing both the length and dosage of polypropylene fibers significantly decreased the drying shrinkage of NaOH-activated slag mortars. Similarly, Vilaplana et al. (2016) found that carbon fibers effectively inhibited drying shrinkage in alkali-activated slag pastes while also enhancing flexural strength.

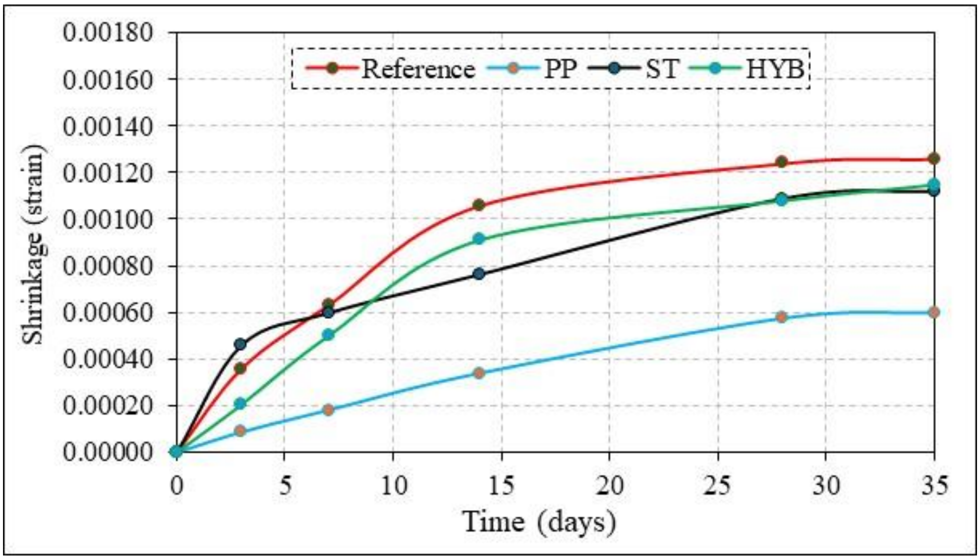

Fig. 5. Shrinkage results of the mixes

4. Conclusion

This study investigates the effects of different fiber types—polypropylene, steel, and hybrid—on the performance of one-part sodium carbonate-activated slag-based mortar mixes. The flow diameter, compressive strength, flexural strength, and drying shrinkage of the mixes were experimentally evaluated.

The key findings derived from the experimental results are summarized as follows:

- The incorporation of fibers reduced the flow diameter of the mixes, with the most significant reduction observed in polypropylene fiber-reinforced mortars. This reduction is primarily attributed to increased interparticle friction and the tendency of polypropylene fibers to form clumps, which hinder fresh-state workability.
- While compressive strength showed a slight improvement with fiber addition, a notable enhancement in flexural strength was achieved through steel fiber reinforcement. The superior performance of steel fibers is mainly due to their higher tensile strength and stiffness, which effectively bridge cracks and resist tensile stresses.
- Polypropylene fiber reinforcement significantly reduced drying shrinkage. This effect is attributed to the fibers' ability to reduce bleeding, promote a more uniform internal moisture distribution, and increase the cohesiveness of the fresh mix. In contrast, steel and hybrid fibers had a negligible effect on shrinkage mitigation.

Abstract. Soil-based composites are gaining more and more attention as sustainable and environmentally friendly alternatives in the construction industry. These materials are characterized by their natural properties, low carbon footprint, and recyclable nature. However, one of the significant limitations of soil-based mixtures is the shrinkage and resulting cracks that occur during the drying process. This study aims to design soil-based composite blends containing clay, lime, alpha gypsum, cellulose, and alginate to reduce the shrinkage problem and increase the utilization potential of soil-based materials. Alginate is a natural polymer and binder that is easily soluble in water and improves the material's workability. Due to these properties, the study aims to increase the stability of the material and reduce shrinkage by using alginate. The study investigated fresh mortar properties and mass losses of mixtures with different compositions, and flexural and compressive strength tests were also performed. The optimum alginate ratio was determined, and material performance characteristics were analyzed based on the data obtained. This innovative approach offers important contributions to improving the mechanical performance of soil-based materials.

Keywords: Alginate; Cellulose; Soil-based materials

1. Introduction

Today, in line with the sustainability goals in the building sector, there is an increasing interest in environmentally friendly materials with low carbon footprint. Sustainability has become an inevitable requirement for the building sector to fulfill its environmental responsibilities (Maierdan et al., 2024). In this context, soil-based building materials developed with natural raw materials stand out with advantages such as production based on local resources, low energy requirement, recyclability and biological compatibility. However, soil-based building materials undergo volumetric shrinkage due to moisture loss during the drying process (Emiroğlu et al., 2015). This causes crack formation and thus structural problems (Assunção et al., 2025). These cracks are a common and important problem for structures' long-term durability and integrity. Recently, significant efforts have been made to improve the low mechanical properties and increase structural stability in soil-based systems. Biopolymer additives such as sodium alginate derived from brown marine algae are used in these studies (Maierdan et al., 2024).

In this study, clay, alpha gypsum and lime were used as binders to produce soil-based composites. In addition, cellulose (Yin et al., 2023) (Patural et al., 2011) and sodium alginate were added to improve workability and stabilize the drying process. The fibrous structure of cellulose increases water-holding capacity and crack resistance, while alginate, as a natural polymer, increases viscosity and limits cracking by reducing drying-induced stresses. Clay formed the base matrix with its high plasticity and binding properties. Alpha gypsum was used to contribute to early setting time (Wang et al., 2023). In addition, lime is an effective stabilizer for earth structures and is particularly well adapted to soils with high clay content. It is also considered an environmentally sustainable material due to its capacity to absorb atmospheric carbon dioxide (Arto et al., 2024).

This study aims to contribute to developing new-generation building materials made of natural materials that are environmentally friendly and resistant to cracking. In this context, four different mixtures were prepared. In all mixtures, the proportions of clay, alpha gypsum, lime, and cellulose were kept constant in grams; only the amount of alginate was changed, and the effect of the alginate substitution rate on the mixture performance was examined. The reference mix represents the control group without alginate. In addition, sodium alginate was preferred at the critical ratios of 0.6%, 0.8%, and 1%, as determined by Maierdan et al. (2024). Within the scope of the study, fresh

https://doi.org/10.31462/icearc2025_ce_mat_810

mortar properties (consistency, workability) and mass loss changes of the mixtures were investigated. In addition, compressive strength and flexural strength tests were performed on the specimens after 7 days. Based on the findings, the effect of alginate admixture on mix stability was evaluated, and the optimum replacement ratio was determined for this study.

2. Material and method

Clay (0-1 mm fineness), silica sand (AFS 30-35), alpha gypsum (0.01-0.08 mm fineness), lime, FBR 500 cellulose (Fiber Kimya), and sodium alginate (ZAG Kimya) for consistency stabilization were used as powder materials to form composite samples with alginate content.

Within the study's scope, four different mortar mixtures were prepared, each with different sodium alginate content. The first mixture was organized as the control group (R) and did not contain an alginate additive. Mixtures A (0.6), A (0.8), and A (1) contained 0.6%, 0.8%, and 1.0% sodium alginate, respectively (Table 1). The indicated alginate ratios were calculated as percentages based on the amount of water used. All materials were first mixed dry for 2 minutes. Then, water and alginate were gradually added to the mixture by mixing it with a mixer for 1 minute, and a homogeneous mortar was obtained. A spreading table test was performed for each mixture in the fresh state, and the workability of the mixture was evaluated by measuring the spreading diameter. In addition, in order to determine the consistency properties of the mixtures in more detail, the number of strokes was determined using the Casagrande apparatus. These two experiments were carried out to determine how fluid and prone the mixtures were to deformation in the fresh state. Each of the mixtures was poured into molds with dimensions of 40 × 40 × 40 × 160 mm, and three specimens were produced for each mixture. The mass losses of the demolded specimens were measured for 7 days. The soil-based composite specimens were subjected to compressive and flexural strength (TS EN 196-1) tests after 7 days.

Table 1. Mixing ratios of the produced samples.

Materials	R	A (0.6)	A (0.8)	A (1)
Clay	35.71%	35.74%	35.71%	35.69%
Silica Sand	35.71%	35.74%	35.71%	35.69%
Alpha Gypsum	3.57%	3.64%	3.57%	3.57%
Lime	3.57%	3.64%	3.57%	3.57%
Water	21.25%	21.26%	21.18%	21.14%
Cellulose	0.18%	0.18%	0.18%	0.18%
Sodium Alginate	0%	0.12%	0.17%	0.21%

3. Results and discussion

3.1. Fresh mortar properties

The reference mortar (R) was generally observed to be a liquid mixture with a spread plate of 14 cm. Mortar A (0.6) was more viscous and stable than the reference mortar. The consistency of the mortar was observed to be similar to kinetic sand. At this point, the diameter of the spreading table decreased. It was noted that the consistency and behavior of mortar A (0.8) was similar to that of mortar A (0.6) (Figure 1). Also, the spreading table and Casagrande test showed the same values. Finally, mortar A (1) had a much more solid consistency than the others. It was recorded as the mixture with the smallest spreading table diameter (Table 2).

When Table 2 is analyzed, as expected, the Casagrande numbers of the series with higher spreading diameters decreased. The experimental results also show that the Casagrande test can be a good option for determining the consistency of clay-based mortars and that there is a negative linear relationship with the spread table values (Mafalda et al., 2023).

Fig. 1. Slump Flow test

Tablo.2. Fresh mortar test results

Series	Casagrande	Slump Flow (cm)
R	2	14
A (0.6)	5	12.5
A (0.8)	5	12.5
A (1)	8	11

3.2. Hardened mortar properties

For compression and bending tests, 40*40*160 mm sized samples were produced from 4 different mixtures, 3 for each mixture. The produced samples are shown in Figure 2 as R, A (0.6), A (0.8) and A (1), respectively. The 1-week mass losses of the produced samples were measured and the daily mass losses of 4 series are shown in Table 3

Fig. 2. Samples from 4 series produced

Table 3. 7-day mass measurements (g)

Day	1. Day	2. Day	3. Day	4. Day	5. Day	6. Day	7. Day
R	496.9	444.6	420.4	416	414.7	413.2	412.6
0,6	498.8	445.1	422.2	419	416.9	415.3	414.9
0,8	503.3	470	425.9	418.6	416.3	414	411.9
1	508.6	471	429.9	423.4	421.3	419.3	416.7

The experimental measurements show that the addition of sodium alginate affects the mass loss of the soil mixtures over time. From day 1 to day 7, the reference sample decreased from 496.9 g to 412.6 g, a total mass loss of about 17%, while the mixture with 0.6% alginate additive decreased from 498.8 g to 414.9 g, a loss of about 16.8%. The 0.8% alginate doped mixture showed a mass loss of 18.1%, while the 1.0% alginate doped sample showed a loss of approximately 18.1%. As the alginate content increased, the mass loss was similar to the reference. Therefore, no linear relationship was observed between the doping rate and mass loss. The lowest mass loss rate was observed in the mixture with 0.6% alginate additive, while at 1.0%, the mass loss remained at a similar level to the reference sample. This indicates that while alginate increases the moisture retention capacity up to a certain level, this effect is limited at higher ratios and saturation is reached. At the end of the 7th day, flexural and compressive strength tests were performed for each specimen for which mass loss measurements were completed. Specimens that were fractured during flexural strength were then used for compressive strength evaluation. The data obtained are shown in Table 4.

Table.4 Flexural and Strength test results

Mixture	Flexural Strength (MPa)	Compressive Strength (MPa)
R	1.16	2
A (0.6)	1.07	2.6
A (0.8)	1.21	2.3
A (1)	1.21	2.8

In Table 4, the flexural strength of the reference (non-alginate) mixture was measured as 1.16 MPa. The flexural strength of the mixture containing 0.6% alginate decreased to 1.07 MPa, a decrease of about 7.76%. With the 0.8% additive, the flexural strength increased to 1.21 MPa, an increase of 4.31% compared to the reference. Similarly, the same strength value of 1.21 MPa was obtained in the mixture with 1.0% alginate additive. This indicates that the alginate admixture reached a saturation level between these proportions and did not provide a further increase in flexural strength.

As a result of the compressive strength tests, an increase in strength was observed in all sodium alginate-amended soil-based composites compared to the reference specimen. The highest increase was obtained in the specimen containing 1.0% alginate additive and an improvement of 40% was achieved. This indicates that alginate plays a binding role in the soil matrix and strengthens the internal structure. In particular, the mixture containing 0.6% alginate showed a significant increase of 30% in compressive strength despite the decrease in flexural strength. This shows that additives can have different effects on different mechanical behaviors and that material performance should be evaluated in a holistic manner with multi-faceted mechanical tests. The 1.0% admixture provided the highest strength, demonstrating that alginate provides optimum binding in soil structure above a certain level.

4. Conclusions

This study investigated the effects of sodium alginate additives in soil-based composites. By varying only the amount of alginate in fixed ratio mixtures containing clay, alpha gypsum, lime, and cellulose, the effects of different additives on material performance were investigated.

The results showed that the sodium alginate additive had a significant effect on the workability, consistency, mass loss and mechanical strength properties of soil-based mortars. In terms of fresh mortar consistency, it was observed that the consistency thickened, and the spreading diameter decreased as the alginate additive increased. This confirms the viscosity increasing effect of alginate. From the flexural and compressive strength results, it was observed that alginate addition, especially at 0.8% and 1.0%, provided a significant improvement in mechanical strength compared to the reference mix. The highest compressive strength was obtained in sample A (1), where an increase of 40% was observed. In terms of loss of mass, optimum results in terms of both mechanical performance and stability were obtained when sodium alginate additive was used in the range of 0.8-1.0% in soil-based composites in this study. It is recommended that the effects of additives not only on strength but also on crack control, water retention and long-term durability should be investigated in detail.

Abstract. Flexible reinforced concrete is used in civil construction and infrastructure. It plays a crucial role in the design of structures in the context of sustainable development. This material can suffer various types of damage and lose its mechanical and physical properties due to a variety of external causes. Such work may be necessary for a number of reasons. In particular, when weather conditions, wear and tear or damage caused by ground movements damage the structure. Pathological phenomena can be linked to the environment, operational constraints or the underlying quality of the concrete. To improve structural performance, techniques can be used to reinforce damaged structures. In addition, the patching repair technique has been used to reinforce and rehabilitate these structures. This work focuses mainly on the repair or strengthening of reinforced concrete structures using numerical analysis. Our numerical study will focus on the use of the ABAQUS calculation code to evaluate the mechanical properties of concrete and FGM patching. This method is proposed for the rehabilitation of civil engineering structures based on bending experiments. In order to determine the flexural strength under the influence of the exposant of the FGM material.

Keywords: Reinforced flexible concrete; FGM patch; Crack; Pathology; USDFLD

1. Introduction

The selection of materials for civil construction and infrastructure is playing an essential role in the design of structures within the framework of sustainable development. Numerous studies on reinforced concrete aim to better understand, understand and predict its behavior and characteristics. However, for structures with high requirements (large-scale structures, structures subject to particular stresses or requiring enhanced safety), the material's limited performance in tension, its poor watertightness and design constraints are driving the development of other topologies combining concrete and steel. Work is in progress to develop a new generation of civil engineering construction with an architecture for the design of cylindrical hull walls, such as those used for deep-water oil storage (Montague., 1975). Because steel is a less porous material than concrete, it will limit attacks from the outside (water, salt, major temperature variations, etc.), reduce spalling and cracking phenomena and thus increase the structure's durability.

Some researchers, such as Vacev et al.,(2023) and Kıpçak et al.,(2023), focus on concrete, analyzing experimentally and numerically the impact resistance of unreinforced concrete slabs. Recent studies aim to model it realistically using the finite element method for the numerical analysis of reinforced concrete structures. Harba et al.,(2022) analyzed the numerical behavior of short reinforced concrete columns, with different levels of confinement and CFRP shells, under concentric loads. Simeonov and Shuaib Ahmad. (1995) highlighted the limitations of predicting the modulus of elasticity of concrete using the elastic prediction model for two-phase composite materials. Kim et al.,(2020) proposed a simulation that uses the linear attenuation coefficient (LAC) of the gray-level pixel values of micro-CT data to characterize the multiphase structure of foamed concrete, postulating a linear correlation between the average LAC value of a single-phase concrete sample and the input parameters. Kunpeng et al.,(2024) have developed a discrete finite element method (FDEM) that combines tomography and X-ray diffraction (XRD) to model concrete microstructures and mineral compositions, enabling the multiphase structure of concrete to be simulated Several studies show that the mechanical properties of concrete vary considerably due to aggregate and void distributions (Yujie., 2016). At the microscopic level, crack propagation and damage accumulation are often influenced by aggregates (Jiangjiang., 2019). Subsequently, a

https://doi.org/10.31462/icearc2025_ce_mat_817

numerical analysis of reinforcement methods for reinforced concrete pavements for various levels of damage was carried out by li et al.,(2020).

In particular, elastic concrete materials, commonly referred to as engineered cementitious composites (ECC), are semi-ductile concretes exhibiting strain-hardening and multiple cracking behavior in tension and buckling. Flexible (elastic) concrete is a class of cementitious compounds reinforced with superplastic fibers. This material is capable of demonstrating significantly improved elasticity. ECC concrete elongates without fracturing, thanks to the interaction between fibers, sand and cement working in a matrix that binds all together in the material.

Over the past two decades, several studies have shown that adding rubber particles to concrete improves its ductility, deformability, toughness and energy dissipation. Other studies evaluate the strength of various flexible concrete mixes by incorporating supplementary cementitious materials, such as fly ash and recycled fibers. Najib et al.,(2020) investigated the effectiveness of concrete containing rubber from used tires in optimizing the deformability and energy absorption of reinforced concrete columns, taking into account different compressive strengths. Alsaif et al.,(2019) developed flexible concrete pavement materials, offering an alternative to asphalt concrete and polymerized rubber surfaces, with a study on steel fiber-reinforced rubberized concrete. These properties, along with the material's high impact and skid resistance, sound absorption, and thermal and electrical insulation, make rubberized concrete a very attractive building material for non-structural applications.

The addition of fibers, such as Recron fibers, is a promising alternative for improving the mechanical performance of rubber. These fibers, used to reduce the brittleness of concrete, offer new prospects for enhancing the safety, strength and durability of tomorrow's civil infrastructures. Hameed et al.,(2022) have developed a special concrete, called ECC concrete, using an optimum percentage of fly ash as a partial replacement for cement and incorporating different proportions of Recron fibers. Medina et al., (2017) examined the mechanical properties of concrete incorporating granular rubber and rubber-coated steel or plastic fibers. They observed that concrete with rubber and fibers exhibits better compressive and flexural behavior, as well as better absorption of impact energy than ordinary rubberized concrete. In addition, ECC uses small quantities, typically 2% by volume, of short, discontinuous fibers. ECC incorporates super-fine silica sand and tiny polyvinyl alcohol fibers covered by a very fine (nanometer-thick), smooth coating. This surface coating allows the fiber to start sliding when overloaded, so that it doesn't fracture.

The first part of this work will consist of an experimental study of the mechanical properties of elastic concrete, as a function of the nature and shape of the fibers. We will determine its resistance to bending and deformation of a beam reinforced with a patch of FGM material. FGM materials outperform traditional materials thanks to their mechanical and chemical resistance, reduced maintenance, freedom of form and ability to extend the life of structures. However, a major drawback of FGMs is the accumulation of stresses at the interfaces of the layers, due to abrupt variations in their mechanical properties.

The aim of our work is to develop a direct numerical solution for determining the interface stresses in the adhesive layer of a damaged flexible concrete beam repaired by FGM.

2. Material and experimental methods

Fiber-reinforced concrete is being actively studied to improve its lightness and flexibility. A large body of research is examining the influence of organic fibers on its properties. This study uses a matrix concrete reinforced with PA6 polyamide chips, a choice justified by its mechanical performance and potential for sustainable reuse.

2.2. Reinforcing fibers

The reinforcing material used in this study consists of PA6 polyamide chips. These chips are recovered from by-products generated during cutting and machining operations typically performed in industrial and mechanical workshops. The shape and appearance of the collected chips are shown in Fig. 1.

Fig.1. The filings used PA6

2.3. Tensile tests

Tensile tests on PA6 samples, prepared according to ASTM D882-12, were conducted at the Mechanical Engineering Laboratory at the University of Msila (Fig. 2).

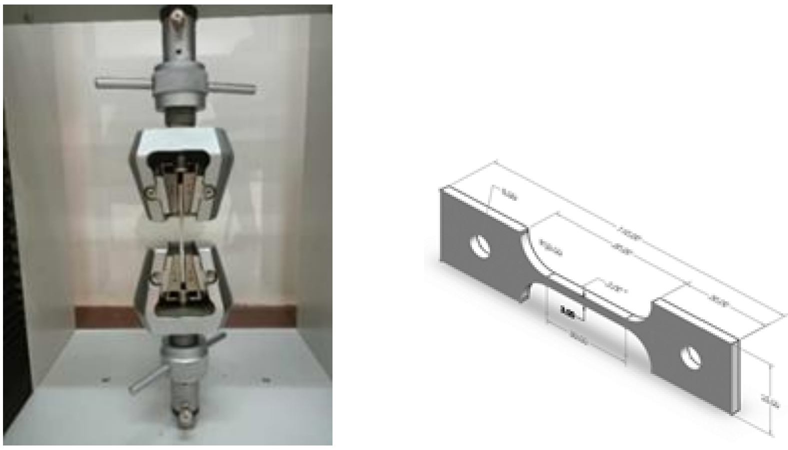

Fig. 2. a) Tensile test specimens, b) The dimensions of test specimens

Table 1. Mechanical properties of PA6

Mechanical properties	Young Modulus MPa	Poisson's ratio	Yield strength $Rp_{0.2}$ (MPa)	Ultimate tensile strength R_m (MPa)	Elongation %
PA6	2850	0.33	40	84	4

The polyamide tensile curve resulting from tensile tests carried out in the M'sila laboratory is shown in Fig. 3. The tensile strength measured is 84 MPa at elastic elongation, giving a precise indication of the polyamide's mechanical properties under controlled conditions. The mechanical properties of PA6 are summarized in the Table 1.

2.4. Manufacturing process

Cement, gravel, and sand are mixed, water is added to create a homogeneous concrete, then a fiber PVC filing/epoxy mixture is incorporated until thoroughly combined and the color is uniform. Fine PVC filings (< 0.5 cm) were manually mixed (Fig. 3.a), and pressed into a mold, then demolded after a 24-hour curing period.

The raw materials were weighed individually, and the percentages of the components in each sample are grouped in Table 2.

Fig. 3. a) Fine PVC filings obtained after sieving, b) The prepared samples

Table 2. The percentages of the constituents in the four samples

Samples	Concret (Wt%)	Fine PVC filings (Wt%)
A	75	25

2.5. Characterization

Three-point bending tests were performed on the composite specimens (Fig. 4) using the Zwick/Roell Z010 universal testing machine (10 kN capacity). Four plastic fiber specimens with equal particle sizes were developed to study the effect of fiber size on the mechanical behavior of concrete.

Fig. 4. Three-point bending test

3. Finite element analysis modeling

Finite element modeling for the nonlinear analysis of concrete is mainly based on spread crack or damageable plasticity approaches. In the spread-crack concrete model, crack initiation occurs when concrete stresses reach a fracture surface, either in biaxial tension or in tension-compression.

3.1. Damaged concrete

At low confining pressures, concrete exhibits brittle behavior characterized by tensile cracking and compressive crushing. Sufficiently high confining pressures prevent cracking, eliminating this brittle behavior. The main elements of the damaged plasticity model for inviscid concrete are: the strain rate decomposition, assumed to be independent of velocity.

$$\dot{\varepsilon} = \dot{\varepsilon}^{el} + \dot{\varepsilon}^{pl} \tag{1}$$

where is the total strain rate, is the elastic part of the strain rate, and is the plastic component of the strain rate. Damaged scalar elasticity governs stress-strain relationships.

$$\sigma = (1-d)D_0^{el}:(\varepsilon - \varepsilon^{pl}) = D^{el}:(\varepsilon - \varepsilon^{pl}) \tag{2}$$

where D is the material's initial elastic stiffness, $D^{el} = (1 - d)\, D^{el}$ its degraded stiffness, and d the degradation variable (0: undamaged, 1: fully damaged). In scalar damage theory, stiffness degrades isotropically, characterized by a single variable, d. The effective stress is then defined according to the principles of continuous damage mechanics.

$$\bar{\sigma} = D_0^{el}:(\varepsilon - \varepsilon^{pl}) \tag{3}$$

Cauchy stress relates to effective stress via a scalar degradation factor.

$$\sigma = (1-d)\bar{\sigma} \tag{4}$$

3.2. TTO model

The TTO model is a metal alloy homogenization method and is used to evaluate locally effective elastoplastic parameters of the FGM (AL/SiC) compound. In the TTO model, the material mixture is treated as elastoplastic with linear isotropic hardening, for which the stresses and strains are related to the constitutive forces σ_m, σ_c and ε_m and ε_c (Tamura et al.,1973) by the relation:

$$\sigma = \sigma_m V_m + \sigma_c V_c \quad \text{and} \quad \varepsilon = \varepsilon_m V_m + \varepsilon_c V_c \tag{5}$$

In the TTO model an additional parameter q is introduced which represents the ratio of stress to strain transfer, note that:

$$q = [(\sigma_c - \sigma_m)/(\varepsilon_c - \varepsilon_m)], \qquad 0 < q < \infty \tag{6}$$

In the TTO model the properties of FGM is based mainly on the plastic part of the metal constituent determined by modulus of elasticity $\mathrm{E(z)}$ of FGM. The initial yield stress $\sigma_{Y_0}(\mathrm{z})$ and tangent modulus $\mathrm{H(z)}$ which are described by the following relations:

$$\mathrm{E(z)} \;=\left[\frac{q+E_c}{q+E_m}.\mathrm{E_m V_m}+\mathrm{E_c}.(1-\mathrm{V_m})\right]\Big/\left[\frac{q+E_c}{q+E_m}.\mathrm{V_m}+(1-\mathrm{V_m})\right] \tag{7}$$

$$\sigma_{Y_0}(z)=\sigma_{Y_0 m}\left[\frac{q+E_m}{q+E_c}\frac{E_c}{E_m}.(1-V_m)+V_m\right] \tag{8}$$

$$\mathrm{H(z)} \;=\left[\frac{q+E_c}{q+H_m}.\mathrm{H_m V_m}+\mathrm{E_c}.(1-\mathrm{V_m})\right]\Big/\left[\frac{q+E_c}{q+H_m}.\mathrm{V_m}+(1-\mathrm{V_m})\right] \tag{9}$$

Where $\sigma_{Y_0 m}$ the initial yield stress of metal, $\mathrm{H_m}$ is the tangent modulus of metal, where $\varepsilon_{m_0}=\sigma_{Y_0 m}/E_m$ and $\varepsilon_{Y_0}(\mathrm{z})=\sigma_{Y_0}(\mathrm{z})/\mathrm{E(z)}$ are the initial yield strains of the metal and FGM AL/SiC, respectively.

3.3. Damage FGM
A non-local damage mechanics approach was used which requires the mesh regularization chosen in our work. The maximum principal stress criterion MAXPS is used to have the crack initiation as well as its propagation direction. The choice of Maximum stresses as the criterion for damage initiation is used to reduce the sensitivity of the mesh in non-local approaches (Houari et al.,2021).

$$\mathrm{f}=\frac{\sigma_{\mathrm{eq}}}{\sigma_{\mathrm{UTS}}}=1 \;\text{ with }\quad \sigma_{\mathrm{UTS}}=\sigma_{\mathrm{UTSm}}.\left[\frac{\mathrm{q}+\mathrm{H_m}}{\mathrm{q}+\mathrm{E_c}}\frac{\mathrm{E_c}}{\mathrm{H_m}}.(1-\mathrm{V_m})+\mathrm{V_m}\right] \tag{10}$$

where σ_{eq} is the equivalent von-Mises stress of FGM, σ_{UTS} is the ultimate tensile strength of FGM, σ_{UTSm} is the ultimate tensile strength of metal, $f=1$: means the occurrence of damage within an enriched element and $\mathrm{H_m}$ is the tangent modulus of the metal.

3.4. Geometric model
For the purposes of our work, we have analyzed a damaged elastic concrete beam, repaired by FGM, on the basis of data from bending experiments. The 250 mm-long beam is subjected to a concentrated bending load of 10 N (Fig. 5). The distance between the end of the beam and the edge of the reinforcing plate (L_R) is 150 mm. The distance between the end of the beam and the edge of the reinforcing plate (L_R) is 150 mm.

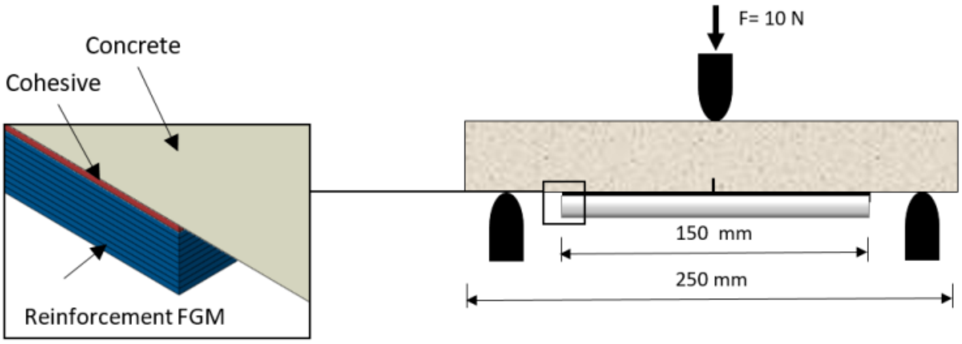

Fig. 5. Loading and boundary conditions

The geometric properties of the materials used are shown in Table (3).

Table 3: Geometric properties of materials

Material	width	thickness	long
Flexible concrete	b_l = 90 mm	t_l = 30 mm	L_l = 250 mm
adhesive	b_a = 90 mm	t_a = 0.2 mm	L_a = 150 mm
FGM AL/SiC	b_r = 90 mm	t_r= 2 mm	L_r = 150 mm

3.5. Mesh and gradient of FGM properties
A 30 mm-thick concrete beam, modeled with C3D8 elements in ABAQUS, is reinforced with a 25 mm-thick composite plate fixed underneath to improve compressive load distribution (Fig. 6). The patch is modeled with C3D8 elements, using concrete's mechanical properties derived from the experimental tests. In ABAQUS, the USDFLD subroutine models the nonlinear behavior and damage of FGM materials, integrating their thickness-

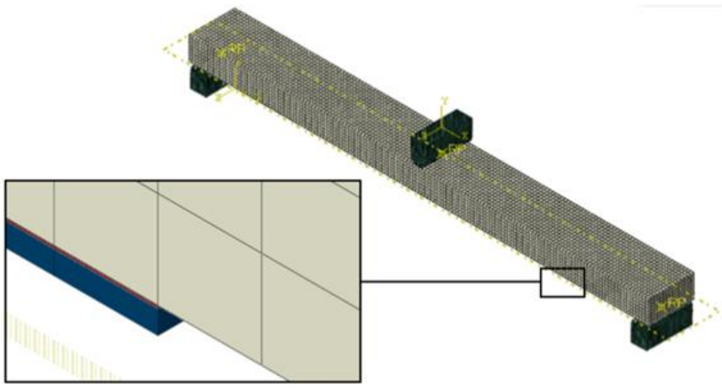

Fig. 6. Meshed model of beam

dependent properties. The choice of finite element model is carried out with elements C3D8 which present the best choice for the numerical modeling of the model and which are used in numerous examples of modeling of FGM.

To avoid the discontinuity of force at the interfaces, a subroutine USDFLD is implemented in ABAQUS to define the material properties of the FGM according to the coordinates of the points of integration in a finite element model. For this purpose, we use integration points arranged across the thickness direction of the FGM (metal/ceramic) plate. The distribution of material properties across the thickness $h(z)$ of the FGM plate according to a power law distribution is shown in the Fig. 7:

$$\mathrm{P(z)} = (\mathrm{P_m} - \mathrm{P_c}).\mathrm{V_m} + \mathrm{P_c} \tag{11}$$

Knowing that P: represents the effective material property, $\mathrm{V_m} = \left(\frac{z}{H} + \frac{1}{2}\right)^n$ is the Metal Volume Fraction, n: is the non-negative volume fraction exponent and the subscripts c and m represent the ceramic and metal constituents respectively. We consider a patch in FGM (AL/SiC), presented in the form of several surfaces (Fig.7a), Each surface exhibits mechanical properties as being a homogeneous and isotropic material. The properties of the two constituents of FGM (AL/SiC), Adhesive and concrete are presented in Table.4.

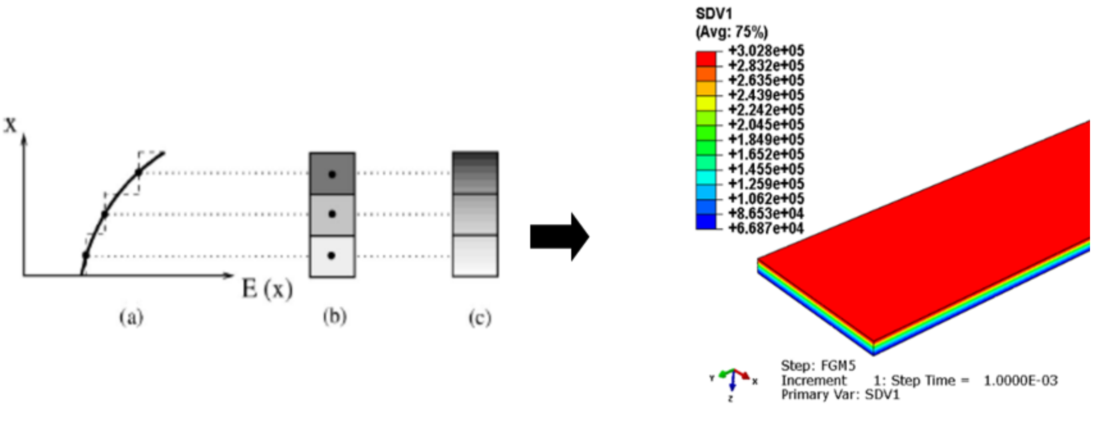

Fig. 7. a) Homogeneous versus graded finite elements, b) Linear distribution of Young's modulus (SDV1) across the thickness h(z) of FGM AL/SiC patches via USDFLD with power law

Table 4. Material properties (Jin etal., 2003)

Property	Metal AL	Concrete	Adhesive	Ceramic SiC
Young’s Modules E (MPa)	67000	34000	2962	302000

Tegant modulus H (MPa)	1000		-	-

7. Results and discussion

7.1. Validation

The current method was validated by comparing the force-deflection curve results of the bending test with those obtained from the finite element method using the ABAQUS calculation code. Fig. 8 shows that the numerical results gave reasonable curvatures with the bending experiments, and the figure also shows that the PVC particle size affects the behavior of the concrete; PVC/micro-concrete specimens exhibit elastic behavior and elastic fracture.

The different factors measured automatically are presented in Table 5. These parameters are essential to calculate the bending stress σ_f, and the bending modulus of elasticity E_f (Young's modulus).

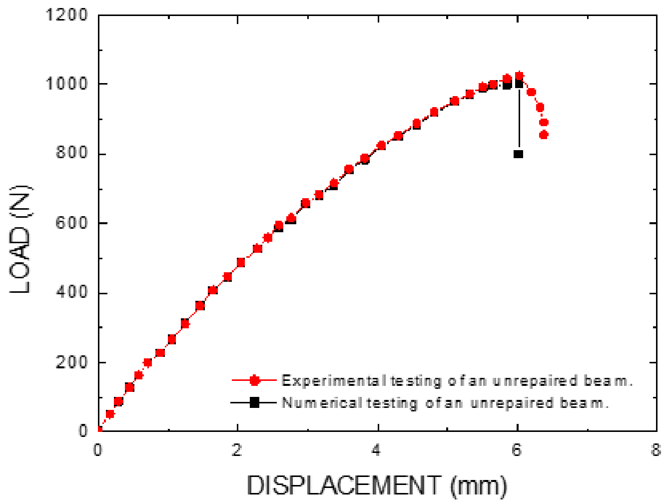

Fig. 8. The fracture behavior Concrete: (a) Concrete/ Fine PVC filings

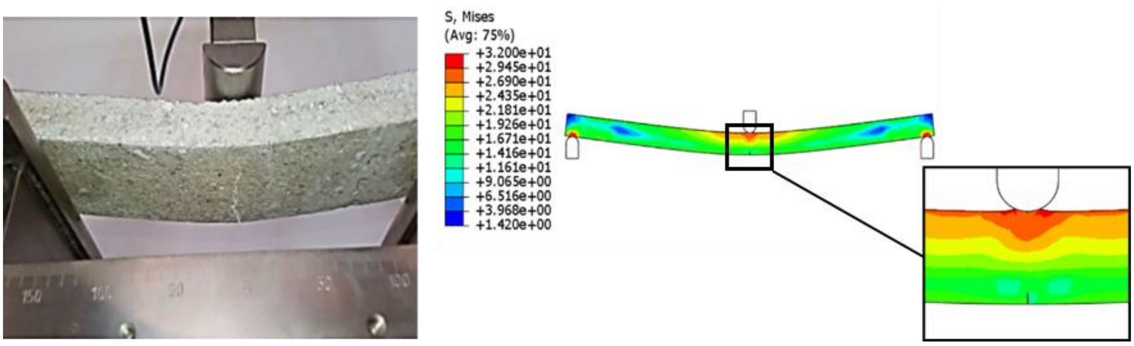

Fig.9. The fracture behavior Concrete

Table 5. Bending tests results

Sample test	F_{MAX} (N)	$F_{rupture}$ (N)	$\varepsilon_{rupture}$ (mm)
1	635.05	547.13	5.49
2	620	530	5.31
3	615	505	5.24
4	640	550	5.42

Table 6. Mechanical properties of the samples

Sample test	K (N/mm)	σ_{Max} (MPa)	$\sigma_{rupture}$ (MPa)	E_f (GPa)
1	123.68	10.45	8.75	0.32
2	122.58	10.15	8.90	0.29
3	110.31	9.18	7.82	0.28
4	129.17	10.93	9.14	0.352

As part of this work, we are interested in the bending stress σ_f, and the bending modulus of elasticity E_f(Young's modulus). Table 6 presents the results obtained using the following formulas:

$$\sigma_f = \frac{3FL}{2bh^2} \tag{12}$$

$$E_f = \frac{L^3}{4bh^3}K \tag{13}$$

where:σ_f: Bending stress in Mpa, F: Force applied in newton, L: Spacing between supports in mm, b: Width in mm, h: Thickness in mm and K: Bending stiffness (K=ΔF/Δy) in N/mm.

7.2. Effect of the exponent n

We considered FGM patch repair in our analysis. The results of the variation in the response of the bending curves are shown in Fig. 10, with a crack length of 5 mm for different FGM repair patch exponent value.

The beam fixed by the FGM patch with a gradient coefficient of n=2 has the highest strength values especially if this patch is rich in ceramic . The presence of the FGM patch significantly improves the strength of the beam and significantly reduces the spread of the crack.

Various FGM plate designs aim to reduce stress concentration in the adhesive. The von Mises analysis reveals similar interferences in the joint. The von Mises stress at the adhesive core decreases considerably with increasing metal concentration in the FGM. This modification significantly reduces von Mises and peel stresses for different geometries (see Fig. 12).

Stress concentrations persist at the edges, and the core is also stressed (Fig. 13). The maximum stress depends on the reinforcement material, and its modification can improve the reinforcement of the flexible beam and significantly reduce the von Mises stress.

With regard to the length of the patch , an increase in von Mises stress is observed in the FGM n=5 metal-rich models. On the other hand, metal models has a minimum stress value at the center of the plate (Fig. 14).

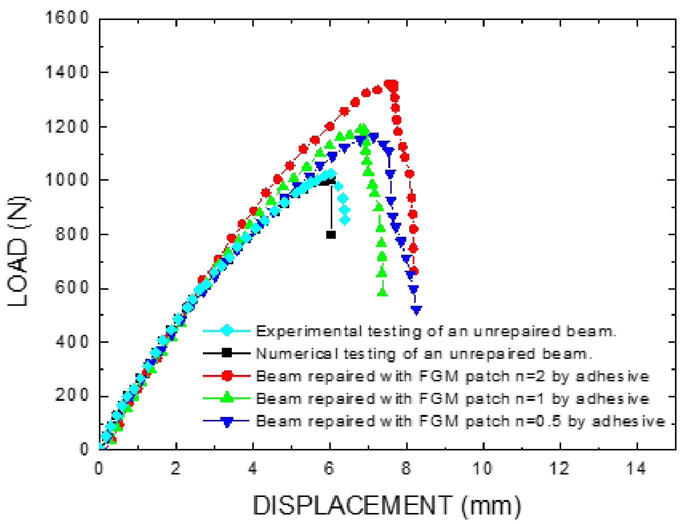

Fig. 10. Variation of the exponent in the damaged beam and repaired by FGM patch

8. Conclusion

The objective of this study is to manufacture flexible concrete characterized by high mechanical properties, using recovered raw materials in the form of filings from cutting processes used in PVC carpentry workshops. The abundance of these materials, which are often considered unusable waste, and the importance of the properties of the two basic materials, namely PVC, encouraged the main idea of this modest work which consists of recovering PVC filings.

An initial analysis of the samples manufactured as part of this study showed the effect of the size and nature of the filings on the microstructure of the surface and the reinforcement-matrix interface. Indeed, the results showed that the adhesion of the PVC filings to the matrix is power, the PVC filings reinforced all the constituents to make the composite more resistant. In our study, we study the stresses at the interface between flexible concrete and FGM materials in a damaged structure repaired by FGM patch. The finite element methods confirmed the results of this solution. At the adhesive layer, the stresses are observed at the edge and in the middle. However, the patch shows the maximum stresses observed in the middle.

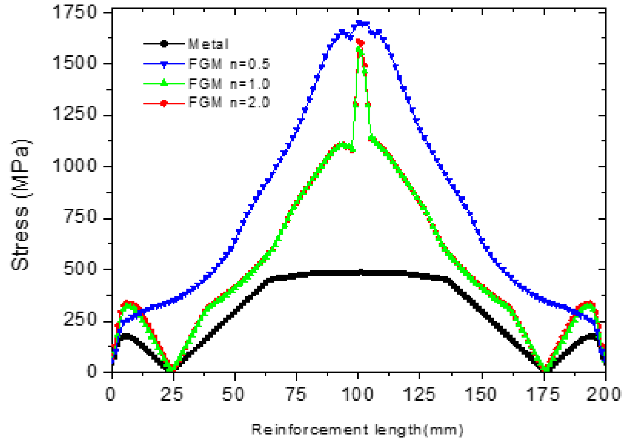

Fig. 14. Stress distributions along the length of the patch for the diferent confgurations

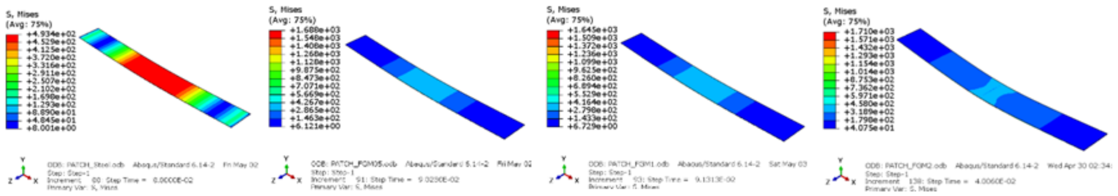

Fig. 15. Von Mises stress level in the patch length joint, a) Metal, b) FGM=0.5 c) FGM=1, d) FGM=2

The numerical analysis by FE in this study aims to analyze the response in the damaged and repaired patch beam, as well as the distribution of main stresses in the adhesive and patch. The parameters highlighted have led us to draw the following conclusions.

- The strength of the damaged plate can be improved by the bonding process of the patches, which can be effective if its nature is taken into account.
- The MGF patch performs better with a ceramic-rich patch if the contact with the adhesive layer is ceramic and the gradation coefficient has a high value compared to the metal-rich patch.

Abstract
Concrete is a construction material that is significantly influenced by atmospheric environmental conditions during and after casting. In Türkiye, as well as in many other countries, standards exist to regulate the requirements for concrete casting during winter. These standards outline the necessary conditions and recommend precautionary measures; however, the specific nature of these measures is often not clearly defined. In this study, the compressive strength development of C30/37 class concrete specimens, cast and cured under real winter conditions in Erzurum and protected by greenhouse plastic sheeting—a potential precautionary method—was experimentally investigated. The concrete specimens were kept under the greenhouse plastic for the first three days after casting, subsequently demolded, and then stored under the same protection until the seventh day. Afterward, they were exposed to natural atmospheric winter conditions until the 28th day. Axial compressive strength tests were conducted on cube specimens at 3, 7, and 28 days to evaluate the strength development experimentally. The results indicated that the 28-day axial compressive strength of the specimens produced with R-type cement reached 17.9 MPa, which corresponds to approximately half of the target compressive strength of 37 MPa.Based on the monitoring of both atmospheric and internal concrete temperatures, it was concluded that the development of maturity–strength relationships specific to winter concreting conditions is necessary for better assessment and control of concrete performance during cold weather construction.

Keywords: Concrete pouring in winter; Compressive strength; Greenhouse nylon sheeting; Temperature monitoring; Maturity index

1. Introduction

Reinforced concrete construction is the most commonly preferred building production method in Türkiye. In regions where winter seasons are long and harsh, the construction season remains short, causing various economic, technical, and social challenges. According to the study by Koç et al. (2017), the construction sector, particularly in Eastern Anatolia where a continental climate prevails, serves as a locomotive sector directly related to more than 200 different industries across the country. The near cessation of construction activities during winter months negatively impacts the regional economy and stands out as a major factor that hampers investment inflows. Erzurum province is a clear and striking example of this situation. This issue has been thoroughly analyzed in the 2014–2023 Regional Current Situation Analysis Report prepared by the Northeastern Anatolia Development Agency (KUDAKA). According to the KUDAKA (2014) report, the economy of Erzurum—located in the TRA1 Level 2 region—is primarily dependent on agriculture, services, and construction sectors, while the manufacturing industry has not yet reached a desirable level. The TRA1 Level 2 region consists of Erzurum, Erzincan, and Bayburt provinces, encompassing 30 districts, 73 municipalities, and 1,665 villages. Moreover, significant findings regarding the construction sector in Erzurum, Erzincan, and Bayburt—the provinces within KUDAKA's jurisdiction—are highlighted in the report:

"The construction sector occupies an important place in the regional economy, employing 8,356 people and accounting for 11.07% of the region's total employment. There are 623 enterprises operating in the construction sector in the TRA1 region, representing 2.54% of the total enterprises. In 2012, the number of construction enterprises was 1,664 in Erzurum, 605 in Erzincan, and 186 in Bayburt. Due to the prolonged winter season, construction projects—even without financial difficulties—often take at least two seasons to complete, leading to increased costs. Additionally, importing construction materials like steel and brick raises transportation expenses,

* Corresponding author, E-mail: burak.gedik@erzurum.edu.tr

https://doi.org/10.31462/icearc2025_ce_mat_835

while skilled laborers tend to migrate to regions where the construction season is longer and demand is higher. The fact that the primary input material, cement, is sourced locally, however, presents a significant advantage."

Despite significant public investments in recent years, it can be inferred from KUDAKA(2014) report that the harsh continental climate is the main reason why the total concrete production in Eastern Anatolia—a region covering the largest geographical area of Türkiye—remains only around 10–11% of the country's total output. This conclusion is highly noteworthy and is supported not only by official statistical analyses but also by socio-economic observations and field studies specific to Erzurum province.The prolonged winter season in Erzurum greatly shortens the construction period, leading to negative economic and technical consequences. Even the simplest building projects often cannot be completed without interruption, causing economic burdens and technical problems due to the inability to properly protect incomplete structures during long and wet winters. In this context, examining the monthly average temperature data presented in Table 1 and Table 2 is considered to be beneficial for concretely assessing the impact of the short construction season in Erzurum.

According to the data provided in Tables 1 and 2, obtained from MGM (2019), and evaluated together; it is evident that atmospheric conditions should be carefully considered in concrete pouring and reinforced concrete manufacturing in Erzurum province. This is particularly important since reinforced concrete structures constitute a large portion of building construction in our country. To ensure that the concrete sections perform their load-bearing function as designed, it is essential to achieve proper adhesion (bonding) between the concrete and the reinforcement steel. This mechanical behavior can only be achieved through quality concrete production. It is well known that concrete is influenced by atmospheric weather conditions, the fresh concrete temperature at the time of pouring, and even the temperature of the molds and the steel reinforcement cage placed inside them.

In national practices, according to the TS1247(2018) standard, full bonding is assumed to be achieved in concrete pours conducted under normal weather conditions. According to the same standard, "normal weather conditions" are defined as the situation where the air temperature does not drop below +5°C or exceed +30°C for three consecutive days at any hour. In other words, for ideal concrete pouring, the ambient temperature must remain between +5°C and +30°C during the pouring process and for the first 72 hours following it. This temperature range is critical for the healthy progress of the hydration process and strength development of the concrete.

However, when the meteorological data presented in Tables 1 and 2 are evaluated, it is observed that in Erzurum, for approximately half of the year, the air temperatures do not meet the normal conditions defined in the TS1247(2018) standard. This situation leads practitioners to refer to the TS1248(2017) standard, which contains regulations for concrete pouring under abnormal weather conditions. According to TS1248(2017), extreme cold weather is defined as conditions where the average air temperature remains below +5°C for three consecutive days. Furthermore, considering the climate map of Türkiye presented in Fig. 1, as quoted from Atalay(1997), it is observed that a significant portion of the country experiences a continental climate, and there are many regions where low temperatures prevail for extended periods, resulting in a short reinforced concrete construction term. Although there is no legal restriction on concrete pouring during winter in Turkey, it is possible that practitioners, due to a lack of knowledge about proper concrete protection during winter, and due to concerns over costs and success, avoid concrete/reinforced concrete production even in situations where it is necessary.

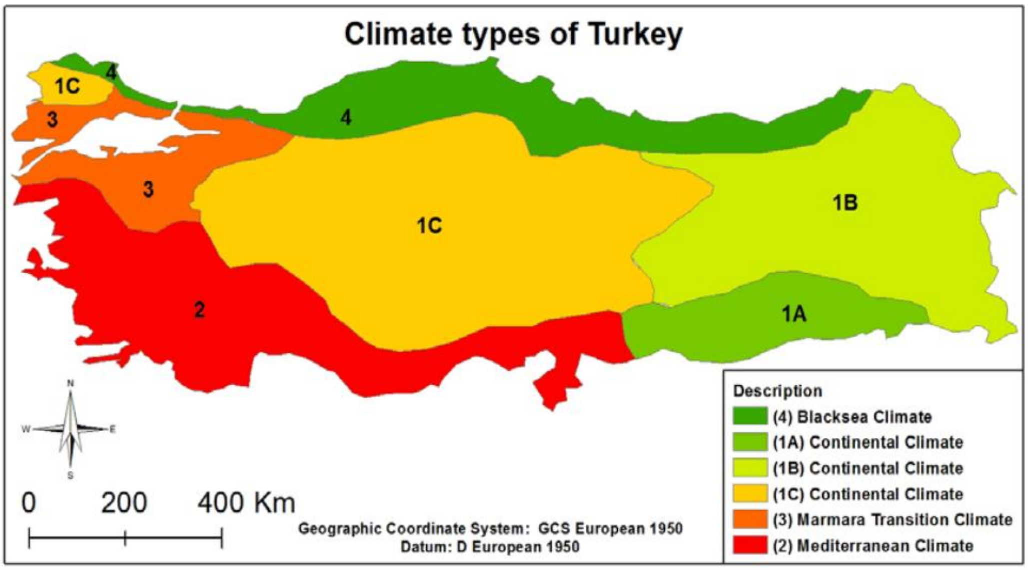

Fig.1. Climate map of Türkiye, Atalay(1997)

Similar to the national standard TS1248 (2017), many international norms such as CSA A23.1/A23.2 (2019), ACI PRC-306 (2016), and JSCE (2007) also define the drop of air temperature below +4/5°C within the first 72 hours after concrete pouring as abnormal weather conditions, requiring that protective measures be taken during casting. However, it can be stated that the issue of which specific measures should be taken remains generally ambiguous. The authors of this paper have conducted comprehensive studies regarding the establishment of bond in reinforced concrete manufacturing during winter and the effectiveness of various protective measures, similar to those of Gedik (2020) and Okuyucu et al. (2023). As a result of experimental investigations, it was evaluated that, under cold weather conditions, instead of using the compressive strength results of concrete specimens cured in the same environment as recommended in TS500 (2000) for determining the formwork removal time, the use of the concrete maturity index values, as suggested by the findings of Okuyucu et al. (2023), would be more meaningful. This evaluation necessitates temperature monitoring inside the concrete for reinforced concrete structural elements produced under cold weather conditions.

Although extensive access to studies on concrete production under cold weather conditions is available in the literature, it is observed that there is a severe shortage of technical studies that provide data on temperature monitoring during real atmospheric winter conditions, as well as on the structural behavior and mechanical performance of reinforced concrete elements cast during winter. Most existing studies on cold weather concreting focus on the effects of chemical admixtures on plain (non-reinforced) concrete, particularly concerning compressive strength and early-age behavior. One of the notable examples in this field, the study by Nmai (1998), evaluated the effects of chemical admixtures on the setting time and strength development of concrete under low temperatures. Karhonen (1990) and Karhonen (1992) conducted experimental studies on curing conditions, the hydration process, and thermal behavior of concrete under cold weather. Suk et al. (2012) and Nassif et al. (2013) analyzed the impact of antifreeze admixtures on the properties of fresh and hardened concrete, presenting comparative results from field and laboratory conditions. The study by Pushpalal et al. (2022), conducted under the severe winter conditions of Mongolia, examined the effects of different mineral admixtures on the performance and long-term durability of concrete. This study comprehensively addressed the role of mineral admixtures in enhancing the mechanical properties, durability, and long-term performance of concrete under cold climatic conditions. In addition, the study by Zhang et al. (2020) investigated the behavior of fresh concrete produced by calcium-silicate-hydrate (C-S-H) seeding under winter conditions, highlighting the great potential of nanotechnological admixtures for accelerating early strength gain and optimizing the hardening process during cold weather concreting.

While these studies and similar ones provide valuable contributions to the knowledge base concerning concrete production and curing processes under cold weather conditions, it is evident that the majority of the literature focuses predominantly on plain concrete specimens and remains limited to evaluating the effects of chemical admixtures on the hydration process. In contrast, critical parameters for reinforced (structural) systems, such as concrete–reinforcement bond, cracking behavior, thermal stresses, and maturity development, have not been sufficiently investigated under low-temperature conditions. The aspect most directly related to this paper is the observation that although various standards recommend taking protective measures during winter concreting, the effects of these measures are scarcely addressed in the accessible literature. Moreover, most of the available studies have been conducted under laboratory conditions, with very limited research carried out under actual winter environments. Therefore, there is an evident need for studies examining the precautions to be taken for winter concreting in regions dominated by continental climates.

In the study presented in this paper, it is aimed to investigate the effect of polyethylene sheet (greenhouse plastic) protection, applied for seven days, on the axial compressive strength of concrete specimens produced without any admixtures under real atmospheric winter conditions. In this context, C30/37 class concrete was used to cast cube specimens under real winter conditions, which were wrapped with greenhouse plastic for the first seven days. After the seventh day, the protective cover was removed, and the specimens were left exposed to atmospheric winter conditions until the 28th day. Following casting, a monitoring system was set up with K-type thermocouple sensors to measure temperatures inside the concrete and in the ambient environment. Temperature measurements were recorded at 10-minute intervals for seven days inside the concrete, and atmospheric temperatures were recorded for 28 days. Using the temperature data, the maturity index values (temperature-time factors) were calculated. The compressive strength results at 3, 7, and 28 days were evaluated in conjunction with the maturity index values.

2. Materials and methods

This study was conducted under real atmospheric winter conditions in Erzurum, Türkiye. For casting, plastic cube molds commonly used in practice, with dimensions of 150×150×150 mm, were selected. A total of nine plastic cube molds were prepared to determine the compressive strengths at 3, 7, and 28 days. Additionally, one more plastic cube specimen was produced solely for monitoring the internal concrete temperature.

It can be stated that during winter concreting, the most commonly used protection method is to isolate the fresh concrete from the atmospheric environment by covering the structure with plastic sheeting or tarpaulins. A striking example of this practice can be found in the repair work carried out in January 2014 on the reinforced concrete spillway support structures of the Altoona Dam, located in the state of Wisconsin, United States. Following observations of cracking and concrete disintegration in the dam body and spillway support arches, an initial plan was made to repair the structures using epoxy injection. However, field evaluations conducted prior to the repair revealed that the existing concrete lacked the necessary integrity to withstand the injection process. Consequently, to ensure the safety of the dam, a portion of the reservoir water was carefully drained in a controlled manner, and the damaged concrete sections were removed and replaced with newly cast concrete. The recasting was performed under very low temperature conditions, approximately -9°C, providing a significant real-world example of reinforced concrete construction under cold weather conditions. Various photographs of this application, cited from the work of Okuyucu et al. (2023), are presented in Fig. 2.

Fig.2. Images from the reinforced concrete pier repair work carried out in the winter at the Altoona Dam in the United States of America, Okuyucu et.al..(2023)

A study related to reinforced concrete construction during winter was also carried out in Erzurum by a team that included the authors of this paper. In this study, a similar protection method was applied by covering the freshly cast concrete with greenhouse plastic sheets.Following a landslide that occurred in January 2020 in the Tekstilkent area of 2nd Organized Industrial Zone of Erzurum, urgent repairs to the damaged factory structures became necessary. Due to this event, production in textile factories employing approximately 900 workers was halted. A decision was made to proceed with the repairs without waiting for the summer season, and reinforced concrete bored pile applications along with structural repair works were initiated in the region.In this project, where winter concreting was required, the authors of this paper also actively participated, particularly in the supervision and technical support of the construction of bored pile cap beams. During the concrete casting process, greenhouse plastic sheet protection was preferred to safeguard the fresh concrete. General images from this application are presented in Fig. 3.

Fig.3. Erzurum 2nd Organized Industrial Zone textile factories repair works,, Okuyucu et.al.(2023)

Although national and international regulations mandate the implementation of protective measures for winter concreting, they generally do not provide detailed guidelines regarding the specific protection methods. This gap constitutes the primary motivation of the present study. Based on this consideration, the commonly preferred method of using plastic sheeting for concrete protection, widely adopted in global practices, was selected for investigation in this research. Despite the extremely low temperatures experienced during winter in Erzurum, the location of the study, the number of sunny days is relatively high. Therefore, instead of using standard plastic sheeting or tarpaulin, greenhouse plastic was chosen for protection in this study. Under real atmospheric winter conditions, after the completion of concrete casting, the molds were covered with greenhouse plastic sheets to provide protection.The protective measures were maintained continuously during the first 72 hours following the casting, and the greenhouse plastic was not removed or opened for any reason. After 72 hours, all specimens were demolded, and the greenhouse plastic protection was continued until the end of the seventh day. At the end of the seventh day, the greenhouse plastic was removed, and the specimens were then exposed to ambient atmospheric conditions until the 28th day.This protection procedure was designed to be consistent with real-world field applications. Apart from the nine cube specimens prepared for axial compressive strength testing, an additional cube specimen was equipped with a type-K thermocouple sensor placed at its center during casting to monitor the internal concrete temperature. Temperature measurements were recorded for seven days inside the concrete, while ambient atmospheric temperature measurements continued for 28 days.The reason for monitoring atmospheric temperature for 28 days was that three of the specimens, after the removal of the greenhouse plastic on the seventh day, remained exposed to atmospheric conditions until the 28th day for axial compressive strength testing. A summary of the protection measures is provided in Table 3, and visual documentation related to the concrete casting and protection procedures is presented in Fig. 4.

Table 3. Protection measures applied to concrete samples manufactured in winter conditions

	3rd day	7th day	28th day
Greenhouse Nylon Protection*	Yes	Yes	**No**
Concrete Internal Temperature Monitoring	Yes	Yes	**No**
Atmospheric Temperature Monitoring	Yes	Yes	Yes

**: All samples were removed from the mold at the end of the 3rd day.*

Fig. 4. Images of concrete casting and protection measures

In the production of concrete, the goal was to produce C30/37 class concrete, and the concrete mix was prepared according to the recipe presented in Table 4. The concrete recipe shown in Table 4 was taken from the project report presented in Okuyucu et al. (2023), using the same materials. To ensure that the concrete gains strength quickly during winter production, CEM II-42.5 R type cement was preferred. No admixtures such as setting accelerators were used in the production. The concrete was produced with a water/cement ratio of 0.54.

Table 4. C30/37 class concrete mixture recipe, Okuyucu et al. (2023)

Material	Volume (dm^3)	Weight (kg)
Cement (CEMII - PC42.5-R)	133	400
Water	214	214
Air	10	-
Sand (0-3 mm)	193	421
Fine gravel (5-12 mm)	450	1134
Coarse gravel	-	-
Total	1000	2163

On February 10, 2025, during the concrete pouring at the western facade of the Engineering and Architecture Faculty of Erzurum Technical University, the fresh concrete temperature was measured at 22°C, while the atmospheric temperature was measured at -3°C. Both the application and various literatures indicate that the optimal range for fresh concrete temperature when placed in the form is between 15-25°C, and the TS1248(2017) standard stipulates that the minimum fresh concrete temperature in cold weather conditions should be 10°C. In this case, it can be stated that the concrete produced meets the standard conditions with a fresh concrete temperature of 23°C. The concrete pouring process began at 11:00 AM, which is the warmest part of the day, and was completed within approximately 1 hour. Considering the possibility that air temperatures may drop below -15°C after concrete production, it should be emphasized that the pouring date was determined based on weather forecasts.

In the study, both the atmospheric temperature and the internal temperature of the concrete cube were recorded using type K thermocouple sensors. The type K thermocouple sensors, as seen in Fig. 5, were locally manufactured and obtained from a company based in Bursa. Since the 3-meter long sensors could not be directly connected to the static data collection unit, a thermocouple connection box, which serves as an adapter, was used to establish the connections to the system. The measurement accuracy of these sensors was cross-verified using mercury or digital thermometers as much as possible at the measurement locations. During the temperature monitoring of the pouring process, data collection systems were supported by online UPS power sources to prevent data loss due to power interruptions. The data collection system and computer were placed inside the building, and the type K thermocouple sensors were introduced through a window opening and connected to the system. Temperature monitoring with the thermocouple sensors continued for 28 days as planned, and no data loss occurred during this period.

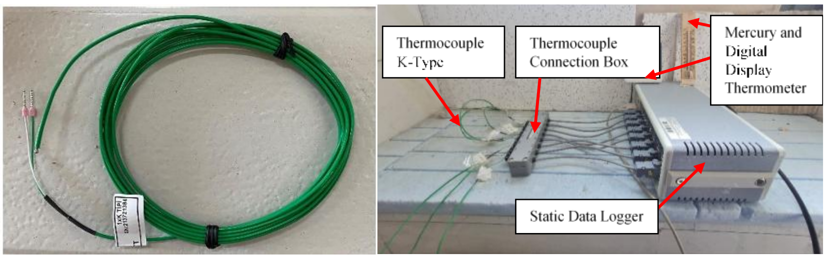

Fig.5. K type thermocouple and static data acquisition unit used in temperature measurement.

During the course of the study, the recorded atmospheric temperature was evaluated to assess the control of abnormal (cold) weather conditions as specified in TS1248(2017) for the pouring and curing conditions. The temperature record taken from the concrete cube sample was used for the calculation of the maturity index. It is beneficial to elaborate on the concept of the maturity index here. TS13508(2012) defines the maturity index as a value indicating the maturity of a cement-based mixture, based on its temperature history, using a maturity function. The calculated index is an indicator of maturity, assuming that the required water for the pozzolanic reaction or hydration of the cement-based materials is provided during the calculation period. The two most commonly used maturity indices are the temperature-time factor and equivalent age. In this study, the temperature-time factor was calculated as the maturity index. The temperature-time factor is calculated using the Equation 1 presented in TS13508(2012):

$$M(t) = \Sigma(T_a - T_o).\Delta t \qquad (1)$$

In Equation 1: *M(t):* temperature-time factor (degree-days or degree-hours) at age t, *Δt:* Time interval (days or hours, T_a*: Average temperature of concrete during Δt (°C),* T_o**:** Datum temperature (°C).

The mathematical expression presented in Equation1 numerically calculates the area under the temperature-time curve for the internal temperature of the concrete, excluding the portion above the initial/datum temperature. The initial/datum temperature used here refers to the lowest internal temperature at which the concrete can start to gain strength/develop strength, and it is clear that this will differ for each concrete mix. According to ASTM

C1074-19e1 (2019), the datum temperature (reference/initial temperature) is the theoretical temperature value used in the maturity method, assuming that the hydration of the concrete has completely stopped. In other words, this temperature represents a boundary beyond which the concrete does not gain any strength, and it is generally considered to be -10°C in ASTM C1074-19e1 (2019). The initial temperature is a parameter that must be determined experimentally according to TS13508 (2012). The initial temperature depends on the type of cement, the type and amount of chemical or other additives that may affect the rate of hydration, and the temperature range to which the concrete is exposed during curing. However, for determining the initial temperatures in this study, no experimental work was carried out as detailed in TS13508 (2012); instead, support was obtained from the literature. A literature review on the selection of the initial temperature revealed that in the study by Elaty et al. (2017), experimental determination of the initial temperature was performed for concretes made with different types and dosages of cement. In the study reviewed, the initial temperature for a mix close to the plain concrete used in the research, in terms of cement type and dosage, was determined to be -2.2°C. Based on the initial temperature value of -2.2°C from the Elaty et al. (2017) study, temperature-time factor calculations were made according to Relation 1. Apart from the calculations performed on the temperature data, the 3, 7, and 28-day axial compressive strength values were experimentally obtained, and the 3- and 7-day strengths were correlated with the temperature-time factor data.

3. Results and discussions

Weather forecasts for air temperature were monitored, and considering the subsequent predictions of low temperatures, the manufacturing date was set for February 10, 2025. The atmospheric temperature recording graph, taken over a period of 28 days after the concrete pouring on this date, is presented in Fig. 6.

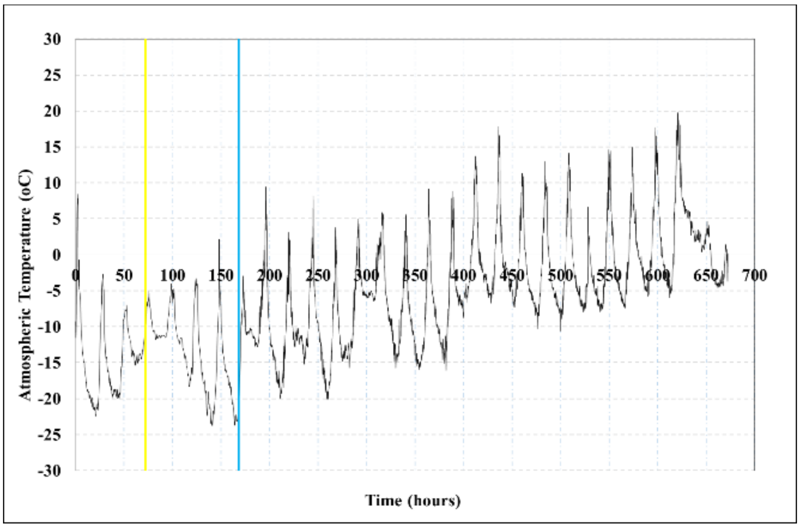

Fig.6. 28-days atmospheric temperature records

Upon examining the temperature record presented in Fig. 6**,** it is observed that within the first 24 hours after the concrete pouring, the atmospheric temperature dropped to -22.4°C, with the minimum temperature measured on the 6th day post-pour at -23.8°C. The average atmospheric temperature was calculated as -6.5°C. Positive temperature readings were recorded during the times when the thermocouple sensors were directly exposed to sunlight and should be considered as data above the meteorological records. However, temperature readings taken when the sample storage area was not exposed to sunlight (in the shade) were found to be consistent with meteorological records. This data indicates that the atmospheric conditions at the site of the concrete pouring met the abnormal (cold) weather conditions defined in TS1248(2017). The yellow line in Fig. 6 marks the end of day 3, while the blue line marks the end of day 7.

In studies focusing on the thermal behavior during the hydration process of concrete, it is possible to access information from the relevant literature regarding the effect of the volume-to-surface area (V/A) parameter on behavior. One such study, conducted by Do et al. (2021), presents findings from an investigation of the early-age thermal behavior of concrete segmental box girders using finite element (FE) analysis. In this study, a segmental box girder diaphragm model was created to assess the effects of flanges, the body, the V/A ratio, and the heat of hydration of cement on the early-age temperature development of the segment. It was concluded that the effect of the V/A parameter diminishes in high-strength concretes. Although high-strength concrete was not used in the work discussed in this paper, the V/A ratio for the cube sample, where temperature tracking was carried out, was calculated as 0.03. The temperature-time graph created using the 7-day temperature tracking data from the cube sample is presented in Fig. 7**.**

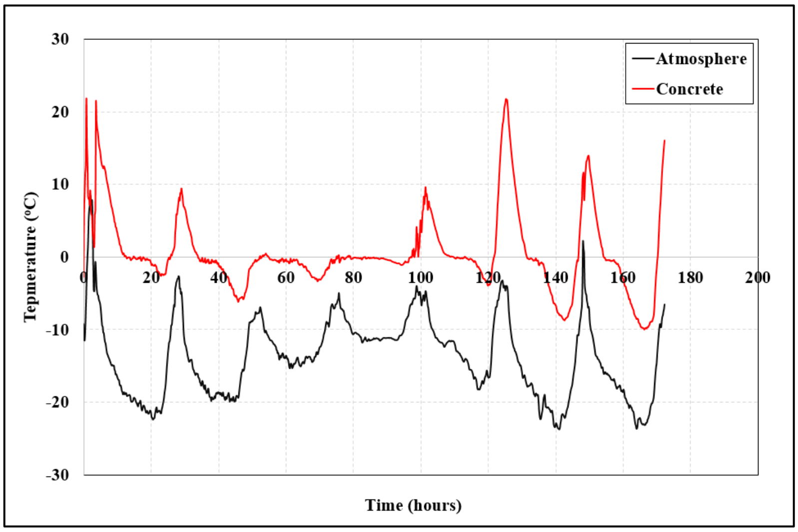

Fig.7. 7-day temperature-time graph measured from inside the concrete cube sample.

Upon reviewing the graph presented in Fig. 7**,** it is clear that the internal concrete temperatures of the cube sample followed a temperature regime similar to that of atmospheric temperatures after the first 24 hours post-pour. Referring to the work of Elaty et al. (2017), with the assumption that the temperature at which hydration stops is -2.2°C, it can be stated that the internal concrete temperature of the sample did not drop below this value during the first 24 hours. It is considered beneficial to closely examine the first 24-hour period of the concrete sample, which was produced under real winter conditions and protected with greenhouse plastic, as it is crucial for hydration processes. Fig. 8 shows the internal concrete temperature measurements of the first 24 hours, along with a visual of the concrete hydration phase from the source Çimsa (2025).

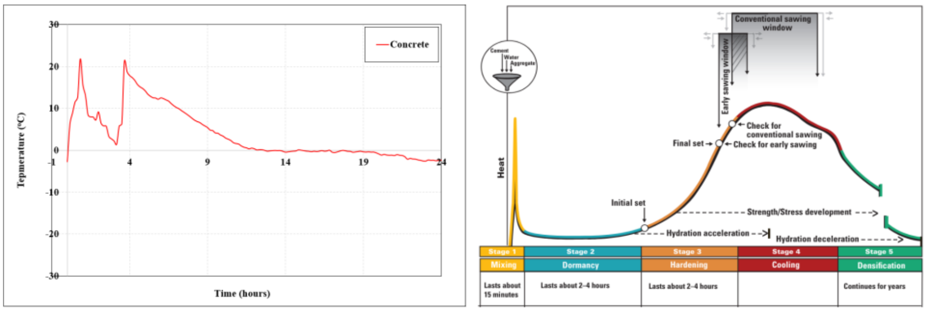

Fig.8. First 24-hour concrete internal temperature-time graph and phases of concrete hydration quoted from Çimsa (2025)

As expressed in Neville (1997), hydration is a series of irreversible chemical reactions that occur between cement and water. During hydration, the cement paste sets and hardens. The hydration process begins as soon as cement comes into contact with water. The cement particles gradually and partially dissolve, and the dissolved components react at different rates. During these reactions, heat is released, and new compounds called hydration products are formed. These new compounds create a solid structure that hardens the cement paste, bonds with the aggregates in the concrete mix, and forms a strong and dense structure. The measurable heat released during hydration does not drop to zero over time, as the reactions slow down. Hydration reactions can continue for years as long as there is water and unreacted cement in the concrete. This process contributes to the continued strength gain of the concrete and the development of desirable properties such as low permeability. Extensive studies have been conducted on hydration phases, and this topic continues to be a subject of research. A general understanding of hydration reactions can help prevent or address issues related to concrete, ensuring that the concrete mix performs as designed. Hydration is considered to occur in five main phases: mixing, dormancy (sleep) period, hardening, cooling, and densification. The mixing phase is when cement first comes into contact with water. The cement particles begin to dissolve, and a thin layer of reaction products forms on their surfaces. Hydration reactions are triggered at this point. During the dormancy (sleep) period, the reactions slow down, and the concrete mix remains workable. This phase provides the time needed to place and shape the mix in the mold. Heat production is at a low level. At the end of the dormancy period, the hardening phase begins, and the reactions speed up. Heat production increases, new hydration products form, and the concrete starts gaining strength rapidly. Setting and early strength development occur during this phase. In the cooling phase, the concrete reacts less actively chemically but continues to gain strength. During the long-term densification phase, reactions between the remaining cement and water continue slowly. The voids in the concrete's internal structure decrease, making the material denser, stronger, and less permeable. This process can take years. Upon examining Fig. 8, it can be concluded that during the winter-poured concrete sample, the mixing, dormancy, hardening, and cooling phases were completed within the first 24 hours, and the densification phase began. The dormancy phase lasted approximately 3 hours, while the hardening phase lasted about 1 hour. The reason the hardening phase was shorter than the expected 2-4 hours is thought to be the use of rapid-setting R-type cement.

The internal temperature monitoring of the concrete has facilitated not only the interpretation of the hydration process but also the determination of the concrete's maturity parameter. The 7-day temperature-time factor graph, calculated using an initial temperature of -2.2°C, with reference to Elaty (2017), is presented in Fig. 9.

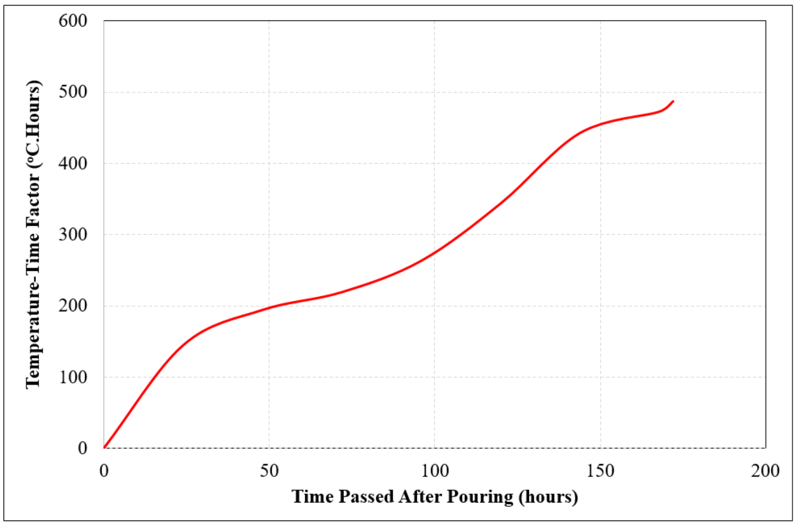

Fig.9. Temperature-time factor graph for the cube sample with temperature monitoring

Upon examining Fig. 9, it can be observed that the temperature-time factor of the cube concrete specimen reaches approximately 220 (°C.Hours) at the 3-day mark and approximately 220 (°C.Hours) at the 7-day mark. The definitive temperature-time factor values, along with the axial compressive strength test results, are presented collectively in Table 5.

Table 5. Temperature-time factor and axial compressive strength test results.

Time After Casting (Days)	Temperature-Time Factor (°C.Hours)	Uniaxial Compressive Strength (MPa)
3	219.1	4.2
7	487.0	9.4
28	-	17.9

The data presented in Table 5 are the results of axial compressive strength tests conducted on concrete cube specimens measuring 150x150x150 mm under load-controlled conditions at a rate of 0.5 MPa/s. Concrete specimens produced with a mix design intended for C30/37 concrete grade did not reach a compressive strength of 37 MPa at the 28-day mark. The expected axial compressive strength of 37 MPa was found to be 17.9 MPa after 28 days. The axial compressive strength data presented in Table 5 indicate that the rate at which the concrete gained strength was slower than the expected rate under normal environmental conditions. According to Eurocode 2 (BS EN 1992 1-1:2004+A1:2014), the expected percentages of axial compressive strength gain when using R-type cement, along with the strength gain percentages of the specimens under study, are provided in Table 6.

Table 6. Axial compressive strength gain percentages of the samples (%)

Time (days)	Tested Samples	Eurocode 2 (BS EN 1992 1-1:2004+A1:2014)
3	11	76
7	25	88
28	48	100

Upon examining Table 6, it is clearly evident that the early-stage (3-7 days) compressive strength gain percentages of concrete specimens produced in winter fall well below the expected 76% value for specimens produced under normal environmental conditions. For the specimens expected to reach approximately 76% of the target axial compressive strength after 3 days under normal conditions, only 11% of compressive strength was achieved. The strength gain regime has shown similar discrepancies for the 7-day and 28-day strengths as well. For specimens expected to gain approximately 88% of their compressive strength after 7 days, only 25% was achieved, and for specimens expected to reach nearly 100% after 28 days, only 48% of the axial compressive strength was attained. However, it should be noted that the volumes of the specimens exposed to atmospheric temperatures below -20°C are considerably smaller than actual reinforced concrete elements and, therefore, are more significantly affected by atmospheric temperatures. The primary reference for this conclusion is the scientific research project final report in Okuyucu et al. (2023).

At this stage, it is beneficial to examine the axial compressive strength values of the specimens produced in winter in conjunction with the maturity index, which is the temperature-time factor data. Since the temperature of the concrete specimens was tracked for a total of 7 days, this analysis was conducted for the 3-day and 7-day axial compressive strength values. The axial compressive strength data for the cube specimens presented in Table 5 were multiplied by a factor of 0.85 to convert them into equivalent strength for standard cylindrical specimens, and the graphical presentations, using the strength-maturity factor relationship provided in ACI PRC-306 (2016) for standard cylindrical concrete specimens cured at 22.8°C in the laboratory, are shown in Fig. 10.

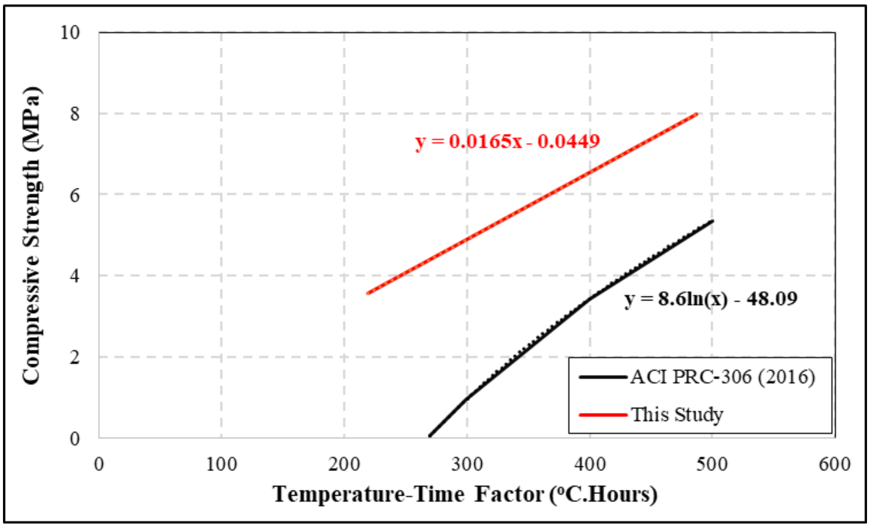

Fig.10. Relationships between temperature-time factor and uniaxial compressive strength.

The TS13508(2012) maturity method stipulates that the concrete strength of a structure (in situ) can be predicted, enabling critical decisions such as the termination of protection measures in cold weather. The prediction of concrete strength in the structure using the calculated maturity index and strength-maturity relationship is fundamental to carrying out this study. As a result of the work carried out for this purpose, Fig. 10 presents the temperature-time factor and axial compressive strength graphs, along with the linear relationship equations generated for these graphs. The main limitation of the study seems to be the fact that the data was obtained from small-volume samples; however, it should be noted that both TS13508(2012) and similar foreign standards provide methods for obtaining mathematical relationships representing the strength-maturity relationship under laboratory conditions. It should also be considered that the model sample volumes that can be used under laboratory conditions will be smaller than those of prototypes. In this context, the strength-temperature time factor relationship for the concrete specimens produced during winter in this study is presented in Equation 2, while the strength-maturity factor relationship for standard cylindrical concrete specimens cured at 22.8°C under laboratory conditions, as presented in ACI PRC-306 (2016), is provided in Equation 3.

$$\sigma = 0.0165M - 0.0449 \quad (2)$$

$$\sigma = 0.86\ln(M) - 48.09 \quad (3)$$

In Equation 2 and Equation 3; *σ:* Axial compressive strength of standard cylinder specimen (MPa), *M*: Temperature-time factor (°C.Hour) calculated with Equation 1, taking the initial temperature as -2.2 °C

Equation 2 was derived for concrete samples produced under real winter conditions, whereas Equation 3 is proposed for standard cylindrical concrete samples cured in a laboratory environment at 22.8°C. It is important to note this distinction. A simple analysis based on the temperature-time factor values of samples produced under two different atmospheric conditions is deemed beneficial. The purpose of this analysis is to assess whether the maturity-strength relationship presented in a significant standard such as ACI PRC-306 (2016) can be used to predict axial compressive strength for samples produced in winter. The 3-day axial compressive strength of the concrete samples produced in winter can be expressed as 3.6 MPa (4.20.85) for standard cylindrical specimens. The corresponding temperature-time factor value for this sample is 219.1 °C-hours. When this temperature-time factor value is substituted into Equation 3, an unrealistic value of -1.7 MPa is obtained. A similar assessment for the 7-day sample data shows that the temperature-time factor calculated as 487.0 °C-hours corresponds to an axial compressive strength of 5.1 MPa when substituted into Equation 3, which is below the expected 8.0 MPa value (9.40.85). This simple evaluation indicates that temperature-time factor-axial compressive strength relationships are required for concrete poured in winter. These relationships could be useful for determining the formwork removal periods in winter. Although the temperature-time factor-axial compressive strength relationship for concrete samples produced with R-type cement in winter is presented in Equation 2, further studies should be conducted to generate relationships with broader data in this field.

4. Conclusions

This study was conducted to examine the effects of the protection method using greenhouse plastic on the axial compressive strength of concrete samples produced with R-type cement in winter without any additives. In the practice, apart from wrapping with greenhouse plastic, no additional protection measures such as heating were applied to the concrete produced in winter. The conclusions drawn from the research can be summarized as follows:

- During the first 24 hours after concrete pouring, the internal temperature of the concrete did not drop below the initial/datum temperature of -2.2°C.
- It was assessed that the first four phases of hydration (mixing, waiting, hardening, cooling) occurred within the first 24 hours, and the process entered the densification phase.
- Concrete samples produced in winter with a C30/37 mix design reached 48% of their 28-day axial compressive strength. Concrete samples produced and maintained under sub -20°C winter conditions did not reach the targeted axial compressive strength values for 28 days. It is believed that higher strengths could be achieved by applying heating under the greenhouse plastic.
- The temperature-time factor parameter was selected as the maturity index, and based on the calculations, a maturity-strength relationship for concrete samples produced in winter was proposed. However, further studies in this area are recommended.

Acknowledgments

The study was conducted as part of the project titled "Experimental Investigation of the Behavior of Reinforced Concrete Beams Poured in Cold Weather (Winter) Under Bending Effects" (TÜBİTAK1001-219M403), using the materials and equipment acquired for the project. The authors of the text would like to express their gratitude to TÜBİTAK (The Scientific and Technological Research Council of Türkiye) for their contributions; special thanks are extended to Batuhan Çınar for his valuable assistance in sample preparation.

Abstract. Non-destructive testing methods based on water penetration into porous materials through a defined surface area are widely used for characterizing construction materials such as concrete, alkali-activated mortars, and soil-based composites. Among these methods, the Karsten tube test stands out due to its practicality and cost-effectiveness, allowing applications in laboratory and field conditions. In this study, water ingress measurements were performed on 3D-printable composites namely, cement based, alkali-activated, and soil/clay based materials using the karsten tube. With the increasing use of 3D-printed structural composites produced by layered manufacturing techniques, the need for rapid and reliable determination of their water transport mechanisms has become critical. In this context, the amount of water transported through the materials over different durations was measured and classified based on material types. The experimental time series data obtained were analyzed using machine learning algorithms to develop predictive models. The performance of the models was evaluated through supervised learning performance metrics, and different algorithms were comparatively assessed. As a result, artificial intelligence-based models with high predictive accuracy were developed to characterize the water transport mechanisms of 3D-printable composite materials.

Keywords: 3D printable building materials; Water transport; Karsten tube; Machine learning

1. Introduction

In recent years, three-dimensional (3D) printable composite materials have emerged as a significant innovation in the construction industry due to their design flexibility, rapid production, and cost efficiency (Khan et al., 2024). With the development of cement-based, alkali-activated, and soil/clay-based 3D composites, there has been growing interest in evaluating their mechanical (K. Liu et al., 2023), environmental, and durability (Sun et al., 2022) performances. However, the water transport mechanisms in these new-generation materials remain insufficiently understood.

Water transport in building materials is critically important for service life and resistance to environmental effects. In this context, non-destructive testing methods are widely used to assess material permeability; the Karsten tube test is one such method used to examine the water absorption behavior of porous construction materials(Alves et al., 2019). The RILEM Test Method II.4 allows for the standardized application of this test under both laboratory and field conditions (PROSOCO, 2021).

Recently, the use of artificial intelligence and machine learning techniques has become increasingly common in modeling complex processes such as water transport. For instance, (Hosseinzadeh et al., 2023) demonstrated that support vector machines, random forest algorithms, and deep learning models achieved high accuracy in predicting the chloride diffusion coefficient in concrete, indicating their strong potential for permeability-related estimations.

In this study, water transport mechanisms were investigated by conducting Karsten tube tests on three different types of 3D-printable composite materials: cement-based, alkali-activated, and soil/clay-based. Time-series data obtained from the experiments were analyzed using machine learning algorithms to develop predictive models for water transport. The performance of these models was evaluated using supervised machine learning performance metrics, and the prediction accuracy of different algorithms was compared. Accordingly, the study aims to enhance the understanding and predictability of water transport behavior in various composite materials.

2. Material and method

2.1. Material

In this study, three different types of 3D-printable composite mixtures were investigated: cement-based, alkali-activated, and soil-based composites. For the cement-based composite, silica sand with a maximum particle size of 2 mm, CEM I 42.5R cement, sodium carboxymethyl cellulose (CMC), and a superplasticizer were used. The alkali-activated composite was prepared using silica sand, sodium hydroxide, sodium silicate, a superplasticizer, and ground granulated blast furnace slag (GGBFS). For the soil-based composite, clay, lime, α-hemihydrate gypsum, and silica sand were used to produce the third type of composite.

2.2. Method

In this study, samples were produced using three different materials: soil-based (clay), geopolymer, and conventional concrete. For each material, a spiral geometry model was first designed and transferred to the 3D printer. The prepared mixtures were printed using a 3D printer to form structures with a base area of 40 cm × 20 cm and a height of 4 cm, following predefined coordinates. After printing was completed, a water absorption test was performed on the printed plates using a Karsten tube. Additionally, samples measuring 4 cm × 4 cm × 16 cm were cut from the plates using a concrete cutter for compressive and flexural strength tests.

Furthermore, three samples for each material were produced from the same mix using molds of 4 cm × 4 cm × 16 cm dimensions. Both mold-cast specimens and those cut from the 3D-printed plates were subjected to compressive and flexural strength tests. These tests were carried out in accordance with the TS EN 196-1 standard. The results from both methods were evaluated comparatively by calculating the average of the values obtained from individual samples. The materials used in the experiments, the testing procedures, and the printing process are illustrated in Fig. 1, while the Karsten tube test and 3D printing applications for the three composites are presented in Fig. 2.

The main objective of the Karsten tube test was to determine the water absorption characteristics and compare the water transport mechanisms of 3D-printed soil-based, geopolymer, and conventional concrete composite specimens. The water absorption performance of the samples was determined using Karsten tubes in accordance with the RILEM testing method. The tubes were attached to the sample surfaces using waterproof silicone and then filled with water. Following the start of the test, measurements were taken at time intervals of 1, 2, 3, 4, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, and 60 minutes. Based on these readings, the total amount of absorbed water was calculated.

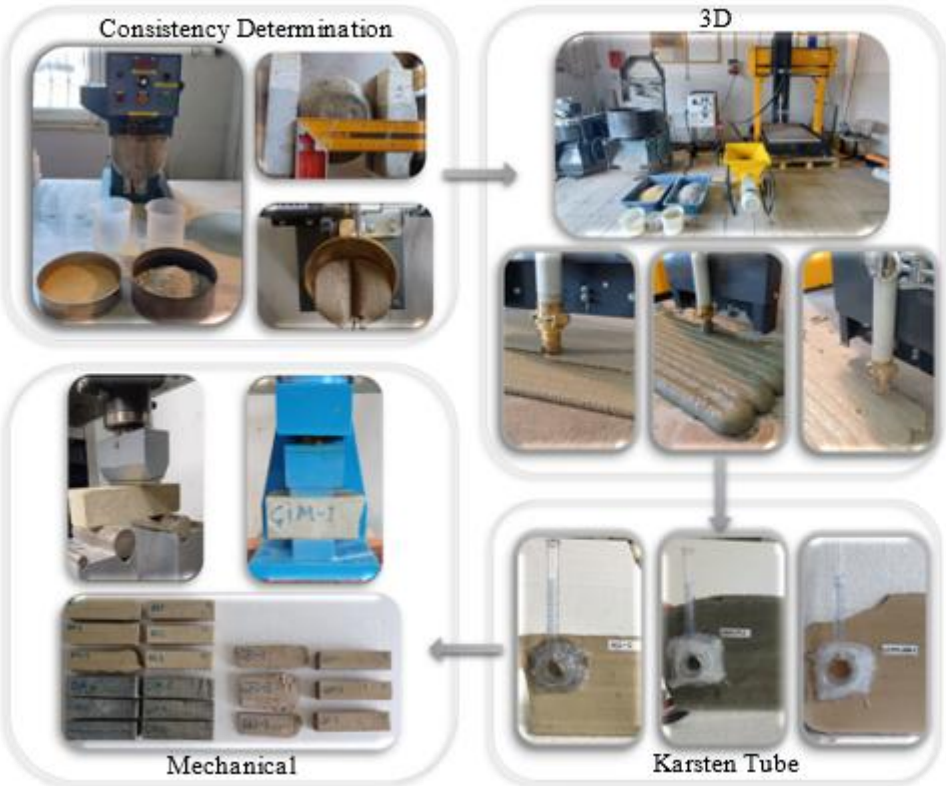

Fig. 1. Experimental steps

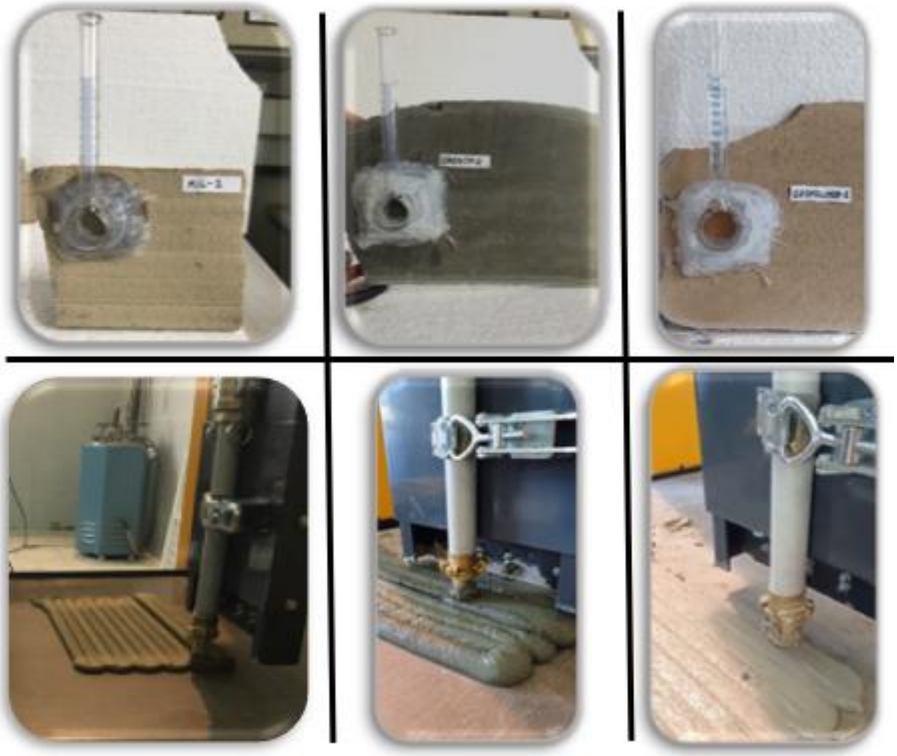

Fig. 2. 3D print and karsten tube experimental steps

In the artificial intelligence phase of the study, regressive prediction models were established using data obtained from the water absorption experiment conducted with the Karsten tube. In the models, the prediction performances of different algorithms are determined. The results are analyzed with regression performance metrics, and at the same time, it is determined how close the algorithms are to reality at different learning-test ratios. Firstly, the models were run with a learning-test ratio of 70%-30% in all algorithms, and the performance metrics SE, MSE, RMSE, MAD, MAPE, R, and R2 were evaluated comprehensively. Then, the prediction performance of different algorithms at different learning-test rates was also tested. In the prediction studies, Karsten tube measurements at different minutes were entered into the system as different feature columns, and the column showing the water absorption values at the 60th minute was entered into the prediction model as the target column.

3. Result and discussion

3.1. Machine learning results

In this study, we used four different machine learning methods—k-Nearest Neighbors (k-NN), Artificial Neural Network (ANN), Support Vector Machine (SVM), and Random Forest (RF) —to predict how much water would be absorbed in 60 minutes, using time-series data from the Karsten tube test. The performance of each algorithm was evaluated across various feature rate percentages using multiple supervised learning metrics, including Mean Absolute Deviation (MAD), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Percentage Error (MAPE), standard error (SE), and the determination coefficients (R and R^2). The comparative results of all models are illustrated in Fig. 3.

According to the results, the ANN and SVM models consistently achieved low error values across all metrics and maintained high R^2 values above 0.98, demonstrating their strong generalization capability and accurate prediction performance. In contrast, the k-NN algorithm exhibited relatively poor performance, with significantly higher MAD, MSE, RMSE, and MAPE values and a noticeably lower R^2 value across the tested feature rates.

The performance of the RF model showed substantial improvement with increasing feature rate. While its error metrics were relatively high at lower feature rates (45–70%), the model's accuracy improved markedly at higher rates (above 85%), where both MSE and RMSE values declined, and R^2 values approached 0.95. This indicates that the effectiveness of the RF algorithm is more sensitive to the proportion of input features used in training.

In addition to numerical performance metrics, the prediction trends of each model were also visualized through fit curve plots under different learning-test ratios (50:50, 60:40, and 70:30), as illustrated in Fig. 4. These plots provide a comparative view of how closely each model's predictions follow the actual values.

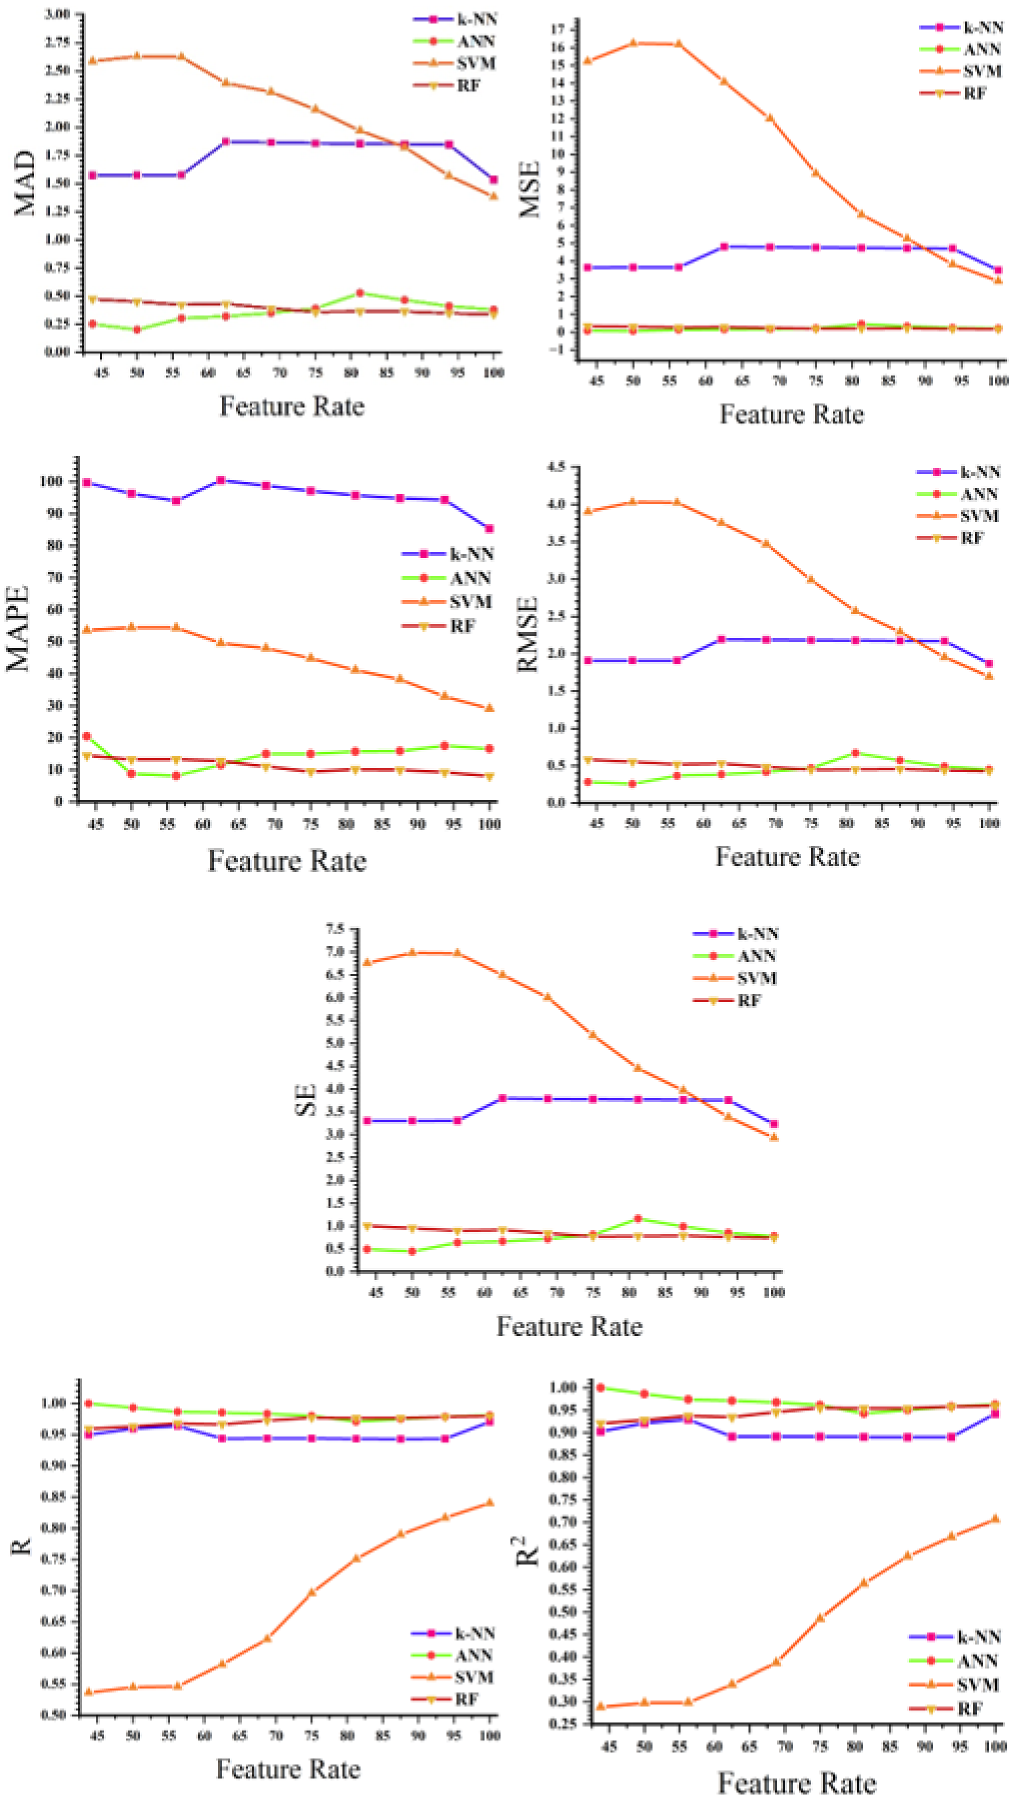

Fig. 3. Performance metrics

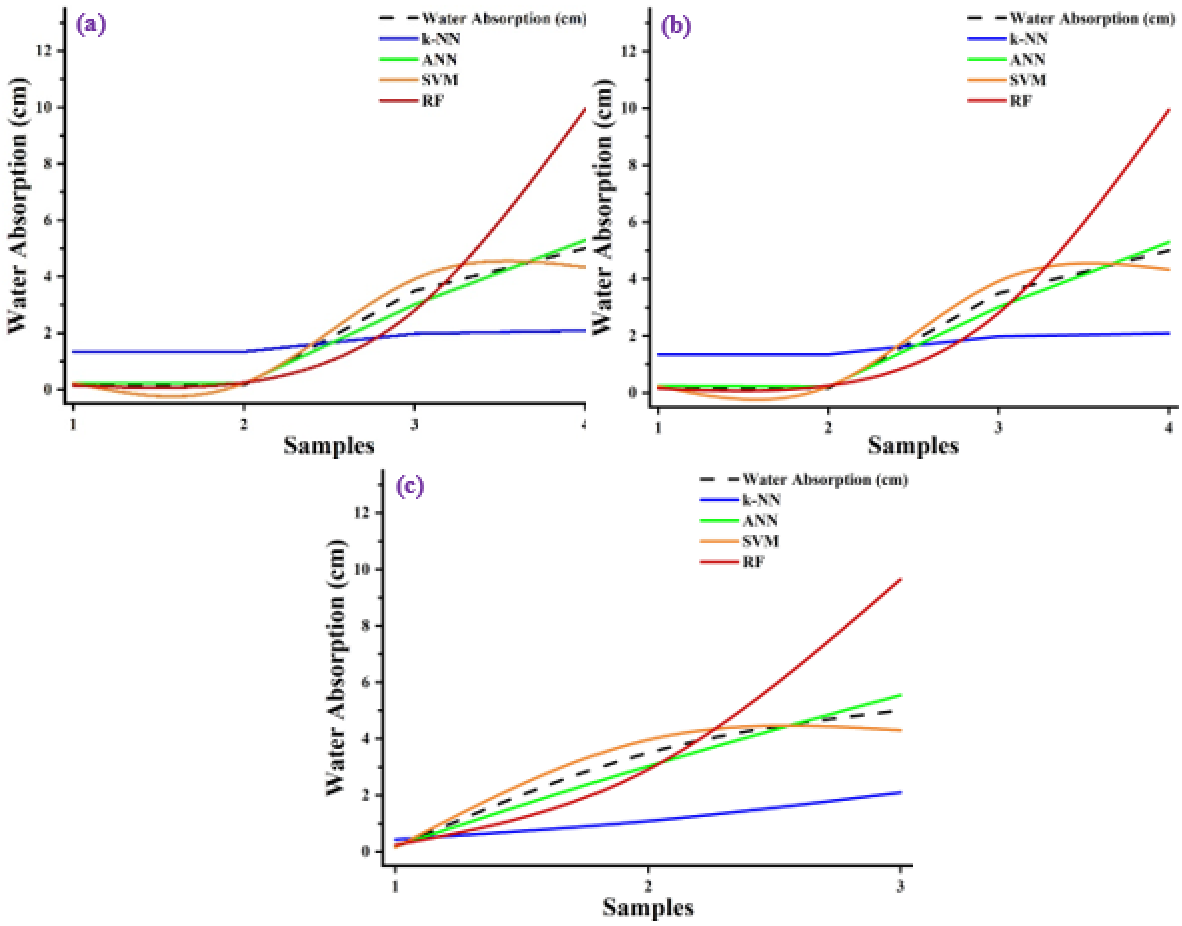

Fig. 4. Prediction performance of k-NN, ANN, SVM, and RF algorithms compared to actual values under different learning-test ratios: (a) 50:50, (b) 60:40, and (c) 70:30

At a 50:50 learning-test split, the RF model showed the closest alignment with the actual data across all samples, followed by the ANN. The SVM model exhibited a sharper deviation at higher sample values, while k-NN produced nearly flat predictions, failing to capture the overall data trend. With a 60% training ratio, the ANN and RF both demonstrated improved alignment with the actual curve. The SVM model slightly improved in the early samples but continued to diverge significantly in the later range. The prediction line of k-NN remained nearly linear and showed limited learning capacity. At the highest training ratio (70:30), the RF and ANN models maintained strong conformity with the actual trend. The RF produced a smoother approximation across the entire range. The performance of SVM remained inconsistent, and k-NN continued to underperform with minimal changes.

When the prediction performances of the algorithms are evaluated in general, SVM and k-NN algorithms exhibited lower performance than ANN and RF algorithms. The fact that the data obtained here are not extensive because they are obtained from a series of experimental samples has highlighted the sensitivity of SVM and k-NN algorithms to the low amount of data due to their nature.

3.2. Flexural and compressive strength results

For each test group, the flexural and compressive strength results were determined by applying the tests to both 3D-printed and mold-cast specimens. The flexural strength values obtained according to the material type and specimen form are presented in Fig. 5. When the graph is examined by material type, the highest flexural strength values in the 3D-printed and mold-cast groups were observed in the cement-based composites, with 8.88 MPa and 8.26 MPa, respectively; while the lowest values were recorded in the clay-based composites, with 1.50 MPa and 1.08 MPa, respectively. These results indicate that the flexural strength of the 3D-printed specimens was either lower than or comparable to that of the cast specimens (Albar et al., 2020).

Fig. 6. presents the compressive strength test results. When the results for the three types of composites are examined, it is observed that similar compressive strength values were recorded between the 3D-printed and mold-cast specimens, except for the alkali-activated composites (C. Liu et al., 2021). The compressive strength values of the 3D-printed samples were 48.85 MPa for cement-based composites, 26.77 MPa for alkali-activated

composites, and 1.86 MPa for clay-based composites. (Ly et al., 2021) concluded that cement-based mortars exhibit higher compressive strength than mortars based on alkali-activated materials. In the mold-cast specimens, the highest compressive strength was recorded for the alkali-activated composite at 60.90 MPa, while the lowest was observed for the clay-based composite at 3.14 MPa.

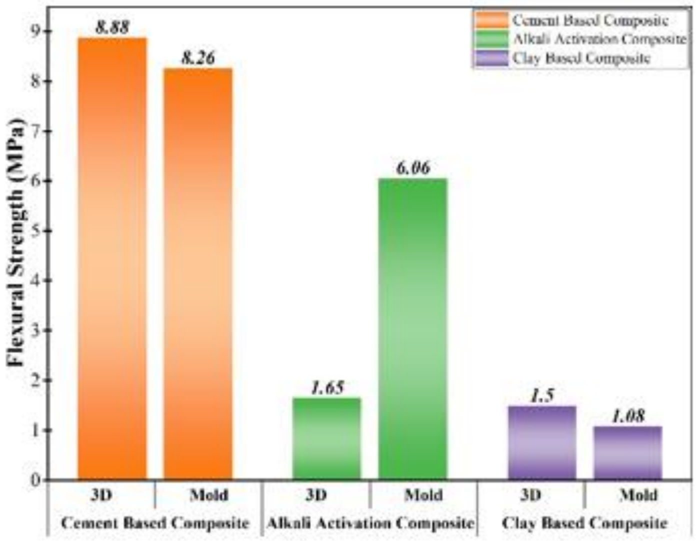

Fig. 5. Flexural strength

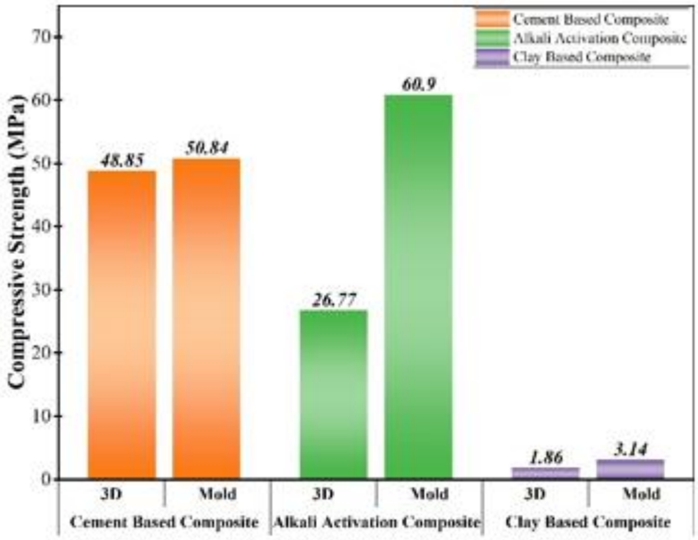

Fig. 6. Compressive strength

4. Conclusions

This study investigated the water transport behavior and mechanical properties of 3D-printable composites through both non-destructive and destructive test methods, supported by artificial intelligence-based modeling. Based on the findings, the following conclusions can be drawn:

- The Karsten tube test effectively distinguished the water absorption behaviors of different material types, indicating that cement-based composites absorbed the least amount of water, while clay-based composites showed the highest uptake.
- Among the evaluated machine learning algorithms, the ANN and RF models yielded the most accurate predictions for 60-minute water absorption, whereas the SVM and k-NN models showed lower predictive performance.
- The prediction performance of the RF model notably improved with higher feature rates, while the ANN remained consistently accurate across all conditions.

- Flexural strength tests showed that cement-based composites exhibited the highest strength in both 3D-printed and mold-cast forms, while clay-based specimens demonstrated the lowest strength levels.
- In compressive strength tests, 3D-printed cement-based composites achieved the highest strength values overall, whereas mold-cast alkali-activated composites outperformed their 3D-printed counterparts.

These outcomes confirm that combining artificial intelligence-based approaches with both non-destructive and mechanical testing provides a reliable framework for evaluating the performance of new-generation 3D-printable building materials.

Acknowledgments
The authors would like to express their sincere gratitude to Fibrobeton Company for providing material support for this study.

Abstract. Seismic resilience of multi-story buildings is critical in mitigating earthquake-induced risks to structural integrity and human safety. This study evaluates the effectiveness of three viscoelastic damper (VED) arrangements—Concentrated, Knee Braced, and Chevron—in enhancing the seismic performance of 10-, 15-, and 20-story steel frame buildings. Using ETABS and finite element analysis (FEA) using ABAQUS, the research models dynamic responses under three seismic records (Hector Mine, Landers, and Manjil) to assess roof displacements, energy dissipation, base shear, and stiffness. Results demonstrate that the Concentrated VED configuration consistently outperforms other arrangements, reducing roof displacements by 18–32%, increasing energy dissipation by 42–46%, and improving structural stiffness by 24–36% across all models. The Chevron arrangement showed notable reductions in lateral drifts (up to 41% in 20-story buildings), while Knee Braced systems provided moderate flexibility but lower overall efficacy. The Concentrated configuration's strategic placement in high-stress zones enables uniform energy dissipation and minimizes residual displacements (29–39% reduction), underscoring its robustness under diverse seismic conditions. Practical implications highlight the configuration's suitability for integration into seismic design codes, particularly for high-rise structures, offering cost savings through reduced post-earthquake repairs and enhanced occupant safety. The study advances the understanding of VED optimization, advocating for their adoption in earthquake-prone regions to balance performance, economic viability, and sustainability. These findings provide engineers with actionable insights for retrofitting existing structures or designing new resilient buildings, ultimately contributing to safer urban infrastructure in seismic zones.

Keywords: Viscoelastic dampers; Seismic performance; Steel frames; Damper arrangements; Comparative analysis

1. Introduction

Seismic resilience is a cornerstone of modern structural engineering, particularly for multi-story buildings located in earthquake-prone regions. Earthquakes pose significant threats to both structural integrity and occupant safety, often resulting in catastrophic consequences such as building collapse, infrastructure damage, and loss of life (Stein & Wysession, 2009).

The dynamic forces generated by seismic events can induce excessive vibrations, leading to structural deformations, material fatigue, and potential failure of critical components (Clough & Penzien). In urban areas with high population densities, the risks are amplified due to the concentration of high-rise structures and complex infrastructure systems (Solberg et al., 2009). The economic and social impacts of earthquakes, including direct property damage, disruption of essential services, and long-term recovery costs, further underscore the need for robust seismic design strategies (Center, 2015; Hecker, 1995). Enhancing the resilience of multi-story buildings is thus imperative to mitigate these risks, ensuring that structures can withstand seismic forces while maintaining functionality and safety.

VEDs have emerged as a highly effective solution for improving the seismic performance of buildings by dissipating energy and reducing structural vibrations. These passive energy dissipation devices utilize materials that exhibit both viscous and elastic properties, allowing them to absorb and dissipate seismic energy through internal friction and deformation (Matsagar & Jangid, 2005; Zhang & Soong, 1992). By integrating VEDs into structural systems, engineers can significantly reduce the amplitude of vibrations during an earthquake, thereby

golden light publishing

minimizing damage to structural and non-structural components (Symans et al., 2008). Unlike traditional bracing systems, VEDs offer a compact and lightweight design, making them suitable for both new constructions and retrofitting existing buildings (Abramovich, 2021).

Their ability to provide non-linear damping across a wide range of frequencies enhances their versatility in addressing diverse seismic loading conditions (Vaiana et al., 2019). The growing adoption of VEDs in seismic design reflects their proven efficacy and alignment with sustainable construction practices, offering a balance between performance and cost-effectiveness (Mehrabi et al., 2017). This study aims to evaluate the seismic performance of various viscoelastic damper arrangements—specifically Concentrated, Knee Braced, and Chevron configurations—in multi-story special steel frame buildings of 10, 15, and 20 stories.

2. Literature review

2.1. Overview of viscoelastic dampers

VEDs are passive energy dissipation devices widely recognized for their ability to enhance the seismic performance of structures, particularly steel frames, by converting mechanical energy into heat through internal friction and deformation of viscoelastic materials (Hao et al., 2024; Matsagar & Jangid, 2005; Zhang & Soong, 1992). This dual behavior enables VEDs to provide effective energy dissipation across a broad range of frequencies and amplitudes, making them highly adaptable to dynamic loading conditions such as earthquakes (Vaiana et al., 2019). Key properties of VEDs include their compact and lightweight design, which facilitates integration into both new and existing structures without significant modifications (Abramovich, 2021). Additionally, VEDs offer customizable damping characteristics through adjustments in material composition, thickness, and geometry, allowing tailored solutions for specific structural requirements (Soto & Adeli, 2013). Their benefits include significant reduction in structural vibrations, enhanced occupant safety, and cost-effectiveness compared to active control systems or tuned mass dampers (Mehrabi et al., 2017; Mortezaei & Zahrai, 2009). In steel frame applications, VEDs have been shown to reduce seismic-induced displacements and accelerations, thereby minimizing structural and non-structural damage (Symans et al., 2008; Wang et al., 2018). However, challenges such as temperature sensitivity and potential long-term material degradation require careful consideration in design and maintenance (Soong & Dargush, 1997; Systèmes, 2016).

2.2. Previous studies on damper arrangements

Research on VED arrangements—specifically Concentrated, Knee Braced, and Chevron configurations—has provided valuable insights into their seismic performance in steel frames. The Concentrated arrangement, where VEDs are strategically placed at centralized locations, has been studied for its ability to maximize energy dissipation and structural stiffness. Studies indicate that this configuration effectively reduces roof displacements and enhances overall stability under seismic loads (Cetin et al., 2019; Hao et al., 2024). Knee Braced arrangements, incorporating VEDs at diagonal brace joints, have been explored for their capacity to improve energy dissipation while maintaining structural flexibility. Research suggests that Knee Braced systems can achieve moderate reductions in seismic response, though their effectiveness is often limited compared to other configurations (Kaleybar & Tehrani, 2021; Marko et al., 2006). Chevron arrangements, characterized by V-shaped bracing with VEDs, have been noted for their ability to increase structural stiffness and provide balanced energy dissipation. However, their performance is generally less pronounced than that of Concentrated arrangements (Chen et al., 2020; Kaleybar & Tehrani, 2021). For instance, Chen et al. conducted field tests on a cable-stayed bridge, demonstrating that VEDs in a Chevron-like configuration provided consistent damping across multiple modes, though with reduced efficacy at higher frequencies.

Despite these advancements, prior studies often focus on individual configurations or specific structural types, lacking comprehensive comparative analyses across Concentrated, Knee Braced, and Chevron arrangements under identical seismic conditions. Furthermore, there is limited research directly benchmarking VED-equipped structures against brace-only systems to quantify their relative benefits (Alhasan et al., 2022; Cetin et al., 2019). This study addresses these gaps by systematically comparing the seismic performance of these three VED arrangements in multi-story steel frames, providing a direct evaluation of their effectiveness relative to brace-only structures. Overall, while prior studies highlight the efficacy of individual VED arrangements, a systematic comparison under identical seismic conditions is lacking, which this study addresses.

2.3. Focus of the current study

This study contributes to the field by conducting a detailed evaluation of the seismic performance of Concentrated, Knee Braced, and Chevron VED arrangements in 10-, 15-, and 20-story special steel frame buildings using finite element analysis. Unlike previous studies that often examine configurations in isolation, this research provides a direct comparative analysis under consistent seismic loading conditions. By benchmarking VED-equipped structures against brace-only systems, the study quantifies the improvements in key performance metrics, including roof displacement, energy dissipation, and structural stiffness. The use of finite element analysis enables precise modeling of dynamic structural behavior, offering insights into the optimal VED arrangement for seismic mitigation. These findings aim to guide engineers in selecting effective damper configurations, enhancing the resilience of multi-story buildings in earthquake-prone regions.

3. Methodology

This study employs a comprehensive FEA approach to evaluate the seismic performance of VED arrangements in multi-story steel frame buildings. The methodology integrates advanced software tools, ETABS and ABAQUS, to model, simulate, and assess structural responses under seismic loading. ETABS facilitates structural design and static/dynamic analysis, while ABAQUS provides detailed non-linear material and interaction simulations, ensuring a robust evaluation of VED effectiveness. Fig. 1 shows the flowchart of the analysis workflow integrating ETABS and ABAQUS, illustrating the transition from structural modeling to detailed FEA.

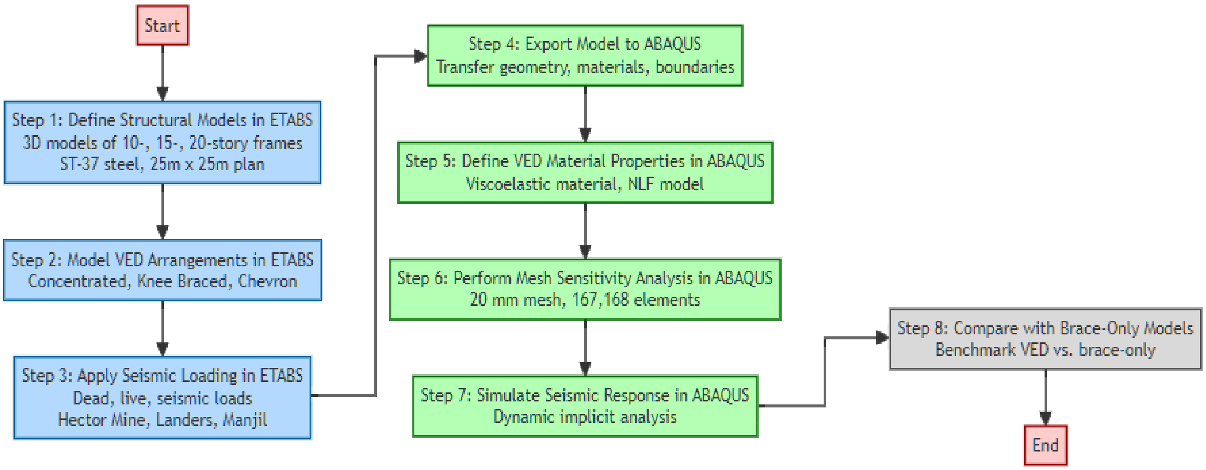

Fig. 1. Flowchart of the analysis workflow

3.1. Finite element analysis approach

The analysis leverages ETABS for initial structural modeling and ABAQUS for detailed FEA. ETABS, known for its robust capabilities in multi-story building design, was used to create three-dimensional models of steel frames, define material properties, and simulate VED arrangements (Concentrated, Knee Braced, and Chevron) under seismic loads (Fig. 2). Its intuitive interface enabled accurate prediction of story drifts, base shear, and roof displacements. ABAQUS complemented these findings by simulating the non-linear behavior of VED materials and their interactions with the steel frame, focusing on energy dissipation and structural stiffness. The synergy of both tools ensured a comprehensive analysis, with ETABS providing the overall structural framework and ABAQUS offering precise material-level insights.

3.2. Structural models

The study examines steel frame buildings with 10, 15, and 20 stories, each with a uniform floor height of 3 meters and a 25 m x 25 m plan dimension, reflecting typical high-rise configurations. The frames are designed as special moment-resisting steel frames, constructed using ST-37 steel (considering nonlinearity of the material) with a yield strength (Fy) of 2400 kg/cm² and ultimate tensile strength (Fu) of 3600 kg/cm² (Rasmussen, 2003). Structural elements, including beams (IPE profiles) and columns (Box profiles), were sized based on seismic design requirements, as detailed in Table 1.

Table 1. Structural and seismic design properties of 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
Plan Dimensions	25 m x 25 m	25 m x 25 m	25 m x 25 m
Floor Height	3 m	3 m	3 m
Total Height	30 m	45 m	60 m
Steel Grade	ST-37 (Fy = 2400 kg/cm², Fu = 3600 kg/cm²)		
Beam Sections	IPE 65.40 (all floors)		
Column Sections	Stories 1–6: Box 300.25 Stories 7–8: Box 250.20 Story 9: Box 200.15 Story 10: Box 150.15	Stories 1–4: Box 350.25 Stories 5–10: Box 300.25 Stories 11–12: Box 250.20 Stories 13–14: Box 200.15 Story 15: Box 150.15	Stories 1–5: Box 450.35 Stories 6–8: Box 400.30 Stories 9–11: Box 350.25 Stories 12–16: Box 300.25 Stories 17–18: Box 250.20 Story 19: Box 200.15 Story 20: Box 150.15

3.3. Seismic loading conditions

Seismic loads were applied based on three earthquake records selected from the PEER database to represent realistic seismic hazards. These records, detailed in Table 2, were first scaled to match site configuration (Huang et al., 2008; Silwal et al., 2015). They vary in peak ground acceleration (PGA: 0.598–1.96 g), duration, and frequency content, capturing a range of seismic intensities. In ETABS, seismic design parameters included a base design acceleration (A) of 0.3, soil type III, and a structural importance factor (I) of 1. Load combinations followed Iranian seismic design codes and ASTM standards, incorporating dead loads (528 kg/m² for steel deck roofing), live loads (200 kg/m²), and earthquake loads (Table 2). In ABAQUS, seismic excitations were applied as time-history accelerations at the base, with fixed boundary conditions to simulate a rigid foundation.

Table 2. Selected earthquake records

EQ.	Station	Distance from Epicenter	5-75% Duration (sec)	5-95% Duration (sec)	PGA (g)
Hector Mine	Hector	10.35	7.6	11.7	0.77
Landers	Yermo	23.62	10.9	18.9	0.598
Manjil_ Iran	Abbar	12.55	10.8	29.1	1.96

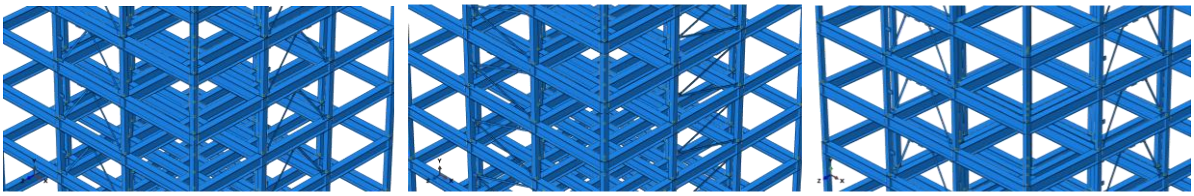
3.4. Details of damper arrangements

Three VED arrangements were modeled: Concentrated, Knee Braced, and Chevron, each strategically placed to optimize seismic performance. The VEDs were composed of viscoelastic materials (Kim et al., 2010) with low temperature dependency, validated through dynamic testing (Xu et al., 2019). Material properties included a density of 2450 kg/m³, Young's modulus of 1000 MPa, and zero Poisson's ratio, ensuring no lateral deformation under stress (Table 3). The arrangements are described as follows:

Concentrated: VEDs are centralized within the frame, typically at high-stress zones, to maximize energy dissipation and stiffness.

Knee Braced: VEDs are placed at diagonal brace joints, enhancing damping while maintaining frame flexibility.

Chevron: VEDs are arranged in a V-shaped bracing pattern, providing balanced stiffness and energy dissipation.



(a) (b) (c)

Fig. 4. VED arrangements (a) Concentrated (b) Knee Braced (c) Chevron

3.5. Sensitivity analysis and verification of the VEDs

In ABAQUS, VEDs were modeled using a non-linear four-element (NLF) mechanical model, comprising two non-linear dashpots and two non-linear springs, calibrated against experimental data. A 20 cm mesh size was chosen to balance accuracy and computational efficiency in the sensitivity analysis. With this mesh, the reaction force in the x direction (RF1) is 127 kN, which is a relatively high level of accuracy compared to larger mesh sizes (e.g., 40–50 cm) while maintaining acceptable computational time. Although finer meshes (e.g., 5–15 cm) can achieve even greater precision, they require significantly longer computational times; for example, refining the mesh from 20 cm to 15 cm only slightly increases RF1, but computation time grows from 1134 to 1225 minutes.

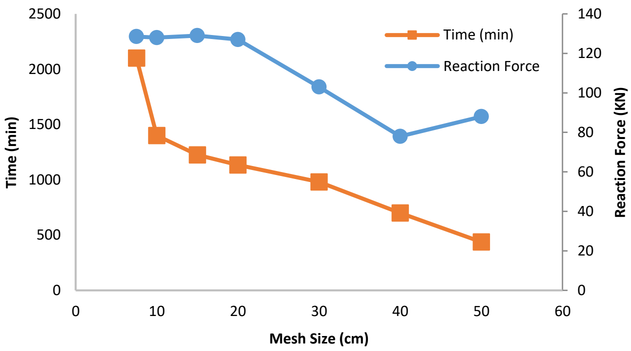


Fig. 5. Mesh sensitivity analysis based on time and reaction force

In the current study, the frame model consists of a three-dimensional geometry with a total of 328,388 nodes and 167,168 elements, meshed using second-order quadrilateral elements (C3D8R). These second-order elements more accurately capture the structure's response under loading compared to linear quadrilateral elements, as they can more effectively represent curvature and deformation. The base of the structure is assumed to be fixed.

To ensure the reliability of the VED model, the material properties and hysteretic behavior were validated against experimental data from a prior study (Xu et al., 2019). The validation process involved simulating a VED sample (70 mm x 80 mm, 5 mm thick, 5600 mm² shear area) in ABAQUS under cyclic sinusoidal loading at a frequency of 0.33 Hz. The loading was applied using a displacement-controlled scheme, with displacements varying sinusoidally between -20 mm and +20 mm. This produced a force-displacement curve representing the VED's response, which was compared to the reference results in (Xu et al., 2019).

Table 3. VED material properties

Parameter	Value
Density (kg/m³)	2450
Young's Modulus (MPa)	1000
Poisson's Ratio	0

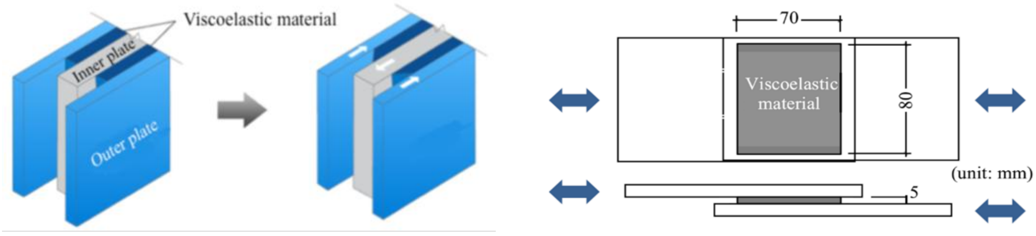

Fig. 6. Viscoelastic damper model from Xu et al. (2019)

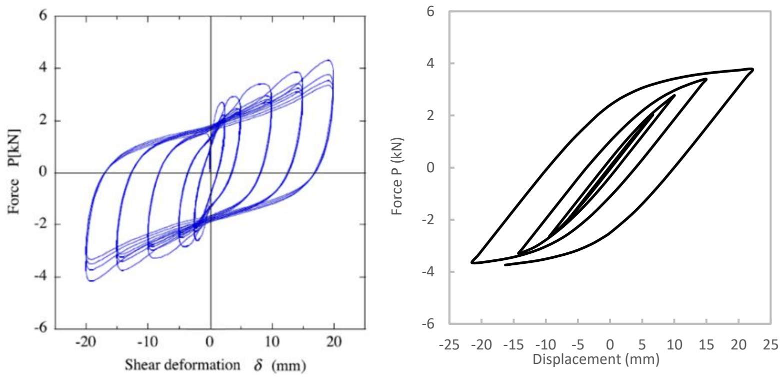

(a) (b)

Fig. 7. Comparison of force-displacement loops: (a) Xu et al. (2019), (b) Current study

The reference curve from (Xu et al., 2019) showed shear deformation (x-axis) from -20 mm to +20 mm and force (y-axis) from -4 kN to +4 kN, exhibiting complex hysteretic loops indicative of real-world behavior with multiple cycles. In contrast, the simulated curve in this study displayed a single, closed elliptical loop within the same displacement (-20 mm to +20 mm) and force (-4 kN to +4 kN) ranges, suggesting a more idealized or controlled response. This difference is attributed to the use of fewer mesh nodes in the current model to enhance computational efficiency, resulting in a simpler hysteretic loop compared to the more detailed, multi-cycle loops in (Xu et al., 2019). Despite this, the discrepancy between the simulated and reference curves was less than 10%, indicating strong agreement and validating the model's accuracy.

3.6. Comparison with brace-only structures

To quantify VED effectiveness, the study compares VED-equipped structures with brace-only structures (without VEDs) under identical seismic conditions. Brace-only models used standard steel bracing (e.g., ASTM A992) without viscoelastic components, designed to match the geometry and loading of VED models (ASTM, 2015). Key performance metrics—displacement, energy dissipation, base shear, and structural stiffness—were evaluated in both ETABS and ABAQUS to highlight the improvements offered by VEDs over conventional bracing. The analysis focused on the ability of VEDs to reduce lateral displacements and dissipate seismic energy, providing a benchmark for their seismic mitigation potential.

4. Results

This subsection evaluates the seismic performance of the Concentrated VED arrangement in 10-, 15-, and 20-story steel frame buildings, analyzed using FEA in ABAQUS.

4.1. Concentrated VEDs

4.1.1. Displacements

This subsection reports roof displacements, lateral displacements, and residual displacements for the 10-, 15-, and 20-story models equipped with Concentrated VEDs, derived from ABAQUS dynamic analyses, summarized in Table 4. Concentrated VEDs reduce displacements by dissipating energy at high-stress zones, minimizing structural sway.

- *Roof Displacements:* For the 10-story model, the average roof displacement without VEDs is 162.3 mm, reduced by 32% to 110.69 mm with Concentrated VEDs. In the 15-story model, the no-VED displacement of 240.2 mm decreases by 21% to 189.93 mm with VEDs. For the 20-story model, the no-VED displacement of 364.52 mm is reduced by 18% to 297.47 mm with VEDs.
- *Lateral Displacements:* For the 10-story model, the maximum drift without VEDs is 213.09 mm, reduced by 27% to 157.22 mm with Concentrated VEDs. In the 15-story model, the no-VED drift of 308.60 mm decreases by 26% to 227.85 mm with VEDs. For the 20-story model, the no-VED drift of 590.30 mm is reduced by 25% to 439.44 mm with VEDs.
- *Residual Displacements:* For the 10-story model, the average residual displacement without VEDs is 70.6 mm, reduced by 29% to 49.9 mm with Concentrated VEDs. In the 15-story model, the no-VED residual displacement of 108.0 mm decreases by 35% to 70.7 mm with VEDs. For the 20-story model, the no-VED residual displacement of 173.6 mm is reduced by 39% to 105.9 mm with VEDs.

Table 4. Roof, lateral, and residual displacements for the 10-, 15-, and 20-story models

Displacement (mm)	Property	10-Story Model	15-Story Model	20-Story Model
Roof	No VED	162.3	240.2	364.52
	Concentrated VED	110.69	189.93	297.47
	Reduction (%)	32	21	18
Lateral	No VED (Max Drift)	213.09	308.60	590.30
	Concentrated VED (Max Drift)	157.22	227.85	439.44
	Reduction (%)	27	26	25
Residual	No VED	70.6	108.0	173.6
	Concentrated VED	49.9	70.7	105.9
	Reduction (%)	29	35	39

4.1.2. Base shear

Base shear forces, calculated in ABAQUS, quantify the total lateral force resisted by the 10-, 15-, and 20-story steel frame models under seismic loading.

According to Table 5, for the 10-story model, the average base shear without VEDs is 56.9 MN, increased by 14% to 65.1 MN with Concentrated VEDs. In the 15-story model, the no-VED base shear of 83.6 MN increases by 23% to 102.8 MN with VEDs. For the 20-story model, the no-VED base shear of 135.3 MN increases by 18% to 159.2 MN with VEDs. Base shear increases with VEDs due to added stiffness, though this is offset by reduced displacements.

Table 5. Summary of average base shear (MN) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	56.9	83.6	135.3
Concentrated VED	65.1	102.8	159.2
Difference (%)	+14	+23	+18

4.1.3. Energy dissipation

According to Table 6, for the 10-story model, the average energy dissipation without VEDs is 341.2 kN·m, increased by 42% to 483.5 kN·m with Concentrated VEDs. In the 15-story model, the no-VED energy dissipation of 484.5 kN·m rises by 46% to 708.2 kN·m with VEDs. For the 20-story model, the no-VED energy dissipation of 774.5 kN·m increases by 42% to 1100.2 kN·m with VEDs.

Table 6. Summary of average energy dissipation (kN·m) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	341.2	484.5	774.5
Concentrated VED	483.5	708.2	1100.2
Difference (%)	+42	+46	+42

4.1.4. Story stiffness

According to Table 7, for the 10-story model, the average story stiffness without VEDs is 468 kN/m, increased by 30% to 609 kN/m with Concentrated VEDs. In the 15-story model, the no-VED stiffness of 688 kN/m rises by 24% to 850 kN/m with VEDs. For the 20-story model, the no-VED stiffness of 1034 kN/m increases by 36% to 1407 kN/m with VEDs.

Table 7. Summary of average story stiffness (kN/m) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	468	688	1034
Concentrated VED	609	850	1407
Difference (%)	+30	+24	+36

4.2. Knee braced VED arrangement

4.2.1. Displacements

This subsection reports roof displacements, lateral displacements, and residual displacements for the 10-, 15-, and 20-story models equipped with Knee Braced VEDs, derived from ABAQUS dynamic analyses.

- *Roof Displacements:* For the 10-story model, the average roof displacement without VEDs is 162.3 mm, reduced by 36% to 104.7 mm with Knee Braced VEDs. In the 15-story model, the no-VED displacement of 240.2 mm decreases by 15% to 204.3 mm with VEDs. For the 20-story model, the no-VED displacement of 364.5 mm is reduced by 24% to 276.4 mm with VEDs.
- *Lateral Displacements:* For the 10-story model, the maximum inter-story drift without VEDs is 94.90 mm, reduced by 13% to 82.16 mm with Knee Braced VEDs. In the 15-story model, the no-VED drift of 113.88 mm decreases by 28% to 81.46 mm with VEDs. For the 20-story model, the no-VED drift of 134.76 mm is reduced by 17% to 111.60 mm with VEDs.
- *Residual Displacements:* For the 10-story model, the average residual displacement without VEDs is 70.6 mm, reduced by 25% to 52.8 mm with Knee Braced VEDs. In the 15-story model, the no-VED residual displacement of 108.0 mm decreases by 37% to 67.5 mm with VEDs. For the 20-story model, the no-VED residual displacement of 173.6 mm is reduced by 34% to 114.8 mm with VEDs.

Table 8. Roof, lateral, and residual displacements for the 10-, 15-, and 20-story models

Displacement (mm)	Property	10-Story Model	15-Story Model	20-Story Model
Roof	No VED	162.3	240.2	364.5
	Knee Braced VED	104.7	204.3	276.4
	Reduction (%)	36	15	24
Lateral	No VED (Max Drift)	94.90	113.88	134.76
	Knee Braced VED (Max Drift)	82.16	81.46	111.60
	Reduction (%)	13	28	17
Residual	No VED	70.6	108.0	173.6
	Knee Braced VED	52.8	67.5	114.8
	Reduction (%)	25	37	34

4.2.2. Base shear

According to Table 9, for the 10-story model, the average base shear without VEDs is 56.9 MN, increased by 17% to 66.3 MN with Knee Braced VEDs. In the 15-story model, the no-VED base shear of 83.6 MN increases by 17% to 97.5 MN with VEDs. For the 20-story model, the no-VED base shear of 144.4 MN increases by 12% to 162.2 MN with VEDs.

Table 9. Summary of average base shear (MN) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	56.9	83.6	144.4
Knee Braced VED	66.3	97.5	162.2
Difference (%)	+17	+17	+12

4.2.3. Energy dissipation

According to Table 10, for the 10-story model, the average energy dissipation without VEDs is 341 kN·m, increased by 40% to 480 kN·m with Knee Braced VEDs. In the 15-story model, the no-VED energy dissipation of 485 kN·m rises by 34% to 647 kN·m with VEDs. For the 20-story model, the no-VED energy dissipation of 775 kN·m increases by 54% to 1193 kN·m with VEDs.

Table 10. Summary of average energy dissipation (kN·m) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	341	485	775
Knee Braced VED	480	647	1193
Increase (%)	40	34	54

4.2.4. Story stiffness

According to Table 11, for the 10-story model, the average story stiffness without VEDs is 468 kN/m, increased by 41% to 661 kN/m with Knee Braced VEDs. In the 15-story model, the no-VED stiffness of 688 kN/m rises by 26% to 866 kN/m with VEDs. For the 20-story model, the no-VED stiffness of 1034 kN/m increases by 37% to 1420 kN/m with VEDs.

Table 11. Summary of average story stiffness (kN/m) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	468	688	1034
Knee Braced VED	661	866	1420
Increase (%)	41	26	37

4.3. Chevron VED arrangement

This subsection evaluates the seismic performance of the Chevron VED arrangement in 10-, 15-, and 20-story steel frame buildings, analyzed using finite element analysis in ABAQUS.

4.3.1. Displacements

This subsection reports roof displacements, lateral displacements, and residual displacements for the 10-, 15-, and 20-story models equipped with Chevron VEDs, derived from ABAQUS dynamic analyses. Chevron VEDs excel in lateral drift reduction due to their V-shaped bracing, distributing forces evenly.

- *Roof Displacements:* For the 10-story model, the average roof displacement without VEDs is 162.3 mm, reduced by 38% to 100.6 mm with Chevron VEDs. In the 15-story model, the no-VED displacement of 240.2 mm decreases by 25% to 179.2 mm with VEDs. For the 20-story model, the no-VED displacement of 364.5 mm is reduced by 28% to 263.3 mm with VEDs.
- *Lateral Displacements:* For the 10-story model, the maximum inter-story drift without VEDs is 188.80 mm, reduced by 38% to 117.06 mm with Chevron VEDs. In the 15-story model, the no-VED drift of 279.42 mm decreases by 30% to 196.35 mm with VEDs. For the 20-story model, the no-VED drift of 554.85 mm is reduced by 41% to 326.96 mm with VEDs .
- *Residual Displacements:* For the 10-story model, the average residual displacement without VEDs is 70.6 mm, reduced by 32% to 48.0 mm with Chevron VEDs. In the 15-story model, the no-VED residual displacement of 108.0 mm decreases by 41% to 63.7 mm with VEDs. For the 20-story model, the no-VED residual displacement of 173.6 mm is reduced by 43% to 99.0 mm with VEDs.

Table 12. Roof, lateral, and residual displacements for the 10-, 15-, and 20-story models

Displacement (mm)	Property	10-Story Model	15-Story Model	20-Story Model
Roof	No VED	162.3	240.2	364.5
	Chevron VED	100.6	179.2	263.3
	Reduction (%)	38	25	28
Lateral	No VED (Max Drift)	188.80	279.42	554.85
	Chevron VED (Max Drift)	117.06	196.35	326.96
	Reduction (%)	38	30	41
Residual	No VED	70.6	108.0	173.6
	Chevron VED	48.0	63.7	99.0
	Reduction (%)	32	41	43

4.3.2. Base shear

According to Table 13, for the 10-story model, the average base shear without VEDs is 56.9 MN, increased by 6% to 60.3 MN with Chevron VEDs. In the 15-story model, the no-VED base shear of 83.6 MN increases by 6% to 88.6 MN with VEDs. For the 20-story model, the no-VED base shear of 129.2 MN increases by 5% to 136.2 MN with VEDs.

Table 13. Summary of average base shear (MN) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	56.9	83.6	129.2
Chevron VED	60.3	88.6	136.2
Difference (%)	+6	+6	+5

4.3.3. Energy dissipation

According to Table 14, for the 10-story model, the average energy dissipation without VEDs is 341.2 kN·m, increased by 30% to 443.6 kN·m with Chevron VEDs. In the 15-story model, the no-VED energy dissipation of 484.5 kN·m rises by 26% to 610.5 kN·m with VEDs. For the 20-story model, the no-VED energy dissipation of 774.5 kN·m increases by 34% to 1038.0 kN·m with VEDs.

Table 14. Summary of average energy dissipation (kN·m) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	341.2	484.5	774.5
Chevron VED	443.6	610.5	1038.0
Increase (%)	30	26	34

4.3.4. Story stiffness

According to Table 15, for the 10-story model, the average story stiffness without VEDs is 468 kN/m, increased by 24% to 580 kN/m with Chevron VEDs. In the 15-story model, the no-VED stiffness of 688 kN/m rises by 20% to 825 kN/m with VEDs. For the 20-story model, the no-VED stiffness of 1034 kN/m increases by 30% to 1334 kN/m with VEDs.

Table 15. Summary of average story stiffness (kN/m) for 10-, 15-, and 20-story steel frame models

Property	10-Story Model	15-Story Model	20-Story Model
No VED	468	688	1034
Chevron VED	580	825	1334
Increase (%)	24	20	30

5. Discussion

5.1. Summary and interpretation of results

The superior performance of the Concentrated VED arrangement stems from its strategic placement in high-stress zones, which maximizes energy dissipation and structural stiffness. By centralizing dampers, this configuration ensures uniform distribution of damping forces across the structure, effectively mitigating localized deformations and enhancing global stability. Results demonstrated that Concentrated VEDs reduced roof displacements by up to 32% in 10-story buildings and increased energy dissipation by 42–46% across all models. These improvements are attributed to the configuration's ability to absorb seismic energy efficiently through concentrated damping pathways, thereby reducing inter-story drifts and residual displacements. While Chevron arrangements excel in specific metrics (e.g., 41% lateral drift reduction in 20-story models), Concentrated VEDs provide superior overall performance.

The Fig. 8 reveals that the No-VED case consistently exhibits the highest roof displacements (162.3 mm, 240.2 mm, and 364.5 mm for 10, 15, and 20 stories, respectively). Among VED arrangements, Chevron VEDs achieve the lowest displacements (100.6 mm, 179.2 mm, 263.3 mm), followed by Knee Braced and Concentrated VEDs. The reductions are most pronounced in the 10-story model (up to 38% for Chevron) and decrease with height, with Chevron still leading at 28% reduction for the 20-story model. The figure highlights the superior performance of VEDs, particularly Chevron, in mitigating seismic-induced roof displacements across varying building heights.

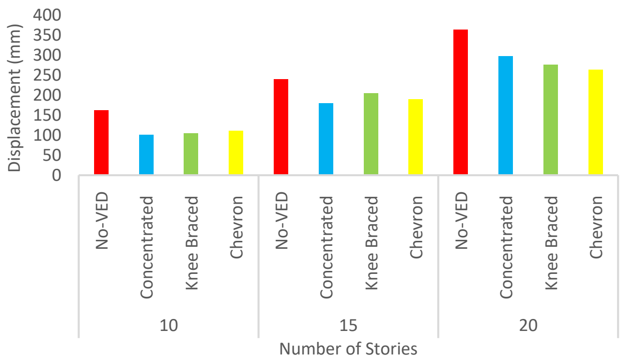

Fig. 8. Roof displacement vs. story height for all VED arrangements and no-VED case

5.2. Practical implications

The findings advocate for prioritizing Concentrated VED arrangements in seismic design codes and retrofitting strategies for multi-story steel frames. Engineers can leverage this configuration to enhance structural resilience without significant modifications to existing geometries, as evidenced by its compatibility with ETABS and ABAQUS modeling workflows. The study's comparative analysis provides actionable insights: for instance, 15- and 20-story buildings benefit most from Concentrated VEDs due to their higher stiffness gains (24–36%) and energy dissipation capacity, while Knee Braced systems may suit structures requiring moderate flexibility. Practitioners should also consider soil-structure interaction and site-specific seismic hazards when selecting damper configurations, though the methodology validated here offers a reliable framework for initial assessments.

5.3. Economic and safety benefits

Adopting Concentrated VED arrangements translates to substantial cost savings by minimizing post-earthquake repair needs. The 29–39% reduction in residual displacements across models suggests less structural and non-structural damage, reducing downtime and reconstruction costs. Enhanced stiffness and energy dissipation further ensure buildings remain operational post-event, safeguarding occupants and critical infrastructure. While initial investments in VEDs are required, their long-term benefits—such as avoided business interruptions and extended service life—outweigh upfront costs. Additionally, the compact design of VEDs aligns with sustainable construction practices, as retrofitting existing structures with these dampers reduces material waste compared to traditional reinforcement methods.

6. Conclusion

6.1. Summary of key findings

This study conclusively demonstrates that Concentrated VED arrangements significantly enhance the seismic resilience of multi-story steel frames. Across 10-, 15-, and 20-story models, this configuration reduced roof displacements by 18–32%, increased energy dissipation by 42–46%, and improved stiffness by 24–36%, outperforming Knee Braced and Chevron systems in overall efficacy. The results underscore the importance of damper placement in optimizing energy absorption and structural integrity under seismic loads.

6.2. Recommendations

Engineers should integrate Concentrated VEDs into seismic designs for high-rise buildings in earthquake-prone regions, particularly for structures exceeding 10 stories. Future research should explore hybrid damping systems combining VEDs with friction or tuned mass dampers, as well as the impact of variable damper densities and material compositions. Additionally, extending this methodology to composite structures or varying soil types could broaden applicability.

6.3. Final Thoughts

Viscoelastic dampers represent a paradigm shift in seismic design, offering a balance of performance, cost-efficiency, and adaptability. As urbanization intensifies in seismic zones, adopting advanced damping technologies like Concentrated VEDs is critical to ensuring sustainable and resilient infrastructure. This study contributes a validated framework for advancing building codes and fostering safer, more durable urban environments.

Abstract. 3D printing construction technology facilitates the realization of complex geometries through rapid production and design freedom; however, challenges in integrating conventional steel reinforcement within the additive manufacturing process impose significant structural limitations on the reinforcement of 3D-printed concrete structures. This study proposes glass fibre-reinforced textile as a solution to these limitations of 3D printed concrete. Glass fibre-reinforced textile stands out as a reinforcement material suitable for additive manufacturing with its lightweight structure, high tensile strength, and flexibility. A 3D printable mixture was specifically designed to achieve optimal rheological properties and printability. Then, using a Delta WASP 3DMT concrete printer, beam-shaped samples consisting of six layers were produced; glass fibre-reinforced textiles were placed on horizontal interfaces. The reinforced and unreinforced specimens were subjected to flexural and compressive strength tests after a 28-day curing period. Experimental results showed that glass fiber textiles significantly enhanced flexural strength and ductility. While the compressive strength of the textile-reinforced specimens remained largely unchanged compared to the control, their flexural strength improved remarkably, increasing by more than 50%. The study's findings reveal that 3D printed concretes reinforced with glass textiles enable the creation of more reliable structures with increased strength and ductility; thus, 3D printing technology may have a wider application area in the construction industry.

Keywords: Additive manufacturing; 3D printable concrete; Textile reinforcement; Glass fiber textile

1. Introduction

3D printing technology has revolutionized the construction industry by offering innovative solutions to traditional building methods. The ability to create complex geometries directly from digital designs has opened up new possibilities for architectural creativity and structural efficiency (Tahmasebinia et al., 2018; Tarhan et al., 2024; Žujović et al., 2022). One of the most significant advantages of 3D printing in construction is the reduction of material waste (Mohamed & Mohamed, 2025). Among the various additive manufacturing techniques, extrusion-based 3D printing of cementitious materials has attracted considerable attention for its potential to revolutionise conventional building practices (M. Khan & McNally, 2024). Nevertheless, a significant challenge that restricts the structural applications of 3D-printed concrete is the complexity of integrating traditional steel reinforcement within the layer-by-layer fabrication process (Liu et al., 2023; Nan et al., 2025; Tarhan et al., 2025).

The absence of effective reinforcement solutions frequently results in diminished mechanical performance, particularly in the context of tensile and flexural stresses. This complicates the extensive use of 3D printing technology in the field of load-bearing structural elements (Arunprasand & Nallasamy, 2024; T. Khan et al., 2024). In concrete structures, it is essential to utilise reinforcement due to inherent limitations in tensile capacity and ductility of cement-based materials. To address these constraints, various reinforcement methods have been investigated, with textile reinforcement standing out as a promising solution (Abtew, 2024; Ramesh, Rajeev, Sanjayan, et al., 2024). The integration of textile reinforcement in 3D printing concrete addresses one of the major challenges in manufacturing structural components, offering high formability, tensile strength, and non-corrosive properties (Ramesh, Rajeev, & Sanjayan, 2024; Ramesh, Rajeev, Sanjayan, et al., 2024). Research has demonstrated that incorporating textile reinforcement into 3D printed components enhances interlayer bonding, thereby mitigating crack propagation and improving load-bearing capacity, particularly in curved members.

https://doi.org/10.31462/icearc2025_ce_mat_941

Specifically, an increase of approximately 10% in peak load-bearing capacity was observed in textile-reinforced 3D-printed specimens compared to mould-cast counterparts (Ramesh, Rajeev, Sanjayan, et al., 2024).

Glass fiber textiles have shown promise for integration into 3D-printed concrete, offering several advantageous properties. Their high tensile strength and corrosion resistance make them suitable reinforcements for concrete structures (Spelter et al., 2019). Glass fibre-reinforced polymer composites are durable materials that are particularly resistant to chemical attack. This makes them a strong contender as a replacement for traditional steel reinforcements in construction applications (X. Yao et al., 2021). Their compatibility with extrusion-based processes and ability to be embedded between printed layers make them suitable candidates for enhancing the structural integrity of 3D-printed components.

This study aims to assess the efficacy of glass fibre textile reinforcement in enhancing the flexural and compressive performance of 3D-printed cement-based concrete. A specially designed printable mixture was developed, and beam specimens were produced reinforced with glass fibre textile. The mechanical performance of reinforced and unreinforced specimens was evaluated through flexural and compressive strength tests, providing insights into the potential of textile-reinforced 3D-printed concretes for broader structural applications.

2. Materials and methods

The cement-based mix was created with CEM I 42.5 R ordinary Portland cement as the primary binder, supplemented with ground granulated blast furnace slag (GGBS) to improve rheological and mechanical properties, and metakaolin clay to enhance 3D printability and dimensional stability. The aggregates used were silica sand with particle sizes of 0-0.5 mm (density: 2.63 g/cm³) and 0.5-2 mm (density: 2.72 g/cm³). A maximum particle size of 2 mm was chosen to achieve improved mechanical performance.

A superplasticiser (CHRYSO Fluid Optima 206) and hydroxypropyl methylcellulose (HPMC, WALOCEL MKS 10000 PF 60) were incorporated to ensure adequate flowability and rheological properties suitable for 3D printing.

The binder content was fixed at 500 kg/m³. GGBS replaced 20% of the cement content, while metakaolin clay was added at a dosage of 5%. The water to binder (w/b) ratio was set at 0.40, with the superplasticiser dosage corresponding to 1.5% of the binder mass and HPMC constituting 0.3% of the water mass. The aggregate composition was 40% fine (0-0.5 mm) and 60% coarse (0.5-2 mm).

CATNIC TFV 44 glass fibre fabric was selected for reinforcing, which is alkali resistant and designed for mechanical reinforcement. The fabric was soaked in a cement-water slurry to improve adhesion and manually applied at horizontal interfaces during printing. Beam samples measuring 110 mm × 110 mm × 350 mm were printed. After fabrication, the samples were cured in a laboratory environment (20 ± 2°C and 50% RH) for 24 hours and then stored in a curing chamber at 20 ± 2°C and 80% RH for 28 days before testing.

The preparation of the cement-based mix involved an initial slow mixing of all dry components (cement, aggregates, GGBS, metakaolin clay, and methylcellulose) for one minute. Half of the mixing water was then added, followed by another one-minute slow mixing phase. The remaining half of the water, pre-mixed with the superplasticiser, was then added. After a further minute of mixing, the mixture was left to stand for one minute and then mixed at high speed for two minutes, giving a total mixing time of approximately six minutes. Continuous mixing was maintained throughout the production phase to minimise false-set effects and maintain workability.

Penetration depth measurements were carried out to assess the fresh state properties of the compound. Although the results indicated acceptable printability, penetration depth alone was not considered to be fully indicative of printability performance. Therefore, actual extrusion trials were carried out using the 3D printer to finalise the mix selection. The material was then poured into 4×4×16 cm moulds. After an initial curing period of one day under laboratory conditions, the specimens were transferred to a curing room maintained at 20 ± 2°C and 80% relative humidity for 3, 7, 14, and 28 days to assess the evolution of their mechanical properties.

All specimens were produced using a Delta WASP 3DMT concrete printer with a nozzle diameter of 10 mm and a layer height of approximately 10 mm. The print speed was maintained at 2 cm/s to ensure dimensional stability and sufficient interlayer adhesion during extrusion. The produced specimens are illustrated in Fig. 1. The CN specimen represents the unreinforced cement-based sample, while the C3G specimen corresponds to the sample reinforced with a glass fibre textile positioned at the third layer.

Fig. 1. Views of the 3D-printed cement-based specimens with and without textile reinforcement

2.1. Experimental program

An extensive experimental programme was conducted to evaluate the flexural performance of 3D-printed concrete reinforced with glass fibre textiles. The programme encompassed the development of a printable cement-based mixture, fabrication of beam specimens via extrusion-based 3D printing, strategic placement of textile reinforcement, and subsequent mechanical testing after curing.

Initially, the fresh properties of the cement-based mixture were assessed. Unit weight measurements were performed following the TS EN 12350-6, 2019 standard, while rheological characterization was carried out using a rotational rheometer (RheolabQC SN80518563, Anton Paar). A constant shear rate of 0.05 s^{-1} was applied for 200 seconds, enabling yield stress determination from the torque peak at flow onset. A vane geometry comprising four blades around a cylindrical shaft with a diameter and length of 1.8 cm was employed. Due to the time-dependent behaviour of cement-based mortars, yield stress values were recorded immediately after mixing, with variations observed over time.

In addition, the thixotropic behaviour of the cement-based mortar was evaluated using the fall cone test method based on the CEN ISO 17892-6, 2017 standard. This test measures the depth of penetration of a cone under a specified load, providing an insight into the evolution of the shear resistance of the material (Baz et al., 2022). As the cone penetrates deeper, the shear resistance increases until an equilibrium is reached between the applied load and the resisting forces. In this study, a cone with an angle of 30° and a weight of 80 g was used. The fresh mortar was placed in a circular steel container with a depth of 4.5 cm and a diameter of 7 cm. The test set-ups for both the rheological and penetration tests are shown in Fig. 2.

a b c

Fig. 2. a) Production of samples, b) vane shear test, c) fall cone test

Specimens measuring 4×4×16 cm were made to evaluate the hardened properties. These specimens were first subjected to three-point flexure tests, and the fractured segments were then used for compressive strength tests.

Flexural strength tests were performed on the 3D printed specimens with approximate dimensions of 110×110×350 mm, following TS EN 12390-5, 2019. Where possible, compressive strength tests were carried out on the remaining sections after flexural failure in accordance with TS EN 12390-3, 2019. However, for cement-based mortars reinforced with textile materials, the change in load transfer caused by the reinforcement made it difficult to obtain suitable compressive specimens after flexural testing. Therefore, equivalent specimens were produced separately by cutting and prepared specifically for compressive strength evaluation.

3. Results and discussion

3.1. Fresh properties results

Table 1 summarises the evolution of unit weight, penetration depth, and mixing torque for the cement-based, 3D-printable mortar over the first hour after batching. Penetration depth falls almost linearly during the first 15 min - from 19.74 mm to 8.52 mm - reflecting the rapid thixotropic build-up that is typical for printable mortars with low water–binder ratios. At the same time, torque more than quadruples (9.4 → 48.6 mNm), signalling an increase in static yield stress as flocculated particle networks strengthen. A brief, low-shear re-mix at 25 min restores penetration depth to 17.32 mm (≈90 % of the initial value) while cutting torque is almost in half (48.6 → 29.8 mNm). This confirms that the mortar exhibits a reversible thixotropic character: network bonds rupture under shear and rebuild during rest. However, the benefit decays quickly; within 20 min, the penetration depth again drops below 10 mm, and the torque climbs above 40 mNm. A second re-mix at 60 min partially recovers flowability (16.13 mm), yet torque remains high (59.6 mNm), indicating that hydration-induced structuration has started to dominate over purely physical flocculation. Combining the penetration-depth criterion adopted by Tay et al. (2017) (≥15 mm for reliable extrusion) with a torque ceiling of ≈50 mNm (to avoid excessive extrusion pressure), the data suggest a practical printing window of roughly 0–35 min from first contact between water and binder, provided a single re-mix is applied at ~25 min. Beyond 45 min, neither penetration depth (<7.5 mm) nor torque (>60 mNm) meets the commonly accepted limits, so continuous printing without an interlayer cold-joint penalty would be challenging.

Table 1. Fresh properties of cement-based mortar

Time	UnitWeight (g/cm^3)	Penetration Depth (mm)	Torque (mNm)
Beginning	2.15	19.74	9.4
10 min later		14.35	28.1
15 min later		8.52	48,6
Second Mixing (25 min later		17.32	29.8
35 min later		10.08	41.2
45 min later		7.34	59.6
55 min later		4.31	66.9
Third mixing (60 min later)		16.13	59.6

3.2. Hardened properties results

Table 2 presents the flexural and compressive strengths of 4 × 4 × 16 cm prisms cast from the cement-based mix. Compressive strength rises from 10.96 MPa on Day 1 to 19.36 MPa on Day 3 and 53.75 MPa on Day 14—a more-than-fivefold increase in two weeks. This rapid hardening, typical of low water-to-binder printable mortars with highly reactive fillers, shows that the mix can already support several subsequent layers only hours after extrusion. By Day 28, the compressive strength reaches 62.9 MPa, placing the mortar in TS EN 206+A2, 2021 strength class C50/60 and qualifying it as a high-performance printable mix. Flexural strength levels off after two weeks at about 8.5 MPa, matching values reported for engineered 3D-printable mortars (Le et al., 2012) and providing adequate resistance to bending in printed elements.

Table 2. Mechanical characterisations of cement-based mortar

Curing Day	Flexural Strength (MPa)	Compressive Strength (MPa)
1	3.93	10.96
3	4.93	19.36
14	8.50	53.75
28	8.70	62.89

The flexural and compressive strengths of the reinforced and unreinforced specimens produced by 3D printing of the cement-based mix, whose characteristic properties were determined, are shown in Figs. 3 and 4. Incorporating glass fibre textile improved these specimens' structural integrity and deformation capacity, as can be seen in Fig. 5.

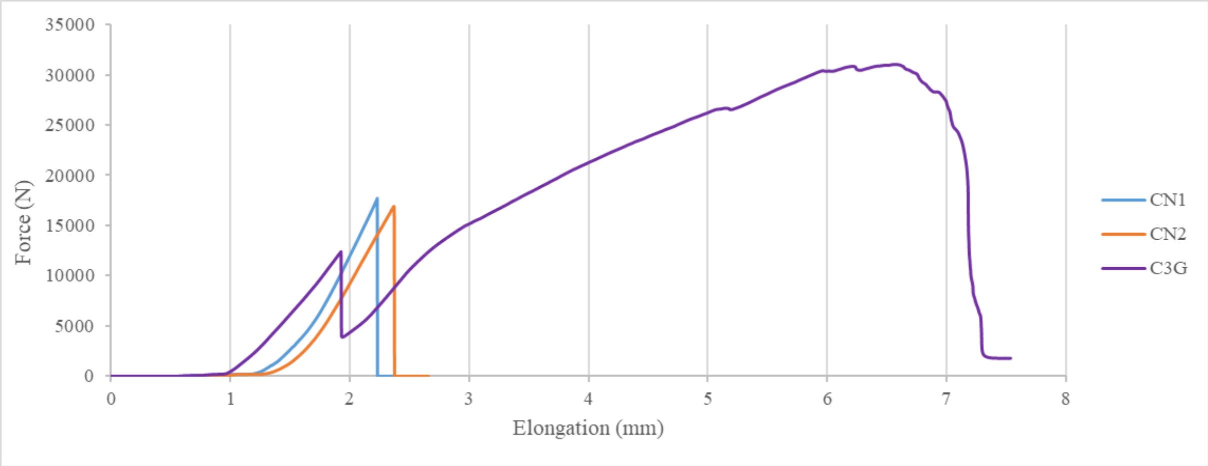

Fig. 3. Flexural strength test results of 3D printed cement-based samples

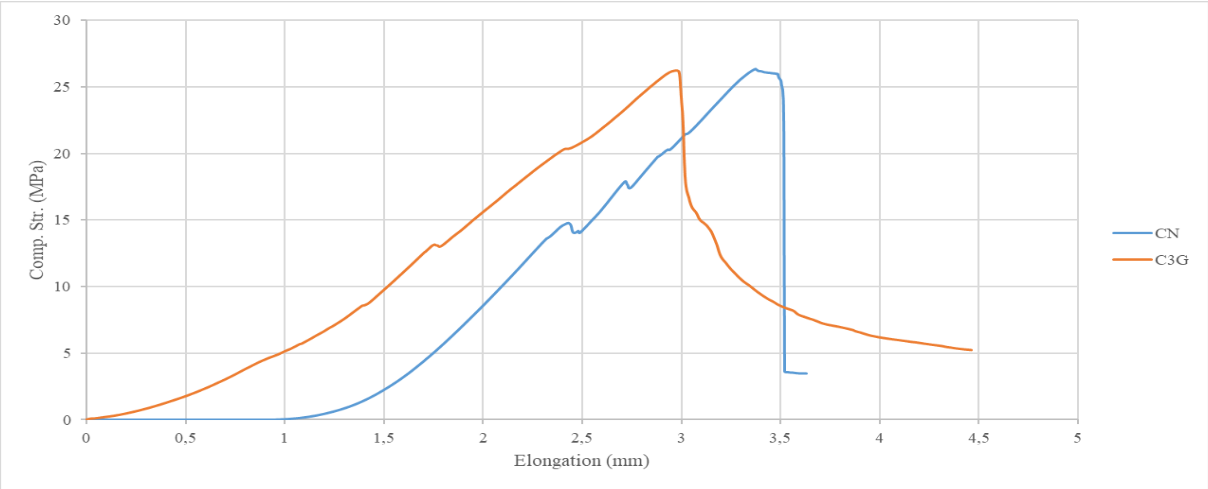

Fig. 4. Compressive strength test result of 3D printed cement-based samples

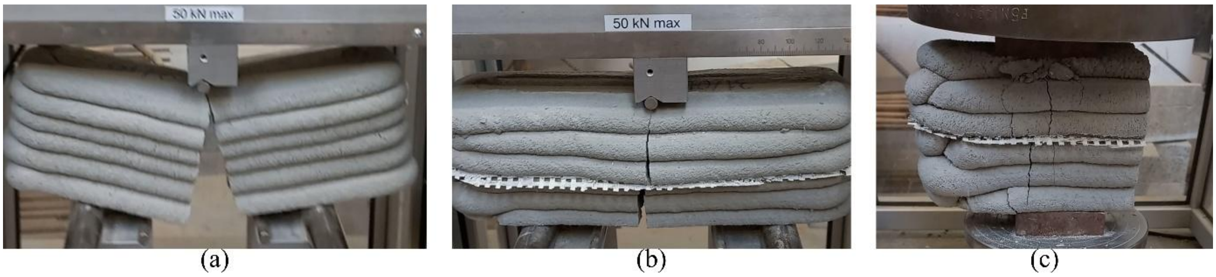

Fig. 5. Failure patterns during the flexural test of (a) unreinforced, (b) reinforced cement-based sample, and (c) the compression test of reinforced sample

Fig. 3 clearly illustrates that the incorporation of glass fibre textiles significantly enhanced the flexural strength of the specimens. Notably, although it was initially not expected that placing textiles along the neutral axis would have a substantial effect, the results from the C3G specimen demonstrated that even reinforcement at the neutral axis contributed to improved flexural performance. These findings collectively highlight the strong potential of textile reinforcement for enhancing the mechanical behaviour of 3D-printed cement-based concretes.

The improvement in flexural performance observed in this study is in line with previous findings reported in the literature. For example, Cao et al., 2024, Y. Yao et al., 2024, Ramesh, Rajeev, Sanjayan, et al., 2024 and Woon Park et al., 2022 highlighted that the mechanical performance of 3D printed concrete can be significantly enhanced by the strategic placement of reinforcement along the layer interfaces. Similarly, Dubey et al., 2024 highlighted that the inclusion of continuous or discontinuous reinforcement in the printing process enhances both strength and ductility, addressing the inherent weaknesses of layer-by-layer fabrication

According to the compressive strength results presented in Fig. 4, no notable difference was observed between reinforced and unreinforced specimens regarding peak compressive strength. While incorporating glass fibre textiles substantially improved the flexural strength and strain capacity, it did not enhance the ultimate compressive strength. However, an increase in strain capacity under compressive loading was still evident, indicating improved ductility.

With regard to compressive strength, the results confirmed that textile reinforcement did not contribute significantly to the peak compressive load, in line with previous observations (Jing et al., 2021; Schladitz et al., 2012). As textile materials, particularly glass fibres, primarily enhance tensile performance and provide minimal confinement under axial compression, their influence on compressive strength remains limited. However, the increase in strain capacity observed under compression indicates improved post-peak ductility, which is highly beneficial for enhancing the structural robustness of 3D printed elements.

4. Conclusions

This study investigated the flexural performance of 3D printed cement-based concrete reinforced with glass fibre textiles. A printable cement-based mix was successfully developed, exhibiting sufficient flowability for approximately 30 minutes after batching, which allowed for controlled extrusion and the integration of strategically placed textile reinforcement. The hardened matrix reached a compressive strength of 62.9 MPa at 28 days, classifying it as C50/60 according to TS EN 206, and achieved a flexural strength of 8.7 MPa - values consistent with high-performance printable mortars reported in the literature. Experimental results showed that the incorporation of glass fibre textiles significantly enhanced the flexural strength and ductility of the specimens, despite having minimal influence on compressive strength. The improved post-cracking behaviour indicates that the fibre reinforced textiles effectively bridge cracks and contribute to energy dissipation, resulting in a tougher and more resilient composite. These findings demonstrate the potential of textile reinforcement to improve the mechanical behaviour of 3D-printed cement-based elements, particularly in bending loading. Further research is recommended to optimise textile placement strategies, extend the workable time window of the mortar, and assess the long-term durability of reinforced printed elements under various environmental conditions.

Mechanical and high temperature properties of geopolymer mortars with dunite powder, fly ash and polypropylene fibers

Merve Ş. Yön*[1], Selim Cemalgil[1]

[1] *Munzur University, Department of Civil Engineering, 62000 Tunceli, Türkiye*

Abstract. This study examines the fresh and mechanical properties, as well as the high-temperature characteristics, of self-compacting geopolymer mortars (SCGMs) incorporating dunite powder (D), class C fly ash (FA), limestone dust (LD), and polypropylene fiber (PF). Six distinct mixtures were created by partially substituting D with FA, while maintaining a fixed ratio of LD. Mixtures were generated at 0%, 15%, 30%, 45%, 60%, and 70% D, with 70%, 55%, 40%, 25%, 10%, and 0% FA, respectively, while maintaining a constant LD ratio. In order to promote energy saving, an assessment of the flexural and compressive strength of water-cured SCGMs was conducted at the 90-day age. The elevated temperature performance of 90-day water-cured SCGMs was assessed following exposure to 300 and 600 °C. Furthermore, capillary water absorption of samples cured in water for 90 days were assessed. According to the data obtained, the desired strengths could not be achieved in both the samples under the effect of high temperature and the samples not exposed to high temperature. The average compressive strengths did not exceed 3MPa. It is thought that the main factor that negatively affects strength is the application of water cure to the mixtures.

1. Introduction

Ordinary Portland Cement (OPC), a primary constituent of cement mortar, generates greenhouse emissions during its manufacturing and requires substantial energy and diverse natural resources. Approximately 1.6 tons of raw ingredients are required to manufacture 1 ton of cement. The production process emits around 0.8 tons of greenhouse gases and consumes around 1,300 kWh of embodied energy. (Bouaissi et al., 2019; Lee et al., 2019). Therefore, research is being conducted on materials that can be preferred to cement (Zhang et al., 2024). Materials such as fly ash, slag, kaolin, silica fume, etc., consist of amorphous SiO_2 and Al_2O_3 with great pozzolanic activity (Khale & Chaudhary, 2007). Filho et al. (2022) their research examined the efficacy of dunite and microgabbro rocks as protective surface layers against thermal shocks in concrete constructions. Thermogravimetric analysis, X-ray diffraction, thermal dilatation, optical microscopy, and X-ray microtomography were conducted to examine the mechanical and chemical properties of these rocks. As a result of the study, they found that while the compressive strength decreased, the thermal expansion improved significantly after heating and both rocks were suitable for use as protection layers in industrial applications (de Mendonça Filho et al., 2022). Yurt et al. investigated the alterations in mechanical characteristics and microstructure by producing geopolymer mixes with varying quantities of basalt and glass powder waste. Mechanical strength tests at 1, 28, and 90 days, together with high-temperature evaluations, were conducted on samples cured at 90 °C for 24 hours. The optimal post-fire compressive strengths were dramatically enhanced up to 800°C in mortars including 75% basalt and 25% glass powder (Yurt et al., 2024). Westgate et al. The study utilized GEMS3 Selector thermodynamic software to build calcium lime mortars utilizing quartz sand aggregate and olivine sand aggregate in varied amounts. The chemical and mechanical properties of mortars were examined using Raman spectroscopy, thermogravimetric analysis (TGA), X-ray diffraction (XRD), morphological analysis, scanning electron microscopy, and compressive strength testing. Dolomite used in mortar exhibits enhanced mechanical characteristics, increasing by 0.5 to 2.5 MPa when moisture is present (Westgate et al., 2019).

This work, in contrast to prior research, created SCGMs utilizing dunite powder (D), class C fly ash (FA), limestone dust (LD) and polypropylene fiber (PF). D and FA were exchanged for one another in proportions ranging from 0% to 70% in the mortars generated while maintaining a fixed LD ratio. The samples were assessed for mechanical properties, water absorption, capillary water absorption, and porosity. The high-temperature performance of SCGM samples cured in water for 90 days was examined at 300 and 600 °C.

2. Materials and methods

In this study, SCGMs were made up of nine different ingredients. These included D, FA, LD, 0-4 mm river aggregate, 12 mm long polypropylene fibers, superplasticizer and water, sodium hydroxide (NaOH), sodium silicate (Na_2SiO_3). Sodium hydroxide (NH) and sodium silicate (NS), with specific gravities of 1.35 and 1.38 respectively, were utilized as activators for the geopolymerization reaction. The SiO_2/Na_2O ratio of the NS used was 3.38. Polycarboxylate-based superplasticizer, possessing a specific gravity of 1.085, was utilized. The specific gravities of D, FA, LD and PL are 2.88, 2.25, 2.3 and 0.91 g/cm^3, respectively, and the chemical and some physical properties of D and FA are presented in Table 1. All dry binder materials used are shown in Fig. 1. The river aggregate designed with a maximum 4 mm aggregate grain size has a specific gravity of 2.63, and the gradation curve is shown in Fig. 2. The overall binder content was established at 500 kg/m^3, with 150 kg/m^3 of limestone dust incorporated into the mixture to enhance the strength (Papayianni et al.)of the fresh mortar and facilitate geopolymerization, resulting in a total binder quantity of 650 kg/m^3. The NH solution utilized in the tests was prepared at a concentration of 12 Molar by dissolving the pellet, which had 99% purity, in water. With an alkali activator/binder ratio of 0.45, the quantity of NS was 2.5 times that of NH. The water-binder ratio is 0.55 for all series. Fresh mortars with dimensions of 50x50x50 mm and 40x40x160 mm were positioned in molds in three phases and subsequently coated with stretch film to mitigate water loss soon thereafter. Three samples were cured in water until they reached 90 days of age. The proportions of SCGMs are presented in Table 2.

2.1 Mini-slump flow

According to the EFNARC (2002) (EFNARC, 2002) standard, the fresh properties of SCGM were determined by the mini slump-flow test. The spreading diameter was measured by filling the mortar into the cone without compaction and spreading it under its own weight.

2.2 Mechanical properties

Compressive and flexural strength tests of 40 × 40 × 160 mm specimens were conducted in accordance with ASTM C109 (ASTM C109/C109M-02, 2020) and ASTM C348 (ASTM C348, 2002) standards at 90 days, as seen Fig. 3. Initially, prismatic specimens underwent the flexural test. The compressive strength test of the split components was conducted. The results were computed based on the average of three specimens.

2.3 Durability test

40×40×160 mm size SCGMs were initially dried at 105 °C for 24 hours and subsequently subjected to temperatures of 300 °C and 600 °C at a rate of 5 °C/min for 2 hours (Fig. 4). The procedure involved attaining goal temperatures of 300 and 600 °C within 120 minutes, followed by maintaining these temperatures for an additional 120 minutes. The samples were maintained in the oven for 60 minutes, subsequently removed, and allowed to cool completely. Upon cooling the samples, their flexural and compressive strengths were assessed.

The capillary water absorption test was performed in accordance with ASTM C1585 (ASTM International, 2007) standard on cube specimens of 50 mm x 50 mm x 50 mm (Fig. 5). The capillary water absorption test for SCGM was performed after 90 days of curing at intervals of 5, 10, 20, 30, 60, 180, 360, and 1440 minutes.

Table 1. Chemical components of D (Saraç et al., 2023) and FA

Ingredients	%SiO_2	%CaO	%Al_2O_3	%Fe_2O_3	%MgO	%Na_2O

3. Results

3.1. Mini-slump values

The workability of all fresh SCGMs comprising D, FA, and LD binders was assessed using the mini-slump flow test. The illustration depicts the spreading diameters of the mixtures in accordance with the EFNARC standards (Fig. 6). The maximum spread diameter among all SCGMs was found in the sample with 70% D, whereas the minimum value was recorded in samples with 30%, 45%, and 60% D. The control mixture including 70% F exhibited a slump-flow value of 245 mm, whereas the incorporation of 30% D, 45% D ve 60% D into the mixture resulted in a reduction of the spreading value by 2.04%. The differing substitution rates in the series did not alter the water/binder (W/B) content of the mixtures. The W/B ratio for all SCGMs was 0.55.

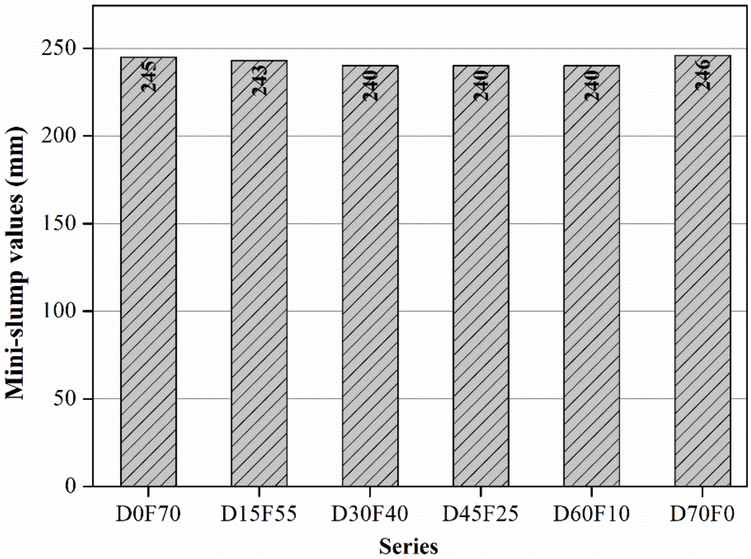

Fig. 6. Mini-slump spreading of SCGMs

3.2. Mechanical tests

Figs. 7a and 7b present the average flexural and compressive strength data for all six SCGM designs in this study. For samples D0F70, D15F55, D30F40, D45F25, D60F10, and D70F0, flexural strengths were below 1 MPa, while compressive strengths were below 3 MPa. The compressive strength of the D0F70 Reference mixed sample at 90 days was 2.54 MPa. The incorporation of 70% D in the mixture diminished the compressive strength to 0.65 MPa. As the D ratio increased (15%, 30%, 45%, 60%, and 70%), the already inadequate strength values deteriorated further, nearing 0 MPa.

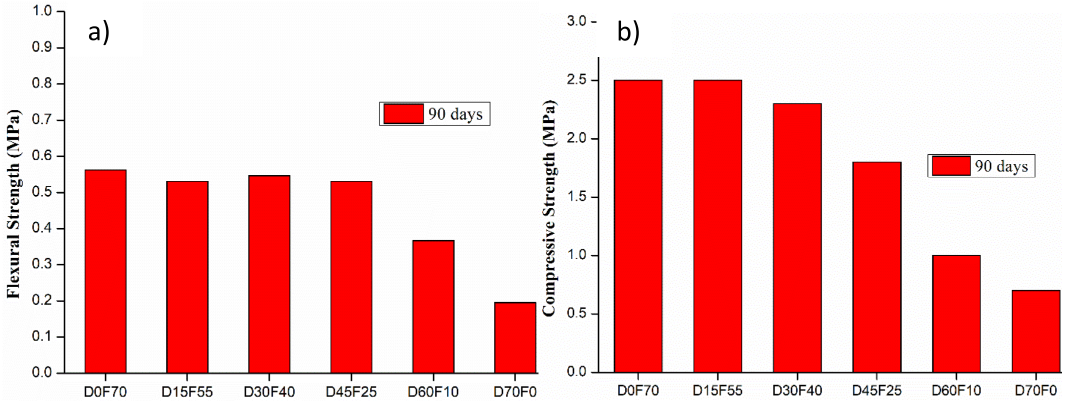

Fig. 7.a) Flexural strength values and b) compressive strength values

3.3. Durability properties

The flexural and compressive strengths of all SCGMs cured for up to 90 days, both before exposure to high temperatures and at elevated temperatures of 300 to 600 ◦C, are as given in Fig. 8a and Fig. 8b. Upon examination of the shape, it was seen that the flexural and compressive strengths diminished further following exposure to elevated temperatures. Fig. 9 illustrates the impact of the 90-day SCGM series on the sorptivity rate, assessed at intervals of 0, 5, 10, 20, 30, 60, 180, 360, and 1440 minutes. No substantial alteration was observed in the sorptivity coefficients of the mortars with the increase of D and the decrease of FA in the mixes. The D45F25 sample exhibited the highest capillary water absorption coefficient, measuring 11.48x10^{-3} cm/$s^{0.5}$. The minimum capillary water absorption coefficient was recorded in D70F0 at 10.5x10^{-3} cm/$s^{0.5}$. The sorptivity value of the mortar with 70% D addition diminished by 8.54% relative to the D45F25 sample.

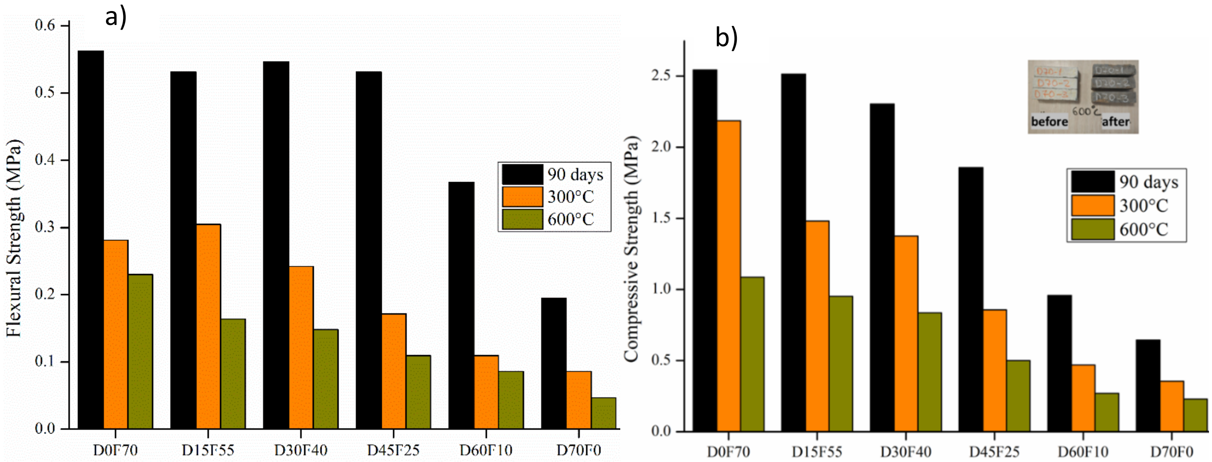

Fig. 8.a) Flexural and b) compressive strengths before and after high temperature exposure

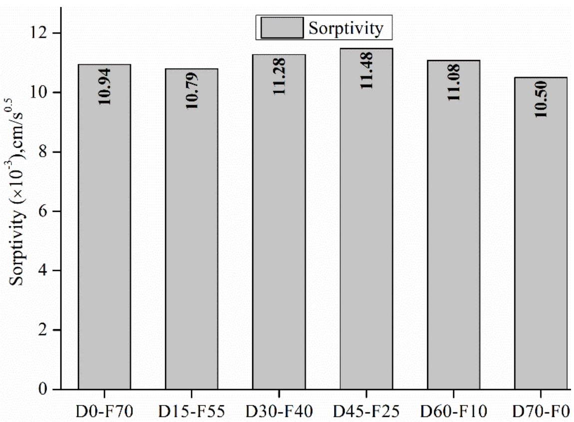

Fig. 9. Sorptivity results of SCGMs

4. Conclusions

This study focuses on the investigation of the fresh and mechanical properties of self-compacting geopolymer mortars (SCGMs) containing dunite powder (D), class C fly ash (FA), limestone powder (LD) and polypropylene fiber (PF) along with the effect of high temperature. The findings obtained from the experimental study are listed below.

- The greatest spreading diameter was recorded in the mixture with 70% D, whereas the smallest spreading diameter was noted in the mixtures with 30%, 45%, and 60% D. Accordingly, it shows that the workability of SCGMs is affected by the D ratio used, and higher D amounts provide better spreading.
- It was observed that both flexural and compressive strengths decreased further after exposure to high temperatures.
- No significant change was observed in the water absorption coefficients of the mortars with the increase in D ratio and decrease in (FA) ratio in the mixtures.
- D0F70, D15F55, D30F40, D45F25, D60F10, and D70F0, flexural strengths were below 1 MPa, while compressive strengths were below 3 MPa.

As a result, it was concluded that water curing does not activate the binder materials. The use of other alternative curing options is recommended with this study.

Understanding risk factors in green building construction: A review

Erhan Arar*[1], Fahriye H. Halicioglu[2]

[1] *Dokuz Eylul University, The Graduate School of Natural and Applied Sciences, Department of Architecture, 35390 Izmir, Türkiye*
[2] *Dokuz Eylul University, Faculty of Architecture, Department of Architecture, 35390 Izmir, Türkiye*

Abstract. This study aims to explore the risk factors of green building projects. This review employs a structured methodology, which includes a thorough search of the Scopus database and a stringent selection process to identify relevant articles. A structured search strategy used keywords related to sustainability, green building, construction, and risk management. After screening and selection, 100 articles were included in the final analysis. The findings reveal various risk categories associated with green building projects, including economic, technical, policy and regulatory, market and stakeholder, quality, maintenance and lifecycle, social and cultural, environmental, material-related, and supply chain risks. The review provides a categorization of these risk factors and discusses the necessity of developing effective risk management frameworks to support the successful delivery of green building projects. The bibliometric analysis also reveals the changing research interests and evolving research trends in this field, with a growing focus on topics such as climate change, resilience, and health-related risks. This study adds value to the existing literature by providing a systematic review of the risk management knowledge areas in green building construction and suggesting potential areas for future research. Industry practitioners can use the findings of the study to develop proper risk response strategies and manage their resources well to address the specific risks that are inherent in sustainable construction projects.

Keywords: Sustainability; Risk; Risk management; Construction; Green building

1. Introduction

The construction of green buildings presents a unique set of challenges and opportunities within the built environment. These projects are characterized by a complex array of potential risks that can lead to delays, cost overruns, and operational issues stemming from the intricate selection of construction methodologies, stakeholders, systems, and materials (Gurgun et al., 2018). While the advantages of green buildings—such as reduced energy consumption, environmental sustainability, enhanced occupant well-being, and resource conservation—are well-documented (Qin et al., 2016), the associated risks have often been overlooked in academic discourse and industry practice.

As the green building sector evolves, it becomes increasingly crucial to address the emerging expectations, regulations, and specific risks linked to innovative technologies (Qin et al., 2016). This evolution necessitates the construction industry to develop and implement novel approaches to risk management. The successful completion and operation of green building projects hinge on effectively managing these unique risks throughout the project lifecycle.

Risk management plays a pivotal role in every phase of green building projects. A critical aspect of this process involves unraveling the intricacies of green building implementation and meticulously examining the risks associated with these complexities. These steps are fundamental to developing robust risk management strategies, facilitating the broader adoption of sustainable building practices across developed and emerging economies (Yang & Zou, 2014; Guan et al., 2020).

A review of existing literature reveals a predominant focus on the financial aspects, performance metrics, and benefits of green projects. However, there is a notable gap in research specifically addressing risk management in the context of green building projects. The studies that do explore this area tend to evaluate risk factors in isolation without considering their interrelationships or cumulative effects.

This review aims to contribute to the body of knowledge by offering a comprehensive perspective on the risk factors inherent in green building projects and proposing corresponding mitigation strategies. The insights from

* Corresponding author, E-mail: erhan.arar@ogr.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_024

this study hold practical value for industry professionals, enabling companies to tailor their risk assessment protocols and mitigation measures to their specific needs. This targeted approach allows more efficient allocation of limited resources to address the most significant risks.

This research seeks to address the following key questions:

1.What are the emerging trends and challenges in risk management research applied to green building construction?

2.How do the risk factors in green building construction differ from those in conventional construction projects?

3.What strategies do construction firms employ to identify and mitigate risks associated with green building initiatives?

4.What are the promising avenues for future research concerning risk management and green building practices?

To address these questions, this systematic literature review examines the implementation of risk management processes in green building construction. This study aims to elucidate risk management strategies from two perspectives: (1) a strategic viewpoint that considers the overarching risks inherent in green construction, and (2) a theoretical approach that synthesizes existing literature on managing the impacts of risks in green building projects.

The structure of this paper is as follows: First, the methodology employed to identify and select relevant literature is outlined. Next, the theoretical framework underpinning the review is presented. A descriptive analysis of the selected papers follows this. Finally, the results, discussion of the review, and directions for future research in this rapidly evolving field are given.

2. Research methodology

The research questions in the introduction have been addressed based on a systematic analysis of the current literature. A systematic literature review is a procedure that adopts a precise, clear, and explicit methodology that requires a series of stages to ensure that the literature review process is sufficiently comprehensive and transparent (Cook, 1997). Integrating bibliometric data and systematic literature review offers a robust and comprehensive approach to analyzing research trends and themes within a field. Bibliometric analysis provides quantitative insights into the structure and evolution of academic literature by examining citation patterns, co-authorship networks, and keyword co-occurrences, thereby uncovering influential works, authors, and emerging research areas. On the other hand, a systematic literature review employs a rigorous and transparent methodology to qualitatively synthesize findings from selected studies, ensuring a thorough understanding of the research landscape. By combining these methods, researchers can leverage the strengths of both approaches: the quantitative rigor of bibliometric analysis to map the intellectual structure of a field and the qualitative depth of systematic reviews to interpret and contextualize the findings. This integrated approach enhances the reliability and validity of the analysis. It provides a holistic perspective that is invaluable for identifying research gaps, guiding future studies, and informing evidence-based decision-making.

Two categories of keywords were selected to comprehensively cover the range of studies pertinent to the research questions. Initially, the specific keywords to be utilized in the study were determined (the asterisk "*" was appended to some keywords to broaden the scope of results, as various papers may use different terms for the same concept, such as "sustainable" instead of "sustainability").

words related to sustainability: “sustain*”, “green building*”, “green*” and

words related to construction risk management (i.e., “CRM” keywords): “construction,” “risk*,” “risk factor*,” and “risk management.”

The full Scopus search string is given below.

TITLE (construction OR building OR project AND (risk OR "risk factor*" OR "risk management") AND ("sustain*" OR "green*" OR "green building"))

A thorough literature review was conducted using the Scopus database, recognized as one of the most extensive multidisciplinary repositories of abstracts and citations for peer-reviewed scholarly works (Geraldi et al., 2011). The theoretical structure and approach of this review can be seen in Fig. 1. Only articles with a risk management and green building construction focus have been selected in this search. The search was restricted to the titles of the articles to prevent retrieving studies that merely mentioned the relevant search terms in the abstract and keywords without addressing the risk factors for green building projects. The search was made on the 3rd of April, 2024. This first step generated a total of 298 papers. While reading the abstract of these 298 papers, three criteria were selected to focus on: (1) does the paper analyze the transfer of risk management practices to the green building base? (2) Does the paper analyze risk factors in construction? (3) Does the paper separate and evaluate green risks from traditional construction risks? Selected papers had to meet at least one of the criteria to be included in the research. From 298 papers, articles that focus on the medicine & health industry are excluded from the research. After eliminating the articles that don’t meet the inclusion criteria, co-citation analysis was conducted for 92 articles from VosViewer. From co-citation analysis, at least 8 articles were cited in 2 selected articles. Using this procedure, 100 papers were left.

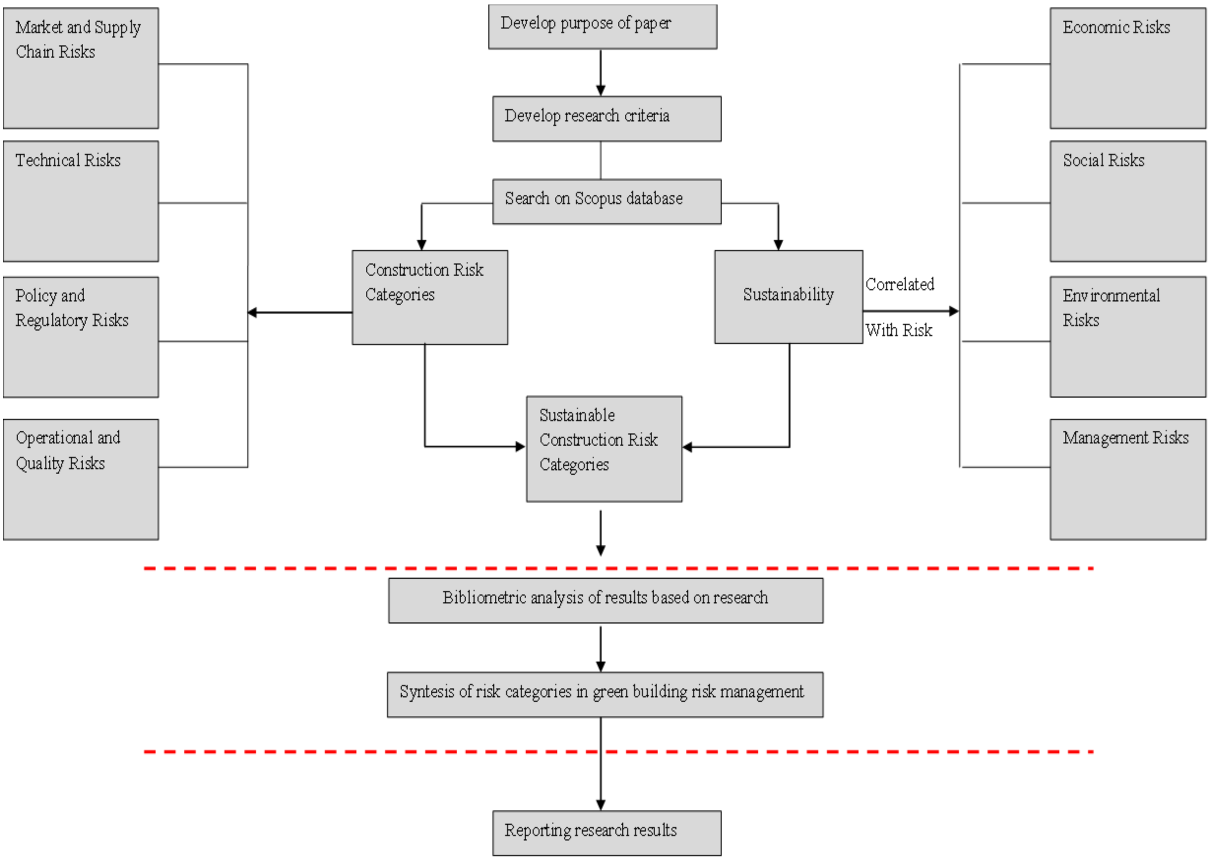

Fig.1. Flow diagram of the systematic review examining risk factors in green building projects

3. Literature review

Green building projects ambitiously prioritize environmental sustainability alongside conventional construction imperatives, yet they are subject to an intricate array of risk factors that differ markedly from traditional projects. These projects, though beneficial for their environmental goals, carry risks across several categories (Table 1), each demanding vigilant management and strategic foresight. The classification of risk categories within green building projects was meticulously developed based on an extensive literature review. This process aimed to ensure a comprehensive yet clear framework, capturing distinct aspects of risk without unnecessary overlap. By consolidating the risk categories into eight distinct groups, the classification reflects a balance between comprehensiveness and clarity, as informed by existing literature. Each category, from economic to technical risks, was defined to address specific challenges identified in the literature, thereby grounding the classification in established academic insights and ensuring its relevance to the unique demands of green building projects.

The taxonomic structure of risk factors in green building projects emerges from a methodical synthesis of existing literature. As seen in Table 1, this eight-category framework reflects an epistemological strategy in risk classification, aiming to integrate theoretical breadth with detailed analytical insight. Rather than serving solely as a heuristic, this classification system is built upon empirical evidence drawn from various fields within sustainable construction research. Initially, the classification aims to reach a level of theoretical completeness where further subdivisions would offer limited additional insights. The eight categories are designed to encompass the full range of risk dimensions without introducing excessive detail that could confuse the inherently interconnected nature of these risks. Secondly, this framework enhances the methodological rigor of risk assessment by clearly defining the boundaries between conceptually distinct risk domains and their interdependencies. Such delineation is crucial for developing targeted mitigation strategies that address the characteristics specific to each risk category. Third, the classification system has construct validity by aligning with established theoretical paradigms in project management, environmental sustainability, and organizational behavior. Each category represents a distinct theoretical construct with its own literature base and empirical support.

Table 1. Risk categories and risk factors extracted from the examined green building literature

Risk Category	Risk Factors
Economic Risks	Higher initial investment for green technologies and materials. Economic feasibility and return on investment uncertainties. Risk of increased operating costs if green technologies do not perform as expected. Currency exchange rate fluctuations for green materials coming from another country Material/labor prices for green building construction may vary
Technical Risks	Complexity in integrating sustainable design elements Risk of choosing inappropriate or unproven technologies. Challenges in design that meet both green standards and user needs. Availability/Unavailability of green materials, equipment, and skilled labor Improper management and storage of eco-friendly materials Insufficient documentation and limited dissemination of knowledge regarding emerging sustainable technologies
Policy and Regulatory Risks	Uncertainty in green building regulations and standards. Risk of not meeting certification requirements. Complexity of approval procedures for green projects. Changes in regulations, disputes, and claims
Market and Supply Chain Risks	Fluctuating market demand for green buildings. Need for stakeholder engagement and managing expectations. Reliance on market conditions for green materials and labor supply. Shortages in obtaining eco-friendly materials. Long-term durability and performance concerns for green materials include the potential degradation of biodegradable materials over time. Suppliers that don't follow sustainable practices throughout the supply chain. Increased carbon footprint from the long-distance transportation of green building materials.
Operational and Quality Risks	Potential for construction delays due to the specialized nature of green building techniques. Risk of lower-than-anticipated performance in energy or water-saving technologies. Difficulty in sourcing and managing the supply of green building materials. Challenges in maintaining green building features. Risks associated with the lifecycle assessment of the building's green components. Unintended consequences, such as poor indoor air quality, may occur if systems are not properly operated or maintained.
Social/Cultural Risks	Public perception of green buildings and their acceptance. Social impact and how well the building is received by users and the community.
Environmental Risks	There is a risk that the building could fail to provide the intended environmental benefits. Unforeseen negative impacts on local ecosystems during the construction phase. Proper disposal and recycling of building materials at the end of their lifespan. Impact on natural resources, resource depletion risks Environmental pollution and waste management risks Unstable operation performance of green buildings Climate change impacts, acts of God
Management Risks	Lack of experienced management personnel, Inefficient communication between project teams Poor team leadership and ineffective resource deployment

Economic Risks: Economic risks transcend conventional cost considerations to encompass the complex interplay between capital expenditure, lifecycle costing, and market valuation paradigms. The premium associated with sustainable technologies necessitates sophisticated financial modeling that accounts for temporal variability in costs and benefits. The economic calculus must incorporate externalities and intangible value propositions that traditional financial metrics may inadequately capture. Economic risks consist of economic and financial risks due to their inherent connection to project budgeting, funding, and cost management. Pursuing green certification frequently necessitates additional investment in cutting-edge technologies and sustainable materials. Such fiscal commitments elevate the stakes, entailing risks related to cost overruns, uncertain returns on investment, and the potential for increased operational expenditures if technologies fail to meet their efficiency targets (Ranaweera & Crawford, 2010; Dewlaney et al., 2012).

Technical Risks: The technical risk domain encompasses the uncertainties inherent in innovative sustainable technologies. These risks manifest as functional failures and performance differentials between theoretical models and empirical outcomes. Integrating disparate technological systems introduces complexity that can propagate failures across interdependent building systems, necessitating robust systems engineering approaches to risk mitigation. It alone addresses the complexities of design, technology, and engineering challenges specific to green building projects. Green projects often involve advanced, sometimes experimental, design philosophies and technologies. Selection risks become a concern, as emerging technologies may lack a proven track record, and their integration into complex building systems might not yield the hoped-for sustainability benchmarks or performance standards (Fortunato et al., 2012; Tollin, 2011).

Policy and Regulatory Risks: The policy landscape for sustainable construction exists within a dynamic regulatory ecosystem characterized by jurisdictional heterogeneity and temporal evolution. Compliance requirements exhibit vertical complexity (across governance levels) and horizontal complexity (across regulatory domains), creating a multidimensional compliance matrix that project stakeholders must navigate. The interpretive flexibility within regulatory frameworks introduces additional uncertainty regarding certification criteria and compliance verification methodologies. This category combines policy and regulatory risks, which involve compliance with laws, standards, and governmental policies. Regulatory environments for green building practices are continually evolving. The dynamics within these frameworks pose risks regarding compliance, certification attainment, or navigating complex government procedures, which can affect project timelines and sanctioning.

Market and Supply Chain Risks: Market and supply chain risks reflect the structural vulnerabilities within the sustainable construction ecosystem. The nascent nature of green building markets introduces volatility in demand forecasting and supply chain resilience. Material provenance verification, supplier certification, and ethical sourcing considerations introduce additional complexity to procurement processes. The specialized nature of sustainable materials can create monopsony or monopoly conditions that exacerbate price volatility and supply constraints. This category integrates market dynamics with supply chain considerations, reflecting the interconnectedness of market demand, material availability, and procurement processes. The construction market's appetite for green buildings can be unpredictable, affecting both material costs and the skilled labor pool. Also, the sustainable supply chain is critical for the timely delivery of green building materials. Fluctuations in the availability of these materials due to market demand or regulatory changes can lead to construction delays and additional costs. Additionally, the procurement of materials from distant locations may contradict the sustainability principles due to the increased carbon footprint from transportation (Gurgun et al, 2018; Polat et al, 2017). The reliance on specialized green materials can introduce risks associated with supply chain vulnerabilities, such as shortages or delays in delivery, which can extend project durations and inflate costs.

Operational and Quality Risks: Operational risks emerge from the dynamic interaction between building systems, environmental conditions, and user behaviors. The performance gap between designed and actual operational efficiency represents a significant risk factor that can undermine green buildings' economic and environmental value proposition. Maintenance protocols for innovative systems may lack standardization, creating knowledge management challenges that compromise long-term performance and sustainability credentials. This category merges operational efficiency with quality assurance, focusing on the performance and maintenance of green building solutions. Post-construction, the ongoing maintenance of green infrastructure and systems carries risks. Ineffective maintenance can nullify the benefits of green technologies, and errors in lifecycle assessments may not become apparent until after project completion, with implications for long-term environmental and structural integrity (Qin et al, 2016; Guan et al, 2020). Specialized techniques required for green construction can lead to unforeseen delays. Moreover, if energy-saving or water-conserving systems underperform, the operational efficacy of the building can be compromised, challenging the project's sustainability claims (Dewlaney et al., 2012; Hwang et al, 2015). The long-term performance and durability of these systems and materials are also critical, as they directly affect the building's ability to maintain its green certification standards over time (Wang et al, 2024)

Social Risks: Social risks encapsulate the interplay between built environment interventions and sociocultural systems. The efficacy of green buildings is partially contingent upon their sociocultural resonance and stakeholder acceptance. Misalignment between design philosophy and cultural paradigms can engender resistance, undermining utilization patterns and compromising the realization of sustainability objectives through behavioral non-compliance or occupant dissatisfaction. Social risks remain distinct when addressing stakeholder engagement, community impact, and social acceptance of green projects. The social acceptance and cultural adaptation to green buildings carry their own risks. Public perception and community receptivity can significantly influence a project's success, impacting everything from occupancy rates to the sustainable behavior of end-users within the building environment. Misalignment with societal expectations or cultural norms can reduce usage or support for green buildings, undermining their intended benefits and market value (Hwang et al, 2015). Additionally, aligning diverse stakeholder interests and expectations heightens risks in material sourcing, cost estimation, and user satisfaction levels (Yang & Zou, 2014; Zou & Couani, 2012).

Environmental Risks: Environmental risks represent the paradoxical potential for ostensibly sustainable interventions to generate unintended ecological consequences. The environmental calculus of green buildings must account for both direct and indirect impacts across multiple temporal and spatial scales. Lifecycle assessment methodologies reveal potential environmental trade-offs that must be systematically evaluated to ensure sustainability initiatives do not inadvertently compromise ecological integrity. While green buildings aim to minimize their environmental footprint, there remains the risk that they may not achieve this goal effectively or could inadvertently cause harm to the local environment during construction. The challenge is also to ensure that the materials and systems used will perform sustainably throughout the building's lifecycle without degrading natural habitats or consuming resources at unsustainable rates (Zhang et al, 2012).

Management Risks: Management risks derive from the organizational complexity inherent in green building projects. The interdisciplinary nature of sustainable construction necessitates sophisticated coordination mechanisms and specialized expertise. Deficiencies in project governance structures, knowledge management systems, or stakeholder communication protocols can precipitate cascading failures that compromise project outcomes through temporal delays, resource misallocation, or suboptimal decision-making processes. Management risks in green building projects encompass project coordination, resource allocation, and stakeholder communication challenges. Key management risk factors include a lack of experienced management personnel, inefficient communication between project teams, and inadequate planning processes (Wuni, 2024). Poor team leadership and ineffective resource deployment can significantly impact project success (Memari, 2023). These management-related risks are particularly critical in green building projects due to their complex nature and the need for specialized expertise. Current studies show that effective management strategies, including clear communication channels and proper resource allocation, are essential for mitigating these risks and ensuring successful project completion.

3. Results and discussion

Key themes, clusters, and their connections within the field of risk management in green building projects are represented in Fig. 2. The map showcases a range of related topics clustered around central themes. Detailed insights derived from this network map can be summarized as:

- Central Themes- Risk Management and Risk Assessment: The most prominent themes indicate their central role in the literature concerning green building projects. The large nodes and dense connections suggest extensive research activity and strong interlinkages with other related topics.
- Secondary Themes - Climate Change, Sustainability, and Stakeholders: These themes are closely linked to risk management and assessment, highlighting the importance of addressing climate change and sustainability in risk-related research. The connection with stakeholders underscores the multifaceted nature of risk management, involving various parties in the construction process.
- Specific Methods and Approaches - Analytic Hierarchy Process (AHP), Fuzzy Logic, and Monte Carlo Simulations: These specific methods are frequently mentioned, indicating their widespread use in evaluating and managing risks in green building projects. Their prominence suggests their effectiveness and acceptance in the academic and professional communities.
- Emerging Topics - Green Supply Chain, Resilience, and Disaster Risk Reduction: These topics are emerging as significant areas of interest, reflecting current trends and future directions in sustainable construction practices. The focus on resilience and disaster risk reduction indicates a proactive approach to managing risks associated with climate change and environmental uncertainties.
- Integration with Broader Concepts - Quality, Investments, and Project Success: Integrating risk management with broader project outcomes like quality, investments, and success underscores the holistic view required for effective risk management in green building projects. This highlights the need for comprehensive strategies that consider multiple dimensions of project performance.
- Health and Safety Considerations - COVID-19 and Health-Related Risks: The inclusion of COVID-19 reflects the recent shift towards health-related risks in construction projects. This indicates an expanding scope of risk management to include health and safety issues, particularly in light of recent global events.
- Evolution Over Time - Color Gradient from 2016 to 2022: The color gradient indicates the temporal evolution of research topics, with newer themes emerging in yellow and older ones in blue. This allows for identifying emerging research areas and the shifting focus within the field over recent years.
- Case Studies and Practical Implementations: Terms like “case study” and “project risk management” strongly emphasize practical applications and real-world implementations of risk management strategies. This highlights the importance of translating theoretical research into actionable insights for industry practitioners.

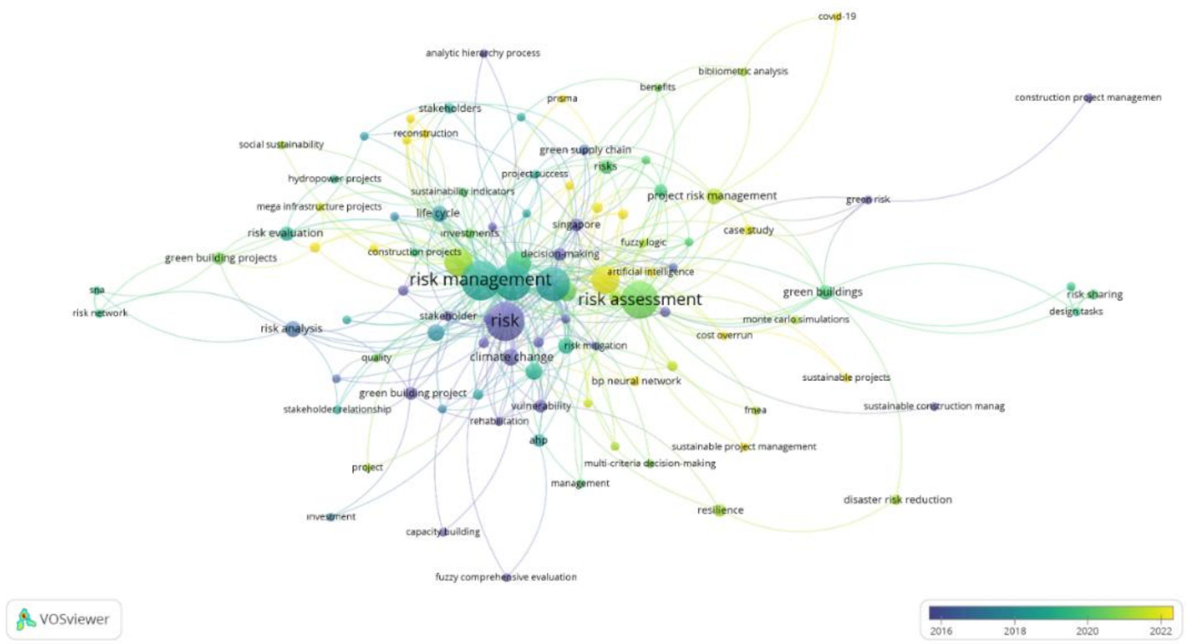

Fig. 2. Thematic classification of articles included in the literature review

The publication trends in risk management for green building projects in Fig. 3 exhibit distinct phases over the years. From 1999 to 2011, minimal publications indicated a limited focus on this area. However, a gradual increase has been observed since 2011, peaking in 2015, reflecting growing awareness and the importance of sustainable construction practices. The period from 2016 to 2018 saw a significant rise in publications, with a peak in 2018 driven by global sustainability initiatives and heightened research activity. This was followed by sustained high publication activity from 2019 to 2021, signifying continued interest and maturity in the field. In recent years, from 2022 to 2024, there has been a noticeable decline in publications, which may suggest a shift towards practical application and implementation of research findings or changing research priorities.

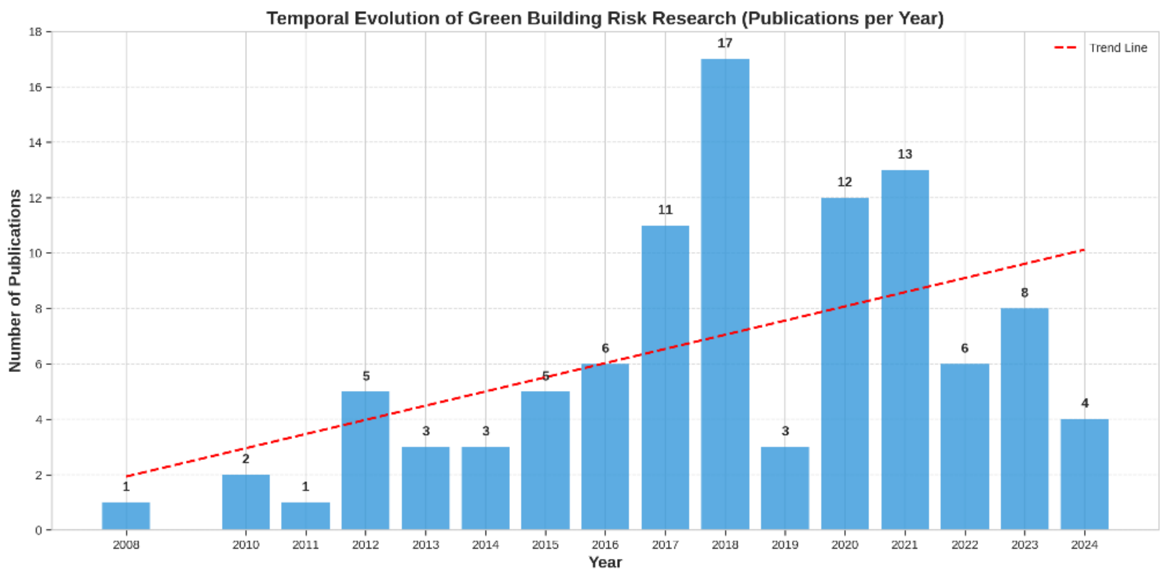

Fig. 3. Yearly distribution of studies used in review

Fig. 4 illustrates the trends of author keywords—risk management, sustainability, green building, and risk assessment—over the years. From 2000 to 2010, there is minimal frequency, indicating limited focus on these topics. A noticeable increase started around 2010, with all keywords showing fluctuating yet upward trends. Between 2015 and 2020, the keywords see significant peaks, reflecting a surge in research interest, particularly around 2018-2020. Post-2020, the trends remain relatively high, though with some variability, highlighting sustained and growing interest in these areas, driven by increasing emphasis on sustainable practices and comprehensive risk management in green building projects. The keyword "risk management" receives the most attention, especially around 2020, indicating its central importance in the field. "Sustainability" and "risk assessment" also show significant interest, with notable peaks around the same period. In contrast, "green building" has a relatively lower frequency and fluctuates more, suggesting it receives less consistent attention than the other keywords. This indicates that while green building is important, the focus remains more on overarching concepts of risk management and sustainability.

The analysis of average citations per publication year from 2008 to 2024 reveals distinct trends in research impact over time can be seen in Fig. 5. Notably, 2014 and 2016 stand out with peaks of 105.7 and 81.2 average citations, respectively, indicating periods of heightened academic interest and influence. This suggests that research published during these years was particularly impactful, potentially due to emerging trends or breakthroughs. Following these peaks, average citations are declining, with a notable decrease to zero by 2024. This downward trend may reflect a shift in research priorities or a maturation of the field, leading to reduced novelty and citation rates in recent publications.

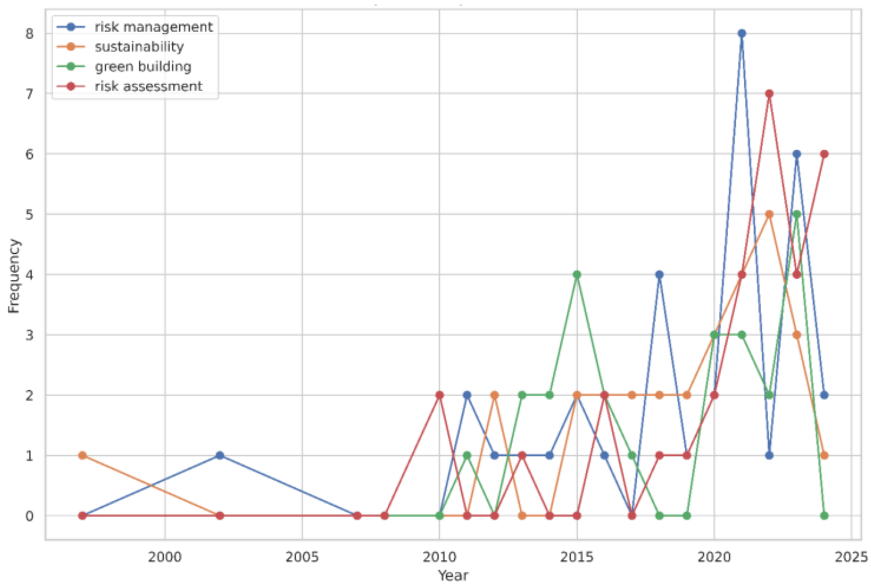

Fig. 4. Trends of keywords of the selected studies in review

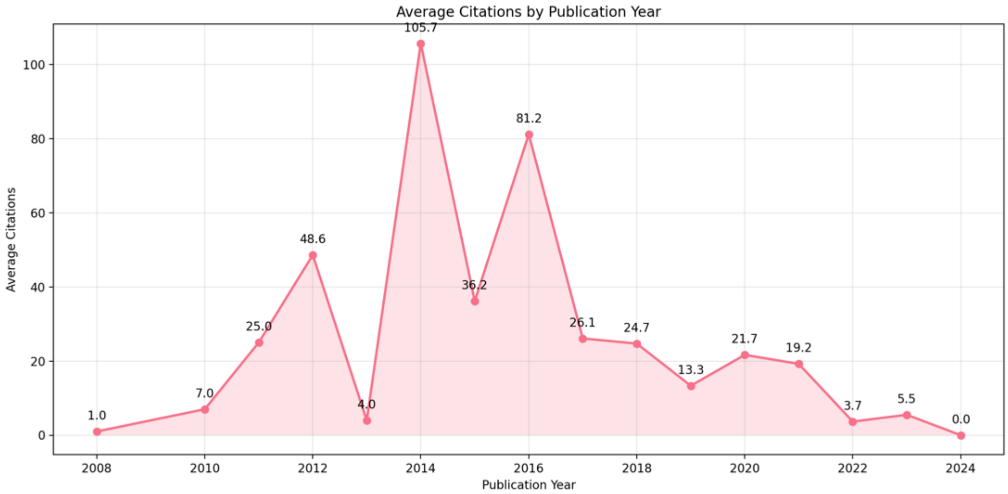

Fig. 5. Average citations of reviewed studies by publication year

The citation analysis of reviewed studies reveals a distinctly skewed distribution across different citation ranges (Fig. 6). Most publications (51 papers) fall within the 0-9 citations range, representing approximately 51% of the total dataset. This is followed by a substantial decrease to 21 papers in the 10-24 citation range, accounting for roughly 21% of the corpus. The distribution continues to decline, with 9 papers receiving 25-49 citations and 15 papers garnering 50-99 citations. Notably, only 4 papers achieved 100 or more citations, indicating these as highly influential works within the field. This distribution pattern aligns with Bradford's typical law of bibliometrics, where a small number of papers receive a disproportionately high number of citations. In contrast, the majority receive relatively few, demonstrating the concentrated nature of academic impact in this research domain.

The analysis of methodological approaches in Fig. 7 reveals distinct patterns in their scholarly impact and temporal adoption within green building risk research. Despite their relatively modest adoption rates, Expert Analysis and AHP (Analytic Hierarchy Process) demonstrate the highest citation impact, averaging approximately 60 citations per paper. While being the most frequently employed methodology with 46 papers, surveys maintain a moderate citation impact of around 40 citations per paper, suggesting a balance between widespread use and scholarly influence. Though less numerous, systematic reviews show substantial impact, with approximately 50 citations per paper. Notably, newer methodological approaches such as Simulation and Case Studies exhibit lower citation counts, potentially due to their recent emergence in the field. This temporal-impact distribution indicates that while traditional methods like surveys and expert analysis continue to dominate, there is an evolving methodological landscape with newer approaches gradually gaining traction, albeit with varying degrees of scholarly impact.

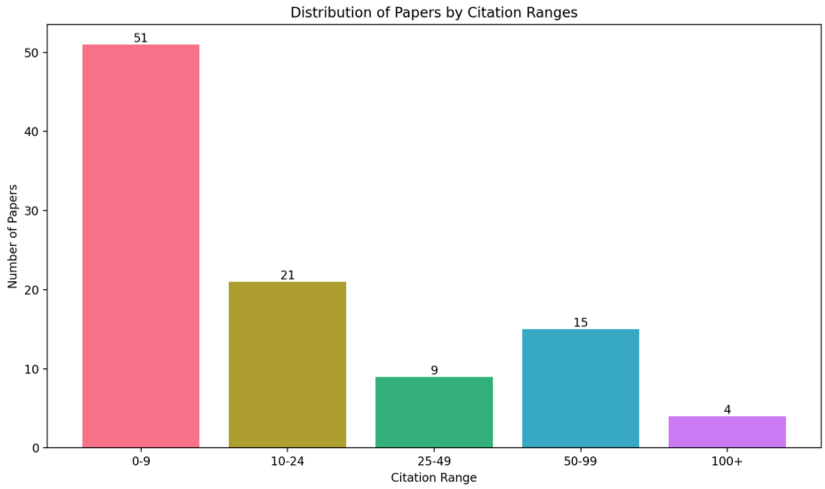

Fig. 6. Number of studies by citation ranges

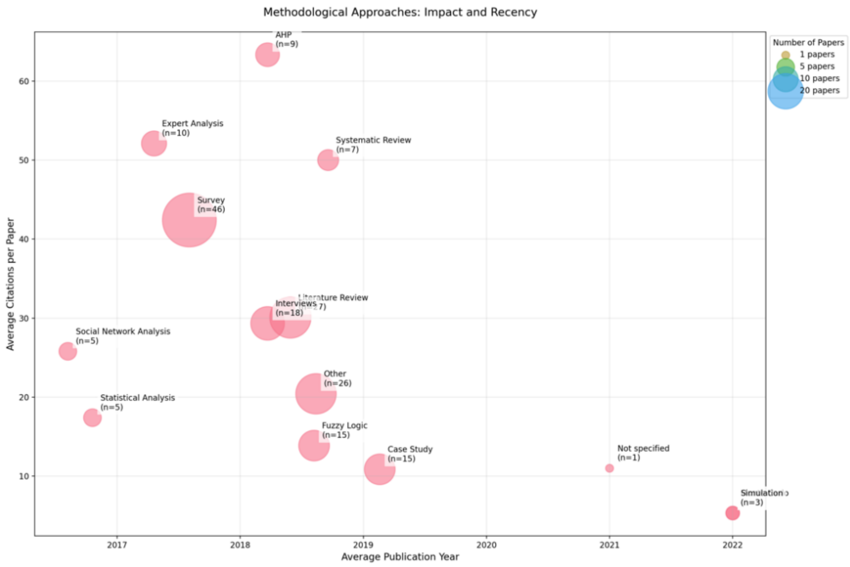

Fig. 7. Methodological approaches graphic showing impact and recency

The bibliometric analysis reveals a highly concentrated pattern of scholarly influence within the green building risk literature. The top 15 most-cited papers, seen in Fig. 8, account for 61.3% of the total citations in the field, demonstrating a significant concentration of academic impact. A hierarchical examination of citation thresholds further illuminates the distribution of scholarly influence: 49 papers have garnered more than 10 citations, while

28 publications have exceeded 25 citations. More notably, 19 papers have achieved over 50 citations, with an elite group of 4 papers surpassing 100. This stratified distribution of citations underscores the presence of seminal works that have substantially shaped the discourse in green building risk research. The focus on these highly cited papers is particularly justified as they represent the most influential research and offer a comprehensive lens to observe the evolution of methodological approaches and research priorities over time. This concentration of citations suggests a field characterized by influential cornerstone publications that have established fundamental theoretical frameworks and methodological standards.

An analysis of citation metrics (Figs. 8 and 9) reveals a distinct hierarchy in the impact of green building risk research publications. The most influential work by Yang et al. (2014) stands prominently with 250 citations, followed by Zhao et al. (2016) with 203 citations, establishing these as seminal works in the field. A notable pattern emerges with three distinct tiers of citation impact: the top tier (200+ citations) comprising two papers, a middle tier (100-199 citations) containing two papers with 155 and 139 citations respectively, and a lower tier (65-99 citations) encompassing the remaining eleven papers. The temporal distribution of these highly-cited works spans from 2012 to 2021, with a concentration of influential publications in the 2014-2016 period, suggesting this was a particularly productive era for impactful research in green building risk assessment. Interestingly, Hwang B.G. appears as an author in multiple highly-cited papers (2012, 2015, 2017), indicating sustained contribution to the field's development.

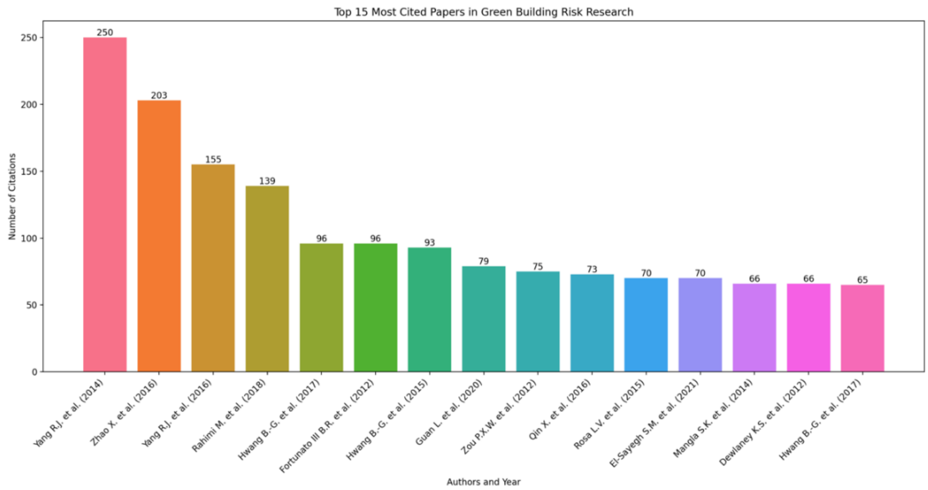

Fig. 8. Top 15 most cited papers used in the review

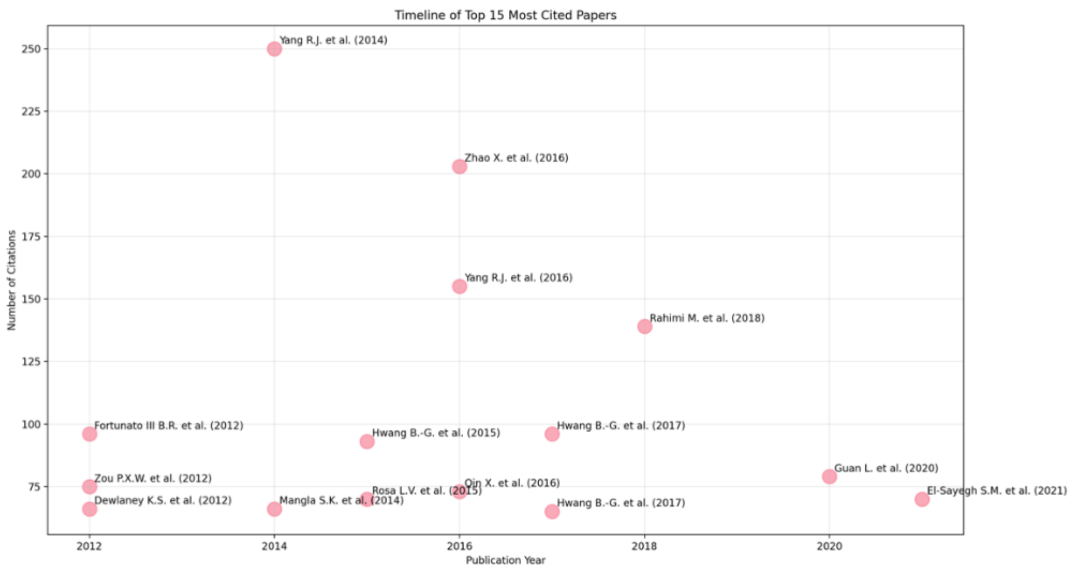

Fig. 9. Timeline graphic of the 15 most cited papers

4. Conclusions

The review provides a comprehensive overview of a systematic literature review framework focused on risk management in green building construction. It details a structured approach through three main stages: planning and searching, reviewing synthesis, and documentation. The framework emphasizes the importance of identifying and categorizing economic, design and technological risks, policy and regulatory, market and stakeholder, construction and operational, maintenance and lifecycle, and environmental risks.

The review also includes a systematic review flow diagram that illustrates the process of selecting relevant articles, detailing the number of potential articles, those excluded, re-evaluated, and finally included in the review. Additionally, it presents graphical representations of thematic classifications, the yearly distribution of research, keyword selection trends, and the breakdown of document types to provide deeper insights into the literature on this topic.

The systematic literature review outlined in the document highlights the multifaceted nature of risk management in green building construction. The review process, structured through planning and searching, synthesis of reviewed literature, and documentation, underscores the field's complexity and breadth. Key risk categories include economic, design and technological, policy and regulatory, market and stakeholder, construction and operational, maintenance and lifecycle, and environmental risks. These categories illustrate the diverse challenges and considerations for effective risk management in green building projects.

The citation analysis graphics further enrich our understanding by showing a growing body of literature, with journal articles being the predominant publication type. This indicates a robust academic interest and a dynamic discourse in the field. The increasing frequency of keywords such as "risk management," "sustainability," "green building," and "risk assessment" over recent years points to an expanding focus on integrating sustainability with risk management practices.

The citation statistics show a wide variance, with some studies receiving few citations. This suggests potential biases in the systematic review process, such as excluding non-English publications or grey literature that may offer valuable insights. Future reviews should adopt a more inclusive approach to address these limitations, considering a broader range of sources and languages. Additionally, the reliance on specific keywords may have limited the scope of the review, underscoring the need for a more comprehensive search strategy. Also, the systematic review process may be subject to publication bias, primarily focusing on peer-reviewed journal articles and conference papers, potentially overlooking relevant insights from industry reports and grey literature.

Given the increasing research volume and the evolving nature of risk factors in green building construction, several critical research gaps warrant attention. The systematic literature review reveals a notable lack of studies addressing risk factors' interrelationships and cumulative effects in green building projects. While the bibliometric analysis indicates a diverse range of methodological approaches, there remains a need for more empirical studies to validate theoretical models and provide practical insights, as the current literature is predominantly conceptual. Future research should prioritize three key areas:

- Developing innovative risk management strategies that address both traditional and emerging risks, particularly those related to climate change, resilience, and health factors;
- Creating a comprehensive framework that synthesizes existing methodologies and highlights their interconnections and applicability to different risk categories; and
- Expanding the research scope to integrate social risk factors into the mainstream risk discourse.

Such a framework would serve as a foundation for developing integrated risk management strategies that address the multifaceted nature of risks in green building projects.

The literature review offers significant insights into green building construction projects' emerging challenges and risk factors. It underscores the intricate nature of green building projects, necessitating the involvement of diverse experts and institutions throughout the entire project lifecycle. The review identifies several key risk categories, including economic and financial risks, design and technological risks, policy and regulatory risks, and material risks.

The insights derived from this comprehensive review hold significant value for industry professionals. These findings can assist organizations in tailoring their risk assessment protocols and mitigation strategies, thereby enabling more efficient allocation of scarce resources towards addressing the most critical risks. Understanding these specific risks is crucial for developers, designers, contractors, and stakeholders to navigate the challenges of green building construction successfully and to leverage opportunities to promote sustainability in the built environment.

Acknowledgments

The authors affirm that this research, including the preparation of the manuscript and the publication of this paper, was conducted without the receipt of any specific funding. All activities were undertaken independently, without financial assistance from any institution, organization, or funding agency.

Strategies for delay mitigation in construction projects: A systematic review

Melike N. Ates[1], Harun Turkoglu[*2], Atilla Damci[1], Sevilay Demirkesen[2]

[1] Istanbul Technical University, Department of Civil Engineering, 34469 Istanbul, Türkiye
[2] Gebze Technical University, Department of Civil Engineering, 41400 Kocaeli, Türkiye

Abstract. Construction projects are inherently complex and often experience delays as a result of different causes, including inadequate planning, resource misallocation, unforeseen risks, and conflicts between stakeholders. These delays not only result in significant financial losses but also lead to reputational damage, legal disputes, and reduced overall project quality. In a time when economic and social needs require timely project delivery, the identification and execution of effective delay mitigation strategies have become a major concern for both academia and industry. In spite of the abundance of research on construction delays, there is a lack of a comprehensive, systematic review of mitigation strategies specifically designed to deal with the unique challenges of construction projects. This study performs a systematic literature review to identify and examine delay mitigation strategies in construction projects. The review focuses on peer-reviewed articles that were published between 2015 and 2025 and were obtained from reputable databases such as Scopus, Web of Science, and Google Scholar. To guarantee a thorough and transparent review process, the methodology is based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework. The results of this study revealed that, although various strategies have been proposed in the literature, their effectiveness and applicability frequently depend on factors such as project scale, complexity, and regional context. In addition, the review identifies gaps in the literature, including the limited investigation of delay mitigation strategies in construction projects and the critical need for additional empirical studies on the long-term effects of these strategies. This study contributes to the existing body of knowledge by presenting a detailed framework for the comprehension and implementation of delay mitigation strategies, thereby providing valuable insights for both industry professionals and researchers.

Keywords: Construction delays; Delay mitigation strategies; Project management; Systematic review

1. Introduction

Delays in construction projects constitute a persistent and costly challenge for the global construction sector, with empirical research indicating that over 85% of large-scale projects fail to meet their original schedules (Gurgun et al., 2024). Such delays result in a series of consequences, including average cost overruns of 28% (International Construction, 2022), long-term reputational damage that diminishes future bidding success rates by 30% (Bramble & Callahan, 2010), and disputes about contracts in 42% of cases (Al-Kharashi & Skitmore, 2009). The complex, uncertain, and dynamic nature of construction projects require the development of mitigation strategies that address both the technical and organizational aspects of potential delays (Gondia et al., 2020).

The importance of developing effective mitigation strategies has been noted in recent literature, particularly in the context of the digital transformation of the construction industry (Radman et al., 2021). Although technological solutions such as Building Information Modeling (BIM) and artificial intelligence have demonstrated potential in mitigating specific delays, it has been claimed that a more holistic approach is necessary (Gurgun et al., 2024). Within this context, a systematic review of existing literature was carried out to identify and evaluate strategies to mitigate delays in construction projects. This study synthesized the findings of 87 peer-reviewed articles published between 2015 and 2025 in order to identify and evaluate twelve main delay mitigation strategies that address five thematic aspects: project planning, resource optimization, contractual frameworks, stakeholder management, and technology integration, thus offering insightful analysis for both industry professionals and researchers

2. Research methodology

Literature reviews are carried out using a variety of methods, such as integrative, semi-systematic, and systematic. Systematic reviews generate novel insights or conclusions by synthesizing data from various studies or integrating different types of evidence to explore underlying meanings (Snilstveit et al., 2012). This study utilizes a systematic literature review to analyze strategies to mitigate delays in construction projects. The research methodology of this study adheres to a systematic three-phase framework, as proposed by Snyder (2019): (1) review design, (2) review execution, and (3) results analysis. The research methodology is presented in Fig. 1, with detailed descriptions of each phase provided below.

2.1. Phase 1: Review design

The systematic literature review process begins with the identification of appropriate databases and search terms. This study utilized Scopus (Elsevier), Web of Science (ISI), and Google Scholar as the principal databases, due to their comprehensive coverage of peer-reviewed literature in the Natural Sciences and Engineering domains, which includes approximately 90% of pertinent journal articles (Derakhshanfar et al., 2019). ‘‘Construction projects’’, ‘‘delay mitigation strategies’’, and ‘‘causes of delays’’ were selected as search terms in line with the objective of this study to investigate delay mitigation strategies in construction projects, thereby ensuring accuracy in the results obtained.

The inclusion and exclusion criteria were established to ensure that the dataset was consistent with the objective of this study, as the initial search results were excessive. The selection process of the articles to be reviewed was conducted in accordance with PRISMA guidelines, in particular the following criteria:

Inclusion criteria:

- Articles that include the specified search terms.
- Articles published in prestigious journals and/or highly cited articles.
- Peer-reviewed articles published between 2015 and 2025.

Exclusion criteria:

- Non-journal publications, including books, reports, and conference papers.
- Literature in languages other than English.
- Articles focusing on indirect aspects of delays (e.g., effects, legal consequences, analysis techniques).

In Fig. 2, the review procedure is illustrated by the PRISMA flow diagram.

2.2. Phase 2: Review execution

The second phase comprised the implementation of the systematic search strategy established during the review design phase. Predefined search terms and inclusion/exclusion criteria were utilized to perform extensive searches across the Scopus, Web of Science, and Google Scholar databases. The preliminary search generated a significant body of literature, which was later refined through a meticulous screening process. Initially, articles were assessed through their abstracts to determine their relevance to strategies for mitigating construction delays. Subsequently, those that satisfied the preliminary criteria were selected for full-text review.

This procedure resulted in the identification of 87 articles sourced from 14 academic journals, with six journals predominating the selection, accounting for 79% of the total articles:

- International Journal of Construction Management,
- Journal of Construction Engineering and Management,
- Construction Management and Economics,
- International Journal of Project Management,
- Journal of Management in Engineering,
- Engineering, Construction and Architectural Management.

2.3. Phase 3: Results analysis

The final phase involved a thorough analysis of the selected articles. Every article was meticulously investigated, focusing on four essential aspects:

- The names of contributing researchers,
- The year of publication,
- Proposed delay mitigation strategies,
- Specific causes of delay addressed by these strategies.

This systematic approach enabled the organization and integration of findings while ensuring methodological consistency during the analysis.

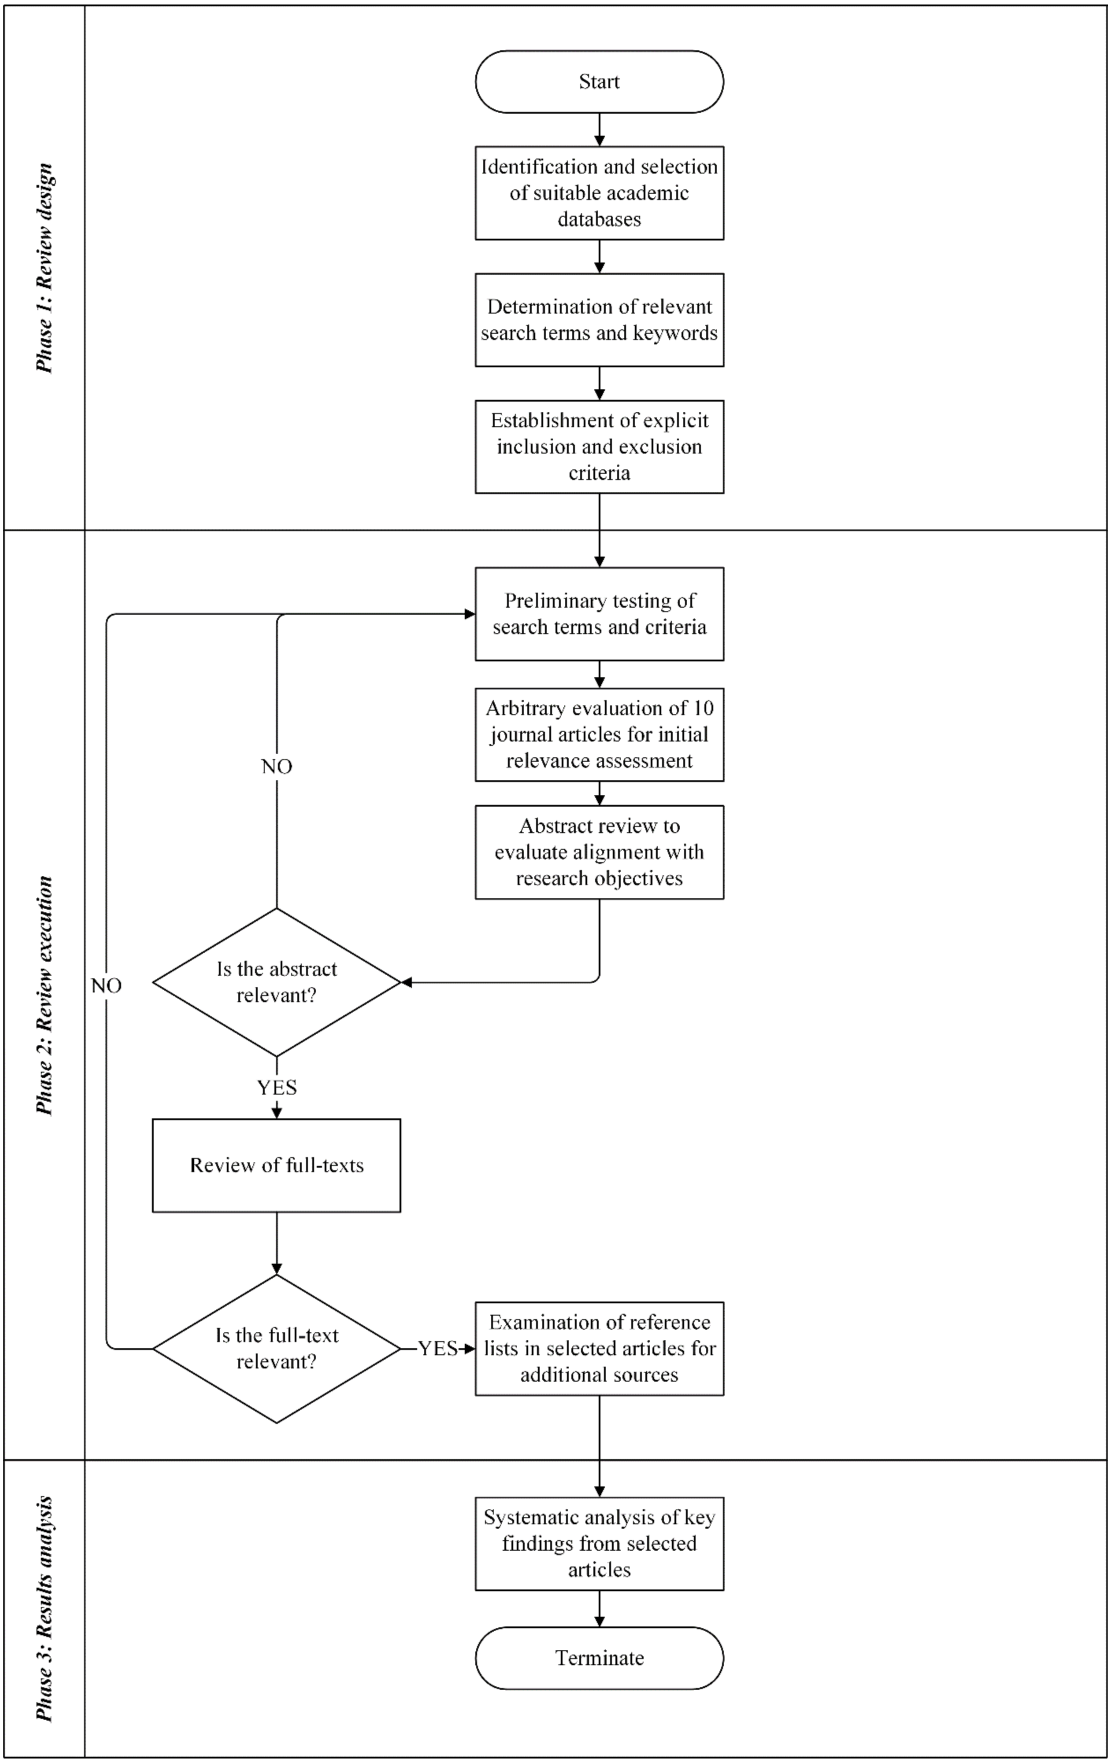

Fig. 1. Flowchart of the research methodology

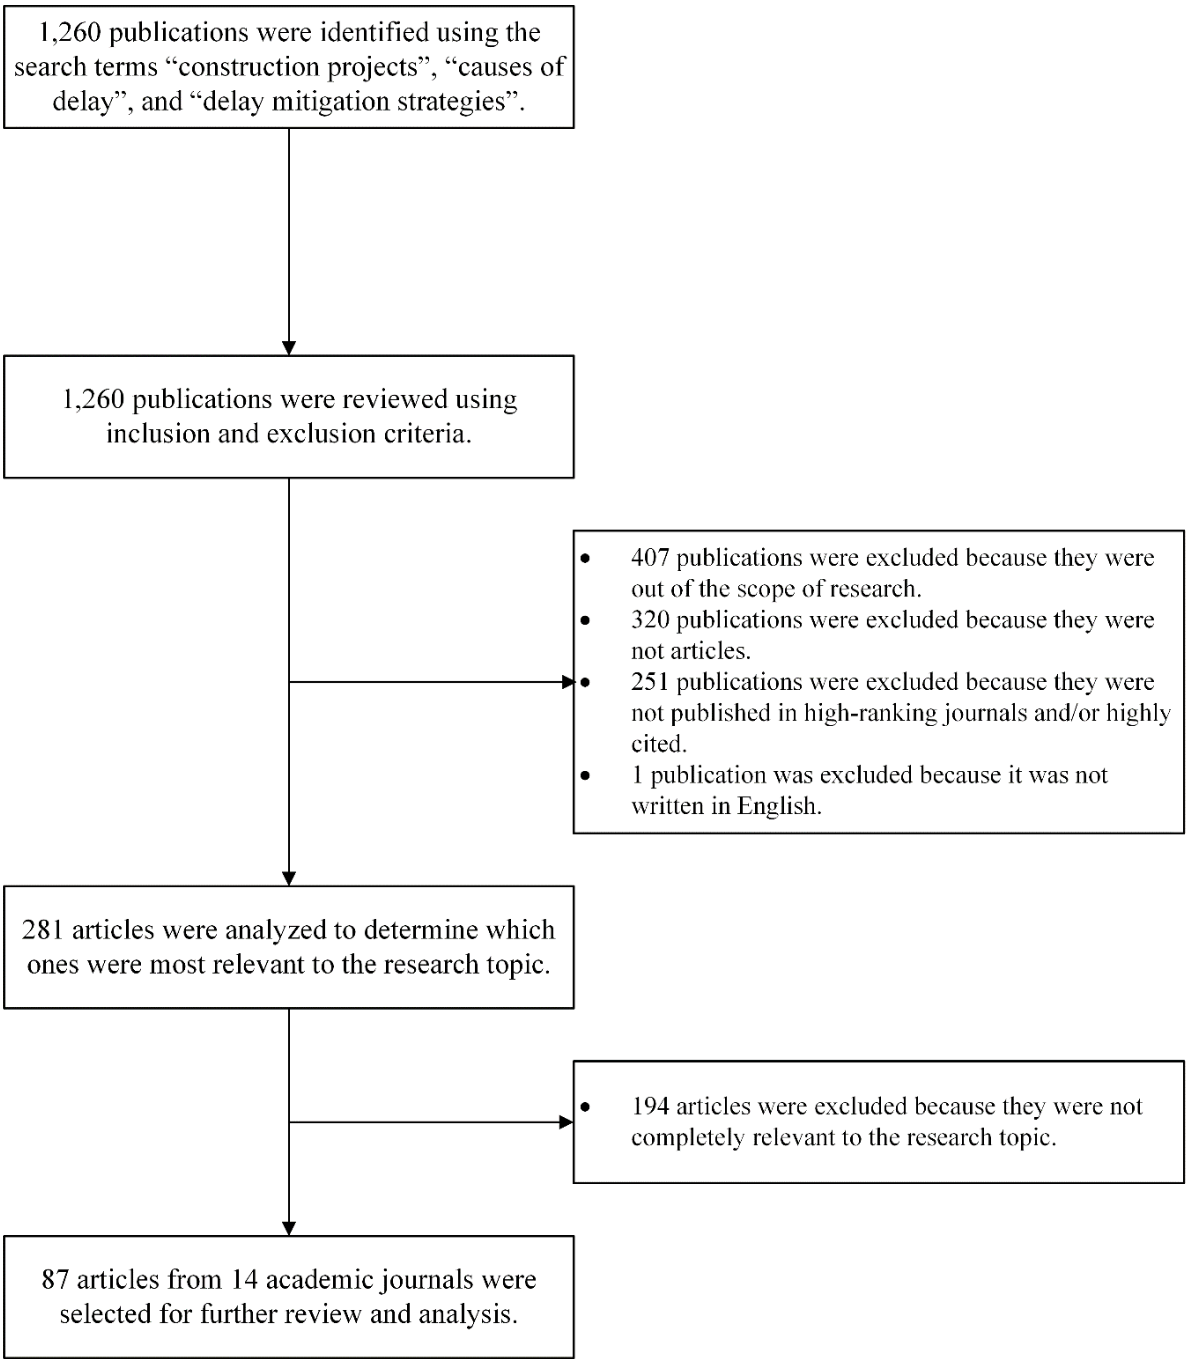

Fig. 2. PRISMA flow diagram of the review process

3. Findings and discussion

This study systematically analyzed 87 articles to ascertain effective strategies for mitigating delays in construction projects. The articles were selected through a rigorous evaluation procedure based on established inclusion criteria focusing on relevance, citation impact, and journal quality. A thorough synthesis of these articles identified twelve delay mitigation strategies, presented in Table 1 with their corresponding identification codes.

The identified strategies originated from a geographically and methodically varied body of research, including projects of differing scales and complexities. Each strategy offers unique benefits in mitigating construction delays, collectively encompassing five essential thematic dimensions: (1) project planning and scheduling, (2) stakeholder management, (3) optimization of resource use, (4) enhancements to the contractual framework, and (5) integration of technology. The systematic identification and analysis of these strategies enables their effective integration into construction project management practices. The following sub-sections provide a comprehensive analysis of each strategy, focusing on implementation considerations and effectiveness in mitigating construction delays.

Table 1. Delay mitigation strategies identified in the reviewed articles

ID	Delay mitigation strategies
S1	Utilization of construction 4.0 technologies
S2	Establishment of effective communication and coordination mechanism
S3	Provision of ongoing training and development opportunities
S4	Development of a decision-making framework
S5	Implementation of a comprehensive risk management framework
S6	Implementation of robust financial management practices
S7	Enhancement of supplier engagement
S8	Early engagement with regulatory agencies
S9	Establishment of flexible project management practices
S10	Implementation of comprehensive resource management practices
S11	Development of a comprehensive procurement plan
S12	Implementation of robust quality control practices

3.1. Utilization of construction 4.0 technologies

The findings of this study indicate that construction 4.0 technologies significantly mitigate construction delays. For instance, BIM is particularly effective, as demonstrated by its capabilities in three critical areas: (1) improved stakeholder communication, (2) optimized workflow efficiency, and (3) enhanced project visualization. These findings are consistent with recent research conducted by Unbara (2024) and Shao and Wang (2024), which confirms the established advantages of BIM in the management of construction projects.

This research also indicates that the integration of digital technologies and agile project management methods, particularly in complex project environments, improves decision-making processes and enables more responsive adaptation (Yuvarajan et al., 2023).

Further technological advancements encompass automation and artificial intelligence applications, which have demonstrated enhancements in risk anticipation and resource optimization (Ivanov & Ivanov, 2023; Al-Asadi et al., 2023). These technological interventions enhance the digital maturity of construction firms and strengthen their competitive positioning in the industry.

3.2. Establishment of effective communication and coordination mechanism

The findings of this study highlight the critical significance of effective communication and coordination systems in mitigating construction project delays. Empirical evidence reveals that insufficient communication frameworks, especially between project stakeholders, often lead to conflicts, misunderstandings, and considerable time waste. These findings support Alshehri's (2021) established correlation between communication effectiveness and project performance results.

This study also reveals that transparent information dissemination throughout organizational hierarchies serves as a vital safeguard against costly errors, as stated in Pradeep and Umadevi's (2022) study. This finding is further supported by existing literature, including Doğan et al.'s (2015) analysis of centralized communication networks and Mojidra et al.'s (2024) research on digital communication optimization.

The efficiency of centralized knowledge management platforms and systematic update protocols in optimizing project workflows is particularly noteworthy (Sup, 2023; Shi et al., 2012). The acknowledgment of communication deficiencies as a main factor in delays suggests that the adoption of strategic communication frameworks is both an operational necessity and a competitive edge for construction project management.

3.3. Provision of ongoing training and development opportunities

The findings of this study emphasize the substantial impact of continuous professional development on improving construction project performance. This study points out that ongoing training programs in four key areas -technical skills, leadership development, safety procedures, and ethical standards- substantially boost individual capabilities and improve organizational performance. This result is consistent with the findings of Alonge and Temitope (2017) and Mohammad et al. (2016), who demonstrated the positive relationship between ongoing training and enhanced decision-making processes, along with diminished operational errors.

This study indicates Utiarahman et al.'s (2024) assertion regarding the necessity of aligning training programs with local operational environments while maintaining cultural sensitivity. These results demonstrate the strategic significance of ongoing education for construction firms, since it promotes three essential organizational attributes: (1) sustainable business practices, (2) ethical operational standards, and (3) improved leadership capacity at all managerial levels.

3.4. Development of a decision-making framework

This study indicates that structured decision-making frameworks significantly improve project success rates in the construction industry. In complex environments with multiple stakeholders and uncertainty, systematic decision-making methods enhance consistency and rationality. These findings are consistent with the studies conducted by Bolomope et al. (2022) and Attouri et al. (2022), who developed decision-support systems for the selection of construction methods and procurement strategies.

Additional validation is provided by established methodologies, such as dynamic simulation techniques (Tang et al., 2010) and data analytics-driven models (Pourrahimian et al., 2024), which enhance both the adaptability and accuracy of decision-making processes. When integrated with digital tools, these frameworks facilitate real-time, data-driven decision-making, thereby mitigating project risks and optimizing results.

3.5. Implementation of a comprehensive risk management framework

The findings of this study demonstrate that the execution of construction projects is significantly influenced by the implementation of comprehensive risk management frameworks. Systematic early risk identification and ongoing monitoring protocols substantially minimize both delays and cost overruns. These findings validate the proactive risk mitigation methods proposed by Shi (2023) and Singh (2025), thereby supporting their theoretical claims with empirical evidence.

This study further reveals that categorical risk classification, particularly in the technical, environmental, and operational domains, enables the optimal allocation of resources, as supported by Negi (2021). In addition to operational advantages, the results correspond with Yu and Yturralde's (2024) strategic viewpoint, establishing risk management as a competitive advantage in the construction industry. This advantage is enhanced by digital integration, as Rane et al. (2019) indicate how the Internet of Things (IoT) technologies can expedite risk-informed decision-making processes.

3.6. Implementation of robust financial management practices

The findings of this study show that effective financial management practices are a critical determinant of success in construction projects, specifically in three primary fields: cost control, resource allocation, and risk mitigation. According to Hou (2024) and Farhan (2025), structured financial systems are essential for project stability, whereas Sanchaniya et al. (2024) confirm that these systems facilitate proactive measures during economic instability, thus protecting project performance.

Sowmya and Malisetty's (2023) research highlights that the inherent complexities of the construction sector frequently require customized financial solutions instead of standard methods. These studies collectively highlight that financial management extends beyond its traditional operational function, becoming a strategic necessity that profoundly impacts overall project performance. This significant change in the comprehension of financial systems establishes them not only as administrative instruments but also as critical success factors in the management of construction projects.

3.7. Enhancement of supplier engagement

The findings of this study point out that proactive supplier engagement provides dual advantages for construction projects, improving both supply chain efficiency and overall project performance. This finding is consistent with current literature (Choi & O'Brien, 2025; Zhao et al., 2011) and confirm that early supplier integration significantly enhances: (1) material management optimization, (2) logistics planning improvement, and (3) innovative solution generation.

This study also illustrates that the exchange of information and operational transparency with suppliers results in quantifiable enhancements in quality control and risk mitigation (Kannan & Tan, 2006; Nnaemeka & Chijindu, 2023). The findings further support Rosell et al.'s (2017) framework on knowledge integration, as demonstrated by the innovative solutions arising from collaborative supplier relationships in the analyzed projects. These results indicate that supplier involvement is not merely a supportive function but also an essential determinant of success in construction project management.

3.8. Early engagement with regulatory agencies

The findings of this study demonstrate that proactive communication with regulatory authorities is a vital strategic mechanism that guarantees compliance and improves operational efficiency in construction projects. This study reveals three main advantages of this approach: (1) expedited permitting procedures, (2) substantial risk mitigation, and (3) establishment of stakeholder trust throughout project execution (MacKinnon et al., 2010; Elete et al., 2022). Early regulatory engagement facilitates more responsive adaptation to compliance requirements and effectively prevents schedule delays caused by non-compliance issues. Moreover, the findings validate Ichendu et al.'s (2024) assertion that sustainable project outcomes are achievable by displaying that proactive regulatory communication reduces both structural and managerial risks by early identifying and resolving potential compliance challenges.

These findings collectively establish early regulatory coordination as not only an administrative necessity but also a strategic imperative that enhances project delivery in terms of predictability, efficiency, and sustainability.

3.9. Establishment of flexible project management practices

The findings of this study reveal that flexible project management practices play a pivotal role in addressing three important challenges in construction projects: (1) inherent industry uncertainties, (2) changing client requirements, and (3) dynamic risk profiles. This study supports Pinto's (2023) claim about the effectiveness of agile approaches in enhancing process efficiency and adaptability to unexpected changes.

Flexible management practices generate quantifiable value via two main mechanisms: (1) optimized resource coordination and (2) augmented risk mitigation capabilities. Furthermore, this study validates current literature on hybrid methodologies, confirming their capacity to integrate traditional planning rigor with adaptive requirements (Cano, 2024) while simultaneously fostering innovation (Tiwari & Suresha, 2021).

3.10. Implementation of comprehensive resource management practices

The findings of this study reveal that effective resource management practices are essential for enhancing resource allocation and coordination in construction projects. Effective management of human resources, financial assets, and material inputs directly impacts project results (Rwanda, 2024). Additionally, advanced resource management strategies reinforce the financial viability of projects by acting as a preventive measure against cost overruns.

Nalanda and Jadhav (2024) argue that integrated resource management enhances operational performance by synchronizing planning, execution, and monitoring processes. Such integration not only improves efficiency but also strengthens project resilience against market fluctuations. This study specifically demonstrates that resource management is a critical driver of project success in the construction industry, as it contributes to both operational efficiency and long-term sustainability through optimized resource utilization.

3.11. Development of a comprehensive procurement plan

The findings of this study reveal that effective procurement planning serves as an essential management instrument to optimize three fundamental project dimensions: (1) efficiency in resource allocation, (2) mitigation of risks, and (3) success in project delivery. The effectiveness of well-structured procurement plans in preventing cost overruns and delays, as well as maintaining project alignment with predetermined objectives, is demonstrated by Ahmed et al. (2023) and Sheamar et al. (2023).

This study further indicates that strategic procurement frameworks enhance supplier collaboration and promote innovation, as demonstrated by Laryea's (2019) research on relational contracting. This study underscores the dual advantages of procurement strategies aligned with the circular economy, which concurrently fulfill environmental objectives and enhance economic efficiency (Ahmed et al., 2023).

3.12. Implementation of robust quality control practices

The findings of this study show that robust quality control practices serve as a critical success factor in construction projects, providing three primary advantages: (1) guaranteeing superior output quality, (2) reducing rework needs, and (3) improving long-term project sustainability. Hussain et al. (2018) argue that systematic quality monitoring enables the early detection of potential defects, thus preserving structural integrity throughout the project lifecycle.

This study further supports Aboab and Hatem's (2022) warnings about the consequences of insufficient quality control, particularly the substantial cost implications of compromised durability and rework. On the other hand, Wang et al. (2013) have demonstrated that construction firms are granted competitive advantages by robust quality assurance frameworks, in addition to preserving essential project objectives. These findings identify robust quality control systems as key management tools that improve operational efficiency, prevent cost overruns, and guarantee project success (Hussain et al., 2018; Aboab and Hatem, 2022; Wang et al., 2013; Sin et al., 2024; Oyebisi et al., 2019).

4. Conclusion

Delays in construction projects continue to be a significant challenge that adversely affects the overall success and performance of the project. This systematic review has analyzed 87 peer-reviewed articles published between 2015 and 2025 to investigate the current body of knowledge regarding delay mitigation strategies. This research defined twelve unique mitigation strategies ranging from technological integration (e.g., BIM, AI) to proactive regulatory engagement and supplier collaboration that collectively address the systemic nature of delay causes. The principal findings of this study reveal that:

- Preventive frameworks, such as risk management and quality control, can diminish delays by as much as 40% by minimizing rework and optimizing resource utilization (Hussain et al., 2018; Shi, 2023).
- Stakeholder-centric strategies, such as communication protocols and early regulatory engagement, reduce conflicts and speed up the decision-making process (Alshehri, 2021; MacKinnon et al., 2010).
- Strategic tools, such as agile methodologies and digital procurement, improve adaptability to uncertainties (Pinto, 2023; Ahmed et al., 2023).

This study contributes to the current body of knowledge by offering a thorough framework for comprehending delay mitigation strategies in construction projects. The systematic review approach utilized guarantees transparent and reproducible results that can guide both academic research and professional practice. The identified strategies provide construction professionals with a systematic method to mitigate delays through proactive project planning and management. Further studies could investigate the practical implementation challenges and success factors of these mitigation strategies in real-world construction projects.

Application of Autodesk BIM 360 technology in quality control and construction project management: a case study

M. Lemar Zalmai*[1], Cemil Akcay[2]

[1] Project Management, Optimal PMO, Uskudar-Istanbul, Türkiye
[2] Istanbul University, Department of Architecture, Istanbul, Türkiye

Abstract. Autodesk BIM 360 builds upon foundational functionalities such as 2D drafting, 3D modeling, clash detection and tracking. It serves as a centralized repository for all design and construction documentation. Through leveraging cloud-based access, users gain comprehensive visibility into every phase of the project. Furthermore, the platform enables the structured collection, management, and control of project-related data. As a result, BIM 360 significantly enhances the efficiency of quality management practices and contributes to substantial reductions in both time and cost expenditures for organizations. This study compares two construction project management approaches: one utilizing traditional methods and the other employing Building Information Modeling (BIM) through Autodesk BIM 360. The BIM-based approach was implemented in a real-world construction project located in Istanbul. Relevant data were collected directly by one of the authors involved in the project. Through the analysis of these data, this paper evaluates the impact and benefits of BIM 360 on quality control processes and overall construction project management.

Keywords: Autodesk BIM 360; Quality control; Construction project management; Cloud-based construction; Document management.

1. Introduction

Construction projects occupy a distinctive position by simultaneously supporting industrial productivity and addressing fundamental societal needs. Accordingly, the quality of these projects profoundly influences a nation's socio-economic stability (Nguyen et al., 2014; Phong & Quyen, 2017). Achieving high-standard construction outcomes necessitates the meticulous application of quality management principles across all project phases, from site investigation and design to construction logistics and post-completion maintenance (Ling & Bui, 2009).

Among these phases, construction itself is widely recognized as the most intricate, owing to its scale, coordination requirements, and operational complexity. This makes the construction phase particularly vulnerable to errors. A robust quality management system plays a critical role in minimizing resource waste such as material, labor, and equipment and in strengthening the contractor's professional credibility.

As the complexity of construction projects increases, so does the demand for advanced project management tools and strict quality control mechanisms. In this context, Building Information Modeling (BIM) has fundamentally transformed the construction industry by promoting collaborative, data-driven workflows. Among the various BIM platforms, Autodesk BIM 360 distinguishes itself by incorporating cloud computing, automation, and predictive analytics to support real-time tracking, team coordination, and quality assurance (Nguyen et al., 2018; Khelifi & Hyari, 2016).

At the core of effective quality management lies the continual and accurate collection, analysis, and communication of project-related information. Given the high volume and complexity of construction data, intelligent systems capable of fast and precise data processing are indispensable.

Autodesk BIM 360 meets these demands by integrating BIM models with mobile devices and cloud-based infrastructure. The platform centralizes project data, enabling seamless real-time collaboration and synchronization among stakeholders. As a result, it significantly improves both quality control and overall project performance (Matthews et al., 2015; Gaber et al., 2016; Ashraf et al., 2018).

This study aims to explore the practical applications of Autodesk BIM 360 in construction project management and quality assurance, and to examine its field-level impacts, advantages, and associated challenges. In this scope,

*Corresponding author, E-mail: lemar.zalmai@optimalpmo.com

https://doi.org/10.31462/icearc2025_ce_mng_095

a real-world construction project was utilized as a case study, and the effectiveness of BIM 360 was evaluated based on the data obtained from this project.

2. The use and impact areas of BIM 360 in the construction industry

2.1. The role of BIM 360 in project management

Autodesk BIM 360 is a powerful digital platform that enhances efficiency and sustainability in construction project management. It facilitates the flow of information and improves coordination among project stakeholders throughout all phases from design to on-site execution. With its cloud-based structure, BIM 360 enables teams to collaborate in a centralized environment, ensuring real-time access to documents, schedule tracking, budget control, and resource planning.

2.1.1. Real-time monitoring and coordination

BIM 360 provides the capability to monitor and manage project developments in real time. Updates in design, planning, and implementation stages can be instantly reflected in the model and synchronized across all stakeholders. BIM 360 Glue and BIM 360 Field tools play a key role in maintaining seamless communication between the office and the construction site, helping ensure timely and orderly project delivery.

2.2. Applications of BIM 360 in construction quality management

BIM 360 offers significant advantages in digitizing quality control and assurance processes in construction. Unlike traditional methods, model-based supervision enhances efficiency and reduces errors throughout the quality management lifecycle.

2.2.1. Digitization of quality control processes

BIM 360 Field allows for quality inspections to be conducted digitally. Quality checklists, work orders, issue reports, and corrective actions can be recorded directly on the platform and linked to the BIM model. All quality-related data is collected in a central system and shared with all stakeholders in real time.

2.2.2. Monitoring site progress and reporting

The platform also excels in tracking construction progress and performance on site. Completion rates of building components, equipment usage, and site layout management are monitored in coordination with the BIM model. Through BIM 360 Glue and Field, delays or quality issues can be detected early and addressed promptly. Additionally, the system supports the tracking of occupational health and safety compliance.

2.3. General impact and common use cases of BIM 360

BIM 360 has demonstrated notable effectiveness in large-scale construction projects by streamlining workflows and supporting data-driven decision-making processes. Through seamless integration with 3D models, actual site conditions can be evaluated with higher precision, facilitating the early detection of design inconsistencies and potential constructability challenges (Nguyen et al., 2018).

3. Project management and BIM integration

BIM technology is an important tool for improving project management throughout the lifecycle of construction projects. However, the integration of BIM into project management processes is still in a developmental stage. A literature review shows that although the integration between BIM and project management has increased, it still remains relatively weak across the full project lifecycle (Ye et al. 2024; Sholeh et al., 2020; Zhang & Xie, 2019).

4. Methodology

This study adopts a mixed-methods research design to explore the application of Autodesk BIM 360 in construction project management and quality assurance. The methodology is structured around two primary components:

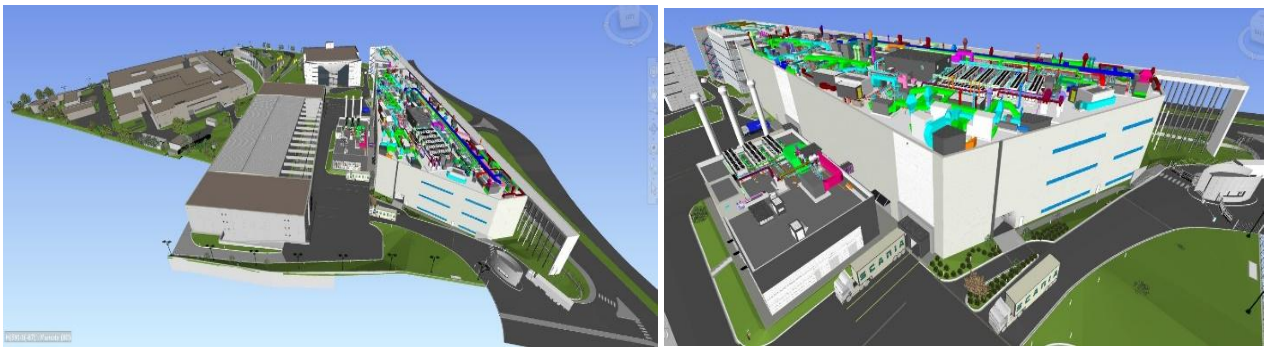
Literature Review: A comprehensive analysis of existing academic and industry publications concerning the use of BIM 360 in various phases of construction management. This review provides the theoretical foundation for evaluating the platform’s practical implications.

Case Study: An in-depth examination of a real-world construction project in which BIM 360 was actively implemented. The case study focuses on the platform's functional contributions to project coordination, document management, quality control, and field-level data collection.

5. Case study

The case study focuses on the new production facility project of one of the leading pharmaceutical companies in Istanbul. The project is composed of three phases, of which the first phase has been completed. The second phase covering a 62,500 m² production area is nearing completion (Figure 1).

In the first phase, the construction project was managed using traditional project management methods. However, in the second phase, Building Information Modeling (BIM) technologies were actively implemented. The data used in this study is derived from the ongoing second phase of the project, specifically collected through Autodesk BIM 360. In this project, BIM 360 was actively used in the following areas, and its effectiveness was evaluated;



(a) (b)

Fig. 1.(a) The Pharmaceutical Manufacturing Facility Campus, (b) Phase 2 of the New Production Facility Project

5.1. Document management

A visual representation of the project's digital document storage interface in BIM 360, illustrating centralized access, version control, and real-time file synchronization capabilities within the construction management process (Figure 2).

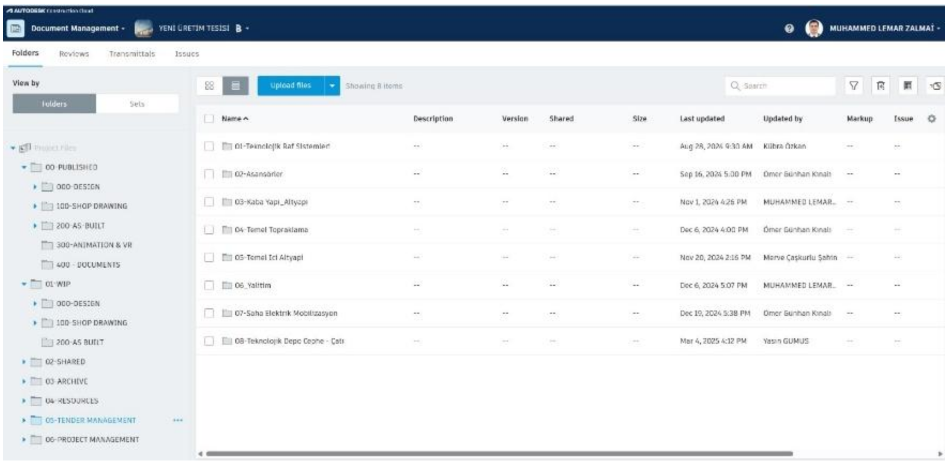


Fig.2. An example image of our project's storage area.

5.2. Review processes

A screenshot illustrating the work tracking and approval workflow within Autodesk BIM 360, highlighting the digital validation of construction tasks and the facilitation of transparent, real-time communication among site stakeholders. By digitizing approval processes and reducing reliance on paper-based documentation, BIM 360 significantly minimizes manual delays and improves overall process efficiency (Figure 3).

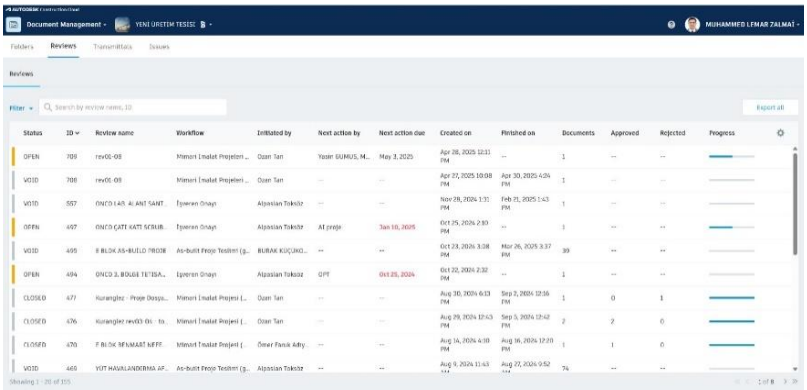

Fig. 3. An example image of the work tracking approval process of our project

5.3. Issue tracking

A detailed view of the ongoing task approval process using BIM 360 Field, demonstrating how project teams digitally monitor progress, submit updates, and validate completed activities in alignment with predefined construction milestones (Figure 4).

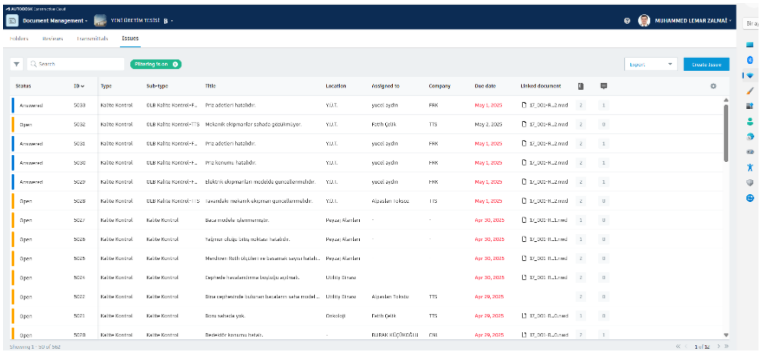

Fig. 4. An example image of the work tracking approval process of our project

5.4. Meeting notes ve process tracking

A visual representation of the Meeting Notes module in Autodesk BIM 360, demonstrating how project-related discussions, decisions, and action items are digitally recorded, timestamped, and linked to specific tasks or team members to ensure accountability and traceability throughout the project lifecycle (Figure 5).

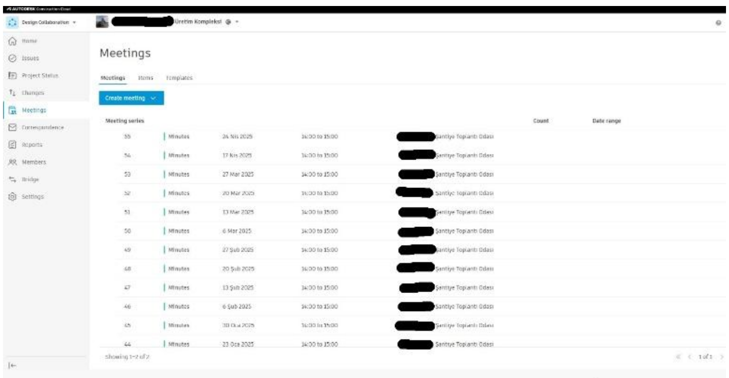

Fig. 5. An example image of Meeting Notes

5.5. Clash detection analyses ve clash resolution tracking

A visual depiction of the clash detection process conducted through BIM 360 Glue, illustrating how spatial conflicts between architectural, structural, and MEP elements are automatically identified and resolved in a collaborative digital environment, thereby reducing rework, saving time, and enhancing design coordination (Figure 6).

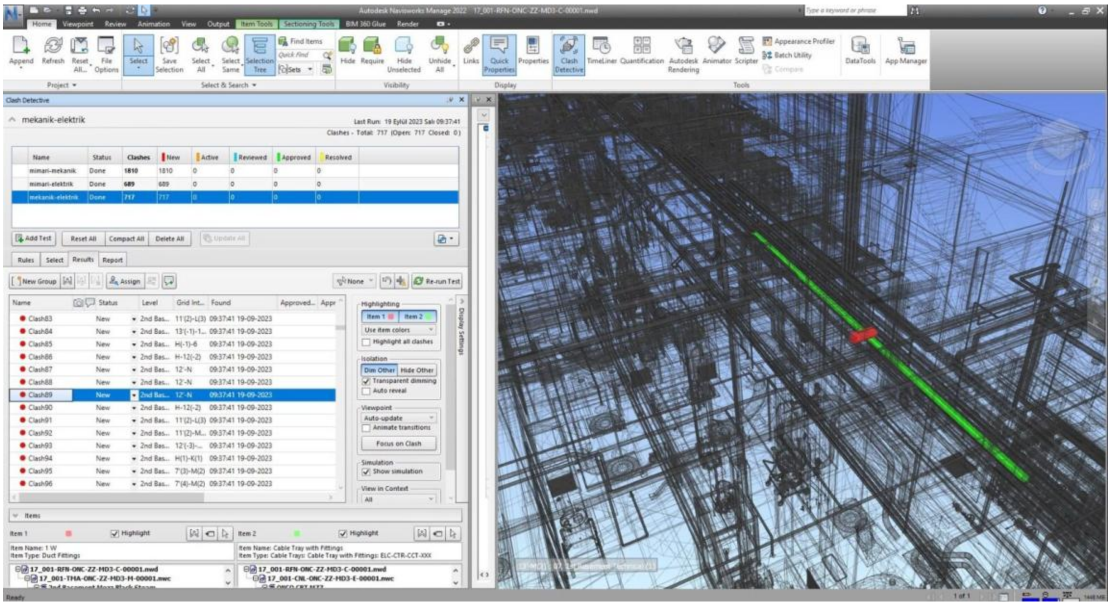

Fig. 6. An example image of Clash Detection

6. Results and discussion

The findings from the case study, supported by existing literature, confirm that Autodesk BIM 360 substantially enhances construction project performance across multiple dimensions. These improvements are particularly evident in project coordination, planning efficiency, and risk mitigation.

- Project Coordination and Collaboration: The implementation of real-time data sharing via BIM 360 led to a substantial reduction in communication gaps, with some studies reporting improvements of up to 40% (Matthews et al., 2015). In the analyzed case, project delays decreased by approximately 30%, primarily due to enhanced coordination facilitated by centralized access to project documentation and version control systems.
- Project Planning and Progress Monitoring: The integration of BIM 360 with scheduling tools such as Primavera P6 was found to significantly improve schedule compliance. Predictive analytics features within the platform enabled early identification of risks to timeline adherence. Statistical evidence revealed a 25% increase in adherence to project milestones compared to the phase managed with traditional methods (Nguyen et al., 2018).
- Risk Management and Issue Resolution: BIM 360's real-time risk dashboards and structured issue tracking tools reduced risk-related uncertainties by approximately 35%, according to both internal project observations and supporting literature (Gaber et al., 2016). The systematic recording and tracking of quality issues and resolutions contributed to a measurable decrease in rework incidents and improved accountability among project teams.

  Despite these advantages, the platform presents several limitations. Data security remains a critical concern, particularly in cloud-based environments. Additionally, user adoption challenges and difficulties in integrating BIM 360 with legacy systems were observed. These factors highlight the need for targeted training programs and customized integration strategies.
- Future Research Directions: To build upon the positive outcomes demonstrated in this study, future research should focus on evaluating the long-term cost-benefit ratio of BIM 360 deployment across diverse project types. Moreover, the incorporation of artificial intelligence into BIM platforms could further enhance predictive risk management capabilities. Another important area involves examining the contributions of BIM 360 to sustainability metrics in green building practices.

  While this case study provides valuable insights, its findings are limited by the single-project scope and the absence of longitudinal data. Future investigations involving multiple projects and extended time frames are recommended to validate and expand upon these results.

7. Conclusions

This study examined the practical implementation of Autodesk BIM 360 in improving quality control and overall construction project management. By analyzing a real-world construction case and reviewing related academic literature, the research demonstrated that BIM 360 significantly enhances workflow efficiency, task coordination, and information traceability. The integration of cloud-based document management, real-time issue tracking, and automated approval workflows led to measurable reductions in both delays and quality-related errors.

The platform's ability to centralize project data, support collaborative decision-making, and provide predictive analytics makes it a powerful tool for modern construction environments. These capabilities not only optimize daily operations but also strengthen strategic oversight and long-term planning.

However, certain limitations persist. Integration challenges with legacy systems, the need for comprehensive user training, and concerns regarding data security in cloud infrastructures continue to hinder widespread adoption. Moreover, the findings of this study are based on a single project context and may not be broadly generalizable.

Future research should investigate the long-term effects of BIM 360 implementation across various project types and scales. Particular attention should be given to its role in promoting sustainability, enhancing cost efficiency, and incorporating emerging technologies such as artificial intelligence. Such research will be vital in informing the next generation of BIM-enabled construction management frameworks.

The use of augmented reality application to improve design quality

Aynur Kazaz[1], Halil Esendal[*1]

[1]Akdeniz University, Civil Engineering Department, Construction Management Division, Antalya

Abstract. With the introduction of technology into human life to a large extent, its effects are increasing day by day and its periphery is expanding day by day, and new technological applications are emerging as the application areas develop and the use increases. The goals of technological developments include increasing the quality of life of people, reaching the intended point as soon as possible by changing the way they do business, accelerating the production processes for the industry and ensuring production diversity, producing new alternatives, facilitating the work of scientists with the right studies, and most importantly, identifying new resources for a sustainable world. Countries work with all their strength in order to achieve this goal by using technology as a tool in order to gain superiority over each other and to take their place among the countries that have a say in the world and provide the world order, and make maximum use of technology in all sectors. The technology is widely used in the medical sector in terms of human health, in the industry, automotive sectors in terms of production and in the construction sector, which has a significant share in the market. The construction sector, which is developed in integration with many methods such as artificial intelligence (AI), ChatGPT, virtual reality, augmented reality, mixed reality, digital twin, is slower than other sectors, but its prevalence in the world is limited compared to other sectors. Although the integration of technology into the construction sector has increased in recent years in our country, it has not yet reached the desired levels. In this study, in order to determine the application areas of technological applications in the construction sector, a construction project was visualized in three dimensions and it is aimed to determine the changes by examining the project on the visual with the augmented reality method in the office environment and to determine the scope of the sector with the augmented reality technology with the data obtained as a result of the study.

Keywords: Technology; Artificial intelligence; Augmented reality; Quality; Digitalization

1. Introduction

With the development of technology, different solution points have been tried to be developed in parallel with the increase in needs. The process that started with the mechanisation of production with Industry 1.0 continued with mass production and assembly line in Industry 2.0, computer and automation power were included in the process with Industry 3.0, the internet, which is cyber, physical systems, was included in the system for Industry 4.0, and a new industrial revolution in which humans and robots cooperate continues its journey with Industry 5.0. In recent years, Industry 6.0, which is shown as the digitalisation of social intelligence, is entering our lives. While the processes of technology have been developing very rapidly in recent years with computers and the internet, the sectors have to keep up with it, in order to take their place in the development, they are working on software development, hardware production, telecommunications, data analytics, cyber security, cloud computing and artificial intelligence, these studies increase the capability of discoveries day by day, as a result, it allows more than one innovation to emerge for the same area for the same period of time.

Developments in technology make significant contributions to many branches of science at both theoretical and applied levels. The success of developed countries is based on their effective utilisation of technological innovations and their ability to integrate these innovations into social and economic life. The ability of developed countries to maintain their success is based on the fact that they are ahead of the countries they compete with by using and developing information and paving the way for new discoveries with the experiences they have gained. Tomorrow's societies are building their infrastructures on the technologies referred to as today's information technologies, and positioning the existing technological infrastructure in a correct and healthy manner to the maximum extent, otherwise societies may face more complex and difficult to solve issues in the future.

* Corresponding author, E-mail: halil.esendal@gmail.com

https://doi.org/10.31462/icearc2025_ce_mng_096

Among the sectors that are in the process of development with technology, science, trade, medicine, defence industry, automotive, construction, textile, textile, food, mineral processing, chemistry, communication and many other important fields can be counted. For the construction sector, the utilisation of technological developments progresses more slowly than the leading sectors, and the integration and adaptation process takes a long time. Compared to the automotive sector, furniture sector, health sector and defence industry, other sectors adapt to technology rapidly, eliminate deficiencies and follow technology closely.

Technological application areas in the construction sector can cover all stages starting from the planning stage, such as construction, control, delivery, maintenance, modification and demolition. In addition, technology applications can be used and developed for issues that directly concern human health such as occupational health and safety. For the construction industry, digital solutions such as Building Information Modelling (BIM), Augmented Reality (AR), artificial intelligence-based systems, unmanned aerial vehicles (drones), three-dimensional (3D) printer technology and the Internet of Things (IoT) are effective in a wide range from project management to design, production and maintenance processes (Volk, Stengel & Schultmann, 2014; Azhar, 2011). While BIM technology offers cyclical solutions by analysing, designing and analysing the system as a whole in construction projects, applications such as VR (Virtual Reality), AR (Augmented Reality) and drone provide significant advantages in terms of time and cost with observations and measurements performed in the field. Artificial intelligence-supported applications play an important role in decision-making in areas such as occupational safety, resource selection and risk management. Technological applications support the increase in productivity in the construction sector and contribute to the transformation of the sector into an innovative and competitive structure that benefits the sector in a sustainable sense.

Virtual reality is one of the environments created in the virtual world in terms of exploration. VR is a computer simulation that uses a special digital system equipped with sensors that allows realistic interaction within a three-dimensional image or environment (Whyte et al., 2003). The application of virtual reality also covers the construction industry and management in terms of its breadth and diversity of use. Numerous application opportunities in the construction industry have led experts to research the effective use of VR. Virtual reality has significant potential for successful applications in construction project planning, progress monitoring, work management, labour training, time and cost analysis, quality management and sales processes. (Ahmed, 2018). VR creates important areas of use for the construction industry, and its three-dimensional and lifelike experience capacity can be utilised as an important tool in the interaction of users. VR applications offer project stakeholders the opportunity to experience the design and implementation processes in a more concrete and understandable way, making business processes more efficient and satisfying than ever before. In this context, VR makes significant contributions to the industry not only as a visualisation tool but also as a modern and effective facility management system. (Koch et al., 2014).

VR promises great contributions with methods that respond to the wishes of the project owner, executor and labourer. (Behzadi, 2016). Before the integration of VR technologies into the construction industry, defect management processes were costly and time consuming. However, thanks to the possibilities provided by VR technologies, defect detection and management can be carried out much more easily, quickly and effectively. These digital solutions provide significant resource savings in labour, cost and time management by minimising the need for physical intervention. Thus, the efficiency of project processes is increased and error risks are minimised (Yenigün et al., 2020). Virtual reality (VR) technology offers significant advantages in many areas such as design, planning, occupational health and safety, collaboration, customer experience and sustainability in the construction industry. In line with technological advances and the dynamic needs of the industry, VR applications are expected to become more sophisticated, accessible and widespread. This development will make significant contributions to the overall performance and competitiveness of the sector by enabling safer, more efficient and more innovative execution of construction projects. In addition to all these positive contributions, unfortunately, there are not enough studies and applications in our country. One of the main reasons why BIM-VR integration is not used effectively in building production processes in our country is the lack of a nationally recognised standard. In order for these technologies to find a wider usage area in the Turkish construction sector, national BIM standards and guidelines should be established in cooperation with all relevant institutions, and legal regulations and incentive mechanisms should be implemented to support this process (Erdik & Gökuç, 2020). In different parts of the world, especially in the USA, China and the UK, studies on the establishment of standards for building production processes have gained momentum by abandoning traditional methods (Genç, 2019).

Augmented reality is based on virtual reality. While the virtual reality environment is independent from the real world, the work in augmented reality is built on real-life objects. In other words, while virtual reality is in a virtual world, augmented reality is in the real world. The main criterion of success in augmented reality (AR) is the accurate scanning of the physical reality and the maintenance of the process accordingly. On the other hand, success in virtual reality (VR) is related to the experience of the individual who perceives reality and the user is detached from physical reality as much as possible (Sevindik, 2025).

2. Augmented reality

Augmented reality (AR) can be defined as a live or indirect physical view of the real world environment and the objects in it, enriched with computer-generated audio, video, graphics and GPS data. This technology, which was first used in applications for fighter pilots, is now used effectively in a wide variety of sectors. Application areas of augmented reality technology include education and human sciences, protection against natural disasters and nuclear accidents, art, advertising and marketing, entertainment industry, healthcare, museology, GPS-based geo-tagging systems, engineering, military and security applications (İçten & Bal, 2017).

Especially AR applications integrated with digital twin technology enable the creation of digital copies of buildings. The health status of buildings can be monitored, ergonomic risks can be assessed and maintenance needs can be predicted in advance. In other words, the concept of digital twin means the creation of an exact virtual counterpart of a physical object. Digital twins can be defined as the representation of physical entities in a digital environment. This virtual representation can include various physical objects such as a car, a machine, a train or a jet engine. In general, a digital twin is a dynamic model of a product, a process or a service created in a digital environment (Tao et all., 2018; Zheng et all. 2022).

Fig. 1. Digital Twin image (https://venturebeat.com/business/Autodesk-discloses-digital-twin-platform-for-aec-industry/)

The areas where AR technology can be applied for construction projects can be listed under the headings of design, planning, construction, training, security, maintenance and repair. If we examine it in terms of design, planning and construction; AR provides visualisation of architectural and engineering designs in a real environment, helps to detect design errors at an early stage, and guides the detection of errors during both the construction and control of complex structures during the implementation phase. In terms of training and safety, AR can be used to teach safety protocols and workflows through virtual scenarios in the training of construction site workers. It can also be used to enable engineering students to learn with visual memory throughout their education life and to enable them to look at problems from different dimensions. Within the scope of maintenance and repair, AR-supported systems provide the necessary information in real time in the maintenance and repair processes of structures, enabling faster and more accurate operations. Apart from these, it expands the scope with its widespread use in the marketing phase. The integration of these technologies increases efficiency, reduces costs and contributes to sustainability goals in the construction sector.

One of the fields where augmented reality (AR) technology is effectively applied is the architecture and construction sector. Thanks to AR applications, it is possible to visualise three-dimensional models on two-dimensional architectural plans, so that both the exterior and interior spaces of the designed building can be examined in detail before it is built (Gökçearslan, 2016).

Studies on the use of augmented reality in the construction sector have been increasing in recent years. The increasing use of this technology in construction sector applications provides significant advantages to the sector. For example, having a view of a building before it is built with augmented reality will be an opportunity to take some precautions in advance.

In one of the studies carried out, a system was developed using augmented reality (AR) technology, in which workers, equipment operators, engineers and managers involved in construction projects are informed about all stages of the manufacturing works they carry out. Thanks to this system designed through smart glasses, users can access training content and construction methods related to the construction and control tasks they undertake directly at the construction site, at the beginning of the work. Thus, it is possible to instantly access the necessary information about the manufacturing processes (Kıvrak & Arslan, 2018).

A mobile application was developed by D. Parmar in 2015 in order to increase the graphic technical knowledge of students studying in engineering departments. The application was designed to run on all Android-based mobile devices and different operating systems of desktop computers. Thus, students had the opportunity to develop their graphic technical skills independent of time and space by accessing from different platforms (İçten & Bal, 2017).

In another study, many articles and theses on augmented reality (AR) technology were analysed and it was determined that AR applications are used for three main purposes in line with the findings obtained. These objectives are summarised as reducing project costs through the integration of digital technologies, saving time in project processes, and increasing quality standards by increasing construction works and worker safety (Hajirasouli et al., 2022).

3. Purpose of the study and application

Today, the construction industry is becoming more difficult to manage due to increasing project complexity and time pressure. In particular, the necessity to complete specialized, sequential and interdependent manufacturing processes in a short period of time significantly increases the risk level of projects; this makes it difficult to balance between time, cost and quality parameters and increases error rates. In this context, digitalization and the use of technology has become a critical requirement not only in the manufacturing and service sectors but also in the construction industry. Integration of digital tools to minimize the margin of error, optimize processes and increase efficiency has become inevitable today. Especially in large-scale projects where time management is of vital importance, Building Information Modeling stands out as a system with high coordination and integration power that allows all disciplines to work on a common platform and is considered as one of the basic building blocks of digital transformation in the sector.

Today, technological developments accelerate digital transformation processes in the construction industry and bring about the integration of a wide range of digital tools into the sector. In this context, computer-aided software, virtual reality (VR), augmented reality (AR), mixed reality (MR), extended reality (XR), digitalization applications and digital twin technologies are among the prominent applications. However, it is observed that these technologies have not been adopted and implemented at the same level in every region on a global scale. This situation reveals the necessity to evaluate the potential contributions of digital tools and to determine their usage areas more efficiently. The main purpose of this study is to systematically examine current theses, academic articles and research on VR and AR technologies in the construction sector, to identify areas where maximum benefit can be achieved in the sector through these technologies and to reveal the application potentials for these areas.

Within the scope of the study, an application was made on augmented reality technology. The application was applied to a construction project at the planning stage, and the data obtained were compared and analyzed in terms of cost, time and design quality. Within the scope of the study, after the preliminary architectural project was drawn in accordance with the zoning conditions, a three-dimensional visual was created, and the necessary corrections were tried to be made on the project by deciding on the changes that may occur later on the project by eliminating the confusion of meaning in visual terms with augmented reality application. In the study stages, it was visualized with augmented reality technology according to the first project created first. After the change decisions taken, the visual was prepared again with augmented technology according to the new project and the final project was decided. The study in question was carried out in an office environment.

A construction project consisting of ground floor + 4 normal floors was selected for the study. According to the preliminary architectural project, three-dimensional visualization was made with Revit program and augmented visualization phase was started with Unity program. The requested design differences were changed on the project, visualized in three dimensions in Revit and finalized with augmented reality. At the decision stage, the work was also detailed with floor-based visualization details. After the final decision, a visual with column beam and slab details was created. In addition, all details such as plumbing, wall phase, finishing works, electricity can be examined.

The Revit program was used for the study, and Figure 2 shows the images obtained from the Revit program. In the image on the left side, there is a three-dimensional drawing of the work whose preliminary project was drawn without revisions. On the right side, there is a three-dimensional image of the final project where the changes determined as a result of the evaluations made were applied.

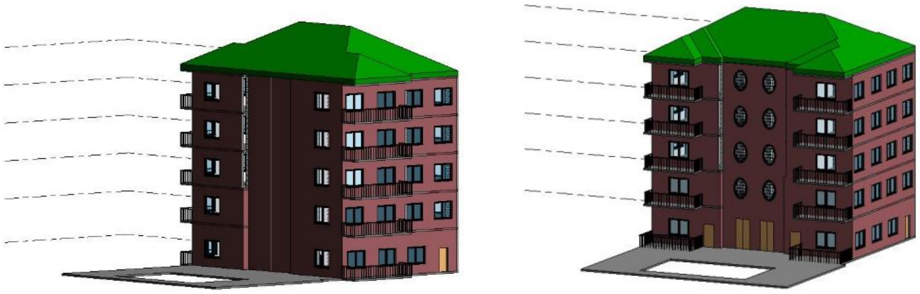

Fig. 2. Images obtained from Revit

After the three-dimensional drawing was completed with the Revit program, the colouring tool was made with a program and the visualisation phase was started with the Unity program. Figure 3. shows the images obtained from the Unity programme. The image on the left side shows the visualisation of the work whose preliminary project was drawn without revisions. On the right side, there is a visualisation of the final project where the changes determined as a result of the evaluations are applied. In Figure 4, there is a floor-by-floor detail visualisation to examine all the details.

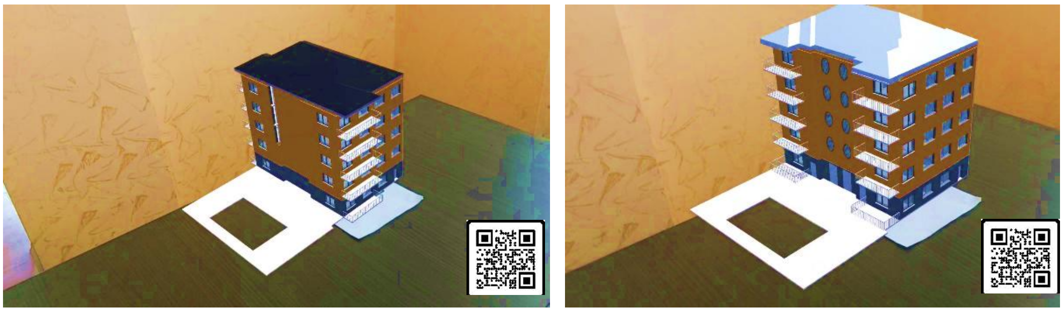

Fig. 3. AR images

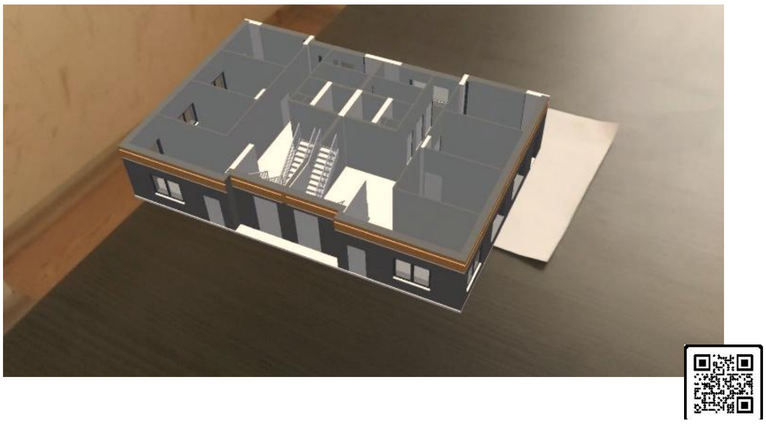

Fig. 4. AR images - Floor by floor

Within the scope of the study, it was determined that there are many construction stages such as licence and project, all floors deck areas, walls, some window and door locations, balcony locations, rough plaster, fine plaster, paint, ceramic areas in the renovations decided to be changed.

Figure 5 shows the visual of the column, beam and slab details of the sample project created with augmented reality application. If the image is compared with the physical building in the construction site environment, it will be possible to examine the situation between the situation that should be in the project and the situation in the neighbourhood. With this method to be used in the application phase, it will play a guiding role in whether the construction continues on time, whether it is in accordance with the legal project, or in solving problems in complex projects in a shorter time with minimum error.

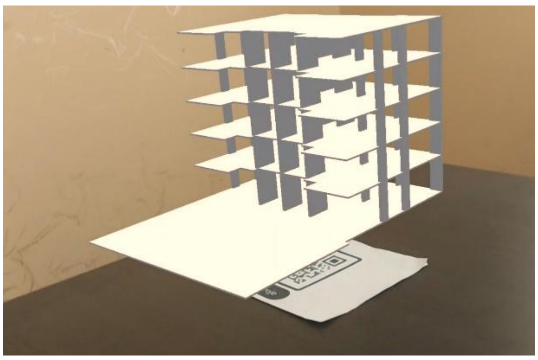

Fig. 5. AR images- column beam slab

When the determination of the differences stated in Figure 3 is analysed in terms of cost, the differences that will occur in the part of approximately 875.000 USD of this investment with an investment cost of 1.000.000 USD have been determined. If the construction is completed, approximately 120.000 USD cost will be prevented in case of reconstruction. While this cost is approximately 14% of the initial construction cost for the part where the differences are detected, it constitutes 12% of the total construction cost. In terms of labour days, it is seen that the works to be affected by the construction activities in the 390-day part of this construction, which is calculated as 600 days in total, will take a total of 90 days, which corresponds to approximately 15% of the total construction process. The ratios of the reconstruction process in terms of cost and labour days are shown in Table 1, Table 2, and graphically in Figure 6.

Table 1. The cost and man-day ratios of the reconstruction process

	Rework Cost/ Initial Construction Cost	Loss of Time (working days)/Construction Time (working days)	Work that negatively affects quality
Projects+Licence	33%	33%	
Column, Beam, Floor, Wall etc Construction Costs	18%	19%	+
Door, Window, Ceramik etc Const. Costs	4%	17%	+
Initial Construction Costs	14%	23%	

Table 2. The cost that may occur and the proportion of the workforce in the total

	Rework Cost/ Total Expenditure	Loss of Time (working days)/Total Construction Time (working days)
Total Expenditure	12%	15%

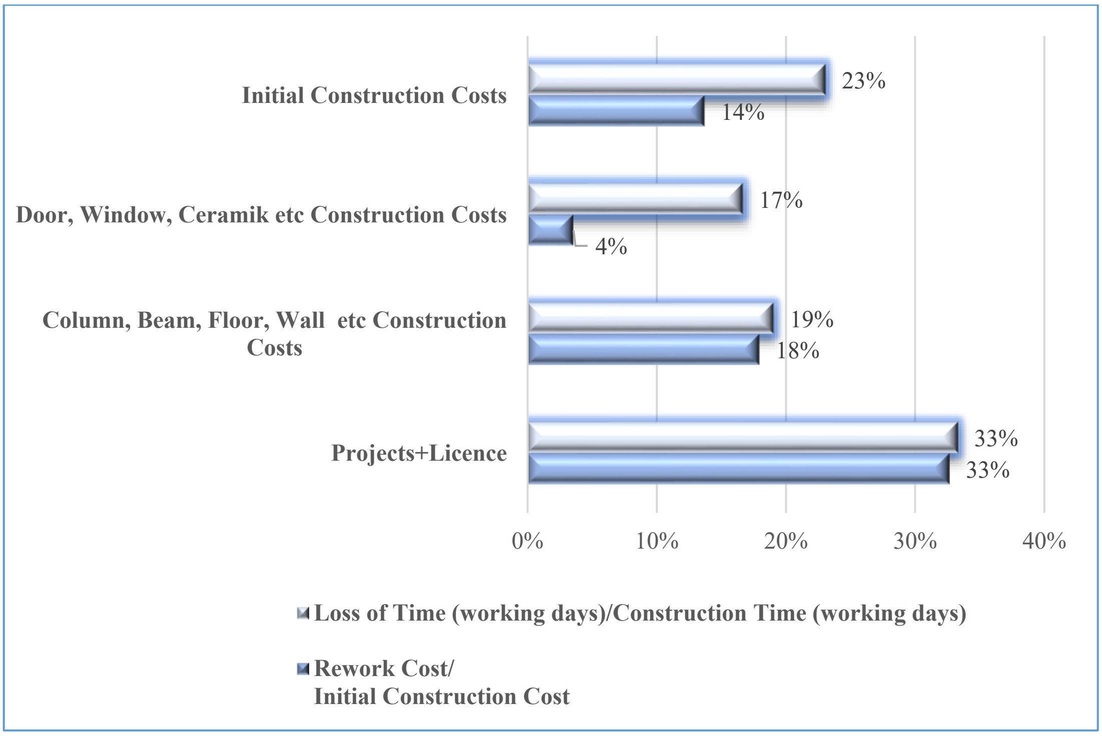

Fig. 6. The cost and man-day ratios of the reconstruction process -graphically

4. Conclusions

Today's world, shaped by the impact of technological innovations, is transforming into an increasingly computer-oriented lifestyle. This extremely rapid transformation has largely eliminated the possibility of maintaining traditional lifestyles. Today's individual, who has transitioned from a mobile lifestyle to a mobilised life, is evolving into a structure that develops communication models based on the need for fast access in a universe where borders disappear. The new requirements brought about by this change and development pave the way for the integration of many technological innovations into the daily life of humanity.

In addition to sectors such as science, commerce, medicine, defence industry, automotive, textile, food, mineral processing, chemistry and communication, the construction sector, which is a pioneer in terms of monetary volume, can also be counted. Adaptation to technological developments for the construction sector is progressing more slowly than other sectors and is not at the desired level especially in our country. The reasons for not being at the desired level in our country include high initial investment and maintenance costs for digitalisation, low level of education of employees, insufficient digital training, resistance to adaptation to innovation, too many subcontractor companies, etc.

Technological applications for the construction sector include BIM technology, VR (Virtual Reality), AR (Augmented Reality), drone, artificial intelligence supported applications. Technological applications support the increase in productivity in the construction sector and contribute to the transformation into an innovative and competitive structure that benefits the sector in a sustainable sense.

Applications such as VR (Virtual Reality), AR (Augmented Reality), drone provide significant advantages in terms of time and cost with observations and measurements carried out in the field. In this study, AR technology application was integrated into a construction project. With the application made in the preliminary project phase, design quality, time and cost management were tried to be made more effective.

Within the scope of the study, a ground + 4 storey project was studied, and the application areas of AR technology were tried to be determined in the initial and application stages. The project image was drawn in three dimensions with Revit program and then visualised with augmented reality with Unity program. After the visualisation, revisions were completed with the feedback received and a decision was made for the final project. In the study, the building was analysed both as a whole and floor by floor. In addition, in order to make the stages such as monitoring and control of the construction more effective during the project implementation, the visualisation of the columns, beams and floors of the project was created and the scope of the project was tried to be determined.

Within the scope of the study, it has been tried to be shown that the factors that have a negative impact on the project in terms of time such as renovation project, renovation licence and reconstruction costs such as deck, roof, wall, window, door, plaster, paint can be prevented with AR application. When analysed in terms of the determination of reconstruction costs, the differences that will occur in approximately 875.000 USD of this investment with an investment cost of 1.000.000 USD were determined. In case the construction is completed, approximately 120.000 USD reconstruction cost will be prevented by identifying these differences. While this cost is approximately 14% of the initial construction cost for the part where the differences are detected, it constitutes 12% of the total construction cost. In terms of working days, it is seen that the reconstruction that will be affected by the construction activities in the 390-day part of this construction, which is calculated as 600 days in total, will take a total of 90 days, which corresponds to approximately 15% of the total construction process.

In addition to the findings obtained within the scope of the project preliminary studies, it is foreseen that augmented reality (AR) technology can provide maximum benefit at every stage from project initiation to completion and beyond. In the planning phase, thanks to the transfer of projects to the virtual environment, important decisions such as the placement of buildings on the parcel, evaluation of sustainability rates and increasing energy savings can be made more effectively. In the implementation phase, AR technology will provide important contributions in many critical processes such as optimising material choices, early detection and intervention of errors overlooked in project design. It is also considered that AR technology will play an effective role in protecting worker health and ensuring safe working environments. In addition, it will also support the reduction of time and resource waste due to paperwork and procedures. After the project is completed, it will be possible to detect and intervene quickly in maintenance and repair processes before damages grow. In line with one of the main objectives of a business, which is to generate profit, AR technology will facilitate marketing processes; it will contribute to increasing market share by enabling customers to be reached quickly and at low cost from anywhere in the world.

Recent studies reveal that virtual reality (VR) and augmented reality (AR) technologies will play a critical role in the future of construction management. It is predicted that the integration of these technologies into different areas of the construction industry will enable cost, time and energy savings, as well as increase productivity in the industry through positive contributions to occupational health and safety. Especially in the sales phase of construction projects, VR and AR technologies will be used as an effective communication tool, thus enabling more efficient use of time by eliminating the need to go to a physical location. In the coming years, mixed reality (MR) and extended reality (XR) applications are expected to pave the way for further technological transformations in the sector. All these findings show that technology has become an indispensable element for the construction industry. Although it has progressed more slowly in technology adaptation compared to other sectors, it is predicted that the construction industry will face digitalisation and technological innovations more intensively in the coming period.

Exploring the feasibility of istanbul as an olympic host: lessons from previous hosts

Ayşe İ. Arasan[1], Mustafa F. Aşkın[1], Semra Çomu*[1]

[1] Boğaziçi University, Department of Civil Engineering, 34342 İstanbul, Türkiye

Abstract. Istanbul's long-standing goal of hosting the Olympic Games represents the city's desire to establish itself as a major center of innovation, sports, and culture worldwide. A symbolic candidate to host the Olympic Games, Istanbul is situated at the meeting point of Europe and Asia and is known for its vibrant metropolitan environment and rich cultural legacy. Achieving this aim, however, requires confronting significant problems in financial planning, infrastructure development, and social inclusion. This study evaluates Istanbul's capacity to host the 2036 Summer Olympic Games by analyzing insights from previous Olympics, doing economic assessments of budgets from former hosts since 2000, and examining the city's current circumstances. The research utilizes a multi-method approach, incorporating findings from a literature analysis, case studies of prior host towns, and economic assessments. Accordingly, this study aims to develop data-driven estimates specific to Istanbul by examining bid budgets and final accounts. Istanbul has considerable potential to serve as an Olympic host city, owing to its physical and cultural characteristics, established infrastructure, and enduring aspirations. However, hosting the games has significant obstacles, such as managing budget overruns, guaranteeing enduring legacy benefits, and addressing socio-economic repercussions. The analysis emphasizes the importance of realistic budgeting and implementing extreme cost control measures, leveraging existing resources and adopting sustainable practices to align with IOC (International Olympic Committee) priorities. As a result, Istanbul's aspiration to host the 2036 Summer Olympic Games may be viable, contingent upon the implementation of stringent cost control measures, sustainable planning, and efficient stakeholder collaboration.

Keywords: Istanbul; Olympics; Olympic hosting feasibility; Budget.

1. Introduction

Mega-events, especially the Olympic Games are considered prestigious yet challenging opportunities worldwide. The Olympics represent not only global visibility but also a testament to economic strength for aspiring cities. Cities all around the world compete for the chance to host the Olympic Games, aiming to showcase their cultural and economic vitality, stimulate urban development, and secure a prominent place on the global stage (Andranovich et al., 2001). As one of those cities, hosting the Olympics has been a long-standing aspiration for Istanbul, symbolizing the city's ambition to position itself as a global hub of culture, sports, and innovation.

Although the Olympics has a very long history, the first modern Olympics dated back to the 1896 Athens Games, and since then the perception of the Olympic Games has shifted. While the Games were merely a sporting event celebrating unity and progress once, they have become an extravagant event to showcase strength to the world, drifting away from the essence of sport, resulting in high costs with limited returns, leaving host cities burdened with debt and underutilized facilities (Koba et al., 2020). Kavetsos and Szymanski (2010) state that "In this 'beauty contest', the winner is frequently the bidder that offers the most lavish showcase for the event, usually a state-of-the-art sports facility of an impressive architectural conception and size." As a result, recent editions have drawn criticism for severe budget overruns, underutilized infrastructure, and long-term economic strain. In response to that, public opposition has grown, leading several cities like Boston and Hamburg to withdraw their bids in response to the local resistance (Baade & Matheson, 2016; Jin & Jeon, 2022; Lauermann, 2022). Recognizing those challenges, the IOC has attempted to reverse those trends through their strategic agendas promoting more sustainable and financially sound Olympic Games.

Despite that shifting priorities, Istanbul has been a persistent candidate to host the Olympics with a total of five bids. Even though none of those bids have been successfull, repeated candidacies have not only increased public awareness and institutional capacity but also resulted in substantial urban investments, especially in transportation and sports infrastructure for Istanbul's residents. Yet, challenges related to political considerations, financial

*Corresponding author, E-mail: semra.comu@bogazici.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_160

concerns, and planning capacity have remained persistent in Istanbul's case and this situation has emphasized the need for more realistic and economically sound strategies in future bids.

These recurring challenges highlight the need to assess one of the most decisive factors in Olympic bids: economic feasibility. Considering Istanbul's long-standing ambitions and the growing attention to the economic challenges of hosting, assessing financial feasibility has become increasingly relevant. This study aims to examine and analyze the budgets of the previous hosts to prepare a preliminary budget for Istanbul.

This paper is structured as follows to address that objective. Section 2, materials and methods, outlines the data sources and preparation process with the analytical approach used. Section 3 reviews the previous studies on the Olympic Games from multiple perspectives to highlight key considerations that inform strategic and financial planning. Section 4 presents the analyses performed and discussion on main outcomes and findings of the analyses with proposed budgets and key insights. Lastly, Section 5 is the conclusion that finalizes the paper by summarizing key insights and offering recommendations, and the paper closes with a brief discussion of its limitations.

2. Materials and methods

First, a temporal scope was set to define the boundaries of the study and ensure consistency in data collection to start. The scope was kept limited to the Summer Olympic Games held between 2000 and 2024, including host cities of Sydney, Athens, Beijing, London, Rio de Janeiro, Tokyo, and Paris. In addition to them, the awarded bids for the 2028 Los Angeles and 2032 Brisbane Games were included to incorporate long-term visions in Olympic budgeting and establish benchmarks. This timeframe was selected due to the availability of financial records and the growing economic complexity that has come to define recent Olympic Games.

Second, the data collection phase was carried out to gather the necessary figures for economic analyses and to examine the existing literature. A substantial body of literature has emerged analyzing the financial, social, and infrastructural consequences of hosting the Olympics as cities around the world have experienced both the benefits and disbenefits of hosting mega-events. These insights, ranging from budget overruns and legacy outcomes to public perception, have formed an important contextual foundation for the comparative approach adopted in this study. Nonetheless, the financial data has served as the main input for the analysis, and two different datasets were incorporated to provide a solid foundation.

The first dataset consists of OCOG (Organising Committee for the Olympic Games) budgets sourced from official bid files that were submitted to the IOC with the candidature file. Those budgets represent estimated operational costs and revenues, and are regarded as the most consistent and comparable financial elements across various Olympic Games editions by academic working on this subject. On the other hand, it is important to note that, non-OCOG budgets, which typically include long-term infrastructure investments and broader public spending, vary widely in scope, content, and reporting quality. Reliable and consistent data for non-OCOG components is lacking in many editions, making meaningful cross-city comparisons almost impossible. Therefore, this study excludes non-OCOG budgets, in line with established academic practice, which often focuses on OCOG budgets as the most analytically robust and accessible component of Olympic financial planning.

The second dataset utilized in the study was derived from the works of Preuss et al. (Preuss & Weitzmann, 2023; Preuss, Andreff, & Weitzmann, 2019). Their research on the financial aspects of the Olympics is widely recognized in the academic literature. This dataset includes figures of the Games held between 2000 and 2016, incorporating both bid-phase budgets and final post-games accounts to evaluate cost overruns and underruns. Even though Preuss et al.'s data also relies on official reports and official committees, what distinguishes his bid budget data from the first dataset is its focus on revised budgets prepared approximately four years prior to the event. These revised figures are considered by Preuss et al. to be the most reliable version of the budget, as they are developed with more grounded assumptions and updated economic expectations. That distinction is important, as it reflects how budget accuracy and reliability can vary depending on the timing of their preparation. Despite these differences, Preuss et al.'s dataset remains rooted in official sources, allowing it to serve as a useful comparative reference in this study.

Third, in order to enable accurate and consistent comparisons across different datasets with different currencies over time, all financial data used in this study were systematically standardized to 2024 values in US dollars. For the first dataset, the first step involved converting figures into local currencies using the average exchange rates applicable in the bid submission year, since data from the official bid file was originally expressed in US dollars in the bid years value. This step ensured that inflation adjustments could be performed based on country-specific figures rather than global estimates. Subsequently, inflation adjustments were calculated using the relevant GDP deflators for each host country, bringing all cost estimates in line with 2024 prices. After the inflation adjustment, the values were converted back into US dollars using 2024 exchange rates. This three-step preperation process produced comparable data for the analyses.

For the second dataset, a similar approach was adopted. Although Preuss et al.'s figures were already adjusted to the estimated price levels of the event year in their local currencies, they were just further standardized to 2024 values using GDP deflators in the respective local currencies. Those values were also converted to US dollars using 2024 exchange rates to ensure consistency and compatibility with the first dataset.

Fourth, two analyses were performed on standardized datasets to assess the economic feasibility of Istanbul's potential Olympic bid. Before starting, it is important to note that, due to differences in reporting structures across cities and years, the analysis focused exclusively on main budget categories. Subcategories were excluded, as they were often inconsistent in definition and reporting scope, making reliable comparisons difficult. This level of standardization aimed methodological consistency and enhanced the reliability of quantitative and percentage-based analyses done for this study. Also, particular attention was given to upcoming editions such as Tokyo 2020, Paris 2024 and Los Angeles 2028, as they reflect the IOC's strategic shift toward cost containment under Olympic Agenda 2020 and serve as forward-looking benchmarks relevant to Istanbul's planning context.

To begin with, a quantitative analysis of the figures was conducted to assess the absolute values of OCOG budget items across host cities and over time. The purpose of this analysis was to determine overall cost levels, highlight variations in spending patterns, and identify trends in budgets. Additionally, the comparison between initial bid-phase budgets and revised budgets from Preuss et al.'s dataset enabled an assessment of the reliability and realism of cost projections made at different planning stages compared with final accounts.

Subsequently, a percentage distribution analysis was carried out to examine how the total OCOG budgets were distributed among spending and revenue categories. This method allowed for the exploration of structural similarities and differences between cities and provided insights into changing budget priorities over time.

The combination of these two analyses provided a comprehensive foundation for evaluating Istanbul's proposed OCOG budget. By comparing both absolute figures and proportional allocations, it was possible to contextualize Istanbul's estimates within broader Olympic budgeting trends and assess their consistency with past and upcoming host cities. The projections were shaped by considering Istanbul's economic indicators, recent infrastructure developments, and historical bidding context, based on trends found in the data. This analysis helped estimate the likely costs of hosting while also identifying opportunities for cost-efficiency in alignment with the IOC's current emphasis on sustainability and the reuse of existing infrastructure.,

A preliminary budget was drafted for Istanbul's candidacy based on the analysis of figures and derived insights. Rather than applying a strict mathematical model, the study projected a realistic OCOG budget by focusing on trends within the dataset, rather than solely using median or average values. The estimations for each category were primarily drawn from the budget structures and spending levels of recent and upcoming Games that particularly reflect the IOC's evolving policy direction under Olympic Agenda 2020 and Agenda 2020+5.

Once an initial budget was drafted, percentage-based allocations were calculated and compared with historical patterns identified through the percentage distribution analysis, the second analysis performed on the datasets. This step was used to verify consistency and to benchmark Istanbul's distribution model against previous Olympic budgets. It also allowed for the identification of any disproportionate expenditures or underfunded areas. Finally, to improve the adaptabilitiy to different scenarios and provide flexibility on the proposed budget, three versions were created: a conservative base case, as described above, and two adjusted alternatives -optimistic and aggressive- each incorporating strategic percentage modifications in both revenues and expenditures. These scenarios provided the necessary flexible framework for assessing Istanbul's economic feasibility under different planning assumptions, despite the absence of a rigid computational model.

To sum up, this study has aimed to provide a standardized and comparative framework based on OCOG budgets from previous and upcoming Games, supported by data from Preuss et al.'s works. Through a multi-step process of data normalization, trend interpretation, and percentage-based validation, a tailored budget structure was produced for Istanbul's potential Olympic candidacy. The proposed scenarios aim to reflect a flexible approach and serve as the analytical foundation for the discussion of results in the following section.

3. Context and previous studies

Academic studies have repeatedly highlighted that the financial variability of the outcomes of Olympic Games, in relation to chronic budget overrun issues with underestimated expenditures and uncertainties surrounding long-term legacy outcomes. (Preuss & Weitzmann, 2023). These concerns are especially pronounced in developing economies, where public spending pressures are high and the promised benefits of mega-events are often delayed or unevenly distributed (Baade & Matheson, 2016). Empirical studies show pre-event estimates frequently and optimistically overestimate economic benefits, while post-event evaluations reveal more modest outcomes, particularly when infrastructure investments lack long-term use or are driven by prestige rather than practicality (Kasimati, 2003). Despite potential short-term gains such as increased tourism, global visibility or stock market reactions (Dick & Wang, 2008), long-term financial returns remains uncertain.

Beyond economic factors, social, political, and intangible factors also play a vital role in evaluating the overall feasibility of hosting the Olympic Games. Studies emphasize growing public skepticism driven by unmet expectations with limited local benefits (Lauermann, 2022). Beyond opposition, research also highlights intangible benefits such as national pride and social cohesion, which can generate significant public support. However, these effects tend to be concentrated in core urban areas and willingness to pay the Olympic bills diminish with distance (Atkinson et al., 2008). On the other hand, studies on legacy underscore the risks of underutilized infrastructures left to the locals as burdens after the games and stress the importance of post-event planning to ensure lasting value (Alm, 2016; Koba et al., 2021).

Recent IOC reforms, particularly those introduced under Olympic Agenda 2020 and reinforced by Agenda 2020+5, mark a significant shift in the Olympic hosting strategy, prioritizing sustainability, cost-efficiency, and the reuse of existing infrastructure (Schnitzer & Haizinger, 2019). Among past hosts, Los Angeles is often cited as the most financially successful model, especially the 1984 Games, which achieved profitability by leveraging pre-existing venues and avoiding excessive construction (Baade & Matheson, 2016). The upcoming 2028 Los Angeles Games intend to replicate this low-cost, reuse-oriented strategy, reinforcing the IOC's broader policy direction. These developments suggest that the era of glory is being replaced by financially responsible and context based approaches. In line with this trend, this study adopts a similar mindset: budget models and strategic recommendations are designed around the assumption that Istanbul's success as a host city would depend on embracing a comparable model focused on infrastructure reuse, realistic spending, and long-term legacy planning rather than spectacle-driven investments that prioritize short-term image over long-term impact.

4. Results and discussion

This section presents the analyses on previous hosts data and explains the results from Istanbul's perspective giving the drafted budget. Building on these, three adjusted scenarios are introduced for Istanbul, each reflecting different strategic planning assumption as previously mentioned. The analyses are structured around the main expenditure and revenue categories typically found in Olympic budget structures, as shown above in Table 1. These categories form the foundation for the analyses as well as the scenario modeling that follow.

To enable consistent comparison across both datasets, the set of expenditure and revenue categories was aligned by codes. Since the budget structure in Preuss et al.'s revised data differs slightly from the original bid file categorizations, most notably through broader groupings or the absence of certain new categories such as Ceremonies & Culture or People Management, several categories from Preuss et al.'s data were grouped to align with the bid file categories. This process aims to ensure methodological consistency maintaining analytical accuracy throughout the study. To achieve this, categories that were present in one dataset but missing in the other, such as People Management, were excluded from comparative evaluations and were examined only through the first dataset based on recent Olympic Games practices and evolving IOC budgeting trends.

By harmonizing the categories between datasets and accounting for structural differences, this approach aim to ensure a consistent analytical framework while accommodating the evolving nature of Olympic budgeting.

Table 1. Expenditure and revenue categories

Categories from Bid File	
Expenditure Categories	**Revenue Categories**
E1. Venue Infrastructure	R1. IOC Contribution
E2. Sport, Games Services & Operations	R2. TOP Programme
E3. Technology	R3. Domestic Sponsorship
E4. People Management	R4. Ticket Sales
E5. Ceremonies & Culture	R5. Licensing & Merchandising
E6. Communications, Marketing and Look	R6. Government Contribution
E7. Corporate Administration and Legacy	R7. Lotteries
E8. Other Expenses	R8. Other Revenues
E9. Contingency	
Categories from Preuss et al.'s Data	
Expenditure Categories	**Revenue Categories**
	R1. IOC Contribution
E1. Venues	R2. TOP Programme
E2. Workforce	R3. National Sponsorship
E2. Services	R4. Ticket Sales
E2. Marketing and Events	R5. Licensing
E3. Technology	R6. Subsidies
E7. Administration and Coordinations	R7. Lotteries
E8-9. Other	R8. Other
	R8. Disposal of Assest
	R8. Donations

4.1 Quantitative analysis of figures

This analysis focused on evaluating the absolute OCOG budget figures from selected Summer Olympics. This comparison utilized two datasets: the initial bid budgets submitted through official candidature files, shown in Table 2 below, and the final accounts compiled by Preuss et al., presented in Table 3 below. To provide clarity, each expenditure category is examined individually based on observed trends and final reported costs below.

E1 covers venue infrastructure which is the most overrun expense category across Olympic Games, with final costs frequently clustering around USD 1 billion. Despite efforts to limit costs, recent hosts like Paris and Los Angeles still approached or exceeded this level. Istanbul's E1 projection is set at USD 1.2 billion, allowing for inflation and necessary upgrades to meet international standards.

E2 covers Sport, Games Services & Operations and it is a category that has shown fluctuations across editions but has consistently exceeded initial projections since 2004. Final expenditures often exceeded USD 1 billion, so, Istanbul's projection is set at USD 1.2 billion, aligned with recent trends and considering historic overruns.

E3 covers technology, a growing category shaped by advances in broadcasting, data, and cybersecurity. Recent Games have shown rising budgets, overruns and figures are reaching up to USD 613 million. Istanbul's projection is set at USD 900 million, reflecting continued growth and alignment with recent IOC priorities.

E4 covers people management which is a recently added category reflecting staffing and volunteer-related costs. Since it appears only in the 2024, 2028, and 2032 budgets, historical comparisons are limited so, projection for E4 is set at USD 800 million, consistent with Los Angeles expecting similar staffing and coordination needs.

E5 covers ceremonies and cultural programs, a relatively small but symbolically important category. The historical average stands at approximately USD 140 million. Based on this trend and recent editions of the Games, Istanbul's E5 projection is set at USD 150 million. This figure is positioned between the average and Paris's allocation, aiming to deliver a compelling program while avoiding extravagance in line with recent IOC agendas.

E6 covers communications and marketing and is a consistent category yet shows overruns. The average is USD 140 million so, E6 projection is set at USD 200 million, slightly above average with in line with recent trends.

E7 covers corporate administration and legacy planning, a consistent category with a pattern of dramatic cost overruns. While the average for past Games ranged from USD 165 to 332 million, final accounts indicate upward revisions across all editions. Istanbul's E7 projection is set at USD 500 million, considering historical overruns.

E8 covers other expenses, a variable and often undefined category used differently across Games. Due to inconsistent content and frequent merging with contingency, past data offers no reliable basis for direct comparison. For Istanbul, no fixed amount is assigned; instead, a percentage of the total budget is allocated to this category in the next analysis.

E9 covers contingency, a category often inconsistently reported or merged with others in past budgets. Rather than assigning a fixed amount, contingency is traditionally calculated as a percentage of total costs based on the risk level of each budgeting scenario, and the same approach is applied for Istanbul in the next analysis.

Table 2. Analysis of initial bid budgets on expenditures *000, USD 2024

Games Edition	E1	E2	E3	E4	E5	E6	E7	E8	E9

Table 3. Analysis on final accounts from Preuss et al.'s data on expenditures *000, USD 2024

Games Edition	E1	E2	E3	E7	E8-9
2000	716.231	945.534	460.305	151.584	420.539
2004	445.244	1.188.609	480.436	376.721	559.656
2008	1.102.049	1.826.491	851.125	519.314	132.540
2012	1.229.080	1.311.457	879.134	532.188	200.691
2016	N/A	N/A	N/A	N/A	N/A

Following the expenditure analysis, the same approach is applied to the revenue side to assess the structure and reliability of projected Olympic income. This evaluation uses data from the initial bid budgets, shown in Table 4 below, and final accounts from Preuss et al.'s, presented in Table 5 below. Each revenue category is examined to understand typical income patterns and inform Istanbul's projections as previous.

R1 covers the IOC Contribution, a core revenue source comes from the IOC's broadcast income share. While past Games have shown fluctuations, recent bids reflect a downward trend, with Paris, Los Angeles, and Brisbane budgeting between USD 750 and 855 million. Istanbul's R1 projection is set at USD 700 million, reflecting this decline and the need for conservative forecasting.

R2 covers revenue from the IOC's The Olympic Partner (TOP) Programme, a global sponsorship initiative that provides financial support to the host city and the broader Olympic Movement. While bid budgets show fluctuation and recent declines, final accounts in Preuss's data consistently exceed initial estimates. Based on this contrast, Istanbul's R2 projection is set at USD 400 million, balancing conservative bids and reliable historical returns.

R3 covers domestic sponsorships, often the largest revenue component in Olympic budgets and highly dependent on local market capacity. While bid data shows wide fluctuations which is expected since finding sponsors directly related to the city, final accounts consistently exceed initial projections. Projection for R3 is set USD 2 billion, reflecting strong national sponsorship potential due to high national pride of Turkish people and the country's proven track record of mobilizing private sector.

R4 covers ticket sales which is the largest non-IOC-dependent revenue stream and traditionally ranking second after domestic sponsorships. While figures vary, recent Games like Paris have seen record-breaking demand even though rising ticket prices, and upcoming host project continued growth driven by rising prices. Projection for R4 is set at USD 1.6 billion, based on the assumption of 8 million tickets sold at an average price of USD 200.

R5 covers licensing and merchandising which is a modest but consistent revenue category across Olympic budgets. Despite fluctuations, actual revenues have typically ranged below USD 150 million. Istanbul's R5 projection is set at USD 150 million, aligned with both historical averages and recent outcomes.

R6 covers government contributions. It is a minor item in most Olympic budgets and often excluded in initial plans. While avoiding public funding may seem ideal, historical data shows that even cities aiming for minimal support often report income from government subsidies post-Games. A contribution of USD 170 million is projected, acknowledging both precedent and the likelihood of partial state involvement despite initial intentions.

R7 covers lottery revenues which is a fluctuating item that has been excluded in some budgets but remains relevant in countries with strong public interest in games of chance. Given Türkiye's engagement with national lotteries and the successful example of 2004, R7 projection is set at USD 300 million, reflecting local potential.

R8 includes miscellaneous revenues including donations and asset disposal and often tailored to the specific strategies of each host city. Historical data shows that final revenues in this category frequently exceed initial estimates, especially in cities relying on temporary infrastructure. Given Türkiye's strong civic engagement and IOC's reuse-focused strategy, USD 500 million is projected for R8, reflecting local potential.

Table 4. Analysis of initial bid budgets on revenues *000, USD 2024

Games Edition	R1	R2	R3	R4	R5	R6	R7	R8

4.2 Percentage distribution analysis

This section presents the second analysis that examines the proportional allocations within total OCOG budgets to highlight shifting priorities. Expenditure data is drawn from the initial bid budgets shown in Table 6 and the final accounts compiled by Preuss et al. presented in Table 7.

E1 ranged from 13% to 38% in bid budgets, with an average of 25%. Recent editions like Paris, Los Angeles, and Brisbane allocated 18%, 22%, and 14%, reflecting a decline probobaly due to re-use strategies. Final accounts confirm this shift, averaging around 24%. So, projection for Istanbul's is set at 20%, in line with this trend.

E2 ranged from 19% to 42% in bid budgets, but Sydney's 42% included ceremonies and cultural programs due to different budget structure. Excluding that, the range tightens to 19–37%. More recent Games show a decrease, 22% in Paris and 19% in LA, reflecting a trend aiming operational efficiency. Final accounts report 32–41% for a broader category including marketing and ceremonies; adjusting for these, the effective average drops to around 25%. Istanbul's share is set at 22%, aligned with recent Games and adjusted for structural changes in budgeting.

E3 ranged from 10% to 19% in bid budgets, averaging 15% while recent editions allocated closer to 12%, reflecting cost-efficiency strategies. Final accounts show a slightly higher range of 16–21%, with an average of 18%, likely due to broader definitions in earlier Games. Istanbul's allocation is set at 15%, balancing cost-efficiency trends with potential future technological demands.

E4 appears only in the 2024, 2028, and 2032 budgets since it is a newly introduced category, with allocations of 15%, 13%, and 16%, respectively. Due to limited historical data, no broader trend can be observed and Istanbul's allocation is set at 14%, matching the average.

E5 ranged from 3% to 7% in candidature budgets, with recent editions clustering around 5% and showing a declining trend. As this category is not reported separately in final accounts, no comparative analysis could be made. Istanbul's allocation is set at 3%, reflecting a more modest and sustainable approach emphasizing a commitment to efficiency and the avoidance of unnecessary extravagance in line with recent Olympic agendas.

E6 ranged from 3% to 9% in candidature budgets, averaging 5% with a median of 4%, showing a downward trend in recent editions. Since second dataset groups this category with Events, no direct comparison was possible. Istanbul's allocation is set at 4%, aiming cost-efficiency with effective communication and branding efforts.

E7 ranged from 4% to 10% in candidature budgets, averaging 7%, with a declining trend in recent editions. Preuss's final accounts show consistently higher allocations suggesting underestimation during planning. Istanbul allocates 7% to this category, balancing historical overruns also keeping the reclining trend in mind.

E8 is a flexible category for unforeseen or uncategorized costs, with inconsistent definitions across editions. It ranged from 7% to 14% in candidature budgets, averaging 5%, while final accounts show 11%. Istanbul allocates 10%, providing a buffer aligned with past trends.

E9 covers contingency, a risk management buffer often grouped with other expenses in earlier budgets. While it ranged from 4% to 16% in candidature budgets, with an average of 9%, it was not separately analyzed in final accounts. For Istanbul, E9 is set between 5-12%, adjusted according to the risk appetite of each budgeting scenario.

Table 6. Analysis of initial bid budgets on expenditures, %

Games Edition	E1	E2	E3	E4	E5	E6	E7	E8	E9
2000	13%	42%	19%	-	-	3%	5%	17%*	
2004	35%	19%	-	-	7%	9%	9%	18%*	
2008	38%	37%	-	-	6%	4%	8%	6%*	
2012	28%	25%	18%	-	4%	4%	10%	7%	4%
2016	24%	30%	17%	-	4%	5%	6%	13%*	
2020	30%	26%	12%	-	3%	3%	6%	12%	8%
2024	18%	22%	12%	15%	5%	6%	6%	6%	11%
2028	22%	19%	10%	13%	4%	4%	5%	14%	9%
2032	14%	21%	13%	16%	3%	4%	4%	8%	16%

*E8+E9 given together in the respective editions

Table 7. Analysis on Preuss et al.'s data on expenditures, %

Games Edition	E1	E2	E3	E7	E8-9
2000	27%	35%	3%	13%	19%
2004	15%	39%	3%	13%	23%
2008	25%	41%	7%	13%	21%
2012	30%	32%	4%	11%	16%
2016	24%	38%	12%	10%	16%

Following the expenditure analysis, the same methodology is applied to the revenue categories to evaluate the internal structure and distribution of projected Olympic income. This section examines how revenue streams have been historically distributed and how they have performed in actual financial outcomes. The analysis draws on initial bid budget data, as shown in Table 8, and final account figures compiled by Preuss et el., presented in Table 9. Each revenue stream is reviewed individually to identify recurring trends, assess the accuracy of past projections, and provide a sound basis for shaping Istanbul's revenue allocation strategy to cross check with previous analysis.

R1 shows a wide range across both bid budgets and final accounts but follows a clear and sharp downward trend over time. Final figures frequently fall short of projections, reflecting systematic overestimation and suggesting declining IOC revenue shares. To reflect this pattern and reduce reliance, Istanbul's share is conservatively set at 14%.

R2 ranged from 7% to 12% in bid budgets, averaging 9%, while final accounts remained within a stable 10% to 12%. Though historically dependable, this revenue also derives from IOC and given potential to mirror the decline in R1, Istanbul's share is cautiously set at 8%, trusting Games-driven efforts over external programmes.

R3 ranged from 9% to 36% in bid budgets, averaging 24% with recent editions showing sharp increases. Final accounts ranged from 14% to 41%, averaging 26%, often exceeding estimates. Given this pattern and Istanbul's strong local and international sponsorship potential, 30% is allocated, reflecting both upward trends and the city's mature business base.

R4 ranged from 9% to 29% in bid budgets and 9% to 27% in final accounts. Recent editions indicate a rise toward 30%, supported by high sales volumes like Paris's record-breaking ticket numbers. As the largest revenue stream not tied to the IOC, 26% is allocated for R4, balancing strong potential with caution due to incomplete recent data.

R5 ranged from 2% to 4% in bid budgets, averaging 3%, while final accounts showed an average of 4%. Although smaller in scale, this revenue often slightly outperforms projections. Istanbul's allocation is set at 4%, aligning with historical reliability and modest growth expectations.

R6 ranged from 1% to 25% in bid budgets, though most cases fall between 1% and 6% when that one outlier is excluded. Some cities initially budgeted zero but still received government support, as seen in final accounts ranging from 0% to 8%. To reflect moderate involvement without overdependence, 3% is allocated for R6.

R7 was included in few editions, with allocations from 1% to 15% in bid budgets and a single 12% share in final accounts (Athens 2004). Despite limited data, Türkiye's strong interest in lotteries and the need to diversify revenue justify a 4% allocation and it is considered as modest yet meaningful within Istanbul's case.

R8 ranged from 4% to 13% in bid budgets, averaging 9%, while final accounts range from 3% to 18%, averaging 10%. Istanbul's use of temporary infrastructure and donation potential further support this stream since it is the current strategy of IOC. A 10% allocation is set, balancing city-specific opportunities with historical norms alongside IOC agendas.

Table 8. Analysis of initial bid budgets on revenues, %

Games Edition	R1	R2	R3	R4	R5	R6	R7	R8
2000	50%	9%	21%	15%	5%	-	-	-

4.3 Comparison and key findings of analyses

This section brings the estimates together made on both the quantitative and percentage distribution analyses to assess their internal alignment. The first analysis focused on absolute figures and the evolution of budget categories over time. On the other hand , the second analysis highlighted the structural distribution of expenditures and revenues, offering broader insights into changing priorities. Table 10 presents Istanbul's estimated preliminary budget, derived from the figures analysis alongside with calculated percentage distributions, allowing for a direct comparison with the results of the percentage distribution analysis. This two layer approach aims to strengthen the reliability of the findings.

The comparisons show strong alignment between proposed figures and the proportional allocations identified in the second analysis. Even though there are deviations, they are minor and fall within an acceptable range for this sstudy. Categories with a history of overruns, such as venue infrastructure and sport operations, were intentionally estimated near the upper limits of the historical range in anticipation of potential financial pressures. On the revenue side, projections remain cautious, especially in areas such as IOC contributions and the TOP Programme, where historical trends indicate both overdependence and sharp recent declines.

The proposed plan reflects a modest shortfall of approximately USD 30 million despite efforts to ensure a balanced budget. This represents around 0.5 percent of the nearly USD 6 billion total. Although this gap is relatively small, closing it is essential to ensure the financial feasibility. Possible strategies may help mitigate this.

On the revenue side, both domestic and international sponsorship can be enhanced by leveraging Istanbul's unique strategic location and market appeal. Engaging Turkish corporations and global brands in a targeted manner may unlock additional funding opportunities. Furthermore, models like dynamic ticket pricing could increase revenue while maintaining accessibility. Although grants and donations from international organizations make up a small portion in the budget, minor increases in these areas also could provide meaningful support. If required, an increase in government funding could resolve the deficit.

On the expenditure side, scaling back non-essential components, simplifying ceremonies, and improving the efficiency of resource allocation could produce measurable savings without compromising overall quality. Moreover, prioritizing the use of existing and temporary venues could help reduce capital investment and long-term financial liabilities increasing potential revenues from asset disposals.

Overall, these findings confirms the internal alignment between two analyses and even though there is a shortfall in this baseline scenario, there are a number of actions that can make small yet meaningful changes to the outcome to ensure financial feasibility.

Table 10.Istanbul's estimated preliminary budget, USD 2024 and %

Expenditures

No	Item	Figures Analysis	%	Percentage Analysis
E1	Venue Infrastructure	1.200.000	21%	20%

	Total Revenue	5.820.000		

4.4 Budget scenarios for Istanbul

To add further flexibility to the proposed figures, two more financial scenarios developed and all of them presented in this section. These scenarios are designated to reflect varying assumptions about revenue potential and cost control, providing another perspevtive to assess how Istanbul's budget performs under different planning conditions with different risk levels. The scenario that drafted under the light of the previous analyses (given in Table 10 above), emphasizes realistic revenues and expenditures and aim avoiding overestimation of income or underbudgeting of costs and thereby accepted as baseline in this section and labeled as conservative scenario.

Building on the conservative scenario, the optimistic model assumes stronger performance in sponsorship, ticketing, and merchandising, supported by increases in marketing and technology investments to achieve that revenue growth. The aggressive scenario aimes even further for maximum revenue generation while implementing strict cost controls, representing a high-risk, high-reward approach.

Table 11 given below presents the detailed percentage adjustments made across revenue and expenditure categories for each scenario, taking the conservative model as the baseline. The optimistic and aggressive scenarios reflect upward adjustments in revenue projections, particularly in domestic sponsorship (R1), ticketing (R2), and other commercial sources (R7, R8), based on potential market performance and strategic engagement. Cost reductions and targeted efficiency measures are applied in these scenarios in areas such as infrastructure (E1–E3), operations (E4), and technology (E6), while maintaining stable allocations for fixed-cost items like government contributions (R6). This approach aims to ensure a stable budget while allowing flexibility in areas responsive to planning strategies or market shifts.

Under the light of these projections, the conservative model presents a $30 million shortfall, about 0.5% of the total budget. The optimistic scenario offsets this with a $27 million cost reduction and a $100.5 million revenue increase, producing a $73.5 million surplus.By boosting revenues and cutting costs further, the aggressive model achieves a $140 million surplus. Though these figures are modest within an overall $6 billion budget, they highlight how strategic adjustments can transform a deficit into a surplus perfectly. While breaking even is typically the goal in OCOG budgeting, a surplus would enhance financial credibility and the Olympic legacy. Demonstrating profitability would boost Istanbul's image and affirm its capacity to host major events.

Table 11. Budget scenarios, *000, USD 2024 and %

Expenditures						
No	Conservative	%	Optimistic	% Change	Aggressive	% Change

5. Conclusions

This study have explored the economic feasibility of Istanbul hosting the Olympic Games by examining past OCOG budgets, conducting comparative analyses, and developing budget scenarios for different risk levels tailored to the city's context. By analyzing both absolute budget figures and proportional allocations across multiple host cities, the research aimed to provide a grounded framework to inform Istanbul's potential Olympic planning for future.

An examination of past Olympics revealed a consistent challenge managing cost overruns, with notable differences between developed developing cities (Baade & Matheson, 2016). While cost overruns are a common issue of Olympic planning today, they are generally better contained in cities with mature infrastructure and greater economic capacity. In contrast, developing cities that pursue event-driven growth and rely heavily on public funding are more vulnerable to long-term financial and social burdens. These often include underutilized venues and growing levels of public debt (Koba, et al., 2020).

From a financial standpoint, the analyses conducted on past data in this study confirm that cost overruns have been a recurring issue, consistent with the findings of researches Holger Preuss (2023, 2019). However, these overruns are frequently accompanied by revenue overruns, revealing a structural tendency to underestimate budgets during the bidding phase (Preuss & Weitzmann, 2023). This pattern, influenced by the competitive nature of the candidature process, underscores the need for more realistic and data-informed financial projections in future Olympic planning.

These findings aim to provide a comprehensive understanding of the opportunities and challenges associated with hosting the Olympic Games. However, framed in the simplest terms, the central question this study seeks to answer was whether hosting the Olympic Games is financially feasible for Istanbul. Based on the conservative baseline scenario, the answer would unfortunately be no. However, the budgetary scenarios presented in this study demonstrate that, hosting the Games in a financially sustainable manner is within the realm of possibility. However even though hosting the Games in a financially feasible manner is achievable it is only achiavable with strategic planning. From managing cost overruns to ensuring long-term legacy benefits, success would require careful alignment of resources, priorities, and stakeholder collaboration since this study also highlights thses issues as the challenges associated with such an ambitious undertaking.

Beyond financial feasibility, the long-term legacy of the Olympic Games holds significant importance for Istanbul. Strategic investments in infrastructure, transportation, and public facilities should be aligned with the city's existing development goals to ensure lasting value beyond the event itself (Baade & Matheson, 2016). As a city that uniquely bridges continents, cultures, and histories, Istanbul carries symbolic significance that could elevate the Olympic narrative on a global stage. However, this distinctiveness also demands careful and context-sensitive planning to integrate Olympic preparations with urban realities and social dynamics. A well-designed legacy strategy would not only enhance public benefit but also strengthen Istanbul's international image and long-term development trajectory.

In the end, it is important to note that, while this study aims to provide a historically grounded perspective, it should be considered a preliminary assessment as a baseline. The projections are deliberately conservative and informed by past data, but the absence of real-time, city-specific inputs and formal stakeholder engagement limits the analysis to an illustrative level. A comprehensive feasibility study conducted by professional experts, integrating current data and insights from municipal and governmental bodies with stakeholder engagement would be essential for producing more precise and actionable results. Nonetheless, the approach adopted here, favoring realism over idealism, establishes a practical foundation for future, more detailed financial planning.

Limitations

This study offers a preliminary evaluation of Istanbul's feasibility as an Olympic host with publicly available data and historical trends. However, it is limited by the absence of access to internal financial records, real-time city inputs, and stakeholder involvement, which would be necessary for an accurate financial study. The budget models are simplified, based on generalized categories without detailed sub-itemization. Additionally, the study does not incorporate the time value of money or cash flow considerations due to uncertainty in economic forecasts. Finally, no formal risk analysis was conducted, leaving certain uncertainties unexamined. Despite these limitations, the findings serve as a data-informed starting point for more comprehensive feasibility studies.

Acknowledgements

This study benefited substantially from the data provided in *Cost and Revenue Overruns of the Olympic Games 2000–2018* by Holger Preuss, Wladimir Andreff, and Maike Weitzmann (2019), as well as the article *Changes of Costs, Expenditures, and Revenues Between Bidding and Staging the Olympic Games from Sydney 2000 to Tokyo 2020* by Holger Preuss and Maike Weitzmann (2023). The extensive empirical data and methodological clarity offered in these works greatly helped inform the direction of this study. Data from their works supported a historically grounded analysis of Olympic budgeting practices, without which the assessment performed in this study would not have been possible in its current form.

Predicting the resolution time of disputes in public-private construction contracts using bayesian network analysis

Buse Un*[1], Ercan Erdis[2]

[2] Iskenderun Technical University, Department of Architecture, 31200 İskenderun/Hatay, Türkiye

Abstract. Construction projects typically involve numerous work items and organizations. Although mutual trust is fundamental to many projects, the parties need well-written contracts in order to have a legal basis. Due to the complex nature of the construction industry and poorly written contracts, disputes are common in this sector. The fact that each construction site in construction projects has its own unique conditions; that it often takes place in a wide and scattered area under natural climatic conditions, with different organizations using cheap labor and personnel and having a culture of working with traditional methods; the presence of unmanaged risks such as cost reduction, compromising on occupational health and safety and quality of work; as well as deficiencies in supervision and control, increases disputes. Although contracts are essential documents to consult in disputes, they are occasionally insufficient to resolve issues. Therefore, parties appeal to a resolution method in order to avoid wasting both time and cost and to reach an effective solution. The objective of the current study is to establish a predictive tool for assessing the duration of decision-making in construction disputes. This study analyzes a dataset comprising characteristics of disputes from public-private construction contracts in Türkiye. The analysis is conducted using IBM SPSS Modeler and the Bayesian Network method. The study's findings reveal that the Tree Augmented Naive Bayes (TAN) algorithm achieved a classification accuracy of 73%. The present study especially aids the disputant parties in making critical scheduling decisions. The findings of the present study contribute to project management and practitioners' decision-making by promoting amicable settling. In additionthe findings of the investigation have implications for subsequent studies on Bayesian approaches in construction disputes.

Keywords: Disputes, Decision-making, Predictive, SPSS modeler, Bayesian network

1. Introduction

Construction projects ordinarily include numerous work items and organizations. Owing to the complex structure of the construction sector, disputes are highly common in this sector. Although contracts are crucial documents for reference in disputes, they are not always adequate for the resolution of issues (Haugen & Singh, 2014; Zhang et al., 2021). Thus, parties appeal to a resolution method to prevent the expenditure of time and cost, and to reach an effective solution (Abwunza et al., 2021).Until the late 1980s, the primary methods of dispute resolution in the construction sector consisted of negotiation, mediation, arbitration and court proceedings. However, in recent years, alternative resolution methods have been developed for the settlement of disputes in this sector. There are 30 different dispute prevention and resolution methods in the literature (Bult, Halligan, Pray ve Zack, 2016: 347). Nonetheless, certain methods (e.g., litigation) can take a long time, affect parties' relationships, induce financial loss, and cause deviation from the aims of projects. Consequently, research utilizing information technology to resolve conflicts has been steadily increasing, with the aim of alleviating the adverse impacts of resolution strategies and providing foresight to the parties involved regarding disputes (Yılmaz 2020).

Researchers developing predictive models for construction disputes generally analyze historical project data to identify patterns and risk factors, aiming to facilitate early detection of potential conflicts and promote informed, proactive decision-making to avert their emergence. The researchers have generally focused on issues involving tendency conflict (Ayhan et al., 2021; J.-S. Chou et al., 2014; J. S. Chou et al., 2016), outcomes of disputes (Arditi et al., 1998; Arditi & Pulket, 2005, 2010; Bagherian-Marandi et al., 2021; Chaphalkar et al., 2015; Pulket & Arditi, 2009; Zheng et al., 2021), appropriate dispute resolution methods (Ayhan, 2019; J. Chou, 2012; Zheng et al., 2021), and cost and time claims (Yousefi et al., 2016). Despite the fact that there are different studies on these issues, no study has been found in the literature on the estimation of the decision duration of construction disputes.

*Corresponding author, E-mail: buseun.mfbe19@iste.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_168

Previous studies on disputes and risks have used the Bayesian network method, which yields robust results in situations where uncertainty is high. Shojaat et al (2025), in order to enhance the management of disputes in construction projects, the Decision Making Trial and Evaluation Laboratory (DEMATEL) and Bayesian Network methods were combined. This combination aimed to clarify the cause-and-effect relationships within disputes and to identify the key factors triggering them. The study by Chou and Lin (2013) assessed the efficacy of Bayesian methods for the early prediction of conflicts in public-private partnership (PPP) projects. Moreover, a scenario-based optimization model was developed in the study by Pourdoustmohammadi and Ansari (2024) to anticipate risks associated with high-rise building projects. Furthermore, the implementation of a Bayesian Network-based decision support system has been demonstrated to be an effective tool for the management of uncertainties. Notwithstanding these advancements, Hon et al. (2022) emphasized the necessity for further research to investigate the implementation of the Bayesian method in contract management.

This study uses Bayesian networks to predict the decision duration in disputes arising from construction contracts. The present study especially aimed to assist the disputant parties in making critical scheduling decisions. To this end, 45 arbitration decisions from the Supreme Board of Construction and Infrastructure, which employs an arbitration model for resolving disputes between the public and private sectors in Türkiye, were utilized to predict decision durations. The analyses were conducted using the Bayesian network method via the SPSS Modeler software package.

Unlike the previous ones, this study addresses the prediction of decision duration in construction disputes to address the gap in the literature. Furthermore, the present study employs the Bayesian network method, which has limited application in contract management in civil engineering, to develop a predictive model for contract-related disputes, thereby enhancing the literature both methodologically and contextually. The findings provide significant insights for project management and assist practitioners in making informed decisions by promoting amicable dispute resolution. Moreover, the results of the study suggest implications for future research regarding the application of Bayesian methodologies in construction disputes.

The remainder of this research is structured as follows: Section 2 contains the methodology, presenting the collection of data, the determination of attributes, and the methods of analysis used. Section 3 provides the results and discussion. Finally, evaluation of the model and conclusion exist in section 5.

2. Materials and methods

The present study employs a research methodology comprising three stages: (1) the development of a conceptual framework for predicting the duration of dispute resolutions through a comprehensive literature review, (2) the collection of data and the elimination of cases with incomplete information, and (3) the development of a predictive model for decision duration (Fig. 1).

The dataset employed in the present paper consists of the decisions made by the Supreme Board of Construction and Infrastructure, which utilizes the arbitration model for public construction projects in Türkiye and assesses and resolves conflicts between the administration and contractors. The data was obtained from the publication "2005-2020 Decisions and Opinions" available on the official website of the Supreme Board of Construction and Infrastructure (The Supreme Board of Construction and Infrastructure, 2020), and specific permission was secured from the board for data utilization. The data utilized in the study were manually extracted from the book, which contained case details spanning approximately four pages per case.

This study primarily focused on identifying critical attributes in construction disputes. To determine these attributes, relevant studies in the literature are examined. Subsequently, the dataset was analyzed by taking into account the significant attributes. Following this, cases with missing information on the attributes were eliminated from the dataset, and the final analysis was performed using the remaining 45 cases. The attributes of the model, along with their subcategories and statistical distributions, are displayed in Table 1.

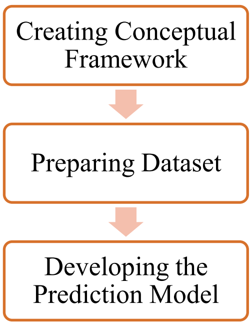

Fig 1.Research methodology

Table 1. Statistical distributions of attributes in the dataset

Attributes	Sub-categories	Frequencies	Percents
İnput Attributes			
Contract Types	Unit Price	36	80,0
	Lump-Sum	9	20,0
Work type	Construction	40	88,9
	Completion	4	8,9
	Renovation	1	2,2
Project Type	Building	25	55,6
	Social facilities	14	31,1
	Water facilities	2	4,4
	Industrial facilities	2	4,4
	Other	2	4,4
Phase of Occurrence	Build/payment	42	93,3
	Temporary acceptance	2	4,4
	Other	1	2,2
Decision	In favor of the contractor	14	31,1
	In favor of the administration	27	60,0
	To some extent in favor of the contractor	1	2,2
	Without clear decision	3	6,7
Output attribute			
Decision Duration	0–10 days	1	2,2
	11–20 days	12	26,7
	21–30 days	15	33,3
	More than 30 days	17	37,8

2.1.The Bayesian networks

The Bayes network (BN) is a probabilistic network in which the attributes are represented by nodes and the probabilistic dependency relationships between the attributes are indicated by directional arrows (Babacan & Karaduman, 2018; Pearl, 1988). This data mining method, frequently employed in classification problems, has been utilized in various domains, including molecular biology, engineering, and information technology (Hon et al., 2022; Wu et al., 2015). The Bayesian Network facilitates the construction of a probabilistic model by combining observed or recorded evidence with real-world commonsense reasoning to determine the probability of events based on seemingly unrelated attributes (*IBM SPSS Modeler 18.3 Applications Guide*, 2023, p. 183). When observed values are added to a network, the network is updated and changed. In other words, the probabilities predicted based on previous observations can be improved according to the results of new information and observations (Babacan & Karaduman, 2018; Sağır et al., 2018).

BN classifiers are standard probability-based classifiers. When all attributes are assumed to be independent, the resulting classifier is called Naive Bayes (NB) (Jiang et al., 2012). In an Bayesian network representation, a NB classifier features a simple structure where the classification node is connected to every other node with an arrow, while no connections exist between the other nodes (Madden, 2009). Tree Augmented Naive Bayes (TAN) is considered a natural extension to the NB classifier, and TAN outperforms NB in terms of accuracy. The TAN model has a structure in which each attribute links the class attribute and at most another attribute. The TAN model was utilized in this study due to its robust performance in data mining, despite its assumption of one-dependence among attributes (Wu et al., 2015). The structures of General BN, NB, and TAN are illustrated in Fig. 2 below.

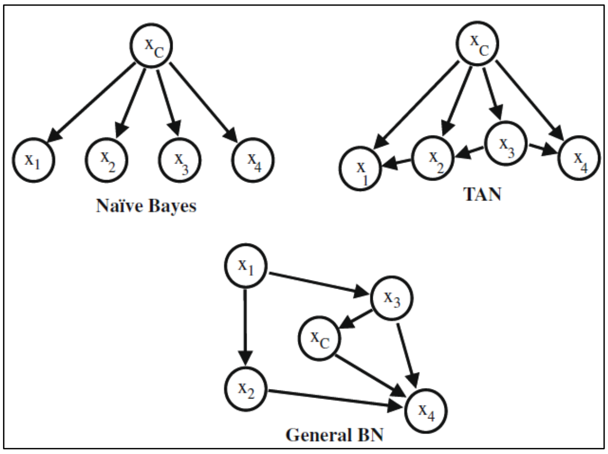

Fig. 2. Structure of Naïve Bayes, TAN, and general BN *(x_c: Class attributes $X_{1\text{-}4}$: attributes)* (Madden, 2009)

2.2.Tools
All analyses in this study were conducted using the IBM SPSS Modeler 18.3 software package and Microsoft Excel 2016. The data were initially organized and prepared utilizing Microsoft Excel 2016. Afterwards, classification analyses were conducted employing the Tree Augmented Naive Bayes (TAN) algorithm with IBM SPSS Modeler software. IBM SPSS Modeler is a data mining application that enables users to rapidly develop predictive models and integrate them into business operations to enhance decision-making. It provides a range of modeling techniques based on machine learning, artificial intelligence, and statistical methodologies (*IBM SPSS Modeler 18.3 Applications Guide*, 2023).

3. Results and discussion
Fig. 3 depicts the TAN analysis process within IBM SPSS Modeller for the categorisation of dispute decision durations.

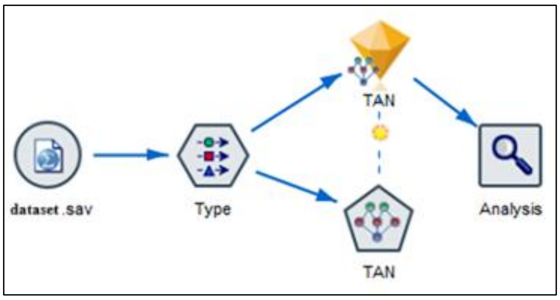

Fig. 3. TAN analysis process in IBM SPSS Modeler

The results indicate that 33 (73.33%) of the 45 data points were correctly classified by the TAN algorithm. However, the algorithm incorrectly classified 12 data points (Fig. 4). In consideration of the limited number of cases and the inconsistency of statistical distributions within the dataset, the achieved accuracy rate can be deemed acceptable (Bagherian-Marandi et al., 2021).

Correct	33	73.33%
Wrong	12	26.67%
Total	45	

Fig. 4. Results from IBM SPSS modeler

This study theoretically contributes to the literature by adapting Bayesian approaches to the field of dispute management in contracts, in response to previous research emphasizing the need for further studies on the application of Bayesian methods in contract management (Hon et al., 2022). Practically, the findings of this study can assist disputing parties in project planning by providing a probabilistic basis for estimating the duration of dispute resolution. The methodology and results presented in this study may also serve as a foundation for decision-time analyses in court and arbitration cases. Moreover, by highlighting the importance of dispute resolution durations, the study may encourage decision-makers to establish new procedures aimed at reducing decision-making times. Overall, this research not only fills an important gap in the theoretical discourse but also provides practical insights that could lead to more timely and cost-effective management of disputes in the construction and broader contract management sectors.

4. Conclusions
This study predicted the duration of decisions in disputes stemming from construction contracts through the application of Bayesian Networks. The main objective was to assist disputant parties in making essential scheduling decisions by offering probabilistic assessments of dispute resolution durations. To accomplish this, 45 arbitration decisions provided by the Supreme Board of Construction and Infrastructure, an organization tasked with adjudicating disputes between the public and private sectors in Türkiye, were examined. The Bayesian network methodology was implemented using the IBM SPSS Modeler software suite. The results show that 33 out of 45 cases (73.33%) were accurately classified using the Tree Augmented Naive Bayes (TAN) algorithm, illustrating the prospective efficacy of Bayesian methods in predicting dispute decision durations.

It is recommended that subsequent studies employ larger and more diverse datasets to enhance the model's robustness and generalizability. In addition to the fundamental-level analyses conducted in this study, comparative analyses using alternative machine learning methods could be performed to benchmark and enhance predictive performance. Incorporating additional variables such as project size, complexity, or the characteristics of the disputed issues could enhance the model's predictive performance. Ultimately, a more comprehensive and refined model could contribute significantly to both academic understanding and practical decision-making in the field of construction dispute management.

A literature review of digital twins (DT) in infrastructure projects: trends, challenges, and future directions

Elif G. Petek*[1], Onur B. Tokdemir[1]

[1] *Istanbul Technical University, Department of Civil Engineering, Istanbul 34469, Turkey*

Abstract. The purpose of this study is to review and analyze the literature comprehensively using a bibliometric approach to the implementation of Digital Twins (DT) in civil infrastructure projects by identifying the current state, recent technologies, key aspects, and challenges while providing insights and guidance to shape the future developments in this field. The application of DT in infrastructure projects is reviewed from the "Scopus" database, carefully analyzed, and appraised, and new ideas are generated for future research. DT technology in civil infrastructure projects enables construction progress monitoring, quality management, and real-time analysis. However, some crucial points in using DT, such as having accurate and consistent data, are crucial. DT is highly beneficial and significant when reliable data is available. Despite its growing importance, implementing DT in civil infrastructure projects remains a nascent field, lacking resources. Therefore, studies can be conducted and further developed in this field. This study includes a comprehensive literature review about implementing DT in civil infrastructure projects. It presents compelling arguments and feasible ideas for efficiently adopting DT in civil infrastructure projects.

Keywords: Digital twins (DT); Civil infrastructure; Bibliometric analysis; Innovation; Data

1. Introduction

The recent studies, rising prominence, and extensive applications of Digital Twins (DTs) have led researchers to diverse definitions. Callcut et al. (2021) interviewed in August 2020 and one of the questions was about the definition of DTs. Most interviewees agreed that DTs are a realistic digital representation of physical assets, processes, and systems; however, they stated that DTs do not have to be physical objects but real, and bi-directional connections are significant. Some organizations also define DT, but they are in their infancy. For instance, according to a study comprising literature research, survey, and interview findings, the Centre for Digital Built Britain (CDBB), which is the leading organization for the development of DTs in the United Kingdom (UK), should reconsider its definition of DT, a systematic approach should be created, uncertainties should be quantified, DT efforts should focus shorter timelines and high safety, investigating how DTs can be used to reduce operational energy, developing networks for secured accessible data, reaching digital maturity and establishing an organization to coordinate government-funded DT projects (Callcut et al., 2021). At a fundamental level, DTs are virtual replicas of physical assets that leverage dynamic, real-time data to enable predictive maintenance and informed decision-making. With the evolution of technology, DTs have been adopted significantly in various fields due to their considerable potential for accurately representing and managing real physical systems. As a result of utilizing DTs in various fields such as water management, transport systems, and traffic optimization, there is no standardization on how to develop DT. Standardization and using CEN/TC 442/WG 9 standards, integration with IoT, digital logbooks, and digital product passports are crucial for DT usage. DTs benefit from real-time monitoring and maintenance, reducing project costs, energy efficiency, sustainability, and public safety. For the full adoption of DTs, a standardized, unified educational framework should be built (Aragón et al., 2025).

In the construction industry, continuous innovation has driven the development of numerous methods and models, which have been researched, tested, and proposed for practical implementation. DTs enable civil engineers to conduct performance analysis that optimizes asset performance by visualizing assets along their service life and monitoring changes (Sanfilippo et al., 2022). However, despite these advancements, the widespread adoption of DT technologies in construction has not yet reached the desired level. Despite ongoing research and innovations in DTs in civil infrastructure systems, the practical applications are insufficient, and this has encouraged a growing body of research aimed at exploring the potential of DTs in complex and long-lived systems, particularly within

golden light publishing

the infrastructure domain in the context of how benefit can be achieved by implementing DTs in the civil infrastructure projects.

Since 2020, the digital twin (DT) approach for infrastructures has gained a lot of interest and development (Li et al., 2025). The United States of America (USA) and the UK are the leading countries in developing DTs (Taherkhani et al., 2024). The importance of DT technologies has become increasingly pronounced within infrastructure projects due to the scale, complexity, and longevity of physical assets such as roads, bridges, pipelines, and utility networks. DTs facilitate proactive maintenance, lifecycle optimization, and stakeholder collaboration by providing a dynamic digital representation of physical infrastructure.

Infrastructure systems require continuous oversight and efficient coordination across their lifecycle stages, from design and construction to operation and maintenance. However, DTs are predominantly applied during construction projects' operation and maintenance phases, which is unsatisfactory. The projects should be monitored digitally by the stakeholders, such as the client, project manager, contractor, and consultant, starting from the beginning of the project, not just in the operation and maintenance stage. If DT implementation starts from the beginning of the project, the defects could be recognized earlier, allowing the stakeholders to save money and time. In light of this, the goal is to broaden DT utilization to encompass the design and construction stages. Automation and coordination in the design and construction stage will reduce project costs and delivery time (Callcut et al., 2021). By creating real-time digital models of physical infrastructure, DTs enable project stakeholders to monitor the performance conditions of the systems, forecast failures, and simulate alternative management strategies. This capability improves operational efficiency and supports enduring sustainability goals, especially in critical service continuity and safety environments. As infrastructure systems grow more interconnected and data-driven, integrating DTs offers a transformative approach to managing assets more intelligently and proactively.

While numerous studies have explored the concept and applications of DTs in the built environment, the literature still lacks a comprehensive and structured synthesis that critically examines current trends, recurring challenges, and emerging research priorities, particularly in the context of infrastructure projects. To close this gap, this paper aims to systematically review existing research on Digital Twin implementations in infrastructure with bibliometric analysis by classifying the findings into key thematic areas—such as current applications, methods, key challenges, and future technologies. This study maps the state of the art and highlights the barriers that hinder wider adoption. Furthermore, the paper outlines future research directions to support more effective and scalable DT applications in the infrastructure sector.

2. Materials and methods

A systematic approach was implemented to conduct a comprehensive literature review on implementing DTs in infrastructure projects. Scopus, a well-known, reputable database for scientific research, was used to conduct this study. The study has no publication date limit; however, recent studies were prioritized to learn and examine the recent trends, technologies, and innovations. The methodology of this study began with defining the scope, which is a comprehensive literature review of DT applications in civil infrastructure. A keyword search strategy was used by Boolean operators, combining the terms "digital twin" and "civil infrastructure." This initial query yielded a total of 64 records. A detailed literature review and bibliometric analysis were carried out to identify the research trends, innovations, knowledge gaps, challenges, key contributors, and future study directions. The research methodology can be found in Fig. 1.

2.1. Bibliometric analysis

Bibliometric metrics are crucial for assessing and capturing innovations in specialized disciplines (Van Raan, 2003). This study exported bibliographic data, including metadata such as authors, title, abstract, publication date, publisher, keywords, and citation counts, from Scopus in CSV format to carry out the analysis. A bibliometric analysis was applied to analyze and examine this data accurately. In this study, bibliometric analysis was conducted using Open Knowledge Maps, Bibliometrix, an R-based package, VOSviewer, and Biblioshiny tools.

2.2. Open knowledge maps

In this study, Open Knowledge Maps, an AI-based visual interface, was utilized as a complementary tool to support the literature review from a conceptual view shown in Fig. 2. While VOSviewer is used for conducting detailed literature reviews through bibliometric analysis, Open Knowledge Maps, on the other hand, is a tool that can visualize the topic to be researched and allows for a conceptual exploration of the literature. It enables a topical overview and provides the most relevant 100 documents based on the research topic by using the Artificial Intelligence (AI) pipeline. The pipeline utilizes natural language processing methods to collate and display publications according to similar topics. Visualizing the research topic is beneficial for taking a broad perspective on the research area. Upon entering the website, the research topic should be written first. Then, keywords related to the topic are visualized, and once one of them is clicked, the related articles are shown. In the tool, the details and links of each article can be accessed by clicking on the articles.

2.3. Bibliometrix and biblioshiny

Biblioshiny, which is the web interface of Bibliometrix, was used to review annual scientific production of DTs in infrastructure shown in Fig. 3 and three-field plot shown in Fig. 4.

2.4. VOSviewer

VOSviewer was used to create co-occurrence analysis maps, as shown in Figure 5. According to the co-occurrence analysis based on the author's keywords, the frequently used keywords are digital twin, civil infrastructure, Structural Health Monitoring (SHM), and Building Information Modelling (BIM). VOSviewer produced structured maps that reflected associations within the dataset.

3. Results and discussion

3.1. Digital twins applications in civil infrastructures

Many studies have been conducted in various sectors about DT applications in civil infrastructure. The number of studies conducted on Digital Twin (DT) applications in the bridge sector is significantly higher than in other fields. A few studies have been conducted for tunnel and road domains. For the aviation and marine sectors, the implementation of DTs mainly focuses on operational management and security issues (Broo & Schooling, 2023). This study analyzes rail and road, transportation, bridge, water systems, waste management, energy systems, telecommunication systems, and tunnels infrastructure applications.

3.1.2. Rail and road infrastructure

DT studies on rail and road infrastructure networks are still lacking. They provide critical service to the public and face many challenges, such as increasing demand, territorial dispersion, a wide range of asset types, and investment backlogs. For this reason, utilizing DTs will help address these issues by providing efficient asset information. DT research in rail and road infrastructure is very recent and has increased at a minimum rate of 100% over the past four years, as indicated in the bibliometric analysis (Vieira et al., 2022).

According to Sanfilippo et al. (2022), DTs can be used in road infrastructure systems by representing them with 3D technology, and the related information can be used via a data management system. Data can be collected by blockchain techniques, automated devices such as mobile and fixed sensors, and multiple mobile robots. They concluded that a systematic design approach for using DTs in road infrastructure is missing in the literature. Therefore, they present this systematic approach by considering flexibility, integrability, and reliability. The Robot Operating System (ROS) and the Gazebo simulator execute the suggested framework. The bottom-up method consists of physical/virtual layer that interconnects physical and virtual road infrastructures. These sensors enable the collection of data such as accelerometers and vibrometers (more sensors means more precise data), carrier layer that will accumulate the important data, add-on layer which enables adding extra sensors, data acquisition layer that gets all raw data from not only the fixed sensors but also from the mobile sensors, annotation layer which enables manually adding information and storing historical data such as damages in the road traffic status and finally application layer (data interpretation) which analysis and examines the data reached and presents it to the users to make determinations, action plans.

Eighty articles were examined in a study that confirmed the advancement of DTs in road engineering. It focuses mainly on virtual geometry models and getting real-world data. It emphasizes that 5D DT implementations are not sufficient enough. Ground Penetrating Radar (GPR) and Internet of Things (IoT) technologies are used to monitor, maintain, and develop DTs. Existing studies examine the incorporation of related physical theories, mechanical rules, and behavioral codes, primarily to construct detailed and multi-level models. There are compelling challenges for data processing and connection-enabling technologies because of the complexity of pavement structures and the built-in inconsistency of materials. The use of DTs in road engineering primarily focuses on the Operational & Maintenance (O&M) stages. Conversely, DTs are less common in the design, construction, and reconstruction stages, especially noticeable in the demolition stage. There is no common understanding of specific application roadmaps and standardization. Further studies should be conducted on developing standardization, real-time interaction, innovative data analysis, expanded lifespan applications, and transformative DTs in road engineering (Yan et al., 2024).

3.1.3. Transportation infrastructure

DT technology has the potential to manage transportation infrastructure; however, the recent implementations are still in the early stages, especially in large urban systems. The studies mainly focused on traffic management and structural health monitoring, which misses a comprehensive full lifecycle approach. This study proposes a full lifecycle DT system from planning to maintenance that introduces a "4 horizontal + 4 Vertical + N" framework for urban transportation infrastructure. The horizontal layers are data, model, service, and application, and the vertical layers are planning/design, construction, operation, and optimization. Moreover, the "Form-Condition-Mechanism-Tendency" concept is analyzed, and it is a robust tool supporting efficient operation and sustainable development (Wu, 2025).

3.1.4. Bridge infrastructure

Data and Knowledge-Driven Digital Twin Modeling (DK-DTM) can be used in civil infrastructure, such as bridges, where there is insufficient data and high certainty. Spatial modeling of bridges can be done to establish correlations between bridge defects and explain the root causes of these structural health issues. Innıvative applications of advanced data processing techniques for SHM, such as YOLOv8, can be used for crack detection of 2D images, PointNet for 3D point cloud deformation analysis, and LTSM networks for sensors and early warnings (Sun et al., 2025).

A five-step framework can be developed for DTs' existing structures, including data and need acquisition, digital modeling, dynamic data transmission, data/model integration, and operation. The framework was applied as a case study to the Grade I listed Clifton Suspension Bridge (Bristol, UK) completed in 1864 and has no BIM data (Mitchell-Baker and Cullimore, 1988; Anderson, 2013). The management and maintenance of The Clifton Suspension Bridge are under the responsibility of The Clifton Suspension Bridge Trust (CSBT), and they have concerns about the operation of the tower saddles as their potential seizure, which may impair the bridge's safety. With the help of DTs, sensor information is taken periodically, enabling managers to see the risk factors, focus on operational needs, select the suitable one, and take safe and cost-effective actions (Pregnolato et al., 2023).

Another publication analyzed the Clifton Suspension Bridge (Bristol, UK) as a case study to show DTs in the Architecture, Engineering, and Construction (AEC) sector. It applies the five-step workflow process for utilizing DTs in the built environment. A Three Dimensional Finite Element Method (3D FEM) was developed, and Midas Gen (MA4) was chosen for initial FE modeling (Pregnolato et al., 2022).

According to another study conducted on a bridge called McKanes Falls Bridge located in NSW, Australia, the accuracy level of two-point clouds acquired based on UAV photogrammetry and Terrestrial Laser Scanning (TLS), TLS is very beneficial for bridge inspection and 3D model reconstruction; however, there are challenges such as expensive pieces of equipment and limited site access (Mohammadi et al., 2021).

3.1.5. Water systems

The structure of urban water systems is inherently intricate, and in case of a failure, it will be tough to repair. Hence, the necessary precautions should be taken before the failure. Supervisor control and data acquisition (SCADA) systems enable hydrological modeling to prevent failures arising from fluctuations in rainfall, population growth, infrastructure wear and tear, and resources. The subsequent step is to use DTs in the water distribution industry for dynamic processing. All types of water infrastructure, such as pipe networks, pumping stations, treatment facilities, and storage tanks, can benefit from and implement DTs (Callcut et al., 2021).

3.1.6. Waste management

Wide-ranging research is conducted in wastewater to improve control strategies and process monitoring systems (Therrien et al., 2020). Research conducted by Ghandar et al. (2021) recommends a decision support system called aquaponics to complement a novel urban farming framework. With the help of this technique, the transportation distance decreases between producers and consumers. However, because of the complex human activity in the system, DTs can be used to gather real-time data to minimize waste. Moreover, wastewater treatment plants (WWPTs) are very significant and critical civil infrastructure for protecting the environment. DT usage will be very beneficial in performing predictive maintenance (PdM) of pumps, critical assets in WWTPs. A DT framework can be created to broaden the scope of PdM by utilizing Building Information Modelling (BIM) and Deep Learning. (Hallaji S.M. et al., 2021). While integrating DTs in wastewater systems, the data types are also very significant. In other words, the data types used in Machine Learning are limited to vibration and flow, which may not be sufficient, especially for Waste Water Treatment Plants (WWTPs) for diagnosing the condition of pumps and their attributes, which can result in inaccurate predictions. To effectively integrate BIM into the digital twin framework, interoperability is needed between IoT and maintenance and operation databases. Deep learning techniques effectively process massive datasets; however, they rely on sensing that might be limited in older WWTP facilities, so this should be considered (Hallaji et al., 2022).

3.1.7. Energy systems

Failure of pipeline assets is a significant problem in the energy sector. Improved operation and maintenance strategies are being sought by oil and gas operators in order to lower downtime from costly planned or unplanned maintenance. For the subsea pipeline system, a conceptual DT with integrated sensors is proposed, which predicts future conditions, recognizes anomalies, and forecasts the remaining life span of the asset (Bhownik, 2019). Another research analysis is PetroChina's proposal of a top-level intelligent pipeline based on DT technology (Xiandong et al., 2020). For maintenance, a proposed DT-based system uses a Russian-made robotic system called Cablewalker and a DT for overhead transmission lines for predictive maintenance (Gitelman et al., 2019).

3.1.8. Telecommunication systems

DTs set a solid foundation for advancing telecommunication networks and aggregating data by harnessing vast datasets, data mining, and neural networks. Using DTs in telecommunication systems is beneficial, especially for emergency traffic monitoring (Seilov et al., 2021). Consolidated Digital Twin for Telecommunication Towers (cDTT) enables real-time analysis, multi-tenant coordination, maintenance, and public safety (Medeisis A. and Radis, 2022).

3.1.9. Tunnels

Civil infrastructures undergo a degradation process over time. A model is developed to predict tunnel performance deterioration using visual inspection data, classification systems, and predictive models. In the model, degradation assessment is first done by conducting visual inspections on tunnel walls and roofs determined from geological-geotechnical mapping. Defects such as cracks, infiltration, and spalling are classified into four degradation states from I to IV. Tunnel Serviceability Index (TSI), which ranges between 0 (worst) to 5 (best), which indicates defect severity, is used. Secondly, prediction modeling is done using an inverse exponential equation, and forecast curves determine intervention timeframes for maintenance target intervention time by a limit analysis of approximately 16 years. Finally, Rhinoceros 3D and EleFront plugins are used to build a 3D virtual tunnel model. Inspection Digital Twin (IDT) has enabled virtual inspection, condition tracking, and lifecycle management (Bellini Machado & Massao Futai, 2024).

3.2. Current technologies and research trends in digital twins-enabled infrastructure

3.2.1. Sensing and data integration

The key enabling techniques for DTs are mechanical modeling, geographic information systems (GIS), City Information Modelling (CIM), machine/deep learning, and extended reality (XR). (Chang et al., 2024). DTs are advancing through sensing technologies, finite element modeling, data analysis, and system identification methods. Load Identification (LID) and Response Reconstruction (RRE) are core techniques that enable the creation of DTs by predicting unmeasurable external forces and reconstructing unmeasured structural responses (Li et al., 2025).

3.2.2. Energy harvesting

Triboelectric Nanogenerators (TENGs) support the development of DTs in the context of Civil Engineering Infrastructure 4.0 by energy harvesting, real-time monitoring, and self-powered sensing. It converts mechanical energy such as vibration, pressure, wind, and raindrops into electrical energy, enables self-powered sensors for Structural Health Monitoring (SHM), and supports wireless communication and integration into IoT systems. It can be applied to smart buildings, roads, rail tracks, tunnels, and ports. TENG enables using materials such as concrete, paints, and wood for energy harvesting in smart structures. Cement-based composites are very effective in performance enhancement. Metamaterial concrete is used for advanced sensing and resilience. (Pang et al., 2024).

3.2.3. Modeling

The literature mainly focuses on visualization and physical modeling using CAD, GIS, and BIM in urban building and evaluation. However, semantic, planning-oriented features also should be used. A method called Fractalopolis, a Multiscaling Zoning system unique in explicitly modeling urban centralities, can be used to show urban structure across scales and allows planners to develop scenarios in coherence (Bonin & Frankhauser, 2025). Finite element-based methods, data-driven approaches, 3D model reconstruction using laser scanning methods, and 3-D model reconstruction using unmanned aerial vehicle (UAV) methods can be used to build DTs in civil infrastructures. (Liu et al., 2023) A graphics-based digital twin (GBDT) is created for civil infrastructure and suggests a method integrating photographic displacement measurements with finite element (FE) simulations through a graphics-based digital twin (GBDT) to improve structural models and assess degradation (Wang et al., 2023). Using mesoscale phase-field modeling and macroscale structural analysis within a unified framework allows the digital representation to show both local damage (pitting) and global structural effects. The two-stage Approximate Bayesian Computation (ABC) method enables continuous calibration, essential for self-adaptive DTs (Qian et al., 2024). An innovative BIM-enabled digital twin framework is created and tested by monitoring and visualizing the deformation of critical structural elements such as beams and columns by a structural frame prototype and laser displacement sensor measurements. The model was used to perform structural analysis to find optimal locations for sensors and guide the creation of a DT model for real-time structural behavior visualization (Hu et al., 2024).

3.2.4. Machine learning

Machine learning enables a new 5th-level damage type classification to be added to 4 level damage detection hierarchy, which includes detection, location, severity, and prognosis) (Malekloo et al., 2022) Physics-informed machine learning (PIML) incorporates past knowledge of the physical world and data-driven solutions. They are practical tools for modeling in DTs (Heidarian Radbakhsh et al., 2024).

3.3. Advanced technologies

Recent Infrastructure Digital Twins (IDTs) are based on BIM and the Internet of Things (IoT) and are mainly used in the Operation and Maintenance (O&M) phase of infrastructure projects. Technologies such as GIS, Point Cloud Data, Finite Element Models (FEM), and Machine Learning techniques are utilized by researchers in order to have a more complex Infrastructure Digital Twin (IDT) architecture. (Naderi and Shojaei, 2023). DTs have started to be implemented in various fields. For instance, prestressed steel structures in the O&M stage are analyzed by a prediction method created by DTs and an improved Back Propagation Neural Network (BP) optimized by the Levenberg-Marquardt (LM) algorithm, a machine learning method. The DT-based solution predicts the impact response of prestressed steel structures with an eight percent fluctuation, showing high accuracy (Liu et al., 2022). Moreover, Proactive Perceptive Road (PPR), which is an innovative DT-driven infrastructure model, can be used to monitor roads. The PPR enables the gathering of real-time, accurate data, comprehensive detection, and simulation of road condition data. It ensures precise mapping and shows the road's observable and internal conditions. It maximizes using sensors to detect explicit state information in the road domain, such as geometric dimensions, physical materials, and surface and structural conditions (e.g., cracks and potholes). Moreover, it utilizes simulation tools and Machine Learning (ML) algorithms to make the models work with high sensitivity and analyze implicit state information of performance, life span, and behavior that is hard to measure. (Han et al., 2025). Fast Bayesian (FFT) and Principal Component Analysis (PCA) can also be used for trend detection and early warnings (Li et al., 2024). Additionally, Proper Orthogonal Decomposition (POD) is used to create a digital twin model framework for real-time prediction of the stress response of tubular joints. Leave-one-out cross-validation (LOOCV) is used to optimize and select the modal order of the Reduced Order Model (ROM). The study confirms that the proposed Reduced-Order Model (ROM) achieves high prediction accuracy (avg. error: 5.16×10^{-7}%) and real-time performance, with 99.86% greater efficiency than the full-order model (FOM) (Leng J C. et al., 2025). Stochastic Subspace Identification with Covariances (SSI-COV) method using real sensor data can detect modal parameters without artificial excitation (Lozano-Allimant S. et al., 2025). A new approach utilizes Convolutional Neural Networks (CNN), Robotic Arms (ROIs), laser line scanners, and 3D LiDAR mapping for automatic crack detection and measurement (Ghadimzadeh Alamdari and Ebrahimkhanlou, 2024). A study collected 204 papers from the Web of Science about Advanced Information Technologies (AITs) used in civil infrastructure planning, construction, and maintenance stages between 2010 and 2020. Key technologies such as Wireless Sensor Networks (WSN), Building Information Modelling BIM), Fiber Optic Sensing (FOS), and Radio Frequency Identification (RFID) are reviewed (Li et al., 2022).

Taherkhani et al. (2024) examined 130 articles from the Scopus and Web of Science databases using VOSviewer. Their findings revealed a notable rise in publications on applying Digital Twins in infrastructure, indicating increasing scholarly interest and growing research momentum since 2018. However, they concluded that the number of studies focused on DT-enabled infrastructure remains insufficient. The co-authorship analysis showed that most contributions originated from the United States, the United Kingdom, and China. According to their citation analysis, the five most-cited articles applied Digital Twins to address wide-ranging challenges through real-time predictive insights and decision-making, with the primary obstacle being acquiring accurate data for their frameworks. Additionally, the keyword co-occurrence analysis revealed that terms such as AI, IoT, BIM, decision-making, structural health monitoring (SHM), visualization, and operation and maintenance are among the most frequently used in the literature.

3.4. DTs in the construction of smart cities

DT applications in the built environment can be classified into five major application areas: Smart cities, Design decision-making, product manufacturing, real-time construction progress monitoring, and facility management (Zribi et al., 2025). civil infrastructure innovations are integrated into real life by smart city applications. Smart Underground Grid Transformation, an Urban Futurability Project managed by ENEL São Paulo, is a great example of smart city applications. The project combines digital tools such as Ground Penetrating Radar (GPR) with civil infrastructure innovations. This case offers a blueprint for future smart cities (Simao et al., 2022).

The infrastructure management framework with the 5D smart city conceptual model in the UN Sustainable Development Goals can be used instead of traditional systems to improve smart cities. The 5D conceptual model integrates five core dimensions of infrastructure management: environmental, financial-economic, political-governance, social people, and technological (Chang et al., 2023).

3.5. Structural health monitoring (SHM) in civil infrastructure

DTs are beneficial for real-time structural health monitoring and are an alternative to non-destructive testing methods and traditional visual inspections. While creating the DTs, selecting suitable software is vital due to the effects of determining the boundary conditions with minimal discrepancies from reality. Moreover, the development platform is crucial as a central hub for data exchange and interpretation. DT designers have key responsibilities in addressing potential challenges early as these can affect the accuracy of the DTs (Sun et al., 2025).

The structural health and behavior should be understood by collecting data from the real-time simulation modeling to develop a DT for intelligent infrastructure maintenance. A case study is conducted on the conveyor jetty at the Dalrymple Bay Coal Terminal (DBCT) in Queensland, Australia. Tiltmeters, strain gauges, and vibrometers are used as sensors and installed on the structure to monitor real-time changes. The collected sensor data is integrated with Finite Element Model (FEM) developed by using ANYS, and data acquisition is made by Senscope, which is a RESENSYS platform that supports continuous monitoring. What-if scenarios are simulated in the digital environment before utilizing them in the physical asset to choose the safer, cost-effective, and evidence-based maintenance planning (Mahmoodian et al., 2022). Another study was conducted by installing a structural health monitoring (SHM) system on the precast concrete bridge, El Cacique Bridge, in the Dominican Republic (DR) to improve the state of knowledge and take information about the vibration characteristics of the structure. The parameters taken from SHM data are integrated with a computational structural model to develop a DT, and the DT is used to formulate a set of fragility curves for different damage limit states. The study presents a more accurate, data-driven method for mitigating seismic risks in critical infrastructure; therefore, the methodology can be adapted for other bridges or infrastructure systems (Rojas-Mercedes et al., 2022).

Despite these benefits, using DTs in Structural Health Monitoring has challenges and limitations, such as data privacy and security problems, data integration from various sources, model calibration and validation, computational complexity, resource requirements, and data quality (Parida and Moharana, 2024).

In order to establish suitable standards and protocols for DT-based Structural Health Monitoring (SHM), a deep understanding of the integration of emerging technologies such as the Internet of Things (IoT), Artificial Intelligence (AI), Augmented Reality (AR), Virtual Reality (VR), Big Data and other Industry 4.0 elements is necessary (Sakr & Sadhu, 2024).

4. Conclusion

Several studies were analyzed, and bibliometric analysis was conducted about DTs in civil infrastructure using Bibliometrix, Biblioshiny, VOSviewer, and Open Knowledge Maps tools. The Scopus database was chosen because of being a reliable source, and 64 articles were examined. According to the research, it has been seen that since 2020, DT applications have gained more importance and started to be studied and implemented in various fields such as rail and road, transportation, bridge, water systems, waste management, energy systems, telecommunication systems, and tunnel infrastructure. Many advanced technologies like BIM, IoT, SHM, GIS, GPR, FEM, AR, and VR can be integrated and utilized with DTs. There are attempts to utilize DTs in civil infrastructure; however, they are still insufficient and need to be improved. Moreover, the implementations are mainly limited by O&M stages of construction. However, DTs should be implemented in the design and construction phases so that action can be taken earlier in case of a defect. DTs are very beneficial for the civil infrastructure sector if they can be sensors that can collect standardized and accurate data. By SHM, the problems and defects in the systems can be recognized, and root cause analysis can be conducted to prevent future issues from happening, which will provide us with know-how. This comprehensive literature review contributes to the academic literature by conducting a detailed analysis using various tools, including reviews of case studies and previous literature reviews and their conclusions. Furthermore, this study is enhanced by reviewing the case studies. The research starts from the definition of DTs and continues with the bibliometric analysis of the publications, mainly focusing on the recent trends of using DTs in civil infrastructure, advanced technologies, and the relation of DTs with other technologies. Although the study has contributions to the literature, using only the Scopus database and publications written in English are the limitations. For future research, the databases used in the studies can be increased.

Clustering of construction business surveys: case of Türkiye

Serkan Aydınlı*[1]

[1] *Çukurova University, Department of Civil Engineering, 01250 Adana, Türkiye*

Abstract. The construction industry is a crucial locomotive industry for national economies. Business surveys in the construction industry are essential instruments for evaluating sectoral health and trends. They provide timely and organized data that serves many stakeholders, including policymakers, enterprises, analysts, and contractors. Since May 2011, TurkStat has begun the publication of construction business surveys to facilitate stakeholders to track sector trends. Some of the key indicators reflecting sectoral health and trends include construction confidence indicator, employment expectations, building activity development, and price expectations. This study aims to reveal the relationships and correlations between construction business surveys. To this end, construction business surveys published by Eurostat are obtained, and the data are clustered utilizing the Dynamic Time Warping (DTW) approach, a commonly used technique for clustering time series data. The clusters that were identified as a result of the analysis were interpreted and their contributions to sectoral trends were analyzed. The study enables the simplification of sectoral health indicators and enhances the understanding of them by sector stakeholders. The clusters also have the potential for forecasting important indicators such as the construction cost index and the construction production index.

Keywords: Business surveys; Dynamic time warping; Time series analysis; Construction industry.

1. Introduction

The construction sector plays an important role in national growth and serves as an engine for several sectors (Alaloul et al., 2021). It also significantly impacts employment, as it is a labor-intensive industry. Construction projects are complex activities that employ several laborers and technical staff. The extensive workforce involvement directly promotes employment rates (Ernst & Sarabia, 2015; Fendoglu & Polat, 2021). The employment in the construction industry directly contributes to economic growth, particularly in emerging nations. The industry also represents a substantial share of Gross Domestic Product (GDP) (Chiang et al., 2015; Qabaja & Tenekeci, 2023). Furthermore, infrastructures, including highways, dams, and bridges, which are essential projects in the sector, enhance economic development and stimulate higher investments (Rephann & Isserman, 1994; World Commission on Dams, 2000). Infrastructure investments boost urban development, leading to an increase in GDP per capita alongside population and investment growth. The industry promotes national economic indicators through various channels and serves as a crucial catalyst for growth, particularly in developing economies.

The construction sector is affected by many internal variables. For instance, restricted access to materials, machinery, labor and money, which are important inputs, can negatively affect production in the sector. Its dependency on financial resources and important inputs such as labor and materials requires close monitoring of economic developments in the construction sector (Hillebrandt, 2000). Tracking major economic developments such as employment expectation, sectoral confidence, and activity developments can be useful for accurate forecasts and guide investment decisions. The increase in production and employment expectations suggests that a positive climate will dominate the sector moving forward, fostering an encouraging atmosphere for investors. Economic expansion in the construction sector is evident in the sales of products utilized to equip real estate properties, and this correlates with an increase in bank loans for residential and commercial transactions. Consequently, advancements in the industry light the future of other sectors. Therefore, sector dynamics must be rigorously observed, and investment decisions should be based on developments.

In this study, cluster analysis of construction business surveys, which are significant indicators of sector dynamics, has been conducted using DTW. Thus, it was aimed to interpret the surveys more effectively. The article is organized as follows. The second section of the study presents data collection and analysis methodologies. The third section elucidates and examines the findings of the analysis. The final section summarizes the study's results and discusses possible implications.

golden light publishing

2. Methodology

2.1 Data collection

The construction business surveys are available as open source on the EUROSTAT database (Eurostat, 2025). The monthly surveys regularly provided by Turkstat since May 2011 are listed below.

- Employment expectations over the next 3 months (EEON3)
- Building activity development over the past 3 months (BADOP3)
- Evolution of the current overall order books (ECOOB)
- Price expectations over the next 3 months (PEON3)
- Construction confidence indicator (CONFIN)
- Factors limiting building activity – none (FLBAN)
- Factors limiting building activity – insufficient demand (FLBAID)
- Factors limiting building activity – weather conditions (FLBAWC)
- Factors limiting building activity – shortage of labour (FLBASOL)
- Factors limiting building activity – shortage of material and/or equipment (FLBASME)
- Factors limiting building activity – other (FLBAO)
- Factors limiting building activity – financial constraints (FLBAFC)

The surveys are conducted by the statistical office directly to sector stakeholders. The survey questions include three response alternatives: positive, no change, and negative. Survey statistics are calculated as in Equation 1 (Eurostat, 2023).

$$Balance = \%\ Positive\ Responses - \%\ Negative\ Responses \tag{1}$$

EEON3 evaluates the expected short-term employment level in the industry. This variable can also be considered an indicator of the sectoral production volume. Another indicator that shows the sector's activity level and hence the production volume is BADOP3. PEON3 indicates whether there is an expectation of a change in construction costs in the near future. Price increases/decreases also significantly impact production and employment. CONFIN refers to the confidence in the sector. This confidence helps to assess the feasibility of investing in the sector in the current period. The final significant business survey category is "Factors Limiting Building Activities." Seven sub-indicators under this category are FLBAN, FLBAID, FLBAWC, FLBASOL, FLBASME, FLBAO, and FLBAFC. FLBAN indicates that there are no substantial barriers to building activities. A positive answer to this survey states that the industry is entirely appropriate for investment. FLBAID examines whether the level of demand in the sector is sufficient. The level of demand is an extremely crucial factor for the sector, directly affecting production and enterprises. FLBAWC is a seasonal indicator and explores whether the current weather conditions are an obstacle to production. FLBASOL and FLBASME reflect access limitations to labor, materials, and equipment, critical inputs for construction projects. FLBAO addresses variables other than the identified barriers, including political situations and legal impediments. Ultimately, FLBAFC relates to the availability of financial resources, including bank loans, during the construction phase. The positive values signify more difficulty in obtaining financing, and negative ones denote enhanced accessibility.

2.2 Dynamic time wraping (DTW) method

Dynamic Time Warping (DTW) is a technique designed to identify similarities in time series data. The method is employed for various purposes, such as time series clustering (Izakian et al., 2015; Wang et al., 2018), voice recognition (Bhadragiri Jagan Mohan & Ramesh Babu N., 2014; Pandey & Singh, 2017), and gesture recognition (Plouffe & Cretu, 2016; Ruan & Tian, 2015).

The first step of the technique is to determine the wraping distances between time series data on the wraping path using Euclidean Distance (Eq. 2).

$$DTW(X,Y) = \sqrt{\textstyle\sum_{(i,j)\in\pi} \left\| X_i - Y_j \right\|^2} \tag{2}$$

The second step of the approach is the clustering analysis. The study has employed "hierarchical clustering" to progressively unveil the associations between the series. In this approach, following the calculation of the distances between the series, the linkages are determined by Ward's method, and all the distances between the series and clusters are shown hierarchically on a dendrogram. The approach offers a straightforward computational framework that efficiently utilizes time series data to cluster them.

3. Results

In the study, twelve construction industry surveys were grouped using DTW, and series that demonstrated temporal alignment were hierarchically clustered. The distances between series are given in a heatmap matrix as given in Figure 1.

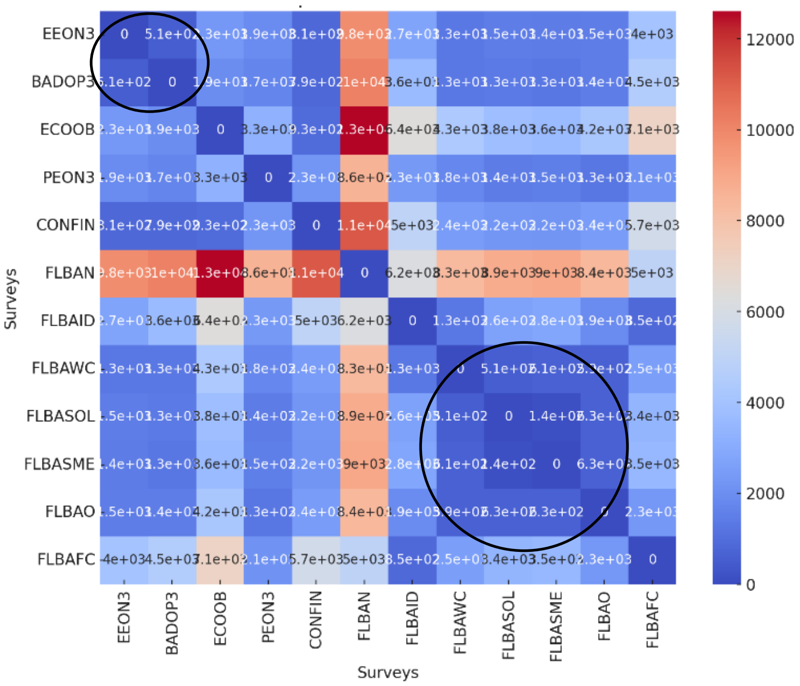

Fig. 1. DTW Distance Matrix

The first striking finding in the matrix is the similarity of the FBLA series with each other. Among these series, only the FBLAN is significantly incompatible with the others. This is entirely comprehensible. FLBAN suggests the absence of obstacles in the sector, fostering a favorable environment, while the other FLBA components indicate the presence of various barriers. On the other hand, the distance between EEON3 and BADOP3 is also relatively low. This points out that the expected increase in production in the industry also generates expectations for employment growth.

DTW grouped the twelve surveys into three clusters and showed them in Multi-Dimensional Scaling (MDS) projection (Fig. 2). MDS enables the visual representation of multidimensional distances in two or three dimensions.

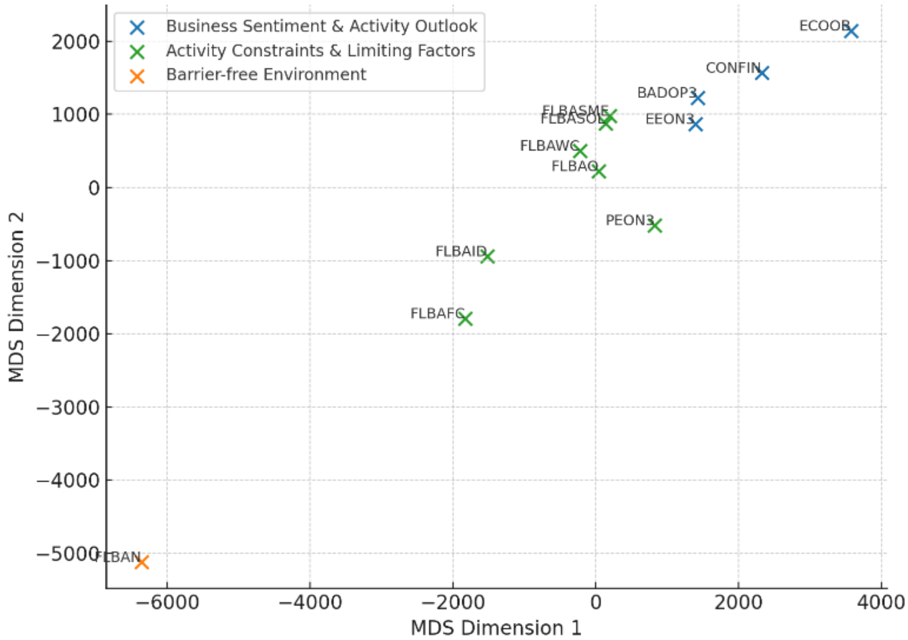

Fig. 2. MDS Projection of Surveys

The first cluster represents the sector's general economic outlook. Therefore, the cluster is labeled “Business Sentiment & Activity Outlook”. The second cluster mostly covers barriers to production. Therefore, the cluster is labeled “Activity Constraints & Limiting Factors”. Finally, FLBAN is labeled “Barrier-free Environment”. Thus, construction business surveys are categorized into 3 major groups. Fig. 3 shows the patterns of the groups over time. The graph indicates that the industry has faced no substantial impediments for an extended period; however, the “Business Sentiment & Activity Outlook” has been persistently negative. Particularly during the pandemic, substantial fluctuations in indices are noted.

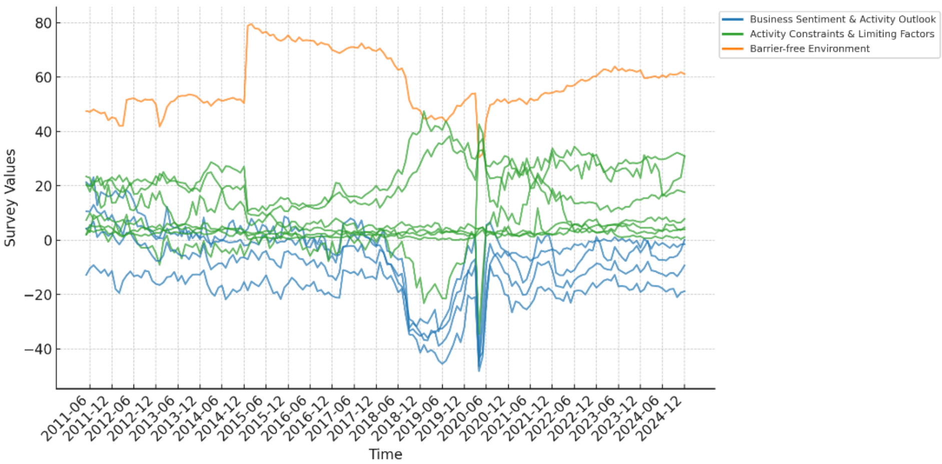

Fig. 3. Clustered Time Series of Business Surveys

The DTW dendrogram clearly illustrates the links among the series and the subsets constituting the three primary groups (Fig. 4). The connections in the graph outline the subgroups, whereas the Y-axis represents the distances between the series. Material, equipment (FLBASME), and labor (FLBASOL) shortages appear to be highly interrelated and trigger each other. Similarly, the proximity between employment expectations (EEON3) and production (BADOP3) is also evident in this graph. The graph shows that insufficient demand and financial constraints produce series close to each other. Financial constraints are a factor that deeply affects not only enterprises but also consumers. The difficulty in accessing financial resources is also reflected in sales, leading to a significant decline in real estate transactions. The graph demonstrates that, despite being in the same cluster, inadequate demand and limited access to financial resources are distinct from other barriers.

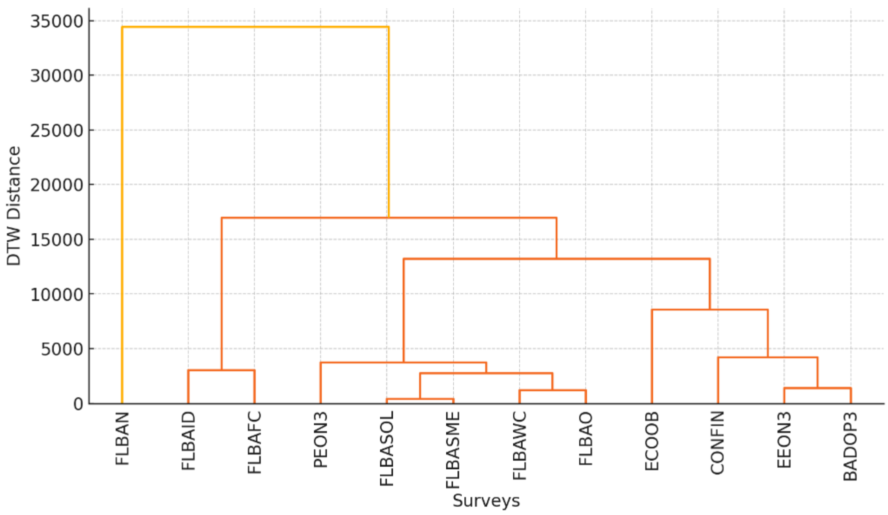

Fig. 4. Dendrogram of Business Surveys

4. Discussion

The study clearly reveals the interrelationship of construction sector business surveys. The initial significant finding of the study is the synchronization between EEON3 and BADOP3. These two variables are deeply interconnected. A recession in the economy initially leads to unemployment, subsequently diminishing production and, consequently, supply within the sector (Le, 2025). Another factor directly affecting employment and production is confidence in the sector. Reduced employment and production will lead to a decline in confidence in the sector. The status of existing orders is associated with these variables as an indicator of production volume.

The second cluster in the study contains the components that limit productivity. It is an unexpected discovery that PEON3 is classified as a factor that limits construction activities. The pessimistic prognosis for price expectations restricts activity, as do issues related to access to materials and equipment. The scarcity of resources results in higher prices, thereby increasing construction costs. Enterprises transfer the increase in costs onto pricing, resulting in price escalations (Guan & Cheung, 2023).

5. Conclusions

Statistical offices publish monthly industrial and consumer surveys. The surveys provide an outlook on the economic environment and are also conducted by sector. The study clustered business surveys of the construction sector, which is particularly critical for emerging economies, using DTW. Consequently, 12 monthly surveys were obtained from the Eurostat database and analyzed. As a result of the study, the questionnaires were categorized into three main groups which are "Business Sentiment & Activity Outlook", "Activity Constraints & Limiting Factors", and "Barrier-free Environment". Business Sentiment & Activity Outlook Business Sentiment & Activity Outlook includes the general outlook of the sector and forward-looking expectations. Activity Constraints & Limiting Factors cover challenges that adversely impact the sector, including inadequate supply and demand, resource scarcity, and obstacles to accessing financial resources. In contrast to the previous factor, Barrier-free Environment refers to the absence of any obstacles for production in the sector.

The study simplifies and clarifies the surveys and enables stakeholders to monitor the surveys more consciously. The results offer a useful categorization of surveys for possible future utilization in generating sectoral forecasts. The study has important implications for the prediction of parameters such as construction cost index and production index, which are of vital importance for the sector.

Leveraging graph-based neural networks for enhancing early-stage screening of construction projects: GraphSAGE model

Fatemeh Mostofi*[1], Onur B. Tokdemir[2], Vedat Toğan[1]

[1] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye
[2] Istanbul Technical University, Civil Engineering Department, 34469, Istanbul, Türkiye

Abstract. Selecting construction projects has long been a multifaceted challenge due to the complexity of variables such as cost, time, environmental impact, and strategic alignment. The critical problem identified is that existing methods in construction project selection are predominantly reliant on conventional machine learning (ML) models, which are unable to effectively capture relational dependencies among project attributes, especially for unseen or evolving data. Despite the popularity of graph convolutional networks (GCNs) in construction project management studies, these models are inherently transductive, requiring all nodes to be available during training, thereby restricting their flexibility in dynamic decision-making systems. To address these limitations, this study integrates GraphSAGE (Graph Sample and Aggregate), a state-of-the-art graph neural network (GNN) algorithm that supports inductive learning by aggregating neighborhood features, into a multi-criteria decision-making (MCDM) framework for project selection. Construction projects and investment records are represented as nodes in a graph, with edges formed based on shared regions or attributes, enabling the model to extract relational insights. Experimental evaluation on over 10,000 project investment records demonstrated that GraphSAGE achieves superior performance, with an accuracy of 92% and an F1 score of 90%, significantly outperforming GCN's accuracy of 57% and F1 score of 56%. This methodology enables enhanced decision-making by modeling project selection as a dynamic relational network, reducing decision uncertainty and improving investment strategies. The practical implications of this study include early-stage project screening, optimized resource allocation, and the development of scalable decision-support systems for construction firms, paving the way for data-driven investment in large-scale infrastructure.

Keywords: Multi-criteria decision-making (MCDM); Project value prediction; Construction investment decision; GraphSAGE; Machine learning (ML).

1. Introduction

Investment decisions have consistently influenced the long-term viability of construction endeavors (Egorov et al., 2018; Munir et al., 2022). Project selection, a pivotal dimension of these investment decisions, conventionally integrates financial analytics, risk profiling, and expert judgment to assess different prospectives within different proposals (Mahad et al., 2020). Nevertheless, selecting from multiple perspective investments remains inherently a multi-criteria decision-making (MCDM) challenge (Amiri, 2010; P. Li et al., 2022; Mehrez & Sinuany-Stern, 1983).

In contemporary practice, decision-makers often adopt structured frameworks, optimization, and decision-support systems to align individual project choices with overarching corporate mandates (Ghasemzadeh & Archer, 2000; Song et al., 2017). Here, MCDM approaches fundamentally addresses the trade-offs that arise when different, and sometimes conflicting, criteria must be assessed within a single decision-making framework. Its strength in examining various proposals has led to extensive applications across a wide spectrum of project environments (Mogbojuri & Olanrewaju, 2023; Pariz et al., 2022; Rouyendegh, 2012). Consequently, scholars have increasingly explored integrated methods, combining MCDM with technological methods like fuzzy logic (Kheyraie et al., 2021), GIS (Hashemizadeh & Ju, 2019; Rębiasz et al., 2014), and system dynamics (Bai et al., 2021). These hybrid approaches allowed more complex ways of accounting for uncertainties and interdependencies, from stochastic economic variables to geographic constraints.

Parallel to these developments, recently there has been an attempt on leveraging machine learning (ML) techniques to enhance project selection and portfolio management (Corsaro et al., 2022; Sezer et al., 2021). most ML research on project portfolio management has centered on numerical optimization (Corsaro et al., 2022) or

* Corresponding author, E-mail: fatemee.mostofi@gmail.com

https://doi.org/10.31462/icearc2025_ce_mng_198

post-hoc performance prediction, leaving a methodological gap concerning how ML could systematically derive preliminary evaluations (i.e., project value ratings) from unstructured or partially structured records. Consequently, there is a clear need to investigate how ML-driven models can be integrated with MCDM principles to improve early-stage project filtering. This gap is particularly salient in construction management, where decisions about whether a proposal is viable are made long before robust cost or engineering data are fully available. By blending ML with MCDM, the sector could realize a more reliable, data-enriched pathway for identifying and prioritizing construction projects likely to yield higher returns and stronger alignment with strategic goals.

In this context, conventional ML methods have also struggled to integrate relational information, thus constraining any complex relational approach like MCDM to construction project selection. Prior studies deployed ML in construction project management but were largely limited to standard models that do not natively capture MCDM factors in networked data, restricting how well they could use geographical or functional interdependencies. This gap has prompted inquiries into more advanced architectures, including graph neural networks (GNNs), which not only digest numeric features but also learn the relational or structural connections between projects and their associated attributes.

Acknowledged for their efficacy in deep learning, graph neural networks became the standard method for addressing relational and connected data (W.-Z. Li et al., 2023). Their functionality included aggregating and disseminating node-level features via defined connectivity mechanisms (Mostofi & Toğan, 2023; Scarselli et al., 2009; Ye et al., 2022). Studies such as those by (Yuan et al., 2021) and (Mostofi, Toğan, Başağa, et al., 2023) confirmed that GNNs, using spatial data, excelled over shallow models like random forests and SVMs (Chen, 2023). The GNN models investigated in construction project management mostly adopted transductive learning, whereby not generalize from the training data to unseen instances; instead, they make predictions based on specific examples that include unlabeled data during the training phase (Rossi et al., 2018).

Developed transductive MLs like graph convolutional network (GCN) (Gao et al., 2023; Mostofi et al., 2022) and graph attention network (GAT) (Mostofi, Toğan, & Tokdemir, 2023; Pan et al., 2022) leverage the relationships among the data points, which are often embodied in graph structures, to make predictions about new data points by inferring from the examples it has seen (Rossi et al., 2018). In contrast, in inductive learning GNN models the algorithm derives a general rule from specific examples within a training set, which then applies to unseen data to make predictions (Rossi et al., 2018). In practice, comprehensive GNN model leverage both inductive and transductive learning methodologies to process data represented in graph form. This is crucial for handling different types of construction projects that may not exactly match the training data but share similar characteristics.

Given that different GNN models are appropriate for different applications (Khemani et al., 2024), there exists a gap to investigate inductive GNN models like GraphSAGE (SAmple and aggreGatE) in context of construction project management. GraphSAGE (Hamilton et al., 2017), in particular, has garnered interest across disparate applications. (Hamilton et al., 2017) introduced it as an inductive system able to generate node embeddings in expansive, evolving graphs, thereby learning to generalize to unseen data points (Hamilton et al., 2017). (Sun et al., 2024) adopted GraphSAGE within a deep reinforcement learning framework to enhance financial portfolio optimization, enhanced the performance and robustness of the proximal policy optimization (PPO) agent on portfolio optimization. Considering graphs as a universal language for describing and modelling complex data structure, (Van Belle et al., 2022) investigated GraphSAGE for fraud detection in credit card networks. In another study (Abdullayeva & Suleymanzade, 2024) adopted GraphSAGE to detect cyberattacks in cloud computing networks, achieved a very high prediction accuracy and F1-scores. In another study, (Verma & Jadeja, 2023) explored GraphSAGE for classifying floor plans, while incorporating centrality metrics like betweenness centrality and clustering coefficients to improve the classification accuracy. Lastly, (Wang et al., 2022) utilized and improved GraphSAGE that accounts for both node and edge features during embedding to process node and edge features for semantic enrichment in BIM models, achieving improved accuracy and efficiency in room type classification tasks. Despite these diverse applications, GraphSAGE had not been fully investigated in construction project management contexts, where relational and temporal aspects can significantly influence a project's success or feasibility.

GraphSAGE as an inductive graph-based learning model is capable of subsampling and aggregating local neighborhood features (Oh et al., 2019). This study models construction projects and their associated investment records as nodes within a graph, connected by edges based on common geographical or regional attributes. This is expected to allow models to effectively handle diverse construction projects by applying learned rules and adapting to new, unseen project data, enriching the models' applicability and effectiveness across various scenarios.

2. Methodology

The methodology adopted in this study focused on integrating GraphSAGE into a multi-criteria decision-making framework for construction project selection. The approach systematically utilized relational graph modeling to evaluate construction projects, and their associated investments based on geographical and temporal attributes.

GraphSAGE was selected due to its inductive learning capability, which allowed embeddings for unseen projects without retraining the model, and its efficient neighborhood sampling, which made it particularly suited for large-scale, globally distributed construction datasets.

2.1 Data collection and preprocessing

Data for this study was sourced from records related to investments in diverse construction projects across various global regions. The dataset included both essential identifiers (e.g., project IDs and names) and a detailed range of features such as project stages, estimated values (in billion USD), timelines (announcement and construction phases), and location-based attributes. These records also captured contextual descriptors, such as business development ratings, geographical specifications, and types of construction work required.

To ensure data quality and relevance, an initial screening of construction projects was conducted based on primary selection criteria established by senior management experts. These criteria encompassed factors such as geographic proximity, alignment with core technological expertise, and historical success in similar projects. Each project was assigned a “project value” score on a scale of 1 to 5, where only projects rated 4 (“high value”) or 5 (“very high value”) were retained for further analysis. This refinement process reduced the dataset to approximately 30,000 entries, concentrating the analysis on projects with significant potential and strategic fit.

Further filtering was performed to focus specifically on energy-related projects, encompassing renewable and non-renewable energy infrastructure, reducing the dataset to 2,906 entries. Key features such as “project name,” “geographical region,” “construction timeline,” and “project scope” were standardized and consolidated into a single “Explanation” column to capture textual insights critical for accurate evaluations. This preprocessing ensured consistency and maximized the availability of relevant data for modelling.

2.2 Graph construction

The pre-processed dataset was transformed into a graph structure, where each construction project was represented as a node, and edges were created based on shared regional or contextual attributes. Specifically, nodes represented individual construction projects, while edges connected projects within the same geographical region to capture shared economic, political, and infrastructural contexts. For instance, projects in Asia were connected within a regional subgraph. A source target dataset was used instead of an adjacency matrix to define the connectivity among nodes, and a two-dimensional tensor (edge index) was created to specify edges in the PyTorch Geometric framework.

The resulting graph captured relational dependencies across 13,399 projects spanning eight global regions: Asia (3,514 projects), North America (2,918), Europe (2,706), MENA (741), Oceania (728), South America (526), Africa (398), and South and Central America (31). To preserve privacy, sensitive data such as specific city names were anonymized using generic mapped identifiers.

2.3 Feature engineering and input preparation

The graph model’s input features were standardized to ensure compatibility with the GraphSAGE architecture. Feature columns, excluding temporal attributes (construction start quarter) and class labels (project value), were normalized and converted into PyTorch tensors. Here, node features (**X**) were employed as a matrix where rows represented projects and columns corresponded to standardized attributes. The class labels (**Y**) was used as a vector indicating whether a project was categorized as high or very high value, encoded as binary labels (0 and 1, respectively). Uniform weights of 1.0 were assigned to edges to indicate basic connectivity. The data object was structured in the PyTorch Geometric format and loaded onto a GPU-enabled computing device for efficient processing. Rolling windows were introduced to simulate temporal dynamics, enabling the model to evaluate new projects based on past and ongoing data. Fig. 1 illustrate the input network and the number of each premium and high-value investment labels in utilized dataset.

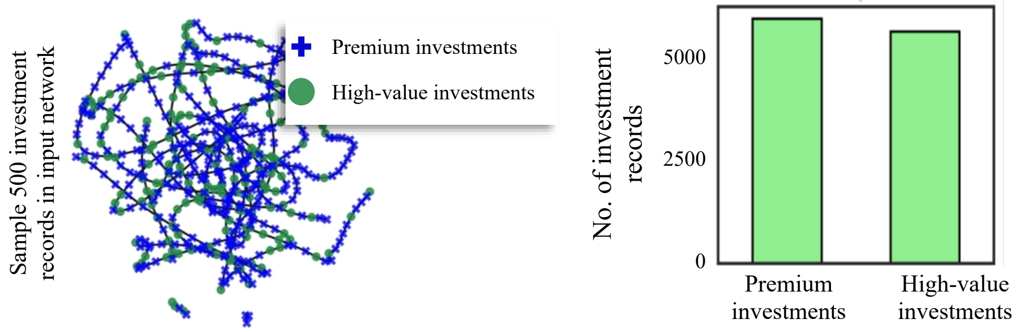

Fig. 1. Premium and high-value investment decision labels.

Temporal data, represented by the “construction start quarter” column, was transformed into a numeric scale to facilitate chronological slicing. The dataset was further segmented into training, validation, and testing sets, ensuring that the temporal ordering of projects was preserved. Fig. 2 displays the number of investment records across training, validation, and test sets.

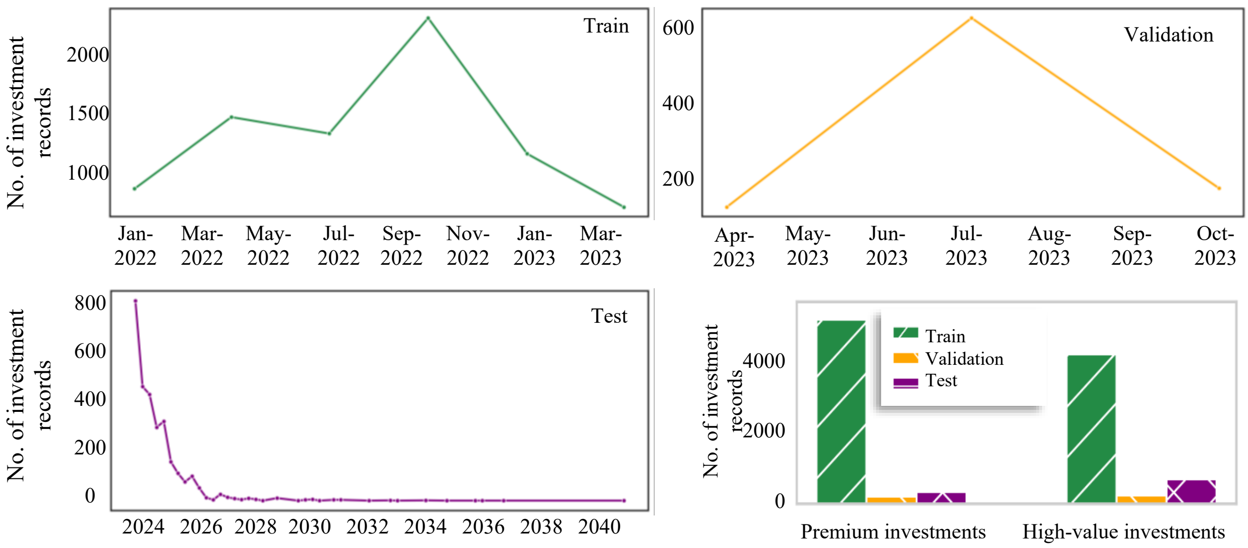

Fig. 2. Distribution of the investment records into training, validation, and test sets across construction start years.

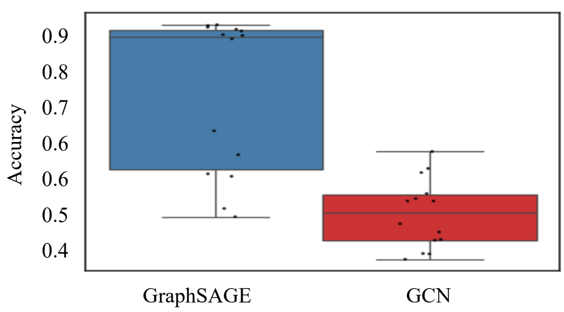
2.4 Model training and evaluation

The GraphSAGE model was trained using a supervised learning approach applied to graph data. Initially, the input network was converted into a PyTorch Geometric Data object, incorporating node features, class labels, and edge indices. GraphSAGE utilized the feature information from neighboring nodes to generate embeddings, enabling relational learning.

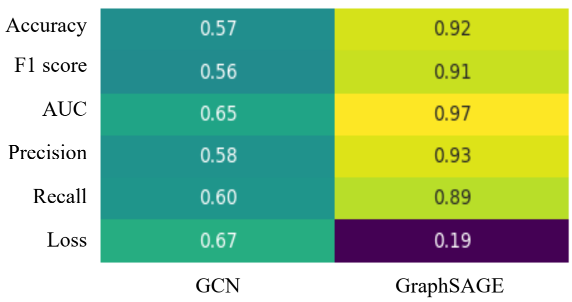
The parameters of the GraphSAGE and benchmark GCN models were tuned iteratively with different learning rates, ranging from 0.1 to 0.0001, and dropout rates from 0.1 to 0.9. Both models were trained with a cross-entropy loss function, 64 neurons, 0.005 weight decay, and a 0.2 dropout rate. The most accurate GCN configuration was achieved with a batch size of 8 and a learning rate of 0.001, while GraphSAGE performed best with a batch size of 64 and a learning rate of 0.01. The models were evaluated using accuracy and F1 score metrics, showing GraphSAGE's superiority over the baseline GCN model.

3. Results and discussions

Fig. 3 the prediction performance of the GraphSAGE and GCN models across various parameter configurations (Fig. 3a), highlighting their respective best configurations (Fig. 3b). Both models were iteratively tuned using multiple parameter combinations, each assessed using accuracy and F1 score metrics.



(a) Prediction performance across different model configurations.



(b) Prediction performance of the most accurate configuration.

Fig. 3. Prediction performance of GraphSAGE and GCN models, (a) across various parameter configurations and (b) for their best-selected configurations.

As depicted in Fig. 3(a), the performance of both models varied across parameter configurations, but GraphSAGE consistently outperformed GCN. The most accurate configuration for GraphSAGE utilized a batch size of 64, a learning rate of 0.01, and a dropout rate of 0.2. Conversely, GCN performed best with a batch size of 8, a learning rate of 0.001, and the same dropout rate of 0.2.

Fig. 3(b) highlights the best configurations for each model, further illustrating the gap in their performances. The GraphSAGE model demonstrated superior predictive performance over the baseline GCN model across a variety of configurations, where results consistently favored GraphSAGE. Under the optimal settings, GraphSAGE achieved a prediction accuracy of 92% and an F1 score of 91%, outperforming the GCN model, which achieved an accuracy of 57% and an F1 score of 56%. Additionally, GraphSAGE showed more balanced performance across precision (93%) and recall (89%), whereas GCN's metrics were less consistent. The area under the curve (AUC) for GraphSAGE was 97%, significantly higher than GCN's AUC of 65%, reflecting GraphSAGE's superior ability to distinguish between premium and high-value investment decisions.

In terms of training duration, GraphSAGE achieved its best performance in 253 epochs, whereas GCN converged in 249 epochs. However, the training time for GraphSAGE was slightly faster at 3.31 seconds compared to GCN's 3.42 seconds, demonstrating its computational efficiency despite its superior performance.

Overall, GraphSAGE's ability to leverage relational features through neighborhood aggregation proved critical in delivering robust and consistent predictions. Its inductive learning capabilities allowed it to generalize better across unseen nodes compared to the transductive nature of GCN. This was particularly valuable given the graph structure's inherent sparsity and the heterogeneity of project attributes.

4. Conclusions

The selection of construction projects remains a complex challenge due to the interactions among cost, timelines, strategic objectives, and environmental factors. Existing GNN methods, like GCNs and GATs have limitations due to their transductive nature, which requires all nodes to be present during training, making them unsuitable for dynamic and evolving datasets. To address these gaps, this study proposed the use of GraphSAGE, an inductive graph neural network capable of learning from graph-based relationships and generalizing to unseen projects without retraining.

The methodology transformed construction project data into a graph structure, where nodes represented projects and edges captured shared regional or contextual attributes. The dataset was processed to include approximately 11,399 projects across eight global regions, with temporal attributes incorporated to simulate real-world scenarios. GraphSAGE was trained and evaluated using a rolling-window approach, ensuring that the model could adapt to new data while maintaining temporal integrity.

The results demonstrated the clear superiority of GraphSAGE over GCN in predictive performance. GraphSAGE achieved 92% accuracy and an F1 score of 91%, significantly outperforming GCN, which achieved only 57% accuracy and an F1 score of 56%. The AUC for GraphSAGE was 97%, compared to 65% for GCN, indicating its ability to reliably distinguish between high-value and low-value projects. GraphSAGE outperformed GCN significantly, delivering higher accuracy, precision, and recall. Its inductive learning capabilities and neighborhood aggregation approach provide a scalable and adaptable solution for complex and dynamic construction project datasets, marking a significant step forward in the field.

Cost estimation in early design stages using regression model-Kuwait case study

Khaled Alrasheed[1*], Ehab Soliman[1]

[1] Kuwait University, Department of Civil Engineering, 17067 Kuwait, Kuwait

Abstract. The project generally passes through many steps, and the cost estimate is supplemented in each step. The accuracy of the cost estimate is crucial to the construction project's success. In the design stage, the accurate cost estimate leads to good cost, resource allocation, value engineering, project feasibility study, and stakeholders' financial management procedures proposed. The design starts by identifying the schematic design and general design layouts with no detailed design. In that design stage, the cost estimate is highly different from the actual cost resulting after the design details or the construction phase. In this study, a regression model is proposed to assist stakeholders in predicting the project cost based on some of the general criteria that can be available in the stage of schematic design. The model takes into consideration criteria such as land area, gross area, excavation volume, and estimated concrete volume. The model will be built based on real gathered data from several construction projects in Kuwait. The model used a multi-regression technique. The model was verified through the root mean squared error. This model can be used as a primary estimator for anticipated construction project costs in its early stage of design.

Keywords: Cost estimate; Design; Multi-regression; Validation

1. Introduction

Estimating costs during the early phases of a construction project is both critical and challenging for all stakeholders involved. Accurately forecasting project expenses while minimizing deviations from actual costs remains a formidable task. Despite decades of research dedicated to enhancing cost estimation accuracy, significant challenges persist due to the influence of fluctuating raw material prices, labor costs, and equipment rates in an ever-volatile market. These uncertainties can have profound implications for a project's ultimate success.

The success of a construction project is a primary concern for both owners and contractors, as it hinges on effective budget allocation and resource management. Accurate cost estimation is vital to these processes and impacts decision-making throughout the project's lifecycle. However, the precision of cost estimates is influenced by numerous factors. A survey by Ibrahim and Elshwadfy (2021) categorizes these factors into three main groups:

- Consultants, Design Parameters, Information & Estimators: This category includes factors such as the clarity and level of detail in project documentation, the expertise of the estimator, and the availability of accurate cost data.
- External Factors: These include market-driven variables such as the cost and availability of materials and complexities related to the importing process.
- Contractor Characteristics: This category highlights the contractor's experience with similar projects, which significantly affects their ability to provide accurate estimates.

Various cost estimation techniques are used during the early stages of construction projects, ranging from simple approaches, like the square meter method, to advanced methodologies incorporating machine learning. These include Artificial Neural Networks (ANN), Fuzzy Logic, Genetic Algorithms (GA), Regression Analysis (RA), and Case-Based Reasoning (CBR), Kim et al, 2012. This research work has two objectives:

- Develop a multi-regression model to predict project budgets based on predefined factors using real data during the early design stages.
- Validate the accuracy and reliability of the proposed model.

2. Background

2.1. The importance of cost estimation in the construction industry

Cost estimation is a critical process in the construction industry, as it helps predict the time, costs, and resources needed to achieve a project's objectives. According to Dysert (2003), cost estimation involves systematically quantifying financial resources and setting a budget based on the project's scope and expected investment. Hatamleh et al, 2018 defined cost estimation as the process of determining the project's scope of work and identifying the financial resources required to meet the project's goals, from initiation to handover.

Hashemi et al 020 identified two main components in the final cost estimate of any construction project: project cost and markup. Layer et al 2002 further classified project costs into direct and indirect costs. Direct costs refer to expenses directly tied to the project, such as labor, materials, equipment, and subcontractor services. These costs can be accurately estimated if there is sufficient information about site conditions, required resources, and the construction methods to be employed. Despite its importance, cost estimation is not always straightforward, particularly during the early stages of a project, where limited information can complicate the process Hegazy, 2002.

2.2. Factors affecting accuracy in the cost estimation process

The accuracy of a cost estimate depends on several factors that influence the overall estimation process. Various researchers have identified different parameters and models to ensure accurate cost predictions. Hyari et al 2016 interviewed with senior engineers in Jordan, concluded that four main factors affect cost estimation accuracy:

- Project Type – the nature of the construction project, such as residential buildings, transportation infrastructure, or land development.
- Engineering Services – including design, construction, or integrated design and construction services.
- Project Location – the geographical context, which can impact costs due to local conditions or regulations.
- Project Costs – covering all expenses associated with the project site.

Conversely, Gunaydın et al 2004 identified other key factors impacting building project costs, including the total building area, floor area ratios, number of floors, floor types, slab types, foundation types, and structural system cost per square meter. Kim et al 2012 proposed additional factors for predicting building project costs, such as land area, building area, gross area, land-to-building area ratio, structural type (e.g., reinforced concrete, steel), and building type (e.g., residential, retail, cultural, educational).

In the context of residential buildings in Korea, Ji et al 2012 highlighted factors such as unit size, number of units per floor, building type, and stair-core design. These findings suggest that the factors influencing the cost estimation process can vary by location and are highly dependent on the specific engineering characteristics of the project.

2.3. Key determinants of cost estimation accuracy

The level of accuracy in cost estimation is influenced by several factors, some of which have been ranked by various researchers. Hatamleh et al 2018 identified the following factors as critical to the accuracy of cost estimates:

- Clear and detailed drawings and specifications
- Experience of the construction project personnel
- Equipment availability, cost, and performance
- Project complexity
- Clear scope definition
- Accuracy and reliability of cost data

Enshassi et al 2013 ranked the factors affecting cost estimation accuracy differently, placing particular emphasis on:

- Material prices, availability, supply, quality, and imports
- Border closures and trade blockades
- The experience of the project team with the specific type of construction
- The experience and skill level of the consultant
- Detailed project drawings and specifications
- Chimdi et al 2020 further expanded on these factors by adding variables such as material price volatility, accessibility, source, and quality; the consultant's expertise and ability; economic conditions in the country; and the financial stability of the client.

Ultimately, the accuracy of the cost estimation process depends on the quality of the available project information and the estimation techniques employed at the time.

2.4. Techniques used for cost estimation: prediction models

There are several techniques employed to predict the final cost of a construction project during the early stages of the tender phase. These techniques primarily fall into two categories: qualitative and quantitative approaches, both utilizing historical and technical data.

- Qualitative techniques rely on the estimator's experience and judgment, often using heuristics (rule-of-thumb methods) to make educated predictions based on similar past projects or expert opinion.
- Quantitative approaches, on the other hand, involve the collection and analysis of data from previous projects to establish cost predictions through various estimation models. The accuracy of these models depends on how accurately the data is gathered, the type of project for which the method is applied, and the specific input factors used in the estimation process.

Quantitative estimation methods can be broadly classified into three main categories: statistical models, analogous models, and analytical models (Figure 1).

Firstly, Statistical Models (also known as parametric models) rely on mathematical formulas and relationships to predict costs. These models typically follow a top-down approach, where the estimator establishes correlations between input factors (e.g., project size, materials, labor) and the final project cost. This approach aims to use known data to predict future costs with a reasonable degree of accuracy.

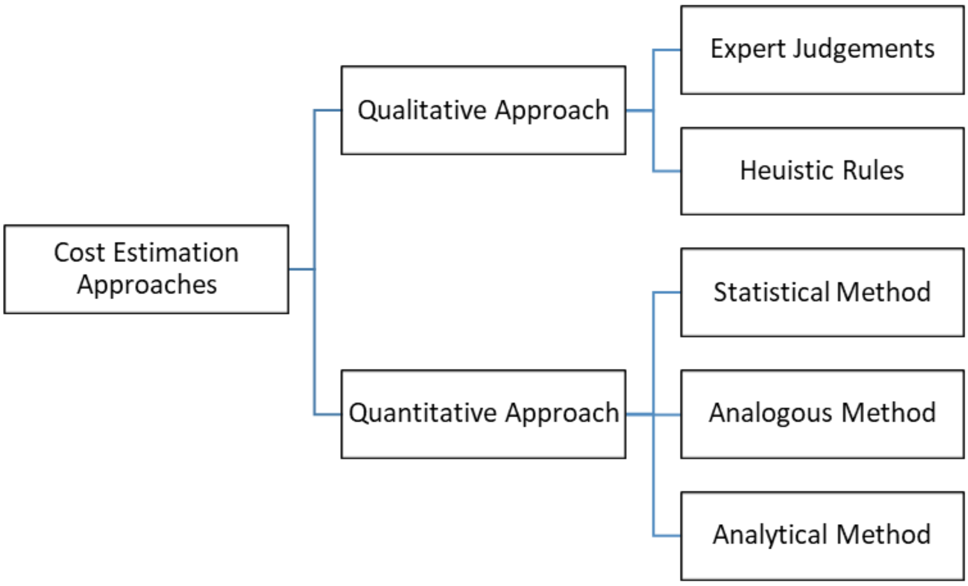

Fig. 1. Cost Estimation Approaches

Secondly, analogous models rely on data from previous projects that are similar in function, design, or other key characteristics such as size, capacity, location, and cost constraints. These projects serve as analogies for the new project. According to Rad 2001, the analogous model is one of the simplest cost estimation tools. It is commonly used in the early stages of a project, such as during the order of magnitude estimate, conceptual estimate, or ballpark estimate phases. These rough estimates help evaluate the feasibility of different project options and allow for the screening of alternatives based on high-level cost projections.

Finally, analytical models take a more detailed approach to cost estimation. They break down the project into its individual components and processes, estimating the cost of each factor and then using a bottom-up approach to sum these costs and determine the final project estimate. Hashemi et al 2020 noted that analytical models typically provide higher accuracy than both statistical and analogous models. However, they require extensive data collection and input from various processes to ensure the most accurate predictions. The accuracy of these models depends heavily on the quality and quantity of the data used.

2.5. Cost estimation in the design phase

Molcho et al 2014 emphasized that approximately 70% of the total project cost is determined during the early design stages, although designers often struggle to provide accurate cost estimates at this point. As the design evolves and more cost-related information becomes available, the cost model becomes progressively more precise. The design phase is typically divided into several stages: conceptual/schematic design, detailed design, construction documentation, bidding, and construction (Manfredonia et al, 2016).

Samphaongoen 2010 categorized cost estimates into three types: conceptual, semi-detailed, and detailed. Each type has its own level of accuracy, with conceptual estimates having an error margin of around 20%, semi-detailed estimates offering a moderate level of precision, and detailed estimates being the most accurate, with an error margin as low as 5%. These variations in accuracy reflect the increasing availability of detailed project information as the design progresses.

3. Methodology

To achieve the research objectives, the study followed these key steps:

- Literature Search: The first step involved conducting a thorough literature review. This was done through desk research, focusing on keywords relevant to the research objectives, such as "cost estimate factors," "cost estimate accuracy," "cost estimation in the design phase," and "techniques for cost estimation." The resulting research works were then analyzed to provide the necessary background and form the foundation for the literature review.
- Identification of Factors for Early Design Stages: The next step was to identify the factors available during the early design stages. In the conceptual or schematic design phase, only a limited number of criteria can be used to estimate costs accurately. The chosen factors for this study are:
  a. Land Area: Land area is typically known before the design phase begins. This area is crucial as it serves as the control area for the project and is measured in square meters (m^2).
  b. Gross Area: Gross area refers to the total built area of the project, which can be determined early in the design process. It can either be directly calculated from the design space program or be constrained by local regulations set by governmental agencies or municipalities. This area is also measured in square meters (m^2).
  c. Excavation Volume: Excavation volume is calculated once the foundation system is defined. After the space program and initial design layouts are approved, the proposed foundation system allows for the calculation of excavation volume, measured in cubic meters (m^3).
  d. Concrete Volume: Concrete volume can be estimated after the general architectural plans and layouts are approved. This volume is measured in cubic meters (m^3).

  These four variables—land area, gross area, excavation volume, and concrete volume—will serve as the independent variables in the multiple regression model used to predict the project budget.
- Data Collection for Real Projects: The next step was to collect data from real construction projects. This data was obtained by contacting several governmental agencies and consulting offices. The data collected were derived from a list of projects that had already completed the design and awarding phases. For each project, the following data points were collected:
  - Project Budget
  - Gross Area (in m^2)
  - Land Area (in m^2)
  - Excavation Volume (in m^3)
  - Concrete Volume (in m^3)

  The collected data spanned a variety of project types, functions, and ownership structures. A total of 22 projects were included in the study. The dataset included several types of projects:
  - Vertical Buildings (e.g., high-rise buildings)
  - Multi-building Projects (e.g., multiple small buildings under one contract)
  - Horizontal Buildings (e.g., low-rise buildings with large horizontal areas)

  The projects were also categorized by ownership type: governmental and private. Figure 2 illustrates the distribution of project types and ownership categories.

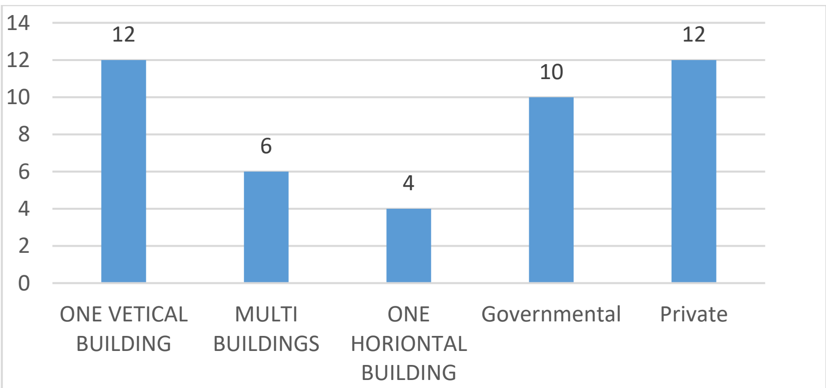

Fig. 2. Project demographic analysis

The collected data spans projects constructed over several years, from 2009 to 2015. Since the projects vary in their tendering periods, a baseline date of 2015 was chosen to standardize all project costs to a common reference point. This ensures consistency in cost comparisons across different years. To adjust the costs to the baseline year, the inflation rates published by the Central Bank of Kuwait were applied, allowing for the conversion of all project costs to 2015 values

- Development of the Multiple Regression Model: The first step in the methodology is to develop a multiple regression model using the collected data. The model will predict the project budget (in Kuwaiti Dinars (KWD), with 1 KWD approximately equal to 3.3 USD) based on four independent variables:
  - Land Area (m^2)
  - Gross Area (m^2)
  - Excavation Volume (m^3)
  - Concrete Volume (m^3)

  The project budget will serve as the dependent variable, while the above four factors will be the independent variables. Since the majority of the collected projects are high-rise buildings, a separate regression model will also be developed specifically for this subset of projects to account for any project-specific characteristics that might affect cost estimation.
- Model Validity Check: Once the regression models are developed, it is essential to check their validity and reliability. To assess the solidness of the models and their applicability for future use, the following steps will be taken:
  - Residual Analysis: The residuals (the differences between the observed and predicted values) will be calculated for each project. This will help assess the model's accuracy and whether the errors are randomly distributed, which is a key assumption in regression analysis.
  - Root Mean Squared Error (RMSE): The RMSE will be calculated to measure the model's prediction error. A lower RMSE indicates a more accurate model, while a higher RMSE suggests that the model's predictions deviate more from the actual values. This will provide an overall evaluation of the model's predictive power and reliability.

  These steps will ensure that the developed regression models are robust, applicable to different project types, and capable of providing reliable cost estimates for new projects based on the available input variables.

4. Analysis and discussion

4.1. Development of the multiple regression model

In this study, a multiple regression model was developed to predict the estimated project budget based on several key independent variables. The choice of these variables is grounded in the early design stages of a project, where they serve as primary factors influencing the overall cost estimation. Specifically, the independent variables used in the model include:

- Land Area (m^2): The total area of land on which the project will be built. This is typically known early in the design phase and serves as a key cost determinant.
- Gross Area (m^2): The total area of the building or structure, which can also be estimated during the conceptual design phase.
- Excavation Volume (m^3): The estimated volume of excavation required for the foundation, which is calculated after the preliminary design and structural system have been proposed.
- Concrete Volume (m^3): The estimated volume of concrete required for the project, which is also determined early on, once the architectural plans and layouts are approved.

These independent variables were chosen because they are among the first elements to be defined during the early design stages. Architectural sketches and plans are usually developed first, followed by the proposal of a structural system. From these early design steps, the excavation volume and concrete quantities are calculated, making them essential factors in estimating the final project budget.

The regression model was built using Microsoft Excel to analyze the collected data. The dependent variable, project budget (measured in Kuwaiti Dinars, KWD), was predicted based on these key independent variables. Figure 3 below presents the results of the multiple regression analysis.

SUMMARY OUTPUT

Regression Statistics	
Multiple R	0.992309172

Fig. 3. Multiple regression model for all samples

As shown in Figure 3, the Adjusted R-squared value is 98%, which indicates that the model explains 98% of the variance in the project budget based on the independent variables. This is a strong result, as an adjusted R-squared value above 95% typically suggests a good fit, meaning the model effectively represents the data from the sample and provides a reliable prediction of the project budget. Additionally, the Significance F value is almost zero, which is well below the 0.05 threshold. This indicates that the overall regression model is highly significant and that the relationships between the independent variables and the project budget are not due to random chance. In other words, the model is reliable, and its coefficients provide meaningful insights into the factors influencing the project budget. These results further reinforce the solidness of the regression model, confirming that it is a reliable tool for predicting construction project costs based on the key factors identified in the early design stages. This model equation can be written as in Equation 1:

$$\begin{aligned} \mathrm{EBC} = &-2340375.831 + 471.1013372 * \mathrm{LA} - 1677.758895 * \mathrm{GA} \\ &-142.792466227889 * \mathrm{EV} + 8511.036254 * \mathrm{CV} \end{aligned} \tag{1}$$

where, EBC: estimate budget cost, LA: land area (m^2), GA: gross area (m^2), EV: excavation volume (m^3), and CV: concrete volume.

As shown in Figure 3, the p-value is 0.023968 for the concrete volume, indicating that this variable is the most significant variable presented by the model.

4.2. The model for high-rise buildings

As mentioned in Figure 2, the maximum number of gathered samples was from one high-rise building project type, the samples of high-rise buildings have been chosen to build a separate multiple regression model. Figure 4 shows model properties as a result of Excel.

Fig. 4. Multiple Regression Model for High-Rise Building Samples

As shown in Figure 4, the Adjusted R-squared value is 98.7%, indicating that the model explains 98.7% of the variance in the project budget based on the independent variables. This is an excellent result, as an adjusted R-squared value above 95% typically suggests that the model fits the data very well, with minimal unexplained variance. Therefore, the model is highly effective in predicting the project budget and provides a strong representation of the surveyed data. Additionally, the Significance F value is almost zero, which is well below the critical threshold of 0.05. This signifies that the overall regression model is statistically significant, meaning the relationships between the independent variables (land area, gross area, excavation volume, and concrete volume) and the project budget are not due to random chance. This further reflects the reliability and validity of the model, confirming that it can be trusted for predicting project costs. Together, these statistical results demonstrate the solidness of the regression model, highlighting its robustness and its suitability for accurate cost estimation in construction projects based on the early design parameters. This model equation can be written as the following equation.

$$\mathrm{EBC} = \mathbf{-1780727} \ \mathbf{-3201.88} * \mathrm{LA} \ \mathbf{+3872.875} * \ \mathrm{GA} \ \mathbf{+377.407} * \ \mathrm{EV} - \mathbf{12237.7} * \mathrm{CV} \tag{2}$$

As shown in Figure 4, the p-value is **0.005646** for the concrete volume, **0.002401** for gross area**,** indicating that this variable is the most significant variable presented by the model values.

4.3. Model validation

To validate the developed multiple regression model for high-rise buildings, two methods were used: residual analysis and the calculation of the Root Mean Square Error (RMSE).

- Residual Analysis: Residuals are the differences between the actual project budget (surveyed value) and the predicted budget (value obtained from the regression model). By calculating the residuals, we can assess how accurately the model predicts the actual costs. If the residuals are small, this indicates that the model's predictions are close to the actual values, supporting its validity. The average residual percentage for the high-rise building projects was found to be 1.5%, which is relatively small. This suggests that the model provides highly accurate predictions, with minimal deviation from the actual project costs. A small residual percentage is a strong indication that the model is well-calibrated and reliable.
- Comparison of Actual vs. Predicted Values: Figure 5 compares the actual project budgets and the model-predicted budgets for the high-rise building projects. The close alignment between the two sets of values further confirms the solidness of the model. The visual comparison demonstrates that the model is capable

of predicting project costs with a high degree of accuracy, making it a reliable tool for cost estimation in the early design stages.

These validation methods—residual analysis and the comparison of actual versus predicted values—demonstrate that the model is both accurate and applicable for predicting project budgets in high-rise construction projects. The small residual percentage and the strong alignment between actual and predicted costs underscore the reliability and effectiveness of the model for use in practical cost estimation scenarios.

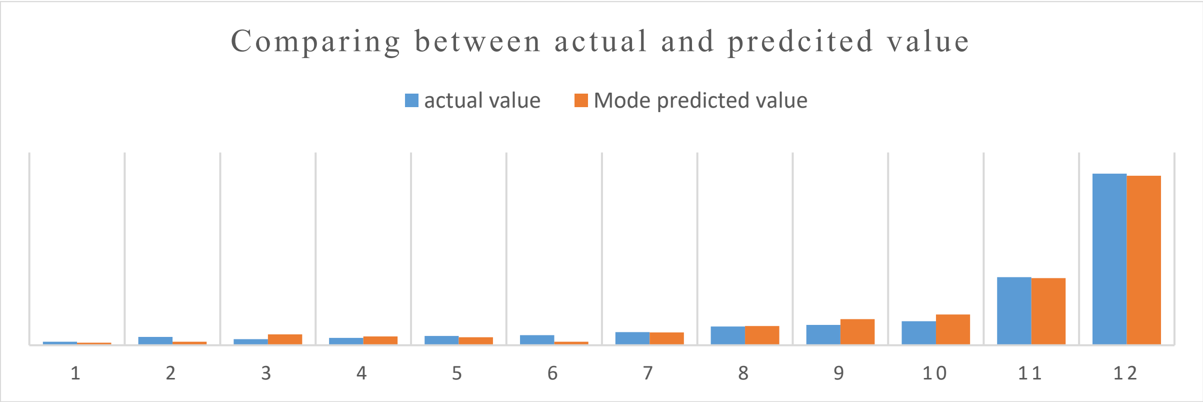

Fig. 5. Comparison between model prediction value and actual values

The model validation will use root mean squared error. This error measures the difference between the predicted value using the model and the actual value used. The root mean squared error can be calculated by the following Equation (3).

$$\text{RMSE} = \sqrt{\frac{\sum_i^n [P - A]2}{N}} \tag{3}$$

where P is the model prediction value, A is the actual value, and N is the total number of model samples used. The Root Mean Square Error (RMSE) for the developed multiple regression cost estimate model was calculated to be 754,235 KWD, which represents approximately 6% of the sample average project budget. This RMSE value is considered acceptable, especially during the early stages of a project, where more uncertainties and limited data are typically present.

According to the American Association of Cost Engineering (AACE) Recommended Practice and Standards (1990), a cost estimate is classified as definitive if the inaccuracy range falls between -5% and +15%. Since the RMSE value for this model is within this range (6%), it confirms that the model's predictions are consistent with the definitive range of cost estimates.

Therefore, the model's results can be classified as falling within the definitive category of cost estimates, indicating that it is a reliable tool for predicting project costs with an acceptable level of accuracy during the early design stages. The fact that the model's accuracy is within the standard industry guidelines further underscores its applicability and validity for use in construction cost estimation.

5. Conclusion

The success of the construction project depends on the level of the cost estimate accuracy, and this level begins in the design stage. Cost estimate in the design stage depends on some general data and information that can be ascertained later. The cost estimate in the design stage has many important aspects, such as feasibility study, bid or not to bid, financial structure preparation, and many other aspects. Two regression models have been proposed to estimate the anticipated project cost in early design stages through collected samples from the state of Kuwait. The first model used data from 22 construction projects, the second model was developed for a selected number of high-rise buildings. The model shows that 98.7% of samples are fitted well in the model parameters. The model results are validated by comparing actual values with model prediction values can be used in construction projects in Kuwait. The model validation will use root mean squared error (RMSE). The calculated RMSE value for this model was (6%), which confirms that the model's predictions are consistent with the definitive range of cost estimates.

Work accident analysis with LLMs: Can LLMs identify liability classifications?

İpek N. Semercioğlu*[1], Mahdis Motamedi[1], Hasan B. Başağa[1,2]

[1] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye
[2] Earthquake and Structural Health Application and Research Center, Karadeniz Technical University, 61080 Trabzon, Türkiye

Abstract. This study investigates the capability of four large language models (LLMs), ChatGPT, Perplexity, Grok, and DeepSeek, to perform accurate stakeholder liability classifications based on expert witness reports of work accidents in the construction sector. Three expert witness reports, originally written in Turkish, were analyzed to assess whether LLMs can accurately determine the responsible parties and assign appropriate liability levels: primary liable, secondary liable and non-liable. The findings reveal that while the LLMs consistently identified primary liable parties, particularly employers, their performance varied significantly in detecting specific roles and assigning detailed liability classifications. Notably, models frequently struggled with accurately attributing liability classifications and recognizing involved parties mentioned explicitly in expert reports. Additionally, certain models introduced entities not referenced in the original reports, raising concerns about potential inferential inaccuracies. Overall, the results suggest that current generation LLMs possess strengths for preliminary stakeholder identification and broad liability classification. However, their limitations underline the necessity of human oversight, indicating that LLMs should currently serve as complementary tools rather than replacements for expert analysis in high stakes occupational safety evaluations. Further research focusing on tailored fine-tuning and hybrid decision-making frameworks is recommended to enhance the accuracy and reliability of LLM assisted liability assessments.

Keywords: Work accident analysis; Large language models; Grok; ChatGPT; DeepSeek; Perplexity

1. Introduction

Artificial intelligence (AI) has recently gained significant prominence due to its ability to reduce labor and operational effort, thereby offering effective solutions to a wide range of problems across various disciplines. Techniques such as machine learning, deep learning, natural language processing (NLP), large language models (LLMs), image processing, and text-to-image generation are commonly associated with AI advancements. Among these, LLMs trained using NLP methods have become particularly popular following the global rise of ChatGPT in 2022. ChatGPT (2022) is an advanced language model developed by OpenAI that can generate coherent and contextually relevant text based on user prompts, making it capable of assisting in tasks ranging from writing and translation to reasoning and explanation across multiple domains.

Following ChatGPT's remarkable success, several alternative LLMs have also gained attention. DeepSeek (2023) is an open-source LLM developed to support multilingual and code-related tasks with high accuracy and transparency. Perplexity (2022) serves as an AI-powered search and reasoning engine that combines language modeling with real-time information retrieval. Grok (2023), developed by xAI, is designed to offer a conversational interface integrated with real-world data streams, emphasizing real-time assistance and personalization.

While LLMs can assist users in everyday tasks, they are increasingly being applied to more complex problems in fields such as medicine (e.g., analyzing medical records (Thirunavukarasu et al., 2023)), marketing (e.g., content generation and trend analysis (Arora et al., 2025)), law (e.g., case summarization and legal provision interpretation (Kim et al., 2024)), education (e.g., automated tutoring and content explanation (Kasneci et al., 2023)) and finance (e.g., financial statement analysis (Li et al., 2023)). In addition, there is growing interest in their potential use within the field of occupational health and safety, particularly in supporting incident investigations, risk assessment, and regulatory compliance (Sammour et al., 2024; Padovan et al., 2025; Tiikkaja et al., 2024). As

* Corresponding author, E-mail: ipeknaz@ktu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_257

such, LLMs are envisioned to eventually take on a consultative role for occupational safety experts, offering preliminary analyses or hypothesis generation based on structured incident reports.

Based on this perspective, the present study investigates whether LLMs can accurately assess stakeholder responsibilities in work accident contexts. For this purpose, three expert witness reports on work accident were examined to explore the reasoning capacities of LLMs in evaluating involved parties' liability. Rather than focusing on a single model, the study comparatively assesses the performance of four different LLMs: ChatGPT, DeepSeek, Perplexity, and Grok. Each LLM was tasked with reading the expert reports and responding with liability classification to the involved parties. The liability classification labels responsed by the LLMs were then compared against the official conclusions presented in the expert reports. This approach allows the study to evaluate how closely the assessments made by LLMs match the official decisions, and how well these models can replicate the legal reasoning typically used in evaluating work accident cases.

2. Materials and methods

2.1. Materials

This study discusses three expert witness reports on work accidents in construction works. These expert reports were selected to reflect prevalent occupational hazards, as of fall from height and equipment failures, which pose significant risks in construction environments. Each report varies in its content but typically includes documents such as worker complaints, witness testimonies, employer statements, police records, inspection reports, and regulatory provisions, offering a robust dataset for assessing LLM performance in liability analysis. To uphold ethical standards, all identifying details in reports, including names, locations, and specific dates, were redacted. Additionally, the liability classification labels determined by the experts were extracted from the reports, while only general descriptions of the work accidents were taken into consideration.

All reports were originally written in the Turkish language. In each report, the responsibilities of the involved parties in the occurrence of the work accident are classified into three main categories. Since the reports are written in Turkish language, the original liability classification labels are also in Turkish: "*asli kusurlu"*, "*tali kusurlu"* and "*kusursuz"*. In this study, these labels are respectively interpreted as "*primary liable*", "*secondary liable*" and "*non-liable*". Detailed information extracted from the expert reports is presented in the remainder of this section.

Report 1: At a construction site operated by a private construction company (employer), during concrete pouring conducted by a concrete supplier (service provider private company), the hose of the concrete pump went out of control and struck two workers involved in the pouring process. As a result, one worker died and the other was injured. Following the examination of the documents included in the report, the individuals identified by the expert witnesses as bearing responsibility for the work accident were as follows: employer's representative, site manager, occupational health and safety (OHS) expert, representative of service provider private company, two pump operators, deceased worker, foreman and injured worker.

Report 2: During ongoing construction activities at a fish processing facility (employer), a worker lost his balance and fell from a height of approximately three meters.The incident resulted in a non-fatal injury, with no immediate threat to the worker's life. Following the examination of the documents included in the report, the individuals identified by the expert witnesses as bearing responsibility for the work accident were as follows: employer and injured worker.

Report 3: During transportation activities on the access road of a hydroelectric power plant construction site (employer), a road roller lost control and veered off toward the riverbank. The machine eventually came to a halt after colliding with a tree. The operator (worker) was ejected from the vehicle upon impact and was subsequently found deceased worker at the edge of the riverbed. Following the examination of the documents included in the report, the individuals identified by the expert witnesses as bearing responsibility for the work accident were as follows: employer's representative, site manager, OHS expert and deceased worker.

2.2. Methods

The study evaluates four LLMs, ChatGPT (2022), Perplexity (2022), Grok (2023), and DeepSeek (2023), to investigate their ability to act like expert witnesses in determining stakeholder liabilities in work accidents. These models were chosen for their advanced natural language processing capabilities and proven efficacy in domain-specific applications. Respectively, each LLM analyzed the three reports to determine involved parties' liability. To ensure a standardized and objective evaluation framework, each LLM in the study was prompted with an identical input. This approach was adopted to eliminate variability arising from prompt differences and to enable a fair comparison of the models' performance.

Given that the expert reports are written in Turkish, the prompts presented to the LLMs were also constructed in Turkish language. This decision is based on the assumption that consistency between the language of the reports and the input prompts would enhance the accuracy and reliability of the LLMs' liability assessments. While constructing the prompt text, careful attention was given to formulating a message that would be most effectively understood by the LLMs. To ensure harmony with the original language of this study, the finalized prompt was translated into English and is presented below:

"I have three expert witness reports related to work accidents. I will share these documents with you sequentially, and I would like you to act as an expert witness. Based on the content of each report, please identify the stakeholders involved in the occurrence of the accident and classify their level of liability according to the following categories: *primary liable*, *secondary liable* and *non-liable*. Conduct your analyses with a professional approach and present your findings in table format. Additionally, I kindly ask you to provide a brief explanation for the evaluation made in each report."

Finally, for each report, the outputs generated by each LLM were subjected to a cross-comparison to identify similarities, differences, and patterns in liability classification, and the findings were systematically presented.

3. Results and discussion

3.1. Report 1

The expert report assigns primary liability to the employer's representative, site manager, and OHS expert due to their failure to enforce compliance with occupational health and safety legislation, as well as construction specific safety directives. Secondary liability is attributed to the service provider company and the pump operators, citing deficiencies in worker training and non-compliance with established operational protocols. The deceased worker is also deemed secondarily liable for failing to utilize the personal protective equipment (PPE) that had been made available. Foreman and the injured worker are identified as non-liable involved parties. Table 1 presents a comparative overview of the liability classifications responsed by the four LLMs for this specific work accident scenario.

Table 1. Liability classifications responsed by LLMs for Report 1

Liability Classification	Expert Report	Perplexity	ChatGPT	Grok	DeepSeek
Primary liable	Employer's representative Site manager OHS expert	Employer	Employer Pump operators	Employer Pump operators	Employer Employer's representative
Secondary liable	Representative of service provider private company Pump operators Deceased worker	Pump operators Site manager Workers	OHS expert Pump operators	OHS expert Site manager Injured worker etc.	OHS expert Pump operators
Non-liable	Foreman Injured worker	OHS expert Assistant control worker	Foreman Deceased worker Injured worker	Administrative affairs officer Representative of service provider private company Witnesses	Deceased worker

In the analysis of the expert witness report, LLMs demonstrated varying levels of success in identifying involved parties and assigning appropriate liability classifications. While some key stakeholders such as the 'employer' and 'pump operators' were consistently recognized across models, more specific roles cited in the expert report, such as the 'employer's representative', 'foreman' and the 'representative of the service provider company', were often overlooked. Notably, only DeepSeek successfully identified the 'employer's representative', who held primary liability in the expert assessment, while other models either generalized this role as 'employer'.

In terms of liability classification accuracy, the LLMs frequently produced results that did not align with the classifications assigned by expert witnesses in the original reports. The 'OHS expert', for instance, was assigned as primary liable in the expert report, yet was classified as having secondary liability by three of the LLMs, while the remaining model assigned as non-liable. Conversely, the 'pump operators', classified as secondary liable in the expert report, were incorrectly elevated to primary liability by ChatGPT and Grok. These inconsistencies reveal a tendency among LLMs to either misjudge severity or adopt overly cautious classifications.

When comparing the outputs across models, DeepSeek demonstrated an ability to identify the 'employer's representative', showing closer alignment with the expert report. Similarly, although Grok misclassified the level of liability, it was able to identify the 'representative of the service provider private company' as an involved party.

On the other hand, ChatGPT demonstrated strong performance by correctly identifying the ‘foreman’ and the ‘injured worker’ as non-liable parties, in alignment with the expert report. Morover, it is worth noting that Grok and Perplexity introduced stakeholders not referenced in the expert report, which suggests a tendency toward over-interpretation and may have contributed to less accurate liability assessments.

3.2. Report 2

The expert report underscores a complete lack of occupational safety precautions, citing the absence of documented risk assessments, safety training, and the provision of PPE, including fall-prevention systems. As a result, the employer is assigned primary liability for the failure to implement mandatory safety protocols, constituting a violation of applicable health and safety regulations. The injured worker, on the other hand, is classified as non-liable, as the lack of training, PPE, and clearly defined work instructions impeded his ability to fulfill personal safety responsibilities. Table 2 presents a comparative overview of the liability classifications responsed by the four LLMs for this specific work accident scenario.

Table 2. Liability classifications responsed by LLMs for Report 2

Liability Classification	Expert Report	Perplexity	ChatGPT	Grok	DeepSeek
Primary liable	Employer	Employer	Employer	Employer	Employer
Secondary liable	-	Injured worker	Injured worker	Injured worker	Injured worker
Non-liable	Injured worker	-	-	Witnesses Others (OHS Expert, etc.)	-

When evaluating the LLMs’ outputs against the expert report, all four models correctly identified the ‘employer’ as bearing primary liability, indicating a strong alignment with the expert judgment. This consensus suggests that LLMs are capable of detecting direct employer responsibility, particularly when the report includes clear indicators of systemic negligence. However, in contrast to the expert report, all four LLMs attributed secondary liability to the ‘injured worker’, whereas the expert report explicitly classified the worker as non-liable. This observation has prompted the opinion that LLMs may inherently tend to attribute partial liability to directly involved parties.

When comparing the models, Perplexity, ChatGPT, and DeepSeek demonstrated similar behavior by limiting their outputs to the two main stakeholders. However, Grok introduced additional involved parties such as ‘witnesses’ and ‘OHS expert’ under the category of non-liable, which were not referenced in the expert report. This may indicate that, compared to the other LLMs, Grok is more inclined to identify a broader range of parties involved in the accident.

3.3. Report 3

The expert report assigns primary liability to the employer’s representative, site manager, OHS expert, and the deceased worker. The report specifically notes that the road roller was not equipped with a functional door or a seatbelt, and that the worker was not wearing any PPE at the time of the incident. Based on these observations, it can be concluded that the employer’s representative and the site manager failed to ensure proper equipment maintenance and enforce essential safety protocols, thereby violating applicable occupational health and safety regulations. The report also notes that the OHS expert failed to document existing risks or enforce necessary safety measures, and that the worker contributed to the accident by operating the defective machine without objecting to the unsafe working conditions. Table 3 presents a comparative overview of the liability classifications responsed by the four LLMs for this specific work accident scenario.

Table 3. Liability classifications responsed by LLMs for Report 3

Liability Classification	Expert Report	Perplexity	ChatGPT	Grok	DeepSeek
Primary liable	Employer's representative Site manager OHS expert Deceased worker	Employer	Employer Site manager	Employer OHS expert	Employer Site manager
Secondary liable	-	-	OHS expert Worker	Site Manager Worker	OHS expert Worker Joint Health and Safety Unit
Non-liable	-	-	-	Witnesses	Forensic medicine Gendarmerie

When comparing LLM outputs to the expert findings, all models identified the 'employer' as bearing primary liability, aligning with the broader institutional responsibility highlighted in the report. Beyond this, DeepSeek and ChatGPT performed well in identifying 'site manager' as an involved party and also succeeded in assigning the correct liability classification in accordance with the expert report. However, the 'deceased worker', who was explicitly assigned primary liability in the expert report, was entirely omitted from all four LLM outputs. This consistent omission may suggest that LLMs are hesitant to assign primary liability to a deceased individual, possibly due to inherent biases in their training data or ethical safeguards embedded in their response generation.

In terms of liability classification, models frequently reassigned roles with varying severity. For instance, 'OHS expert' was shifted between primary and secondary liability across ChatGPT, Grok, and DeepSeek. DeepSeek uniquely introduced external stakeholders such as 'joint health and safety unit', 'forensic medicine' and 'gendarmerie'.

Across the models, Grok and DeepSeek demonstrated greater stakeholder coverage but also a higher likelihood of introducing involved parties not referenced in the original report. Perplexity demonstrated the most limited perspective, identifying only the employer as an involved party and disregarding all other potentially responsible stakeholders. ChatGPT adopted a moderate approach by identifying relevant stakeholders, however, it failed to accurately assign their corresponding levels of liability.

Across all three expert reports, the models consistently identified the 'employer' as a primary liable involved party, aligning with the dominant attribution of responsibility in construction-related incidents. However, when it came to role-specific stakeholders such as the 'employer's representative', 'site manager', or 'OHS expert', performance varied widely. In future studies, increasing the number of expert witness reports analyzed may allow for more specific and nuanced observations.

4. Conclusions

This study explored the effectiveness of four LLMs -ChatGPT, Perplexity, Grok, and DeepSeek- in performing liability classifications from expert witness reports of construction related work accidents. The results indicate that while LLMs are successful in identifying the main parties involved and assigning general liability classifications, they often have difficulty with more detailed judgments such as determining the level of each involved party's responsibility and correctly identifying specific roles cited in the expert reports.

The consistent ability of models to assign primary liability to employers highlights their potential usefulness as preliminary tools for rapid identification of principal responsible parties. However, recurrent errors, such as the misclassification of non-liable injured workers or the omission of deceased individuals, underscore critical limitations, possibly influenced by inherent biases or ethical filters within model behavior. Given these insights, it can be concluded that although current generation LLMs may assist experts by providing initial assessments or supporting comparative analysis, they are not yet capable of independently delivering fully reliable or legally robust liability evaluations. Their role should therefore be considered complementary to expert judgment rather than a substitute for it. Future research may focus on adapting LLMs more closely to occupational safety and legal reasoning contexts through fine-tuning with domain specific datasets or developing hybrid frameworks that combine AI reasoning with human oversight.

Identification of gaps in civil engineering undergraduate education in Turkey

Ilker B. Alkan*[1], Hasan B. Basaga[1]

[1] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye

Abstract. Civil Engineering undergraduate education is of even greater importance in countries like Turkey, which is located in an earthquake zone and has witnessed major disasters. This is because engineers who graduate with the right education can shape the industry and make cities prepared for earthquakes. In Turkey, the Chamber of Civil Engineers and some researchers have identified a number of shortcomings in undergraduate education. However, these findings are often one-sided and may not fully reflect all perspectives. To accurately identify the shortcomings in undergraduate education, the opinions of both academics and representatives from the private sector are necessary. Furthermore, the opinions of academics who have worked both in Turkey and in developed countries are also of great importance.In this study, in order to identify the shortcomings in civil engineering undergraduate education in Turkey, open-ended interviews were first conducted with private sector employees, and the responses were classified. The first survey was conducted in an open-ended manner to prevent participants from focusing on specific problems based on predefined views. Participants answered general questions such as, "What shortcomings do you think exist in civil engineering undergraduate education?" The new questions that emerged from the classification were then presented to academics who have worked both in Turkey and in developed countries. After conducting interviews with 8 experts, the shortcomings in undergraduate education in Turkey were identified. There were topics where the experts did not agree, as well as topics where all were in agreement. However, the vast majority of experts do not agree with the private sector on the inadequacy of university undergraduate education.

Keywords: Mechanics; Civil engineering education; Undergraduate education shortcomings; Turkiye; Private sector; Academic perspectives

1. Introduction

In Turkey, earthquakes with a magnitude of 7 or higher occur approximately every five years. In the most recent one—the Kahramanmaraş earthquake on February 6, 2023—39,000 buildings collapsed, 53,597 people lost their lives, and 107,213 were injured (Özmen & Varol, 2024). In a country where earthquakes have such devastating effects, it is essential to evaluate all processes related to the construction sector, identify deficiencies, and implement necessary improvements.

Undergraduate education in Civil Engineering is a critical area of research that warrants careful consideration, including the identification and resolution of any existing deficiencies. This is because graduates of this program will eventually hold managerial positions in various disciplines within the industry. Therefore, addressing shortcomings in their education will have positive impacts across all areas of the sector.

To date, numerous studies have been conducted to identify the deficiencies in undergraduate civil engineering education in Turkey. One of the most prominent among these is the study carried out by TMMOB (2024). According to this study, although the undergraduate civil engineering program was among the most popular fields at the beginning of the 2000s, it has rapidly lost both its popularity and significance. This decline in popularity is attributed not only to macro-level factors—such as the reduction of sectoral investments in parallel with economic fluctuations—but also to planning errors, which have negatively affected the programs and driven them into a state of crisis.

According to data from the Council of Higher Education (YOK, 2024), there were fewer than 40 undergraduate civil engineering programs in Turkey at the beginning of the 2000s. However, as of 2024, this number has increased to programs offered in 126 faculties. This rapid expansion in enrollment capacity has occurred not as a result of strategic planning, but rather as an outcome of populist approaches. Today, Turkey is producing more civil engineering graduates than are demanded by the industry.

*Corresponding author, E-mail: ilkerbakialkan@gmail.com

https://doi.org/10.31462/icearc2025_ce_mng_271

In the early 2000s, as in other developing countries, undergraduate civil engineering programs in Turkey gained significance due to extensive infrastructure investments. During this period, graduates had little difficulty finding employment, earned higher incomes compared to graduates of other engineering programs, and consequently, the profession's popularity increased. However, this high level of interest was transformed by decision-makers into an unplanned expansion of enrollment quotas.

Many new universities have launched Civil Engineering programs, and in existing faculties, enrollment capacities have been expanded without increasing the number of faculty members or improving laboratory facilities. In some universities, a second Civil Engineering program has even been established within different faculties. This situation has negatively impacted the quality of education and posed serious risks to the sustainability of the profession.

Since the 2010s, the number of civil engineers in Turkey has increased, while the demand for this profession has followed a downward trend. Particularly after 2018, infrastructure investments have shown a declining trend (Yıldız et al., 2023).

With the enrollment quotas reaching their highest level in 2018, graduates of civil engineering programs have struggled to find jobs or have had to work for low wages. This has led to what can be described as an "inflation of civil engineers" in the country. Due to difficult living conditions and the challenges of finding employment, the Civil Engineering undergraduate program has ceased to be a popular field and has gradually become one of the less preferred programs. At this point, a significant portion of the 126 Civil Engineering programs that have been established either cannot attract any students or are trying to continue with very low enrollment numbers (TMMOB, 2024).

The significant decline in the popularity of the undergraduate program has forced Civil Engineering programs to face an issue they had not encountered before: a student profile with low academic performance. The preference of students with lower achievement levels for this field has negatively impacted the quality of undergraduate education, particularly due to their deficiencies in mathematics and physics.

The study by Demirtürk & Tunç (2021) examined how many mathematics and physics questions students who chose the Civil Engineering program in the university entrance exam answered correctly. The findings clearly reveal a significant decline in the quality of undergraduate programs. For example, in 2018, students who were admitted to the Civil Engineering program at Fırat University were only able to correctly answer an average of 1.12 out of 14 questions requiring basic knowledge of physics.

In the early 2000s, Civil Engineering undergraduate programs were preferred by Turkey's most successful students. However, as a result of planning mistakes made over nearly a decade, these programs have turned into fields chosen by students who lack even basic knowledge of physics.

Another significant issue identified in the study conducted by TMMOB (2024) is the inability to adequately develop laboratory facilities and academic staff in parallel with the increase in enrollment quotas. The study emphasizes that many universities in Turkey lack the minimum laboratory infrastructure required for Civil Engineering undergraduate education. Additionally, due to the inability to meet the need for faculty members, it is noted that many lecturers from outside the department have been assigned to Civil Engineering programs.

In addition to the major problems that have led to a rapid and nationwide decline in the quality of Civil Engineering undergraduate programs, there are also additional issues threatening these programs.

Demirtürk & Tunç (2021) evaluated the civil engineering undergraduate education in Turkey from a curriculum perspective and identified several deficiencies by comparing the curricula of some Turkish universities with those of institutions in developed countries. While this study provides valuable initial insights, expanding its scope could yield more concrete results. In fact, regularly conducting such comparative studies and reviewing curricula annually against international standards would be important to ensure that programs remain up to date. This is especially crucial because curricula in Turkey are often not flexibly adapted to new problems and emerging topics of the modern era. Similarly, Bayram et al. (2015) conducted a study on the adequacy of technical courses in undergraduate education. However, their study focused more on enhancing the understanding of existing courses.

Other researchers who have studied the deficiencies in undergraduate civil engineering education have emphasized the lack of practical training. Karaçor et al. (2021)) noted that students learned more effectively through active learning methods during their internships and capstone projects, which better prepared them for their future professional lives. They also highlighted the need to extend the duration of internships.

Bayer Öztürk et al. (2022), emphasized that undergraduate education should include not only technical subjects but also courses on social issues. In their survey study, they found that 76.9% of the participating fourth-year civil engineering students had not taken a course on Engineering Ethics.

Aydinli et al. (2020) focused on students' readiness and questioned whether those who chose to study civil engineering at the undergraduate level made this decision consciously. Their study revealed that 13% of the students surveyed enrolled in the civil engineering program due to social pressure, despite not wanting to become civil engineers. Furthermore, 31% of the participants had not included civil engineering among their top five university choices, but registered in the program because they were not admitted to the departments they initially preferred.

Although some basic-level studies have been conducted to identify deficiencies in undergraduate civil engineering education in Turkey, a comprehensive assessment that detects and categorizes all deficiencies has not yet been carried out. Although Birinci & Koç (2007) provided a general evaluation compiling these deficiencies, the study is outdated—having been conducted in 2007—and its scope is limited as it relies solely on the opinions of the study group.

The aim of the study presented in this paper is to identify the deficiencies in undergraduate civil engineering education in Turkey. In doing so, the study will compile findings from all previous research conducted on the topic, and further expand its scope and depth through expert opinions.

2. Method

Undergraduate civil engineering programs in Turkey, when compared to those in other countries, unfortunately exhibit a low performance profile. Global rankings of civil engineering programs show that universities in Turkey are not listed among the top institutions. For example, in the 2024 QS World University Rankings, no Turkish university is ranked within the top 100 for civil engineering programs (QS, 2024). Similarly, in the 2024 Times Higher Education rankings, no civil engineering program from Turkey is included in the top 250 universities (THE, 2024). In contrast, programs from countries such as the United States and the United Kingdom rank much higher in these lists.

For Turkey to rank higher in these prestigious rankings, various improvements need to be made. These improvements can be identified by comparing Turkey's civil engineering undergraduate programs with those in developed countries and analyzing the differences between them. This will help pinpoint the specific shortcomings of Turkey's educational system, and strategic steps can be taken to address these deficiencies. Such research could present a significant opportunity to enhance Turkey's international academic prestige.

The most common approach in comparing undergraduate programs is the comparison of written materials and curricula. This method is widely preferred by many researchers and provides valuable data. However, written sources may not always fully reflect the realities of a program. For example, the curriculum of the Civil Technology two-year associate degree program at Gümüşhane University's Keşap Vocational School includes courses such as Statics and Strength, Structural Mechanics, Reinforced Concrete, and Soil Mechanics, which cover the challenging calculations found in Civil Engineering undergraduate programs(Giresun University, 2025). These courses offer similar content when compared to the leading Civil Engineering undergraduate programs in Turkey.

However, when student success profiles are taken into account, it cannot be expected that courses with similar curricula will be delivered with the same quality. This indicates that comparisons based solely on written sources and curricula may not fully reflect the quality of the programs. Therefore, attempting to identify the shortcomings of Civil Engineering undergraduate programs in Turkey solely based on written sources may lead to incomplete and misleading information. To evaluate the effectiveness and quality of the programs more accurately, more comprehensive analyses are required, including student performance, teaching methods, and industry alignment.

In order to identify the differences between Civil Engineering undergraduate programs in developed countries and those in Turkey, expert opinions that are familiar with the education systems and cultures of both countries are necessary. This is because the cultural structure of a program cannot be fully conveyed through written sources, and researchers unfamiliar with the culture may not notice these differences without significant effort. Therefore, identifying the areas in which Civil Engineering undergraduate programs in Turkey are lacking compared to developed countries can only be done by experts who have experience in the educational cultures of both countries.

The depth of the research has been enhanced by the opinions of experts who have either studied, worked, or taught in Civil Engineering programs in developed countries such as the UK, the US, and Japan, as well as in Civil Engineering programs in Turkey. The experts' opinions were gathered through interviews, not surveys, as face-to-face verbal communication is a much more effective method than written communication. At the beginning of the interview, the purpose and objectives of the study were explained to the experts, and their suggestions for future versions of the research were also gathered. To ensure that no information was lost, all interviews were recorded on video, and each interview was transcribed and analyzed individually.

In order for the interview to be conducted within specific boundaries, five different topics were addressed to the participants. These questions were formulated based on feedback received from the industry. The questions are as follows:

- Do you agree with the view that individuals graduating from undergraduate education in Turkey are insufficient in transferring theoretical knowledge to practical knowledge? If you agree, could you explain the reasons for this problem by highlighting the differences between your experiences in Turkey and those in the United States/United Kingdom/Japan?
- Do you think that internship processes in Turkey are not being carried out efficiently? If so, could you explain the reasons for this problem by highlighting the differences between your experiences in Turkey and those in the United States/United Kingdom/Japan?
- Do you think that universities and faculty members in Turkey are less advanced compared to developed countries in terms of collaboration with the industry, and that this negatively impacts undergraduate

education? If so, could you explain the reasons for this problem by highlighting the differences between your experiences in Turkey and those in the United States/United Kingdom/Japan?

- Do you think that students graduating from the civil engineering undergraduate program in Turkey enter their professional careers without sufficient knowledge in social areas such as communication, management, and hierarchical relationships? If so, could you explain the reasons for this problem by highlighting the differences between your experiences in Turkey and those in the United States/United Kingdom/Japan?
- What do you think are the most important shortcomings in civil engineering undergraduate education in Turkey? What needs to be changed or improved? Could you explain the reasons for these issues by highlighting the differences between your experiences in Turkey and those in the United States/United Kingdom/Japan?

The interview process was conducted with 8 experts who have experience in civil engineering undergraduate programs both abroad and in Turkey. Four of the experts have experience in the United States, three in the United Kingdom, and one in Japan. Since the areas of expertise in developed countries may vary, it was considered that their overseas experiences could be in more specific fields such as Construction Management rather than Civil Engineering. However, since these fields are considered within the scope of Civil Engineering in Turkey, experts with experience in these areas were also included in the interview process.

Some experts agreed with each question, while others disagreed. The reasons for agreement or disagreement were asked individually to each expert, and these reasons were taken into consideration in the evaluation. The experts' opinions sometimes contradicted each other, and these differing views were also analyzed. All opinions were compiled into a single text as a unified pool of responses. The process of transcribing the interviews was carried out entirely through the efforts of our research group. Since the experts only shared their own opinions, they are not responsible for any errors or flaws in the final product.

3. Findings and discussion

In this section, the responses provided by the experts are presented under separate headings for each question.

3.1. Criticism of the ınability to transfer theoretical knowledge to practical knowledge

This issue is a common criticism in Turkey. Experienced engineers in the country often express that recent graduates are lacking in applying theoretical knowledge in practice. Industry stakeholders, on the other hand, point out that newly graduated civil engineers are inexperienced in site applications and graduate without being prepared for the industry environment or the conditions of construction sites.

The first of the five questions we asked the experts during the interview addressed this issue. We asked the experts whether there is a gap in the teaching of practical knowledge in undergraduate education in Turkey. The responses provided valuable insights, allowing for a deeper analysis of the issue and enabling it to be viewed from different perspectives.

Out of the 8 participants, 4 disagreed with the criticisms from the industry regarding recent graduates and criticized these expectations. The experts emphasized that it is not the correct approach for universities to directly train engineers to meet industry expectations.

It was stated that the expectations from industry—such as recent graduates being proficient in commonly used software packages and having full command of all stages of site operations—are unrealistic. It was emphasized that engineers who are trained only to meet the current system's needs will lack the capacity to improve or transform that system. Such knowledge and skills were considered more appropriate for technician or technologist profiles. It was argued that engineers should be educated with a strong theoretical foundation to be able to solve future and yet undefined problems.

The experts also criticized the expectation from industry that recent graduates should fully adapt to work processes from the outset. It was emphasized that professional life should be seen as a continuous learning process, and that companies should offer educational and innovative working environments to support this. Otherwise, it was stated that such companies would struggle to compete with their rivals and in the global market. If a company performs the same tasks repeatedly without change or development, it was noted that such a company is likely in need of a technician who already knows the job from day one, rather than an engineer. The view was shared that Turkey should train engineers for innovative and forward-thinking companies that can compete globally. Moreover, expecting new engineers to already know the specific software used in a workplace was deemed an inappropriate approach. It was emphasized that it is unrealistic to teach all industry-specific software and operational procedures during undergraduate education, and that the responsibility to develop such skills lies with the employer.

Some experts pointed out that experienced engineers tend to evaluate recent graduates based on the conditions of their own education period. It was emphasized that access to information has changed significantly and that engineering codes and technical knowledge have become far more comprehensive than in the past. For example, while the Turkish Earthquake Code in force in 1975 was only 63 pages long, it has now expanded to 376 pages.

Therefore, while it may have been realistic for engineering students in the past to learn a 63-page regulation in its entirety, it is no longer realistic to expect students today to memorize every detail of a 376-page modern regulation. In this context, experts argued that rather than memorizing all information, it is more important for students to know how to access information when needed. They also emphasized that students with a strong technical foundation can learn practical skills relatively quickly once they enter the workforce.

Additionally, some experts noted that this issue should not be reduced solely to the structure of undergraduate education. It was stated that new graduates often experience a loss of motivation due to low wages and poor working conditions, and that industry stakeholders harshly criticize young engineers without giving them adequate time to demonstrate their potential. Therefore, criticisms targeting new graduates were described as part of a complex issue with social, cultural, and economic dimensions, making it difficult to resolve.

Four out of eight participants offered suggestions for improving the teaching of practical knowledge within undergraduate education in Turkey. Experts pointed out that such practices have been successfully implemented in developed countries and could also be adapted for Turkey.

Firstly, it was noted that engineering education in Turkey is excessively theoretical, and practical training remains insufficient. Most course content is designed for office-based work, although many engineering graduates end up working on construction sites. Currently, only a few courses cover site management, and experts argued that these are not sufficient to prepare graduates for managing the harsh conditions of construction sites. In contrast, developed countries offer dedicated undergraduate programs in "Construction Management" where students take hands-on courses in site supervision, planning, and project management. These programs also include opportunities for students to work on real-world projects, receive mentorship from industry professionals, and become directly prepared for the sector.

Experts also emphasized the need to improve assessment and evaluation methods. In developed countries, student performance is not measured solely through written exams but also through reports prepared using professional software and tools. This method allows students to demonstrate their knowledge more comprehensively and become better prepared for industry expectations. However, for such a system to be feasible in Turkey, it was noted that class sizes would need to be reduced; while this approach is effective in classrooms of 15–20 students, it poses challenges in large groups of 80–100 students, as is often the case in Turkey.

Finally, it was highlighted that in developed countries, students often begin working part-time in their field during their undergraduate studies. In particular, the high cost of education in these countries compels students to balance their studies with early work experience. This process helps students reinforce their theoretical knowledge through practical experience and better prepares them for professional life upon graduation.

3.2. Evaluation of internship efficiency

In Turkey, the short duration and inefficiency of internship programs are frequently criticized. One of the most significant issues is that some internships are not actually completed in practice but are merely shown as completed on paper. Moreover, in the majority of internships, students are not paid and are assigned passive observer roles, where they are expected to simply watch rather than actively participate. To identify whether such inefficient practices also occur in developed countries and, if so, how they are addressed, expert opinions were consulted. Some experts stated that they had not personally witnessed such ineffective internship examples in Turkey. However, all experts provided suggestions for improving the internship system, which are summarized below.

In Turkey, the internship process typically ends when the student submits their internship report to the university; during this process, neither the company nor the university is actively involved. In contrast, in developed countries, universities and companies jointly manage the internship programs, and internship committees conduct periodic on-site visits to monitor both the company conditions and the student's active participation. Furthermore, in these countries, it is highly unlikely for a company to allow a fake internship. Such behavior poses a reputational risk for the company and is also avoided due to the potential for legal sanctions.

In Turkey, the oversupply of engineering graduates leads companies to view interns as "additional labor" and therefore not value them sufficiently. Conversely, in developed countries, the limited number of engineers and interns fosters an understanding of interns as a strategic investment and potential future employees. In these countries, companies assign concrete responsibilities to interns, closely monitor their performance, and enhance motivation by offering compensation—thus making the internship process more efficient and effective. In Turkey, however, most interns work without pay. Companies that do not perceive any benefit from the process assign students passive observer roles and feel no obligation to pay them. This approach significantly undermines the internship experience and the professional development of students.

In developed countries, the high cost of higher education and living expenses places a substantial financial burden on students. Therefore, many students are compelled to seek paid internships or part-time jobs to support themselves during their studies. This reality increases students' motivation to demand paid internships and encourages companies to offer fair compensation. In Turkey, however, the absence of tuition fees and the fact that students' basic living expenses are largely covered by their families reduce the need to demand payment for internships. This contributes to the prevalence of unpaid internships and weakens students' bargaining power regarding their economic rights.

In Turkey, compulsory internships are usually limited to the summer months and do not exceed a few weeks. In some developed countries, however, an entire academic year may be allocated to internships, or through the "cooperative education" model, students undertake long-term internships during different periods of the year. These practices not only allow students to experience work processes in different seasons but also make internships more attractive and beneficial by providing income. Short and compulsory internships often fail to create effective learning environments, while long-term and flexible internship models enhance both students' professional experience and their motivation.

In developed countries, the rights of interns are clearly protected by law. Companies are obligated to pay interns, provide suitable working conditions, and document the process to ensure traceability. Moreover, internship supervisors regularly monitor the students' daily tasks and performance. In Turkey, due to both legal infrastructure deficiencies and a lack of enforcement of existing regulations, fake internships have become widespread. This situation decreases student motivation and leads companies to undervalue the process. While unpaid internships are prevented by labor laws and effective monitoring systems in developed countries, in Turkey, employing unpaid interns has become a normalized practice. Therefore, similar to the legal obligation to employ persons with disabilities, the regulations surrounding internship employment must be clarified by law and effectively monitored to protect interns' rights.

3.3. Criticism of industry-university collaboration

Some experts do not agree with the criticism that universities in Turkey do not have sufficient collaboration with industry, and they have evaluated the topic from different perspectives. On the other hand, some experts have pointed out that universities in Turkey have areas that need development in this field and have listed these points. Experts who do not agree with the criticism emphasize that the main responsibility for the weakness of university-industry collaboration in Turkey lies with the industrial sector. They argue that the insufficient development of R&D culture in Turkish companies, the lack of vision for developing innovative technologies and methods, and their failure to invest adequately in R&D are key barriers to collaboration. These experts have stated that while academics are willing to share knowledge and research results, companies are not as willing to allocate financial resources for these results. It has been suggested that government incentives could be effective in solving this problem. They reminded that, as in the defense industry example, public support has allowed companies to establish more effective collaborations with universities.

Furthermore, these experts emphasized that it is not correct for universities to become entirely focused on the private sector. They noted that the cultures of the private sector and universities are different, and universities should not be reduced to just training labor for the private sector or conducting R&D. While the private sector expects quick and direct results from research, universities must evaluate the impacts of scientific studies in detail. Therefore, it has been argued that if universities adopt the same cultural structure as the industry, it could weaken the university's originality and its ability to produce science. Experts holding this view have stressed that universities should protect their status and academic freedom; therefore, they did not consider it a deficiency for academics not to engage in industry-specific or mandatory collaborations.

On the other hand, some experts have pointed out that there are areas where Turkish universities need improvement to establish stronger relationships with industry. In Turkey, for a faculty member to be promoted, conducting scientific research is considered sufficient, while the quality of teaching and updating curricula are not taken into account as promotion criteria. This situation may cause faculty members to lack sufficient motivation to reflect industry collaborations in their undergraduate programs, update curricula, and offer innovative courses, even if they collaborate with industry.

In contrast, in developed countries, faculty contracts can be arranged with both research and education-focused terms, and faculty members can be promoted by updating curricula and developing course content. Moreover, in these countries, securing funding for projects and research is also an important criterion for promotion. It has been suggested that Turkish universities could make institutional arrangements to encourage and monitor faculty members in obtaining funding.

In developed countries, there are special units managing industry relations, which contact companies through databases and effectively coordinate processes such as internships and course contributions. Furthermore, these universities regularly meet with industry representatives to keep their curricula up to date and maintain this process in a dynamic and systematic manner. Although similar meetings are held periodically in some universities in Turkey, it has been stated that this process is more limited and irregular compared to developed countries.

Experts have also pointed out that professional chambers play an important role in industry-university collaboration. In developed countries, professional chambers closely follow the course processes in universities and make various suggestions. Universities update their curricula based on these suggestions, enabling them to better respond to industry expectations. In Turkey, while there is some relationship between professional chambers and universities, it is said to be weak and limited.

Additionally, it has been suggested that practices such as private sector managers giving seminars at universities and making better use of alumni networks could better prepare students for industry expectations. In developed countries, the rankings of universities in international rankings are of great importance for institutional prestige. Criteria such as graduate employment rates and employer opinions stand out in these rankings, which motivate universities to enhance the employability of their graduates and establish stronger relationships with the business world. Therefore, in developed countries, industry collaboration in universities has become a structural and sustainable priority.

Some experts have expressed the need to strengthen the R&D centers in universities and stated that companies could carry out research and development activities more efficiently and cost-effectively through these centers. It was highlighted that this process would bring significant benefits to the industry, as establishing in-house R&D systems in companies is a costly and labor-intensive process. In contrast, joint R&D centers to be established within universities and structured on a national scale would contribute to both universities and industrial organizations. Moreover, it has been suggested that increased participation from various sectors in organizations such as Teknofest would enhance the culture of industry-university collaboration.

3.4. Management and communication skills deficiencies

In this study, professionals with more than 10 years of industry experience in civil engineering were asked for their opinions on the shortcomings of undergraduate education. The participants noted that recent graduates particularly show deficiencies in areas such as management, communication, and handling relationships between subordinates and superiors, and stated that these deficiencies should be addressed during the undergraduate education process. The findings were presented to faculty members with academic experience in both Turkish universities and universities in developed countries for evaluation, and expert opinions are summarized below.

Some experts argued that communication problems seen in low-profile firms in Turkey lead to criticism of new graduates. Communication issues such as disrespect, gossip, and blind obedience to authority, commonly observed on construction sites, were mentioned as reasons why new graduates are seen as "incompatible." In this context, it was emphasized that not only universities but also workplaces need to adopt modern communication approaches.

On the other hand, some experts pointed out that Turkish universities need to improve in terms of equipping students with social skills. They noted that communication and leadership workshops, which are part of advanced education systems, help students develop skills such as effective listening, empathetic communication, and team management, and suggested that such practices could provide significant benefits if implemented in Turkish universities.

Experts also emphasized that the written exam-based assessment methods commonly used in Turkey highlight analytical skills but neglect social interaction. In contrast, in the educational models of developed countries, both technical and communication performance are evaluated through project assignments and report presentations, ensuring continuous faculty-student dialogue. These methods were stated to contribute to the development of students' coordination and public speaking skills outside the classroom.

Furthermore, it was mentioned that faculty-student interaction in Turkey is largely limited in crowded classrooms (80–100 students), while in developed countries, the one-on-one guidance, presentations, and feedback opportunities in 15–20 person classrooms help strengthen students' social skills. It was also emphasized that communication and leadership skills should not only be developed at the undergraduate level but must be foundational in primary, middle, and high school periods, and even within the family environment. The university should be considered as the final stage that reinforces and enhances these skills.

3.5. General options of experts

In this section, experts were asked an open-ended question: “In which areas do you observe shortcomings in education?” without adhering to a predefined framework regarding undergraduate education in Turkey. The participants were asked to freely describe the aspects of the program they found weak, and the opinions obtained in this way are summarized and presented below.

The dominant one-size-fits-all educational model in Turkish civil engineering undergraduate programs forces students to take courses from all main branches, even if only superficially. However, in universities in developed countries, after the first year, students choose a specialization, and it becomes possible to focus on specific fields, such as hydraulics or structural courses. The "everything for everyone" approach in Turkey, however, prevents the younger generation of engineers from specializing according to their personal interests and abilities.

Civil engineering undergraduate education in Turkey is still largely shaped within the framework of classical engineering understanding. While the curriculum heavily emphasizes traditional subjects like reinforced concrete calculations, it does not allocate enough space to modern necessities such as construction management, digital construction applications, and virtual laboratory technologies. Sustainability, climate change, and the social and environmental dimensions of engineering are offered only as elective courses in most programs, leading to a lack of sufficient awareness among students in these areas. However, classical civil engineering topics are largely solved problems today. While performing reinforced concrete calculations for a building may offer a satisfying learning process for students, these calculations can now be easily performed by advanced software. Leading universities in the world have largely abandoned investing in classical calculations. When determining their curricula, they consider the interests of scientific funding bodies and their investment priorities, enabling easier access to funding and keeping their education programs continuously updated. At the same time, by following the areas of focus of leading companies in the industry, curricula are shaped according to the needs of next-generation engineering. Today, large firms are still building skyscrapers, but universities no longer need basic knowledge based on fundamental calculations to design such structures. The pursuit of innovation in energy projects, sustainable urbanism, and digital construction makes universities attractive for collaboration. Instead of sticking to old curricula that revolve around solved problems, Turkish universities need to focus on training engineers who can solve the complex, multidisciplinary problems of the new world. It is clearly seen today that students who can see the big picture, think interdisciplinarily, and have the ability to develop solutions to the problems of the new world are more successful, not just those who are good at static and reinforced concrete calculations. Restructuring education programs in this direction has become a necessity, not just a choice.

It is argued that free higher education reduces the value placed on universities and knowledge, and since students do not financially invest in their learning process, their sense of ownership and responsibility remains low.

Quality assurance mechanisms and self-assessment processes in Turkish universities are extremely weak. Universities do not conduct curriculum, resource, and process evaluations internally or through external committees; accreditation processes generally remain formal rather than substantial. In contrast, in many developed education models, departmental committees conduct periodic audits, submit deficiency reports, and follow up with improvement plans.

The lack of institutional accountability is also reflected in the protective structure of state universities. Faculty members or administrative staff can serve for long periods without undergoing performance evaluations, and mistakes and inefficiencies can go unpunished. This "immunity" culture weakens both academic and administrative initiative.

4. Conclusions

In this section, the problems in Turkey's Civil Engineering undergraduate education are presented in bullet points based on the data obtained from interviews with experts and the results of previous studies. The identified problems are the conclusions drawn from the findings of our working group. The experts interviewed are not responsible for the errors or deficiencies found. The identified deficiencies are presented below:

- Every year, more Civil Engineers are graduated in Turkey than needed. The quotas are not created as a result of a proper planning process.
- The mathematics and physics foundations of Civil Engineering undergraduate students are insufficient.
- There is no determination of which laboratory facilities universities should have for Civil Engineering undergraduate education, and these facilities are not periodically inspected for their existence.
- No study has been conducted on which fields of expertise universities should have in their faculty for Civil Engineering undergraduate education, and the qualifications of the academic staff to deliver this education are not inspected.
- The assessment and evaluation system consists solely of written exams, which is insufficient to comprehensively assess all the knowledge students have acquired throughout the semester. Additionally, it does not contribute to preparing students for the workforce or developing their communication skills, as advanced educational systems do with reporting evaluation systems.
- Although the majority of graduates work on construction sites, the curriculum lacks courses focused on site management that students will need during their careers, and the course hours are insufficient.
- The curriculum does not include courses where students, like in advanced educational systems, can collaborate on real projects and perform tasks such as time scheduling and cost calculations, or establish cooperation with industry managers.
- Students cannot gain work experience during their undergraduate education. There is no opportunity for students to spend a year between their 3rd and 4th years in the industry, extending their undergraduate program for this purpose.
- Internships are solely managed by students. The internship process is not conducted in collaboration between universities and industry. University internship committees passively evaluate only the internship report, do not determine the internship placements, do not inspect the internship sites, and do not communicate with the industry during the internship. Furthermore, the committees do not monitor what competencies students should gain during the internship or track these competencies.
- The excess supply of engineers leads to industries viewing interns as a burden. Rather than actively seeking interns, industries accept interns through special requests, do not pay them, and instead of giving them active tasks, they want them to observe passively in the work environment.

- The rights of interns regarding payment are not adequately protected. An unjust environment is created where unpaid interns are employed.
- The inefficiency of internships, the non-payment of interns, and the lack of sufficient supervision by both universities and the Ministry of Labor lead to a widespread phenomenon where internships are reported as completed but are not actually performed.
- The lack of a research and development culture in the industry, and the absence of firms with a vision for leadership or innovation, prevents industries from collaborating with universities on R&D, which indirectly affects the quality of undergraduate education.
- Faculty members can only be promoted through academic research. Curriculum updates and the programming of innovative courses are not criteria for promotion. Unlike in advanced educational systems, faculty members cannot be promoted by producing course content or keeping teaching processes up to date. This results in a low motivation for updating curricula.
- There is no department within Turkish universities that tracks industry relations, keeps records of companies and relationships with managers, offers internship opportunities to students, or ensures industry contributions to courses.
- Turkish universities do not have a systematic curriculum update follow-up program that would allow them to learn about the needs of industry and update their curricula accordingly, or meet with industry and professional associations. While some universities hold such meetings, this process does not proceed continuously or systematically. Curricula that are completely shaped according to industry needs are not supported, and curricula that are outdated and created without listening to the legitimate demands of industry are seen as a problem.
- Undergraduate programs do not include workshops where students can develop their communication and social skills.
- A one-size-fits-all education model is applied in Civil Engineering undergraduate curricula. Students are required to take courses from all sub-disciplines, even if they are not interested in those areas, preventing them from specializing in the fields they wish to work in. This "one size fits all" approach hinders young engineers from specializing according to their personal interests and skills. This lack of specialization also manifests in internships and thesis work.
- The Civil Engineering undergraduate curricula focus on the classical engineering mindset, offering courses on solved problems that all students take, without providing courses that would equip students with the ability to solve new, complex problems or give them knowledge and awareness of future challenges they may face.
- Universities lack internal and external audit mechanisms to inspect their curricula, academic staff, educational conditions, and resources within the department, university, or by other universities.

Each deficiency identified in this study needs to be addressed individually, and valuable findings should be developed for improvements. In an area where so many problems have been identified, it is clear that existing academic work is insufficient. We invite researchers to work in this area for more efficient and effective undergraduate education.

Acknowledgments
We would like to thank Prof. Dr. Ayhan İrfanoğlu, Prof. Dr. İrem Dikmen, Prof. Dr. Ertuğrul Taciroğlu, Assistant Professor Fatih Sütçü, Associate Professor Abdulhakim Zeybek, Prof. Dr. Erkan İstanbulluoğlu, Dr. Zafer Yılmaz, and Dr. Vahaddin Alperen Baki for their valuable insights and contributions that helped us identify the issues and improve the process.

Enhancing tunneling projects with digital twin technology: Applications and benefits across the tunnel lifespan

Abdolsattar Roudini[*1], Melek H. Beşer[1], Serkan İnal[1], Kerim Aydiner[1]

[1] *Karadeniz Technical University, Department of Mining Engineering, 61080 Trabzon, Türkiye*

Abstract. Tunnels are structures utilized across various fields of engineering, ranging from mining, where they serve as the main access points, to civil engineering, where they are used as road tunnels or subway tunnels or for water supply and drainage. Digital twin technology is increasingly being embraced in both mining and civil engineering sectors, as these fields utilize its potential to improve operational effectiveness, safety measures, and environmental sustainability. By generating virtual models of the entire tunnel lifespan, engineers can observe ongoing tunnelling operations in real time, replicate excavation techniques, and anticipate ground reactions. This enables proactive risk management and streamlined decision-making processes. The construction of a tunnel encompasses design, construction, and maintenance phases. For each phase, engineers need to have access to different data to make a decision. Digital twin will be a useful tool for engineers to have a full vision of the project and make an accurate decision. In this paper, the Scopus database is used to collect papers related to the different applications of digital twins in tunnelling projects to give a comprehensive view of digital twin applications in this field, find the gaps that should be filled and suggest future works. Despite substantial advancements, current research primarily emphasizes digital twin applications in the construction and maintenance phases, focusing on real-time data acquisition, risk management, and operational efficiency. By synthesizing the findings, this paper underscores the role of digital twin in streamlining decision-making across all project phases and suggests pathways for extending its application to underexplored areas.

Keywords: Digital twin; Tunneling projects; Tunnel lifespan; Operational effectiveness; Risk management

1. Introduction

Tunnel infrastructure is highly essential and often serves as the foundation upon which modern transportation systems and industrial operations depend. Tunnels also have an extra vital role to play for the mining industry by providing access to ore bodies, improving ventilation, and carrying out haulage operations. In hydropower development, diversion tunnels carry water from reservoirs to turbines, while utility tunnels are used for space wherever water, gas, and data had to be conveyed. Notwithstanding such, because of the strategic importance, such projects often bear upon themselves issues regarding complex designs, construction risks, safety, and large maintenance costs.

Digital twin (DT) technology involves creating a virtual replica of a physical system, which can be used for monitoring, analyzing, and optimizing the real-world counterpart. This technology is increasingly being applied in various sectors to enhance operational efficiency and safety. DT technology can be utilized in various stages of tunneling projects, delivering many benefits throughout the life cycle from design to maintenance. During the design process, DT facilitates the generation of precise virtual representations of tunnels for planning and detailed design verification, which can reveal possible problems before physical construction (Zhang et al., 2024; Zhao et al., 2024). DT also permits simulation of various construction scenarios to check adherence to safety regulations and streamline design decisions without physical trials(Diren & Althen, 2023).

During construction, DT aggregates data from various sources such as IoT sensors, GNSS technology, and 3D modeling to provide real-time monitoring and control, reducing on-site inspection and minimizing errors (Cheng et al., 2024; Xu et al., 2023). Additionally, DT maximizes safety management through continuous monitoring of unsafe habits, machinery status, and environmental conditions, improving overall on-site safety performance(Attar et al., 2024; Zou & Ma, 2023). In Tunnel Boring Machine (TBM) construction, DT applies intelligent geological awareness to predict and manage subsurface conditions, ensuring safer excavation and efficiency (Xu et al., 2023).

Throughout the operation and maintenance period, DT facilitates digital maintenance of tunnels through the integration of surveillance data to create a virtual model of the structure, enabling efficient traffic management,

golden light publishing

rapid accident response, and systematic facility maintenance (Wu et al., 2022). Further, DT architectures for rail tunnels integrate data flow and application processes to enhance the intelligence and efficiency of maintenance operations, including state perception, data analysis, and decision support (Zhao & Ma, 2024). By integrating data from all phases of the tunnel's lifecycle, from design and construction through to operation and maintenance, DT systems provide a comprehensive perspective to guide decision-making and optimize resource allocation (Maxwell & Grasmick, 2021;Wu et al., 2025).

Despite these advantages, full realization of DT in tunneling projects is hindered by challenges related to data integration and standardization among heterogeneous stages and systems, and the need for harmonized standards and improved data collection practices (Li et al., 2024; Zhang et al., 2024). Future research is therefore aimed at integrating emerging technologies such as 5G communications, artificial intelligence, and cloud computing to continue enhancing the functionality and scalability of DT in tunneling applications(Li et al., 2024; Xu et al., 2023).

In the this study, an effort is made to present a comprehensive review of existing applications and advantages of DT technology throughout the whole lifecycle of tunnel projects encompassing the design stage, construction process, operation process, and maintenance stage. The study also categorizes the real-life applications of DT, assesses real-time monitoring and risk reduction ability, and highlights current research trends. In doing so, it also identifies knowledge gaps that already exist, most significantly those related to data integration, interoperability, and lack of representation of DT applications in initial design or terminal maintenance. Finally, this paper provides future research directions by proposing directions for increasing the use of DT and the utilization of future digital technologies such as AI, 5G, and cloud computing in tunneling applications.

2. Research methodology

This research aims to identify current research trends in the application of digital twin technology in tunneling projects across their design, construction, operation, monitoring, and inspection phases. The objective is to gain a clearer understanding of the current state of adoption, the challenges encountered, and the potential future directions of digital twin integration in tunnel engineering. The main steps of the systematic literature review presented in this study include the formulation of research questions, development of the search protocol including query and database selection, definition of screening and inclusion/exclusion criteria, and synthesis and analysis of the retrieved information.

The review focuses on addressing the following research questions:

1- How and within which main phases (design, construction, operation, monitoring, and inspection) has digital twin technology been adopted in tunneling projects?
2- What are the main challenges and advantages reported when applying digital twin technology in tunneling?
3- How has the research and application of digital twins in tunneling evolved over time?

Research question 1 investigates the main lifecycle phases of tunnels where digital twin technology has been applied to better understand the focus areas of current research. Research question 2 aims to capture the main reported benefits and limitations encountered in practical and experimental applications of digital twins in tunneling projects. Research question 3 aims to synthesize the evolution of digital twin applications in tunneling over time and identify trends and gaps for future research.

The search was conducted for publications from the year 2012 up to April 15th, 2025, in the Scopus database, which was selected for its extensive coverage of peer-reviewed literature in engineering, construction, and technology disciplines. The search query used is presented below:

TITLE-ABS-KEY (("digital_twin") AND ("tunnel") AND ("design" OR "construction" OR "operation" OR "monitoring" OR "inspection")) AND (EXCLUDE (LANGUAGE, "Chinese") OR EXCLUDE (LANGUAGE, "German")) AND (EXCLUDE (EXACTKEYWORD, "Wind Stress") OR EXCLUDE (EXACTKEYWORD, "Wind-tunnel Testing") OR EXCLUDE (EXACTKEYWORD, "Air Navigation") OR EXCLUDE (EXACTKEYWORD , "Air Transportation") OR EXCLUDE (EXACTKEYWORD , "Aircraft Models") OR EXCLUDE (EXACTKEYWORD , "Wind Tunnels")

The search targeted articles that mention the digital twin concept explicitly linked to tunneling projects across different lifecycle stages, while excluding studies related to wind-tunnel testing, aviation, or aerodynamics that were irrelevant to the focus of this study.The search protocol consisted of the following sets:

- *Keywords for technology:* "digital twin"
- *Keywords for domain:* "tunnel"
- *Keywords for lifecycle phases:* "design", "construction", "operation", "monitoring", "inspection"

Each set was combined using the AND operator to ensure that papers contained at least one keyword from each conceptual group. Irrelevant topics and unrelated languages were filtered out through EXCLUDE operators.

By applying the defined search query and inclusion criteria, a total of 139 papers were retrieved from the Scopus database. Following a review of the titles and abstracts, 99 papers were identified as relevant and selected for detailed analysis of research areas and trends. The overall process of the literature search and selection is illustrated in Fig. 1.

3. Systematic review

3.1. Classification of literature

A total of 139 papers were retrieved based on the defined search query and inclusion criteria. After reviewing the titles and abstracts, 99 papers were identified as relevant for a detailed analysis of the research areas and trends, while 40 papers were deemed irrelevant and excluded. The distribution of relevant papers across different years is summarized in Fig. 2. A notable increase in the number of relevant publications was observed in recent years, particularly from 2020 onwards. The number of relevant papers progressively grew, with a significant rise in 2023 and 2024, reflecting a surge in research interest and advancements in digital twin technology applied to tunneling and related construction processes.

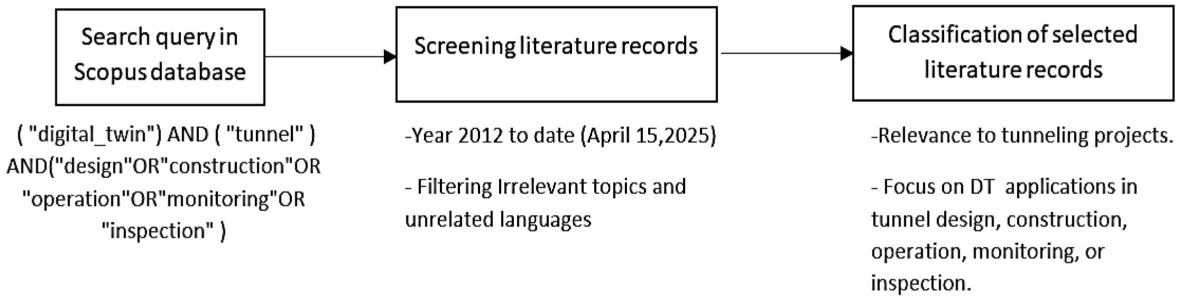

Fig. 1. Framework for literature retrieval and analysis

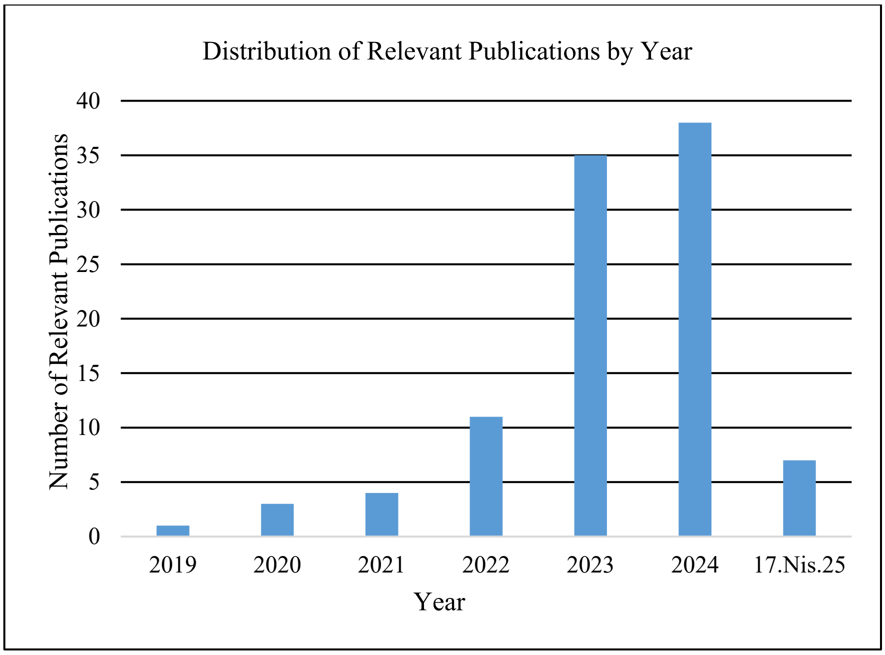

Fig. 2. Annual distribution of relevant publications related to the application of digital twin in tunneling projects

3.2. Keyword co-occurrence analysis

A keyword co-occurrence analysis was performed in order to identify the main research topics and relations between main topics in the selected literature. The visualization map, created using VOSviewer, displays several clusters demonstrating closely related research areas (Fig. 3).

- The keyword "digital twin" comes as the primary and prevailing term, reflecting its central significance along the whole period of the research. Around "digital twin," several significant clusters could be seen.
- An information and technology-based cluster (green) linking "technology," "infrastructure development," "challenge," and "research," indicating high interest in the development and application of digital twin technology for tunneling and infrastructure projects.

- A cluster of modeling and performance (red) linking "model," "efficiency," "performance," "problem," and "digital," indicating research aimed at developing digital twin models to enhance operational performance and efficiency.
- A cluster of project and information management (blue) centered on "project," "risk," "information," and "analysis," indicating a focus on the application of digital twins in project management, risk analysis, and information analysis.
- A small cluster concerning methodology and structure (yellow-green) indicates research founded upon the methodological frameworks employed in the application of digital twins in tunneling projects.

The complex interconnections among keywords echo the multidisciplinary character of digital twin solutions for tunneling, encompassing elements of engineering design, project management, technological development, and operational enhancement.

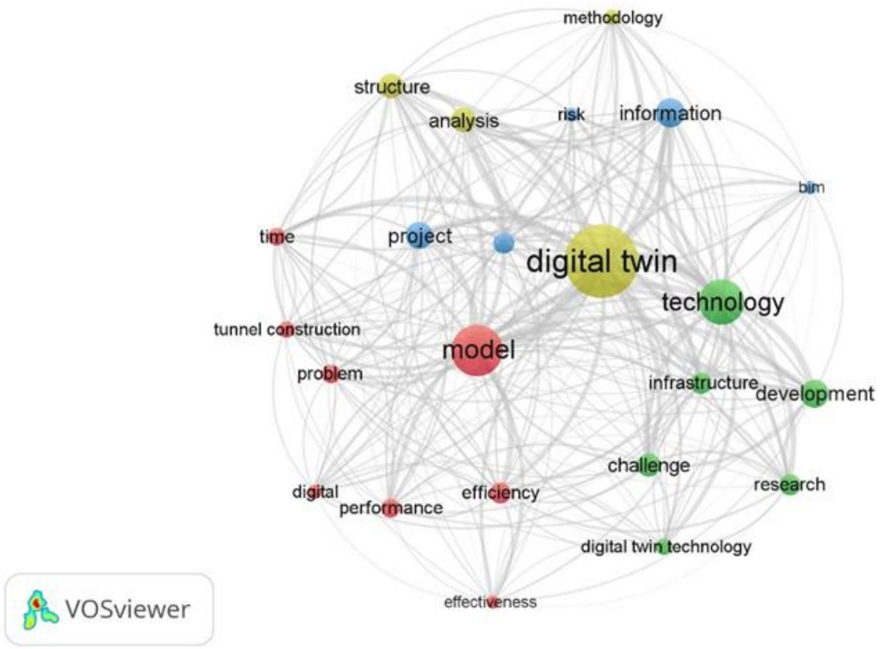

Fig. 3. Keyword co-occurrence network map of the selected literature, created using VOSviewer

4. Results and discussion

The distribution of applications according to the project phase is illustrated in Fig. 4. The most researched phase is construction, with 19 studies aimed at DT solution application in this phase. This is followed by applications during the entire lifecycle (14 studies), operation and maintenance (13 studies), and combined design and construction phases (9 studies). The quantity of studies exclusively on maintenance (7 studies) or just design (3 studies) was less.

This distribution illustrates that the construction phase continues to be the key area of ongoing DT research within tunneling construction projects. Such focus is perhaps expected in view of the pressing need for acquiring real-time data, monitoring, and decision-making processes during the process of excavation work. Still, the shifting interest towards lifecycle, operational, and maintenance phases signifies the greater realization of the value proposition of DTs as far as ensuring long-term asset management, predictive maintenance, and risk management measures are concerned. The lack of research particularly focusing on the design stage suggests a research gap, offering opportunities for future studies to examine how the integration of DT in the early stages can be used to improve project planning and lifecycle performance.

More detailed analysis identified ten research clusters with distinct differences between them, mirroring the diversity of DT applications to tunneling and underground infrastructure. The clusters, their key applications, and associated key authors are listed in Table 1. From Table 1, DT research on tunneling can be divided into some principal clusters. Visualization & Inspection explores 3D and VR-based systems for asset inspection and stakeholder communication. Maintenance & Asset Management deals with digital maintenance planning, O&M decision support, and lifecycle asset management. Safety & Risk Assessment uses DTs for safety risk prediction, deformation monitoring, and hazard simulation.

The results indicate that DT technology in tunneling projects is primarily applied in the construction phase, enhancing real-time monitoring, safety, and excavation efficiency. However, there is a clear trend toward integrating DT across the entire project lifecycle, especially in maintenance and asset management, where it improves decision-making and optimizes long-term operations. Despite these advancements, areas like Tunnel Boring Machine (TBM) applications and early design phase integration remain underexplored. Table 2 summarizes the application and benefits of DT across different phases of tunneling projects, highlighting its growing impact. Real-world projects, such as Crossrail and the Brenner Base Tunnel, demonstrate the practical benefits of DT, indicating its transformative potential in the industry.

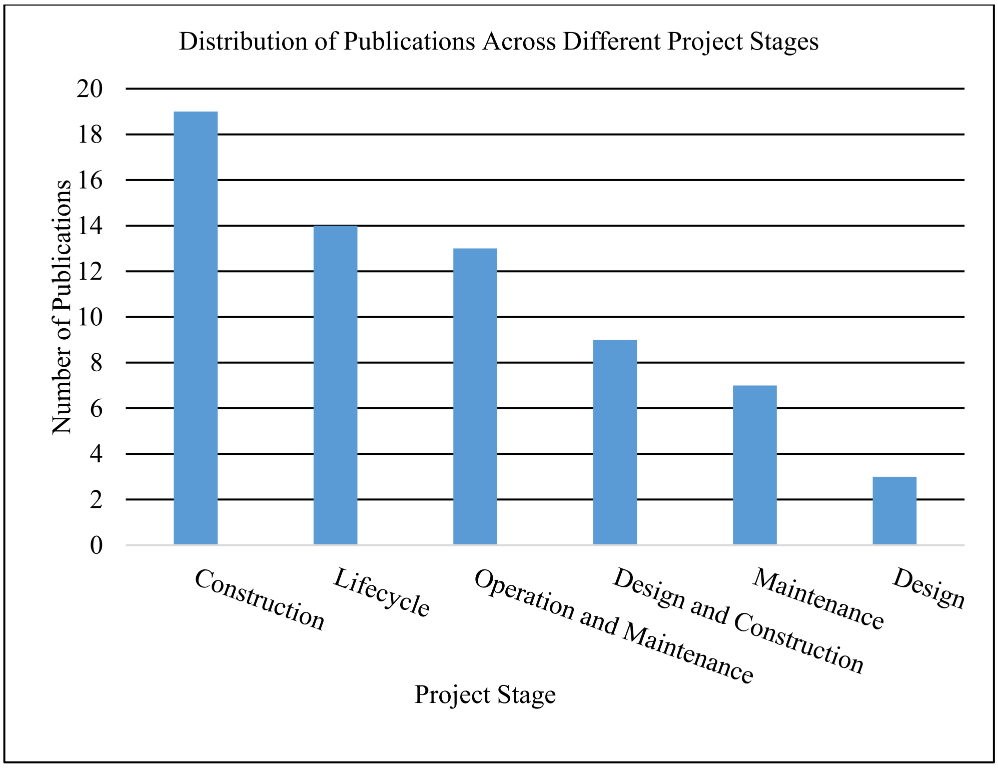

Fig. 4. Distribution of relevant publications across different stages of tunneling projects

Table 1. Detailed clusters on Digital Twin (DT) applications in tunneling, with core focuses and key authors

Cluster	Core Application(s)	Authors
Modeling & Simulation	High-fidelity modeling, scenario testing, maturity evaluation, ontology & graph-based modeling	(Liang et al., 2024), (Zhao et al., 2024), (Li, Rui, Zhao, et al., 2024), (Li, Rui, et al., 2024), (Li, Li, et al., 2024), (Beigel et al., 2024), (Wang et al., 2024), (Sakr & Sadhu, 2024)
Construction Monitoring & Control	Real-time monitoring, status update, excavation control, JIT design	(Fang et al., 2024), (Latif et al., 2023), (Zhang, et al., 2024), (Cheng et al., 2024), (Liu et al., 2024), (Li et al., 2023), (Chang et al., 2022), (Zendaki et al., 2024), (Hegemann et al., 2023)
Visualization & Inspection	3D/VR visualization, inspection, virtual-real fusion	(Wu et al., 2022), (McDonald et al., 2022), (Ding et al., 2024), (Traxler & Chmelina, 2023), (Li, et al., 2024)
Maintenance & Asset Management	Digital maintenance, O&M decision support, ventilation/lighting control, planning	(Yang et al., 2024), (Yu et al., 2023),(Zhou et al., 2024), (Tomar et al., 2019), (Spallarossa & Pasqualato, 2024), (Chen et al., 2023), (Sanfilippo et al., 2023), (Diren & Althen, 2023), (Rezakhani & Kim, 2023)

Table 2. Continued

Safety & Risk Assessment	Safety risk assessment, deformation prediction, hazard simulation	(Zhao et al., 2022), (Feng et al., 2024), (He et al., 2024), (Gu et al., 2023), (Fukuda et al., 2023)
Intelligent Geological & Rock Analysis	Geological perception, rock mass classification, advanced grouting	(Martens et al., 2022), (Song et al., 2023), (Wang et al., 2021), (Delport et al., 2023)
Specialized TBM & Robotic Systems	TBM tool-replacing, robotic simulation, performance learning	(Liu et al., 2023), (Gannouni et al., 2023)
Cybersecurity & Output Control	Attack simulation, belief rule base for operational control	(Masi et al., 2023), (Chang et al., 2022)
Multimodal Data Fusion & Feature Extraction	Sensor fusion, point cloud & imagery, feature extraction	(Lee et al., 2023), (Yang et al., 2024)
Concept & Platform Development	Interactive concept creation, holistic platforms	(Bauer & Lienhart, 2023), (Zhou et al., 2022), (Lu et al., 2024), (Petschen et al., 2023)

Table 3. Applications and benefits of Digital Twin technology across the lifecycle of tunneling projects

Lifecycle stage	Applications for digital twin	Benefits
Design	High-fidelity modeling, simulation, and scenario testing	Identifies potential issues early, optimizes design choices
Construction	Real-time monitoring, safety management, intelligent geological perception	Reduces on-site errors, enhances safety, ensures efficient excavation
Operation & maintenance	Digital maintenance, intelligent operation and maintenance, lifecycle data integration	Improves management efficiency, supports intelligent decision-making, provides comprehensive view

5. Applications of DT in some tunneling projects

5.1. Application of DT in hypertunnel innovative tunneling method

The application of DT technology in hyperTunnel's innovative tunneling method revolutionizes traditional underground construction by integrating advanced AI, swarm robotics, and real-time data. Unlike conventional methods where a hole is dug first, hyperTunnel 3D-prints the tunnel structure inside the ground, using a digital twin to guide the process(Fig. 5-a). A fleet of hyperBot robots, guided by the digital twin, operates in parallel along the tunnel path (Fig. 5-b), enhancing productivity and reducing construction time. These robots perform tasks such as drilling, cutting, and material deployment through a collaborative swarm method. The digital twin provides a rich, data-driven representation of the tunnel and surrounding geology, which supports real-time monitoring, virtual reality (VR) training, and predictive maintenance. This integrated system minimizes uncertainty, cuts costs, and ensures faster, safer, and more sustainable tunneling. By merging advanced technologies, hyperTunnel transforms how tunnels and underground structures are designed, built, and maintained, promising substantial efficiency gains over traditional methods (URL1).

5.2. Application of DT in Wuhan Metro Line 2 Phase I (China)

The application of Digital Twin (DT) technology in Wuhan Metro Line 2 Phase I represents a significant advancement in urban transportation management. The Smart Metro Service Platform (SMSP), as illustrated in Fig. 6 (Zhou et al., 2024), integrates physical tunnel data with virtual models and real-time sensor inputs to monitor key parameters such as settlement, convergence, leakage, and structural degradation of the metro tunnels. This system is crucial for assessing and managing the long-term structural performance of the metro's underground infrastructure, which spans 60.8 km with Phase I operational since 2012. By leveraging DT technology, the SMSP enhances operations and maintenance (O&M) capabilities by providing early warnings and predictive maintenance insights, thus improving the overall lifecycle management of the tunnels. This proactive approach ensures the safety and service quality of the metro system, effectively mitigating risks posed by geological and train-induced stresses. The integration of DT in the Wuhan Metro demonstrates its potential to optimize maintenance practices and extend the lifespan of critical urban infrastructure.

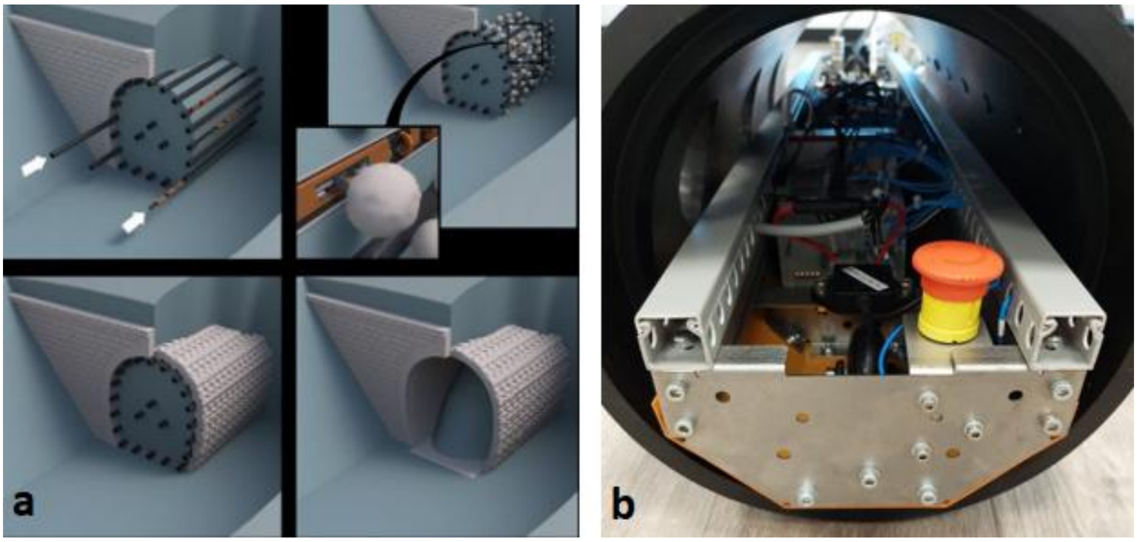

Fig. 5. a) HyperTunnel 3D-prints the structure inside the ground, working with a digital twin b) Using swarm construction methods according to a digital twin of the tunnel, a fleet of 'hyperBot' robots enters the ground via an arch of HDPE pipes (credit: hyperTunnel)

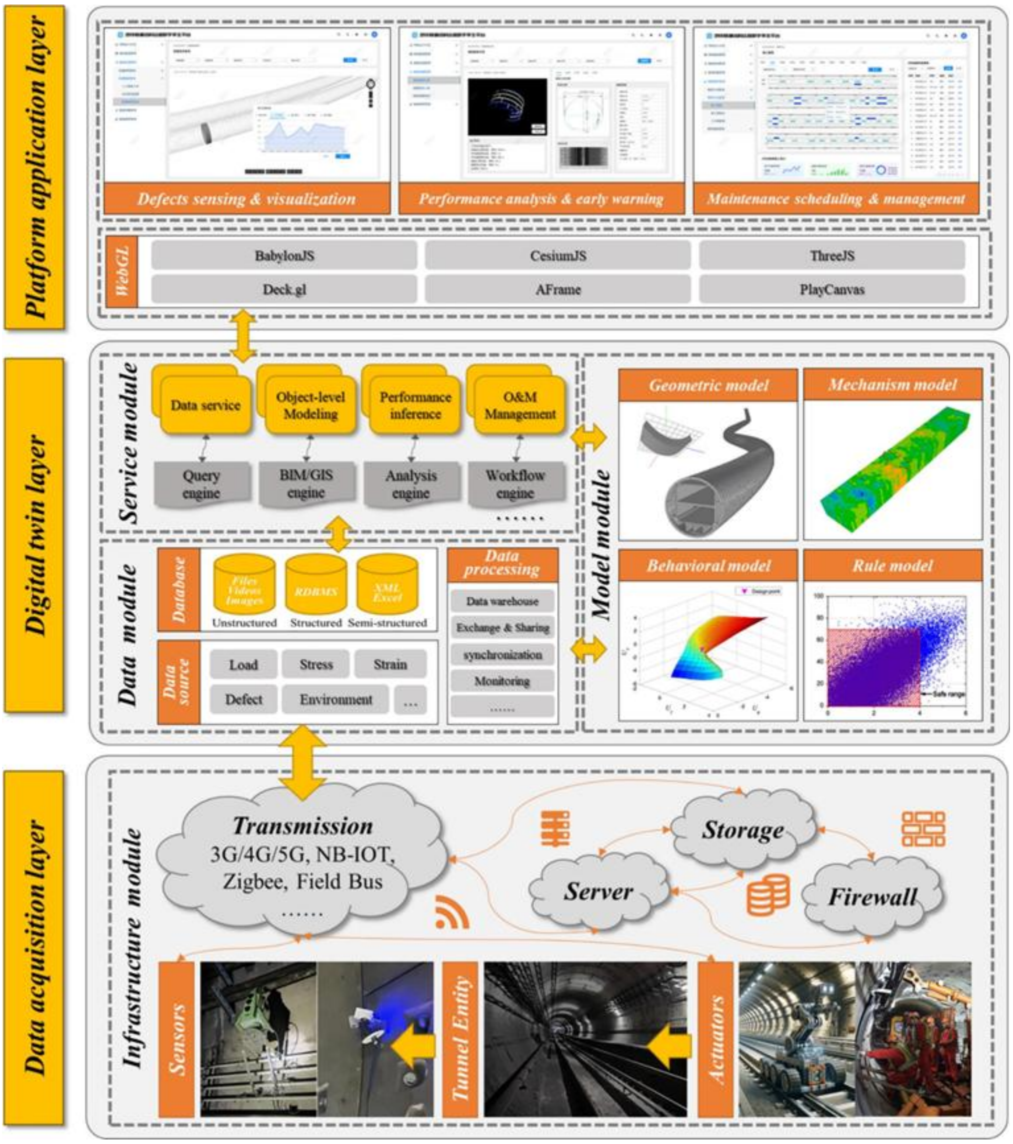

Fig. 6. Applied Smart metro service platform framework for Wuhan Metro Line 2 Phase I (Zhou et al., 2024)

Table 3 summarizes various tunneling projects that have implemented Digital Twin (DT) technology to enhance tunnel construction, operation, and maintenance. Notable examples include the Grand Canyon Tunnel in China, which uses DT for automatic rock grade identification and dynamic support (Zhu et al., 2021), and the Swalmen Tunnel in the Netherlands, where DT supports supervisory controller design during renovation (Van Hegelsom et al., 2021). Other applications span pavement performance prediction, remote inspection, automated excavation assessment, and intelligent asset management, with projects such as the Guizhou Tunnel and Altona Tunnel employing DT for lifecycle management and system integration (Fang et al., 2024; Diren & Althen, 2023). These implementations highlight DT's growing role in improving tunnel safety, efficiency, and maintenance across different regions and project phases.

Table 4. Summary of tunneling projects that have adopted Digital Twin (DT) technology

Tunnel Name	Application of Digital Twin (DT)	Author(s)
Grand Canyon Tunnel (Sichuan Ehan High-Speed Project, China)	Automatic identification of surrounding rock grade and digital dynamic support	URL2
Swalmen Tunnel (Netherlands)	Supervisory controller design support during renovation	Hegelsom et al., (2021).
Dalian Highway Tunnel (Shanghai, China)	Pavement performance prediction via MTSS for lifecycle management	Yu et al., (2020).
Wuxi Qingqi Tunnel (China)	Electromechanical DT system using IoT and BIM for 3D monitoring and remote inspection	China Jiangsu Net.
Guizhou Tunnel Project (China)	'Status' DT for automated over-and-under excavation assessment using BIM and point cloud data	Fang et al., (2024).
Zizhi Tunnel (Hangzhou) (China)	BIM-based construction system; groundwork for DT using 3D Tunnel Information Model	Wang et al., (2015).
Tunnel Laboratory 01 (TL 01) (Brazil)	Tunnel performance prediction and condition monitoring using visual inspection data to build a digital inspection twin	Machado & Futai, (2024).
Sipicciano & Collecervo Tunnels (Italy)	Digital twins created from ARCHITA multi-dimensional survey system for tunnel management planning and design	Foria et al., (2023).
Altona Tunnel (Germany)	Managed digital twin integrating BIM, asset and traffic management, and simulation	Diren & Althen, (2023).
Tunnel Schöneich (Zurich)	DT for improved operation and maintenance workflows using laser scanning and BIM	Sanfilippo et al., (2023).
Niu Tingling Tunnel (Lishui, Zhejiang) (China)	Intelligent O&M of electromechanical equipment using digital twin	Chen et al., (2023).

6. Conclusions

Based on the systematic literature review using the Scopus database, this study examined the applications and benefits of Digital Twin (DT) technology across the tunnel project lifecycle.

The review found a significant increase in publications on DT in tunneling, especially since 2020. Currently, the construction phase is the most researched area, reflecting its need for real-time monitoring and decision-making during excavation. However, there is a growing trend towards applying DT across the entire project lifecycle, particularly in operation and maintenance, for long-term asset and risk management. A research gap was identified specifically in the initial design and terminal maintenance stages.

Digital Twin technology offers substantial benefits throughout the tunnel lifespan. In design, it aids in planning and simulation to identify issues early and optimize choices. During construction, DT enables real-time monitoring, enhances safety, and improves excavation efficiency. For operation and maintenance, it supports efficient management and decision-making. These applications contribute to overall effectiveness, safety, and sustainability. Real-world examples demonstrate DT's practical benefits.

Despite these benefits, challenges, primarily related to data integration and standardization, hinder the full realization of DT's potential. Future research should focus on integrating emerging technologies like 5G, AI, and cloud computing and expanding DT applications into the underexplored design and terminal maintenance areas.

An analysis of course contents and educational materials in strengthening university-industry collaboration

Ediz Boz*[1], Vedat Toğan[2]

[1] Bayburt University, Aydıntepe Vocational School, Construction Technology Department, 69020 Bayburt, Türkiye
[2] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye

Abstract. Rapidly evolving sector dynamics and technological advancements highlight the growing importance of university-industry collaboration. Incorporating stakeholder perspectives into students' education is crucial for institutions engaged in quality assurance and accreditation, such as the Higher Education Quality Council of Turkiye (YOKAK) and the Association for Evaluation and Accreditation of Engineering Programs (MUDEK). This study examines how civil engineering students relate their courses to practical applications, evaluate the adequacy of educational materials, and perceive their professional competence post-graduation. To achieve this, multiple-choice and semi-structured Likert-scale surveys were conducted, and the alignment of course content with industry needs was assessed. The findings reveal that courses like "Reinforced Concrete" and "Construction Management" are strongly linked to professional practice, yet traditional teaching methods in these courses are insufficient. Students recommended integrating advanced technologies such as virtual reality (VR) and augmented reality (AR) to improve educational effectiveness. Additionally, students reported difficulties in courses requiring three-dimensional thinking, such as "Steel Structures" and "Structural Analysis" and emphasized the value of modern technological integration. The results underscore the need for civil engineering programs to adapt to sectoral advancements and contribute to quality assurance processes. Updating course content and incorporating innovative technologies into education can better equip graduates for the workforce, strengthening the university-industry relationship and enhancing professional readiness.

Keywords: Civil engineering education; University-Industry collaboration; Construction management; Practical education

1. Introduction

In today's construction industry, continuous change and renewal are driven by technological advancements, sustainability requirements, and global competitive conditions. Training engineers who can adapt to this dynamic environment necessitates practice-oriented educational processes that go beyond the mere transmission of academic knowledge (Moezabadi, 2024). In this context, university-industry collaboration plays a pivotal role in civil engineering education. Such collaboration enables students to integrate theoretical knowledge with practical experience. While universities provide future engineers with a theoretical foundation in basic sciences, engineering principles, and design processes, industry partnerships offer opportunities to encounter real-world applications of this knowledge. This integration enhances students' professional competencies, contributing to their graduation as more prepared and qualified individuals who are ready to meet sectoral demands (Jonassen et al., 2006). Particularly, quality assurance and accreditation bodies such as the Higher Education Quality Council of Turkey (YOKAK) and the Association for Evaluation and Accreditation of Engineering Programs (MUDEK) define stakeholder involvement namely, the inclusion of industry representatives' perspectives and the subsequent updating of educational content accordingly as a key quality criterion (URL-1 & URL-2). In this regard, systematically reflecting current industry needs in engineering curricula not only increases the effectiveness of quality assurance processes but also strengthens the reputation of educational institutions within the sector.

In the field of civil engineering, gaining direct experience in areas such as site practices, construction management, project development, and engineering design significantly contributes to the development of students' problem-solving, decision-making, and leadership skills (Boz & Toğan, 2021). Moreover, internship programs, industry-led seminars, joint project collaborations, and simulation-based applications facilitated through university-industry partnerships enable students to enhance not only their technical knowledge but also essential professional competencies such as teamwork, communication, and ethical responsibility (Shah & Gillen, 2024).

* Corresponding author, E-mail: edizboz@bayburt.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_359

On the other hand, the industry benefits from these collaborations by actively contributing to the education of future engineers and supporting the development of a skilled workforce aligned with its needs (Murray, 2024). This mutual benefit necessitates the establishment of a sustainable collaboration model between universities and industry stakeholders. In civil engineering education, university-industry cooperation holds strategic importance not only in terms of individual student outcomes but also for the overall advancement of the sector, the prestige of the engineering profession, and broader societal development. Therefore, it is essential to promote the active involvement of industry partners in the design of educational programs, increase the availability of practice-oriented learning environments, and expose students to real-world problems at earlier stages of their education (Litzinger et al., 2011). Through such approaches, it becomes possible to cultivate innovative and responsible engineers who can effectively respond to the evolving needs of the construction industry.

Evaluating the extent to which undergraduate education meets industry expectations enables the anticipation of potential challenges graduates may encounter during their transition into professional life and allows for necessary improvements in educational programs. In this context, assessments based on students' self-perceptions provide valuable data for directly linking educational outcomes to industry needs. Similarly, gathering student feedback on which courses need to be better understood to meet industry expectations helps identify critical knowledge domains and prioritize course content. Such analyses are particularly useful in determining areas that should be prioritized for the development of applied engineering skills (Mukherji & Sisale, 2022). Moreover, questioning the adequacy and engagement level of traditional educational materials (chalkboards, textbooks, 2D slides) plays a significant role in enhancing course learnability and fostering the development of student-centered teaching approaches. Finally, identifying which courses should be supported by advanced educational technologies such as virtual reality (VR), augmented reality (AR), 3D modeling, and simulations offers concrete suggestions for the integration of next generation learning tools in engineering education (Suhail et al., 2024; de Carvalho, 2019). In this regard, the integration of technology into educational processes directly contributes to students' ability to concretize abstract concepts, visualize complex structural systems more effectively, and acquire the practical competencies demanded by the industry. Systematic analysis of these questions yields findings that can significantly contribute to the restructuring of civil engineering education programs in alignment with industry expectations, ultimately supporting efforts to train future engineers as more competent and well-equipped professionals.

The aim of this study is to analyze which courses civil engineering students associate with practical application in order to achieve success in professional practice, to evaluate the adequacy of current educational materials, and to assess students' self-confidence in performing their profession after graduation. In line with this objective, multiple choice and semi structured Likert type questionnaires were administered to students, and the alignment of course content with industry requirements was evaluated based on the collected data. Addressing the research questions within the scope of this study holds critical importance for both individual and institutional development in civil engineering education.

2. Method

There are certain limitations regarding the sample selected for this study. The participants consisted of senior students enrolled in the Department of Civil Engineering at Karadeniz Technical University (KTU). Senior students were chosen because they are nearing the completion of their education and have acquired at least one internship experience. Therefore, fourth-year civil engineering students were considered the most appropriate sample group to evaluate the contribution of course content and educational materials to the enhancement of university-industry collaboration. A total of 173 students participated in the study, of whom 136 were male and 37 were female. Among the participants, 132 were enrolled in the Turkish program and 41 in the English program. The age of the students ranged between 21 and 28 years. According to KTU's civil engineering internship regulations, students are required to complete a total of 60 days of internship. The research questionnaire was administered face to face during class hours with the permission of the course instructor. Students were given 10 minutes to complete the survey, and all participants submitted their responses within this timeframe.text.

In this study, a questionnaire developed for civil engineering students was used to address the following research questions:

- The adequacy of their undergraduate education in meeting industry expectations,
- The sufficiency and attractiveness of traditional educational materials,
- The courses most closely associated with the knowledge required during internship experiences,
- The courses that need to be better understood in order to meet industry expectations,
- The courses that should be supported with advanced educational technologies (virtual reality, augmented reality, 3D modeling, simulation, etc.) to enhance professional competencies.

Questions related to the adequacy of undergraduate education in meeting industry expectations and the sufficiency and attractiveness of traditional educational materials were presented in a Likert type format. For the remaining questions, students were asked to select the specific courses they considered relevant. The course options provided included: Reinforced Concrete, Steel Structures, Transportation, Construction Management, Occupational Safety, Water Resources, Foundations, Soil Mechanics, Structural Analysis, Construction Materials, Strength of Materials, and Other. The data obtained were analyzed using the SPSS 26 statistical software package.text.

3. Findings and discussions

Students' responses to the following questions are presented in Table 1:

Table 1. Students' perceptions of their education and traditional educational materials

Question	Likert Scale				
	Strongly Disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly Agree (5)
Do you think the education you have received in the civil engineering department is sufficient to meet the expectations of the industry	%8 N=13	%15 N=26	%29 N=51	%39 N=67	%9 N=16
What is your opinion regarding the adequacy of traditional educational materials in terms of understanding, comprehension, and the ability to visualize the content presented during undergraduate education	%10 N=17	%24 N=42	%29 N=51	%31 N=53	%6 N=10
What is your opinion regarding the attractiveness of traditional educational materials in terms of stimulating interest in the course, motivation to learn, and willingness to conduct further research	%13 N=22	%33 N=57	%34 N=58	%16 N=29	%4 N=7

When examining students' responses to the statement "Do you think the education you have received in the civil engineering department is sufficient to meet the expectations of the industry" it is observed that 23% expressed a negative opinion, 29% remained neutral, and 48% responded positively. This suggests a level of uncertainty regarding how well the current education system prepares students for the demands of the industry, although the overall tendency appears to be positive.

In the literature, a gap between the competencies expected by employers and the skills provided by higher education is frequently emphasized (Kwan, 2016; Leong & Elleithy, 2016). A discrepancy seems to exist between the findings of this study and those reported in the literature. While a significant portion of students (48%) believe that their education sufficiently meets industry expectations, scholarly studies often underline a mismatch between higher education outcomes and sectoral needs. This discrepancy highlights the potential divergence between students' perceptions and the evaluations made by employers or academic researchers regarding the readiness of graduates for the workforce. Students tend to assess the relevance of their education based on their perceived gains in knowledge and skills. In contrast, employers evaluate graduates through their ability to solve real-world problems and apply knowledge in professional contexts. The survey results suggest that the theory–practice gap emphasized in the literature may not yet be fully perceived by students, as they have not been extensively exposed to the complexities of real-world professional environments. Consequently, while students may believe their education is adequate prior to graduation, this perception may shift once they enter the workforce and encounter practical challenges that reveal potential deficiencies in their training.

An analysis of responses to the statement "What is your opinion regarding the adequacy of traditional educational materials in terms of understanding, comprehension and the ability to visualize the content presented during undergraduate education" reveals that 34% of students expressed a negative opinion, 29% remained neutral, and 37% indicated a positive view. These results demonstrate a clear divide among students regarding the adequacy of traditional educational materials. While some participants consider these materials sufficient, an almost equal proportion believes they are inadequate. Furthermore, a discrepancy can be observed between students' perceptions and the findings reported in the literature. Li et al. (2018) emphasized that the effectiveness of instructional materials in contributing to the learning process is closely linked to the level of student interaction. Their study also suggests that active learning methods, such as XR (Extended Reality), VR (Virtual Reality), and AR (Augmented Reality), are more effective than traditional, passive teaching tools. One possible explanation for this discrepancy is the limited exposure of students to active learning experiences. In educational environments where such approaches are not widely implemented, students may perceive the current system as adequate.

However, research in the field of educational sciences consistently indicates that traditional methods, being rooted in passive knowledge transmission, limit student engagement and hinder long-term learning retention.

An examination of responses to the statement “What is your opinion regarding the attractiveness of traditional educational materials in terms of stimulating interest in the course, motivation to learn, and willingness to conduct further research” reveals that 46% of students expressed a negative opinion, 34% were undecided and only 20% responded positively. These findings indicate that a significantly higher proportion of students perceive traditional materials as unengaging compared to those who find them appealing. Moreover, the relatively high percentage of neutral responses suggests that many students lack a definitive stance on the matter; however, the dominant trend points toward a general perception of disengagement. This outcome implies that traditional educational tools may be considered insufficient in capturing and sustaining students’ interest during the learning process.

The responses of students to the question “Which courses do you think are more closely related to the knowledge you are expected to acquire during your internship?” are presented in Figure 1

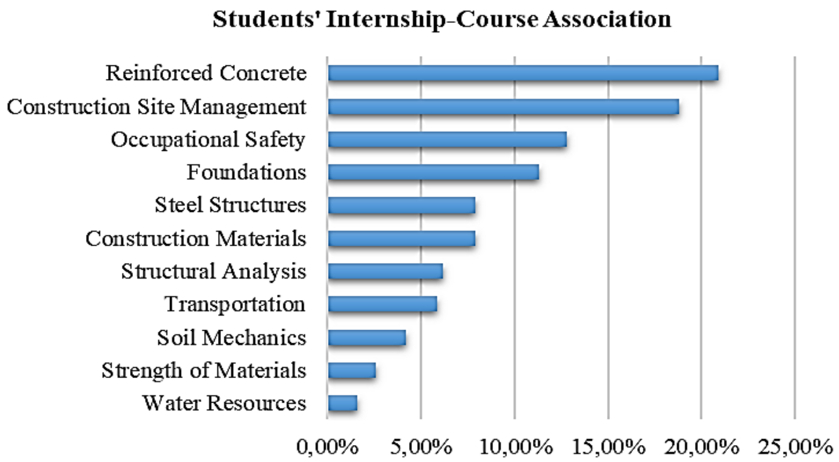

Fig. 1. Students’ internship-course association

As seen in Fig. 1, Reinforced Concrete Structures (20.90%) and Construction Site Management (18.80%) received the highest percentages. This indicates that students believe they need applied engineering knowledge and site management skills the most during their internships. Occupational Safety (12.80%) ranked third, suggesting that being aware of on-site risks and knowing the relevant safety precautions is considered a critical issue by students. In addition, more theoretical courses (Mechanics of Materials, Water Resources, Soil Mechanics) appear to be less emphasized during field experience. These results reflect civil engineering students’ perceptions, based on their internship experiences, of which courses are more directly related to practical applications in the field.

Fig. 2 presents the responses to the question: “Which courses do you think should be better understood during your undergraduate education in order to meet industry expectations?”

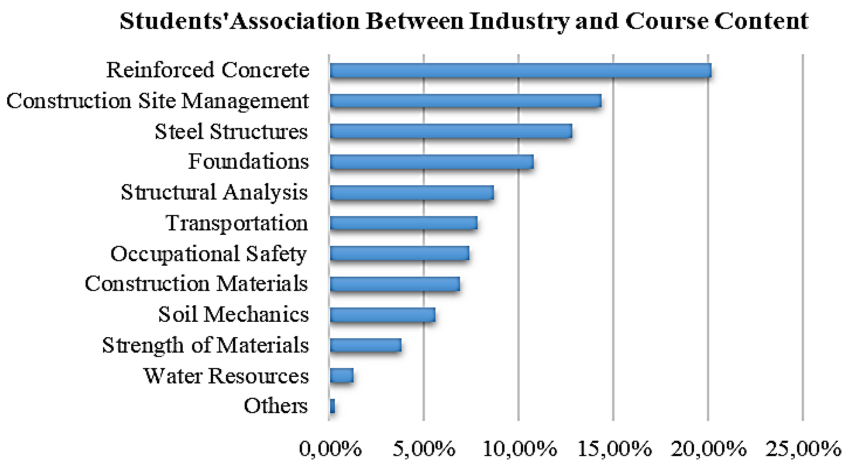

Fig. 2. Students’ association between ındustry and course content

As shown in Fig. 2, the courses “Reinforced Concrete” (20.20%) and “Construction Site Management” (14.40%) stand out with the highest proportions. This indicates that students believe they need a deeper understanding of structural design and site management. In particular, given the widespread use of reinforced concrete structures in the construction industry, students’ expectations to gain a better grasp of this course’s content can be considered a meaningful outcome. Similarly, the high preference for the Construction Site Management course suggests that topics such as project management, work planning, and site organization are perceived as critically important by students. The findings also show that the courses “Steel Structures” (12.80%) and “Foundations” (10.80%) are considered significant by students. This result implies that knowledge in load bearing system design and foundation engineering is viewed as essential for professional success. On the other hand, more theoretical courses such as “Mechanics of Materials” (3.80%), “Soil Mechanics” (5.60%), and “Water Resources” (1.30%) received relatively lower preferences. This suggests that students tend to value courses that have direct applications in the field more highly.

Students’ responses to the question, “Which courses in your undergraduate education should be supported with advanced educational materials (such as virtual reality, augmented reality, 3D modeling, animation, simulation, gamification, etc.) in order to improve your understanding of the profession?” are presented in Fig. 3.

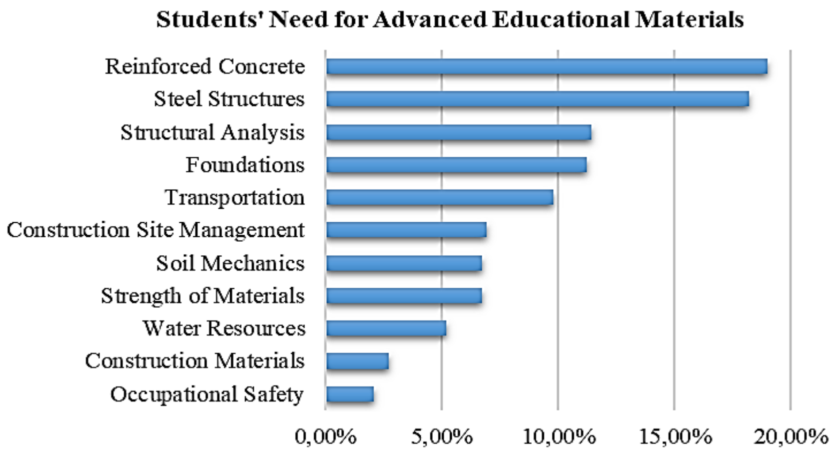

Fig. 3. Students’ Need for Advanced Educational Materials

As shown in Fig. 3, the courses “Reinforced Concrete” (19.00%) and “Steel Structures” (18.20%) received the highest percentages. This indicates that students particularly feel the need for advanced visualization and simulation techniques to better understand structural system design, structural analysis, and material behavior. The modeling of topics covered in Reinforced Concrete and Steel Structures courses often involving complex calculations and three-dimensional structural behavior in virtual environments is considered potentially beneficial for enhancing students’ professional learning. The relatively high preference for “Structural Analysis” (11.40%) and “Foundations” (11.20%) suggests that visual and interactive educational materials supporting the understanding of load bearing system behavior under loads and fundamental principles of foundation design could be valuable learning tools for students. In particular, simulations and interactive applications can be considered critical for improving comprehension of static and dynamic systems. The notable percentages for “Transportation” (9.80%) and “Construction Site Management” (6.90%) also reveal students’ support for teaching topics such as site organization, project planning, traffic engineering, and transportation infrastructure through virtual models. Virtual reality and simulations can enhance the acquisition of professional knowledge by providing students with immersive experiences that replicate real-world construction site conditions.aliqua.

4. Conclusions

This study aimed to reveal civil engineering undergraduate students’ perceptions of their education, its alignment with industry expectations, and their needs for advanced educational materials. The findings indicate that there may be significant differences between students’ perceptions and the findings reported in the literature when evaluating educational processes.

Approximately half of the students (48%) reported that they found their education sufficient in meeting industry expectations. However, existing literature frequently emphasizes a notable mismatch between higher education curricula and sectoral demands. This discrepancy may be attributed to the fact that students have not yet fully encountered the realities and dynamics of professional practice, leading them to assess the adequacy of their education primarily based on perceived knowledge and skill acquisition. In contrast, employers typically evaluate educational outcomes based on practical problem-solving abilities and application competence, which may explain the divergence between student perceptions and industry realities.

A similar divergence was observed regarding the adequacy and appeal of traditional educational materials. While a significant portion of students (34%) found traditional materials insufficient, another group (37%) expressed positive views, and a noteworthy percentage (29%) remained undecided. Furthermore, responses to the statement “Traditional educational materials are engaging” revealed that 46% of the participants disagreed, suggesting that traditional materials may fall short in maintaining student interest. These findings align with the literature, which asserts that conventional, passive teaching methods often limit student engagement and long-term learning retention.

Based on their internship experiences, students particularly highlighted that “Reinforced Concrete” (20.90%) and “Construction Site Management” (18.80%) are closely related to industry practices. The practice-oriented nature of these courses aligns well with students’ on-site experiences, reinforcing the importance of such courses in preparing them for the profession. Similarly, students identified “Reinforced Concrete” (20.20%) and “Construction Site Management” (14.40%) as the courses that require a deeper understanding to meet industry expectations. These results suggest that professional competencies such as structural system design, construction management, and project planning should be prioritized during undergraduate education.

Another key finding of the study was students’ strong demand for the integration of advanced educational technologies. In particular, they emphasized the need to support courses like “Reinforced Concrete” (19.00%) and “Steel Structures” (18.20%) with innovative tools such as virtual reality, augmented reality and simulation. These results indicate that abstract and complex engineering concepts can be more effectively learned through three-dimensional, visual, and interactive materials. Additionally, courses such as “Structural Analysis”, “Foundations”, “Transportation” and “Construction Site Management” were also identified as potentially benefiting from enhanced technological support.

In summary, students view practice-oriented courses as more critical for both professional development and preparation for the industry. Moreover, the limited interest in traditional educational materials and the expressed need for advanced technologies highlight the importance of adopting active learning strategies in engineering education. In this context, updating curricula, incorporating innovative teaching tools, and expanding hands-on learning environments are essential steps for universities to better respond to industry expectations.left.

A spreadsheet application for the heuristic solution of Time Cost Trade-off Problem

Ayşe Nur Şengül*[1], Önder H. Bettemir[1]

[1] İnönü University, Department of Civil Engineering, 44280 Malatya, Türkiye

Abstract. Time Cost Trade-Off Problem (TCTP) is an important problem in construction management since its optimum solution minimizes the total project cost. Although there are meta-heuristic and mathematical programming algorithms for the optimization of the problem, optimum or near-optimum solutions can also be obtained with heuristic methods with very few operations and computation. In this study, an spreadsheet application that automatically performs most of the operations and logical tests required for the solution of TCTP with heuristic methods was developed and TCTP was solved with minimal human effort. At the initial stage, the project diagram of the problem was drawn in Activity-On-Arrow type. The nodes of the networks and crashing alternatives are defined to the application. Since the application is coded to have the feature of determining the critical activity with the lowest crashing cost, it offers the most suitable crashing option to the user. If the number of critical paths is more than one, the critical activity with the unit cheapest crashing alternative is accelerated first, but the project duration does not change. However, the number of critical paths drops to one and the cheapest crashing alternative of the remaining critical path is suggested by the application. In this way, although the best solution cannot be guaranteed, the near-optimum solution can be obtained with very little human effort. As a result, the developed spreadsheet application offers a practical and accessible approach for the solution of TCTP by heuristic methods. The created spreadsheet application solves the entire problem again after shifting the crashing modes of the critical activities, which minimizes user mistakes, speeds up decision-making processes and enables projects to achieve cost and time targets more effectively. Although the best solution cannot be guaranteed, the proposed approach stands out as an effective and applicable alternative for engineers when considering the constraints and time pressure encountered in real life.

Keywords: Time-cost trade-off problem; Optimization; Heuristic algorithm; Project management.

---

1. Introduction

The time-cost trade-off problem aims to obtain the most suitable construction time and total construction cost by creating different construction alternatives for the work items that constitute a construction project. Meta-heuristic methods are widely used to solve this problem.

Ballesteros-Pérez et al. (2019) focused on a Genetic Algorithm (GA) that applies crashing and fast tracking separately and together for a 10-activity project. Anagnostopoulos and Kotsikas (2010) examined different annealing algorithm variants that address the problem of minimizing the total cost in activity networks when certain time and cost modes are allowed in the project activities. The most effective variant produces local optima very close to the global optimum and is the slowest algorithm, although it is time efficient (Anagnostopoulos and Kotsikas, 2010). Bettemir and Bulak (2022) aimed to develop an integrated method that includes the steps of preparing quantity take-off, determining activity durations and resource requirements, creating a work schedule, and determining the construction cost and duration with unit prices in the project management process. Optimum or near-optimum solutions were obtained by using the GA with Simulated Annealing which increases the convergence ability of the GA. Banihashemi and Mohammed (2022) proposed an optimization model by examining construction projects in four dimensions, namely time, cost, risk and quality, and considering real projects, and the NSGA-II meta-heuristic algorithm and goal programming approach were used to solve this model. The results showed that the NSGA-II algorithm provides results close to the optimal solution (Banihashemi and Mohammed, 2022). Jun and El-Rayes (2010) developed a multi-objective optimization model for scheduling multiple shifts in construction projects, and the developed model minimizes the negative effects on project performance by optimizing the distribution of limited labor resources between shifts. Bettemir and Yücel (2021) developed an application that enables the creation of construction alternatives with minimal human intervention.

golden light publishing

Since the application works on a spreadsheet and is automated independently of human intervention, it ensures that results are obtained quickly. This application can help them achieve significant savings in construction costs.

Bettemir and Yücel (2023) proposed a framework to provide the optimal time-cost balance with minimum effort for construction projects. For this purpose, a spreadsheet application was developed to calculate the quantity extraction of construction materials with minimum data input from the user, and this application can provide significant cost and time savings in the planning process. Cheng and Tran (2015) demonstrate the effectiveness of the OMODE algorithm using numerical case studies on two construction projects. The OMODE algorithm resulted in shorter project duration and lower cost compared to other algorithms. Luong et al., (2021) used the Differential Evolution (DE) algorithm, one of the most popular evolutionary algorithms, to solve the DTCTP. In terms of time, all models exhibit similar time performance, while OMODE provides higher quality and lower cost. Agarwal et al., (2024) developed a model that increases the efficiency of construction projects and contributes to their successful management by facilitating the decision-making process by simultaneously optimizing project duration and cost. The effectiveness of the MOPSO approach demonstrates its potential to improve scheduling options in the construction industry and maximize project outcomes (Agarwal et al., 2024). Al-Shihabi and AlDurgam (2020) developed a mixed integer linear programming (MILP) model to balance the extension and acceleration processes of projects. This problem is called the "discrete time, cost, and credit trade-off problem" (DTCCTP). This model aims to meet budget and credit limit constraints while minimizing the project duration (Al-Shihabi and AlDurgam, 2020). Yilmaz and Dede (2023) examined the effectiveness and performance of the multi-objective Rao series optimization model, which was used for the first time in the field of construction management. The results show that the developed model is an outstanding alternative for solving the multi-objective time-cost trade-off optimization problem in construction management. Maravas and Pantouvakis (2012) developed a computer program that performs fuzzy calculations for activity durations and costs and displays the results in graphical and tabular form. Network Analysis Algorithm (NAA) searches for the optimum solution by accelerating the activities step by step. The algorithm has been tested in terms of finding the global optimum and fast convergence. The results show that the algorithm quickly reaches optimum or close solutions (Bettemir and Birgönül, 2017). Geem (2010) tested the HS model on two network examples and compared to other evolutionary algorithms, GA and ACO, it found Pareto solutions as good as or better than other applications in (Geem, 2009). For the solution of the seven-activity problem, HS found the global Pareto set faster than ACO, while GA could not show this success. For the eighteen-activity problem, HS obtained a better Pareto solution than ACO, while GA did not give certain results. Akkoyunlu and Engin (2011) examined HAA as a new algorithm that reaches satisfactory results within an acceptable time within the search space containing infinite number of solutions. Since the variables of optimization problems in daily life are more discrete, KHAA was emphasized. As a result of the examinations, it was determined that KHAA method would be an alternative method in solving optimization problems for discrete data. To optimize the traditional time-cost trade-off problem, a least-cost mathematical optimization model has been developed by associating CPM, mathematical programming and DCF techniques. This model allows projects to be used for all types of projects without being limited to certain techniques (Ammar, 2011). Cura (2008) optimized a nonlinear function with the Tabu search algorithm. The developed algorithm was tested on a seven-variable minimization problem and significant results were obtained. The TA algorithm has achieved successful results for this problem (Cura, 2008). The cited studies present successful results for the solution of TCTP but the construction sector cannot implement the sophisticated optimization methods. Therefore, the construction schedules are not optimized by considering construction cost and duration.

Besides meta-heuristic algorithms DTCTP was solved by heuristic methods. Bettemir and Birgönül implemented minimum cost slope based heuristic algorithm to determine the activities to be crashed. The proposed method obtained the optimum solution of 18-Activity project and obtained near optimum solution of 63 Activity project (Bettemir and Birgönül, 2017). The obtained near optimum solution is used to generate population and better solutions are obtained (Bettemir and Birgönül, 2025).

2. Method

In this study, a heuristic method for solving the time-cost trade-off problem of a construction project is coded into a spreadsheet application. In the solution process, critical activities are accelerated to shorten the total project duration and the relationship between the increase in direct costs and the decrease in indirect costs is evaluated. A network diagram is created as shown in Fig. 1 by considering the physical relationships between the activities.

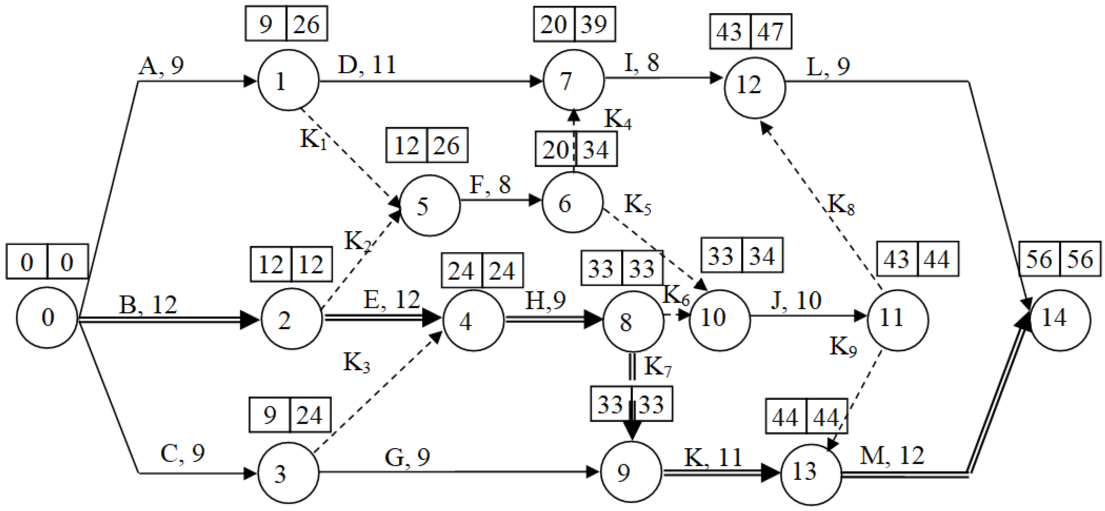

Fig. 1. Hypothetical thirteen activity project diagram

Different construction duration and construction cost options of the activities are entered to the spreadsheet application. To assist the selection of different construction alternatives the application computes the crashing costs of each activity. Early Event (EET) and Late Event times (LET) of the nodes are automatically calculated in a separate table which enables automatic computation of the activity start and finish time. The spreadsheet automatically assigns duration and cost values and recalculates the construction schedule. In this way, when a different alternative is selected for any activity, the project completion time is automatically updated. In order for the network drawn as an arrow diagram to be transferred to the spreadsheet application, it is necessary to define the activities connected to the nodes. The EET and GOZ calculations of the nodes are given in Fig. 2.

Here, the LET calculation of node number 2 is shown as a representation. Since the dummy activity is connected to node number 5 from the mentioned node point, C26, and since there is also activity E between it and node number 4, the smaller of the C25-D7 values are assigned as LET to this node point. The specified calculations are performed for all nodes and the network is introduced to the application. When the activity durations change, the network calculations are automatically updated.

Activity	Start	Finish	Duration	Cost	Selected Alternative
A	0	1	6	31875	3
B	0	2	8	25000	3
C	0	3	20	30350	1

Fig. 2. Preparation of Excel application for automatic calculation of activity start and end times.

The calculation of the acceleration cost of the activity to be accelerated is shown in Figure 3. The acceleration cost is calculated as presented in Eq 1.

$$CrashingCost = \frac{C_{next} - C_{current}}{D_{next} - D_{current}} \tag{1}$$

In Eq 1:
Cnext is the cost of the next selected construction alternative.
Ccurrent is the cost of the currently selected construction alternative.
Dnext is the duration of the next selected construction alternative.
Dcurrent is the duration of the currently selected construction alternative.

The formula entered into the spreadsheet application to apply Equation 1 is given in the expression below.
"=IF(AND(F3<G3;L3=0);(VLOOKUP(A3;$A$3:$S$15;F3*2+15;FALSE)-VLOOKUP (A3;$A$3:$S$15;F3*2+13;FALSE))/(VLOOKUP(A3;$A$3:$S$15;F3*2+12;FALSE)-VLOOKUP (A3;$A$3:$S$15;F3*2+14; FALSE)); 9999999999)"

The unit acceleration cost of the relevant activity in the project is calculated in TL/day and is used to select the activities that will increase the direct cost the least. If the activity is not a critical activity, acceleration of the activity will not provide an improvement in the project cost. The equation defined to eliminate non-critical activities assigns very high acceleration costs as shown in the equation defined in MS Excel.

Fig. 3. Calculation of acceleration costs of the activities

The spreadsheet recommends the most suitable activity for acceleration, as shown in Fig. 4. In making this recommendation, it considers the activities whose total float time is 0, that is, the activity that is on the critical path in the network and has the lowest acceleration cost. Activities on the critical path are prioritized. Since the critical path may change after each acceleration operation, the duration of an activity is recalculated each time it is updated. The total float time of the activities is calculated as in Equation 2.

$$TF = LFT - EST - Duration \tag{3}$$

Here TF is the total float time, LFT is the late finish time, and EST is the early start time. Also, LST is the latest start time and EFT is the earliest finish time. The time unit is days. The formula used in the spreadsheet application to show the recommended activity for acceleration is represented as

"=INDEX(A3:A15;MATCH(M18;M3:M15;0);1)". In the expression, cell M18 represents the lowest acceleration cost and the INDEX function finds the activity with the cheapest speedup cost.

Fig. 4. Display of critical activities and automatic computation of available acceleration alternatives

The prepared spreadsheet identifies the critical activities and calculates the acceleration cost if there is any acceleration alternative for critical activities. The acceleration alternative with the minimum acceleration cost is suggested by the developed application. The scheduler can assign the activity to be accelerated by examining the suggested acceleration alternatives.

3. Case study

A network diagram showing the constraints between the activities is given in Figure 1. Different duration and construction alternatives for each activity are presented in Table 1. Alternative 1 is the daytime working option. The project is completed with standard working hours and has the lowest cost. However, the duration is the longest. Alternative 2 is the daytime working option with overtime. The duration is shortened by shortening the daytime by adding overtime, but the cost slightly increases since overtime payments are higher than normal payments. Alternative 3 is the night + day double shift option. The night + day shift alternative is implemented with the shortest duration but the highest cost. The costs increase due to acceleration. The cost unit is TL and the daily overhead for this schedule is 5000 TL.

The formed construction cost and duration alternatives are entered into the spreadsheet application as shown in Fig. 5.

Fig. 5. The early start schedule of the network.

The formed application highlights the activities B, E, F, H, J, and L since they are critical activities with feasible crashing modes. In column M the application proposes crashing activity L since it has the least unit crashing cost with 450 monetary units per day.

The activity L is crashed by changing the alternate mode from 1 to 2 as shown in cell F14 which is illustrated in Fig. 6. Similarly four crashing steps are implemented and the resulting schedule is shown in Fig. 7.

After the 4th acceleration, it is suggested to accelerate the activity J in the 5th step. However, since there are other critical paths besides the line where the activity J is located, the project duration did not shortened and the total cost increased. Therefore, the next suggested activity M was also accelerated in the 5th step and the schedule given in Fig. 8 was obtained.

Fig. 9. Uncrashing activity J to the 1st alternative after the 5th acceleration of the heuristic DTCTP solution algorithm.

Activity J becomes noncritical activity after the acceleration of the activity M. Therefore, the activity J was uncrashed and was reversed to its previous state to prevent cost increase.

Crashing of Activity B was suggested in step 9, but crashing only the activity B was not enough to reduce the project duration and total cost alone because of the existence of the other critical paths.

In the 9th acceleration step, the next proposed activity, activity K, was also accelerated in addition to activity B. However, since there was another critical path, no decrease was observed in the project duration. On the other hand, total cost of the project in increased.

In the 9th acceleration step, the acceleration of activities B and K, which was suggested due to multi critical path, could not reduce the project duration and cost. As illustrated in Fig. 11 the application proposed acceleration of activity F. When the next suggested activity F was accelerated, the project duration decreased from 56 days to 53 days, and the total project cost decreased by 6250 TL to 592793.75 TL.

Fig. 13. Optimum result achieved after 16 acceleration steps by the heuristic algorithm

After 16 acceleration steps, heuristic solution algorithm has reached the optimum result. The optimized project duration is 42 time units and the total project cost is 563912.5 TL. The short revision of the construction schedule provides a reduction of 40 time units and a saving of 146837.5 TL compared to the initial schedule obtained with the first construction modes of the activities.

Time-cost trade-off problem is solved by selecting proposed alternatives for the appropriate activities by the spreadsheet application. When the proposed activities are accelerated in order, the results presented in Table 2 are obtained. In Table 2, Cr A represents the crashed activity. Direct costs are the construction costs of each activity for the selected alternative. Indirect costs are obtained by multiplying the daily cost by the total project duration. In the later stages of the optimization process, the network has more than one critical path. In this case, more than one activity may need to be accelerated. In some table rows, the total project duration does not change even if a critical activity is accelerated. In this case, the accelerated critical path becomes non-critical and the remaining critical path prevents the project duration from being shortened. The project duration is 84 time units and the total cost is 710750 TL. The optimized project duration is 42 time units and the total project cost is 563912.5 TL. The short revision of the construction schedule provides a reduction of 40 time units and a saving of 146837.5 TL.

4. Conclusions

Construction sector is focused on the execution of the project scope on time and within budget. Therefore, utilization of sophisticated algorithms during the scheduling phase is not the priority of the construction firms. As a result of this, initial construction schedule is not improved and the contractors lose the opportunity of reductions in the total project cost. In this study time-cost trade-off problem is solved by a heuristic method which is based on minimum cost slope. The computations are formulated with parameters and the solution process is automated.

The developed application is used to solve 13-activity problem. The application proposed the most suitable critical activity to be crashed and the necessity computations of the crashing process is done. The spreadsheet application significantly reduces the computational burden and assists the scheduler to make deeper analysis and investigations as the scheduler only shifts the utilization mode of the alternative and the rest of the calculations are done by the developed application. The construction sector frequently utilizes spreadsheets for their scheduling tasks and therefore the proposed approach can be utilized by the construction companies.

Generating a Dynamo-based quantity takeoff from BIM models: A case study

Ümit Bahadır*[1], Vedat Toğan[1]

[1] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye

Abstract. Nowadays, Building Information Modeling (BIM) tools offer significant opportunities for automation, integration, and data consistency in the design and management phases of construction projects. This study aims to generate comprehensive quantity takeoff for all critical project components by extracting the concrete and formwork quantities of structural elements—such as foundations, columns, beams, slabs, and staircases—as well as the quantities of walls, doors, and windows from 3D BIM models using Dynamo software. The developed algorithm will be tested on a sample project. Compared to traditional quantity surveying processes, the proposed method provides faster data processing and a reduced error rate, thereby making important contributions to project management and cost control. When integrated with on-site construction practices, the model-based data collection process facilitates decision-making based on up-to-date information. This study underscores the impact of effectively utilizing digital model data in the quantity estimation process, particularly for large-scale construction projects. The findings indicate that systematically integrating tools such as BIM and Dynamo can enhance efficiency throughout construction processes.

Keywords: Automated data processing; BIM; Dynamo; Quantity takeoff

1. Introduction

Quantity takeoff (QTO), a critical component of construction project management and cost control, traditionally involves manual calculations based on two-dimensional (2D) drawings. This process is labor-intensive, time-consuming, and prone to errors, primarily due to the varied interpretations of project details (Monteiro & Martins, 2013; Khosakitchalert et al., 2020). These inconsistencies can lead to significant discrepancies in project budgets and planning processes (Monteiro & Martins, 2013; Pham et al., 2024). Measurement errors in building components result in incorrect material orders and disruptions in scheduling, jeopardizing timely project completion and adherence to projected budgets (Tserng et al., 2006; Bahadır, 2025).

In recent years, Building Information Modeling (BIM) has significantly improved QTO processes by enabling automated data integration and providing higher accuracy compared to traditional methods (Bečvarovská & Matějka, 2014; Heigermoser et al., 2019). BIM-based methods allow the geometric and semantic information of building elements to be automatically extracted directly from digital models, substantially reducing errors and accelerating the QTO process (Sacks et al., 2018). For instance, BIM methods reportedly achieve up to 80% time savings and accuracy rates above 97% compared with traditional approaches (Olsen & Taylor, 2017). However, inaccuracies in BIM-based quantity takeoffs can still occur because of a low Level of Development (LOD) or incomplete modeling processes, resulting in lower-quality data (Smith, 2014; Le & Cong, 2023).

The current literature indicates that BIM models created during the design stages often lack the necessary detail required for accurate quantity extraction (Khosakitchalert et al., 2019; Sattineni & Bradford, 2011). Typically, these models focus on architectural visualizations and presentations, necessitating further refinement and adjustments for quantity calculations (Kensek & Noble , 2014). This issue limits the full potential of BIM-based QTO, adding extra time and cost (Franco et al., 2015; Bahadır, 2025). Additionally, incorrect modeling, such as geometric clashes or improperly modeled layered components, can lead to quantity overestimation, negatively impacting cost estimates (Khosakitchalert et al., 2018).

Recently, visual programming tools, such as Dynamo, have gained attention for automating the extraction of quantities from BIM models. Dynamo facilitates the rapid analysis of building elements, detection of overlapping areas, and accurate calculation of quantities, thus significantly speeding up the QTO process (Url-1, 2025; Cepni et al., 2020). The current study adopted this approach to automatically generate comprehensive quantity lists

covering a wide range of building elements, from structural components (foundations, columns, beams, slabs and walls) to architectural elements (walls, doors and windows).

The primary objective of this study is to develop a Dynamo-based method for comprehensive and automated quantity extraction from BIM models. This aims to enhance cost control and resource planning efficiency in construction projects. By addressing existing gaps in the literature, particularly errors arising from incomplete or incorrect BIM modeling, this study seeks to significantly improve the accuracy and reliability of BIM-based QTO processes.

2. Literature review

Traditional QTO has historically relied on manual methods using 2D drawings. Jadid & Idrees (2007) proposed an automated approach that recognizes structural elements from 2D CAD drawings, significantly enhancing accuracy and efficiency. Manrique et al. (2015) introduced a 3D CAD-based system that generates detailed material quantities for wood-framing walls, streamlining the shop-drawing production process. However, such solutions rely on consistent layer naming and drawing quality, which limits their broader applicability (Khosakitchalert et al., 2020).

The shift towards BIM has introduced advanced methods for QTO, significantly improving efficiency and accuracy. BIM-based approaches facilitate the direct extraction of geometric and semantic data from digital models, thereby reducing the manual errors inherent in traditional methods (Sacks et al., 2018). Bečvarovská & Matějka (2014) conducted comparative case studies demonstrating substantial reductions in both time and inaccuracies through a BIM-based QTO compared with conventional approaches.

However, several studies have highlighted the challenges associated with BIM-based methods, which are primarily linked to model quality and completeness. Smith (2014) emphasized that insufficient BIM model quality and validation methods limit their effectiveness for QTO. Firat et al. (2010) concluded that BIM models need clearer guidelines and standards to ensure their usability for accurate QTO. Olsen & Taylor (2017) identified that BIM models often contain only half of the required data for comprehensive quantity takeoffs, particularly lacking detail in areas like architectural finishes and temporary structures.

Researchers have proposed numerous innovative solutions to address these limitations. For example, Choi et al. (2015) developed a BIM-based system specifically designed for quantity extraction of structural elements at early design stages, including built-in quality checks to enhance reliability. Rajabi et al. (2015) proposed a logic-based approach to estimate the quantities of lighting and heating appliances typically omitted from BIM models, integrating additional calculations to fill the gaps in standard modeling processes.

Cho & Chun (2015) combined BIM-based quantity extraction with data prediction algorithms to accurately estimate the quantities of reinforced concrete structures, thereby addressing uncertainties in early stage modeling. Lim et al. (2016) introduced algorithms specifically tailored for automated rebar quantity extraction from 3D structural models, which significantly improved the precision of structural engineering projects. Kim et al. (2009) developed an automatic modeling system to generate interior wall finishes directly from room data, enhancing accuracy and reducing manual workload.

Moreover, Aram et al. (2014) proposed a knowledge-based system framework aimed at automating precast concrete QTO processes, leveraging detailed BIM data to improve precision and efficiency. Cheung et al. (2012) introduced a real-time cost estimation system based on gross floor areas extracted from early stage BIM models, enabling rapid and accurate preliminary cost assessments. In the domain of schedule-driven material planning, Khosakitchalert et al. (2018) computed zone-specific concrete and formwork volumes, whereas Cepni et al. (2020) employed Dynamo to calculate formwork for complex geometries and benchmarked automated outputs against manual take-off durations. However, these contributions typically concentrate on a single material category or structural subsystem, and few integrate architectural components, such as openings, doors, windows, and façade finishes, into a unified bill of quantities (BOQ).

The LOD of BIM models significantly influences QTO accuracy. Monteiro & Martins (2013) highlighted that LOD 300 is generally sufficient for QTO; however, compound elements require at least LOD 350 for accurate layer separation and detailed quantity extraction. According to Leite et al. (2011), transitioning from one LOD to another can substantially increase the modeling time and costs, creating a critical practical consideration for BIM-based QTO implementation.

The literature consistently supports the assertion that BIM-based QTO significantly enhances productivity, accuracy, and completeness of cost estimation compared to traditional methods (Alathamneh et al., 2024). Recent studies have provided empirical evidence and discussions highlighting the advantages of various digital tools and methods (Wardito & Husin, 2024; Wahab & Wang, 2022). Commonly proposed solutions involve the use of specialized software platforms such as Autodesk Revit, Navisworks (Shick Alshabab et al., 2020), Cubicost (Tamrin et al., 2024; Soon et al., 2024), and Allplan (Saputra et al., 2020). Alternative approaches include IFC-based BIM (Yang et al., 2024), ontological algorithms (Ergen & Bettemir, 2024), knowledge graph frameworks (Liu et al., 2022), and digital technologies like scan-to-BIM (Jamal et al., 2021) and virtual reality (Bademosi et al., 2019), each aimed at automating and improving QTO processes. However, many theoretical models lack validation through practical implementation (Nguyen et al., 2024). Despite this, advanced integrated frameworks incorporating automatic data extraction, precision checking modules, and interactive visualization dashboards, such as those utilizing Microsoft Power BI, demonstrate high-level automation capabilities and effectiveness in BIM-based QTO (Valinejadshoubi et al., 2024).

These studies collectively underscore the evolving nature of BIM-based QTO methodologies, emphasizing continuous improvements in automation, data integration, and model accuracy. This study proposes a Dynamo-based method that extracts concrete, formwork, and key architectural quantities from a single Revit model without additional modelling effort, thereby extending previous algorithmic approaches to a broader set of building components and delivery requirements.

3. Methodology

The research methodology was structured to demonstrate how a fully digital workflow, grounded in Autodesk Revit 2024 and Dynamo 2.19, can deliver a complete BOQs without additional manual modelling effort. Drawing on the goals established in the preceding sections, this study isolates three sequential phases. First, a project-specific BIM model was prepared with sufficient geometric and semantic details to support the quantity extraction. Second, Dynamo visual-programming scripts were developed to filter model objects, resolve overlaps, and compute material volumes and counts for both structural and architectural components. Third, the workflow was validated through a real-world case project in which automated outputs were benchmarked against conventional takeoff records and on-site measurements. The following subsections elaborate on these phases, highlighting the interplay between model preparation, script logic, and empirical verification.

3.1. Creation of the 3D BIM model

The reliability of the automated workflow depends on the rigorous modelling protocols applied in Autodesk Revit. Therefore, two fundamental constraints were imposed: (i) delimitation of the building elements to be analysed, and (ii) enforcement of a consistent naming scheme that enables unambiguous filtering by Dynamo scripts.

Scope of building elements: The model is limited to primary structural members—foundations, columns, beams, slabs, stairs, and shear walls—and to key architectural items such as walls, doors, and windows. Mechanical, electrical, plumbing, façade systems, and temporary works were excluded to avoid superfluous geometry and parameters that could compromise data integrity.

Element naming scheme: Because the Revit categories frequently host heterogeneous objects, a keyword-based convention was adopted to eliminate selection errors during script execution. In this study, the Type Name attribute of some object must include a distinguishing keyword— the term “Foundation” for structural foundation elements, “Floor” for slabs, “Structural” for shear walls, and “Wall” for all other architectural wall instances—thereby eliminating selection errors during script execution. No additional keywords are required for the remaining elements. Table 1 shows the elements and naming conventions used in this study.

The two constraints outlined above underpin the data integrity of subsequent methodological steps. Compliance ensures that the Dynamo scripts operate without misclassification and that the resulting QTO is both accurate and reproducible.

3.2. Development of Dynamo scripts

This study implements three dedicated Dynamo scripts—Parameter Creation (DYN-01), Formwork Calculation (DYN-02) and Quantity Schedule Generation (DYN-03)—that operate sequentially on the Autodesk Revit model. The cascade ensures that the output of each stage is passed directly to the next, thereby limiting user intervention and eliminating cumulative error throughout the workflow.

Table 1. Considered elements and naming conventions

Element	Category	Naming convention
Structural Foundation	Structural Foundations	Must include the “Foundation”.
Structural Column	Structural Columns	There is no rule.
Shear Wall	Walls	Must include the “Structural”.
Beam	Structural Framing	There is no rule.
Slab	Floors	Must include the “Floor”.
Stair	Stairs	There is no rule.
Architectural Wall	Walls	Must include the “Wall”.
Door	Doors	There is no rule.
Window	Windows	There is no rule.

3.2.1. Parameter creation script (DYN-01)

Because Revit lacks several fields required for the planned QTO, DYN-01 programmatically inserts three instance parameters: Total Formwork Quantity (Structural Foundations category), Volume (Stairs category) and Formwork Quantity (Generic Models category). Each parameter is defined through the Project Parameters API as a Number data type and assigned to the General group for ease of inspection. Table 2 summarizes their principal attributes, and an overall diagram of the parameter workflow is presented in Fig. 1.

3.2.2. Formwork and stair concrete volume calculation script (DYN-02)

The second Dynamo script automatically derives formwork areas and stair concrete volumes from the 3D BIM model through a three-stage procedure. In the first stage, stair elements are isolated and converted to solid geometry; their volumes are computed via the Solid.Volume node, converted to cubic meters, and written to the Volume instance parameter. The concrete requirement for all stairs is therefore stored directly at element level and can be referenced in later reporting without re-calculation. Fig. 2 shows the Dynamo script developed for calculating the stair concrete volume.

The second stage targets elements that require formwork: foundations, columns, beams, slabs, shear walls, and stairs. These objects were unioned into single solids (Solid.ByUnion), converted to polysurfaces (PolySurface.BySolid), and decomposed into individual faces (PolySurface.Surfaces), as shown in Fig. 3. Face normals were examined to classify surfaces as horizontal or vertical; the corresponding areas were converted to square meters and populated in the Formwork Quantity parameter. At this point, all formwork surfaces, except the underside of the stairs, were quantified.

The third stage addresses the stair soffit. Geometric and specification data already embedded in Revit—Desired Stair Height, Actual Tread Depth, Desired Number of Risers, and Minimum Run Width—are retrieved through Elements.GetParameterValueByName. Using the formulation implemented in Fig. 4, the soffit area is calculated and added to Formwork Quantity.

Table 2. Defined project parameters and key features

Parameter name	Parameter application type	Application category	Data type	Revit group
Total Formwork Quantity	Instance	Structural Foundations	Number	General
Formwork Quantity	Instance	Generic Models	Number	General
Volume	Instance	Stairs	Number	General

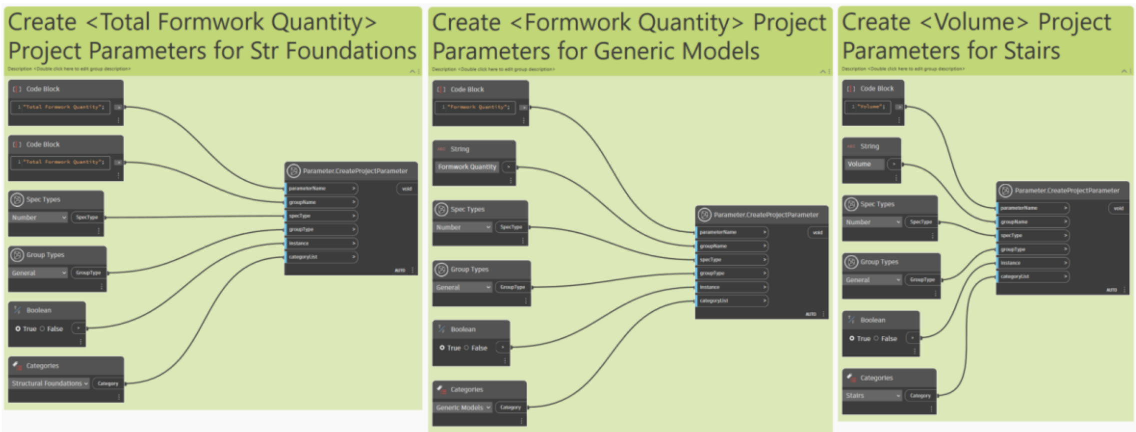

Fig. 1. Parameter creation script

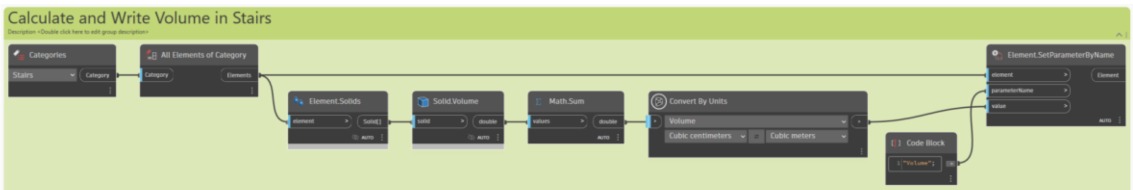

Fig. 2. Stair concrete volume script

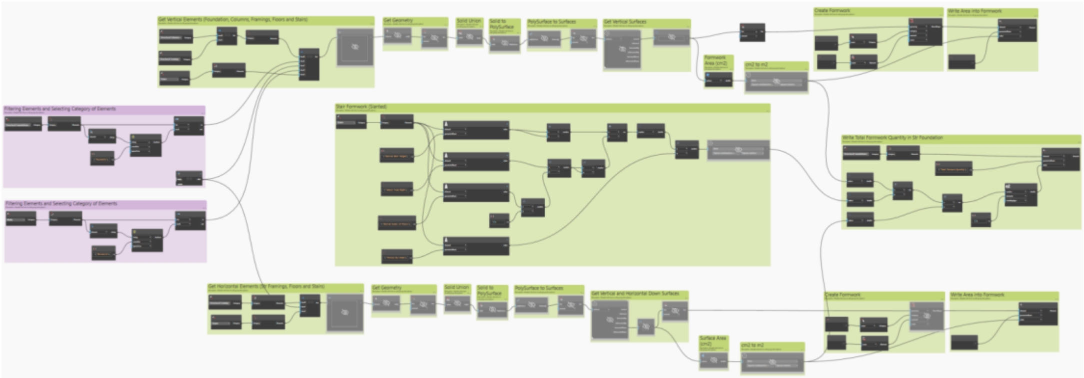

Fig. 3. Formwork calculation script

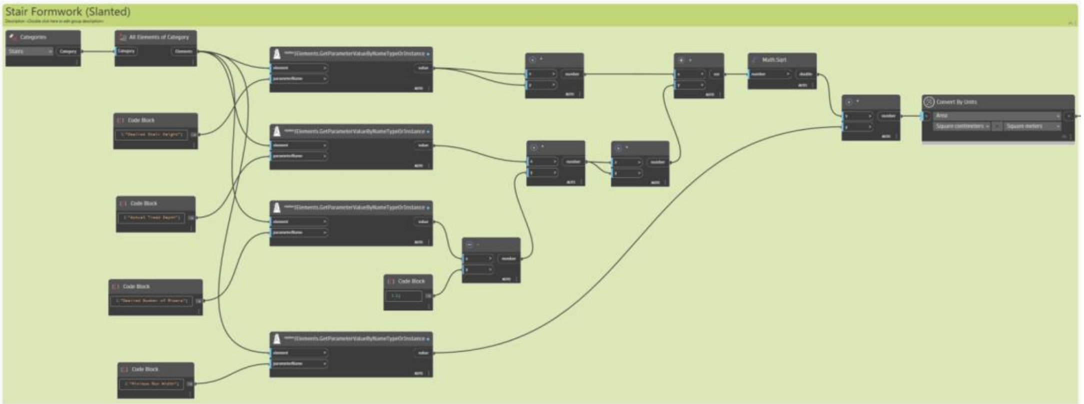

Fig. 4. Stair soffit formwork calculation script

Finally, the horizontal and vertical surface areas, together with the calculated stair soffit, were aggregated and assigned to the Total Formwork Quantity parameter (Fig. 3). This layered strategy ensures that the complete formwork requirement is consistently reported, even when Generic Model surfaces extend across multiple levels or cannot be directly attributed to a single building element.

3.2.3. Quantity schedule generation script (DYN-03)

The third Dynamo script automatically compiles quantitative data for the selected categories into Revit Schedule/Quantities tables, thereby unifying geometric metrics (e.g., volume, area, length) with the project-specific parameters created in earlier steps. The overall logic of the script is illustrated in Fig. 5.

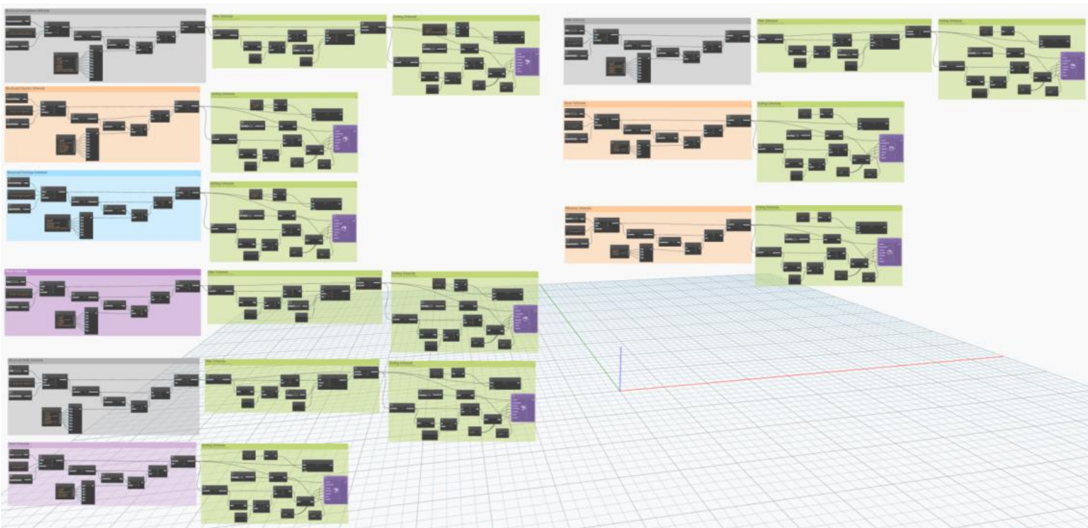

Fig. 5. Quantity schedule generation script

The script first defined the scope: foundations, columns, beams, slabs, shear walls, stairs, architectural walls, doors, and windows, and the set of fields to be displayed for each category. A schedule is then instantiated per category; rows are filtered by element name and level to retain only relevant items (Fig. 6), whereas an embedded Python node sorts the output in ascending order and appends automatic totals for selected fields (Fig. 7). This approach enables rapid verification of both native and user-defined parameters before exporting the data to external cost-control tools.

As shown in Figs. 5-7, DYN-03 enables users to obtain up-to-date, category-specific quantity reports within seconds, verify the values populated in earlier scripts, and export the results as a BOQs ready for cost-management applications.

3.3. Case study

To assess the proposed Dynamo-based QTO workflow, a single-family villa in Trabzon (Türkiye) was modelled as a case study. This project was modelled in Autodesk Revit 2024 and developed to LOD 300, corresponding to the detailed-design phase. All modelling guidelines specified in Section 3.1 were strictly followed, ensuring that every structural and architectural element required by the study—foundations, columns, beams, slabs, shear walls, stairs, walls, doors, and windows— were present and correctly named. Additionally, only those elements expressly required by the study were modelled, whereas finishes, such as floor and wall coverings or ceiling systems, were purposefully excluded to avoid extraneous complexity.

The villa consists of three storeys—basement, ground, and first—each with a uniform storey height of 3.0 m. Perspective views from the northwest and southeast, together with an overall structural view, are shown in Figs. 8, 9, and 10, respectively. The floor areas amount to 40 m² for the basement and 127 m² for both the ground and first floors.

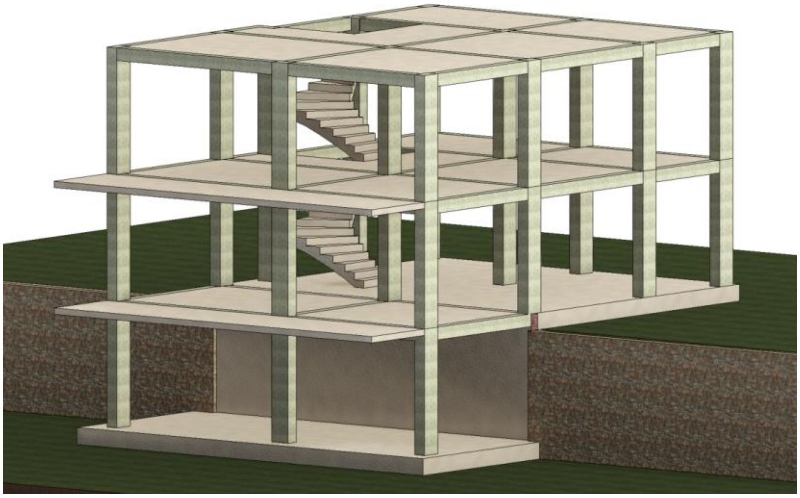

Fig. 10. Structural view of the 3D model

4. Results and discussion

The Dynamo-based automated QTO methodology was successfully validated through a real-world case study of a single-family villa project located in Trabzon, Türkiye. The practical implementation of the qualitatively studied Dynamo scripts (DYN-01, DYN-02, and DYN-03) demonstrated correct performance, efficiency, and reliability.

The Parameter Creation script (DYN-01) accurately adds the necessary parameters to the designated elements. Fig. 11 illustrates the successfully integrated parameters for the structural foundations and stairs within the Revit interface. These custom parameters provided the basis for subsequent quantity calculations, enabling precise and consistent data collection.

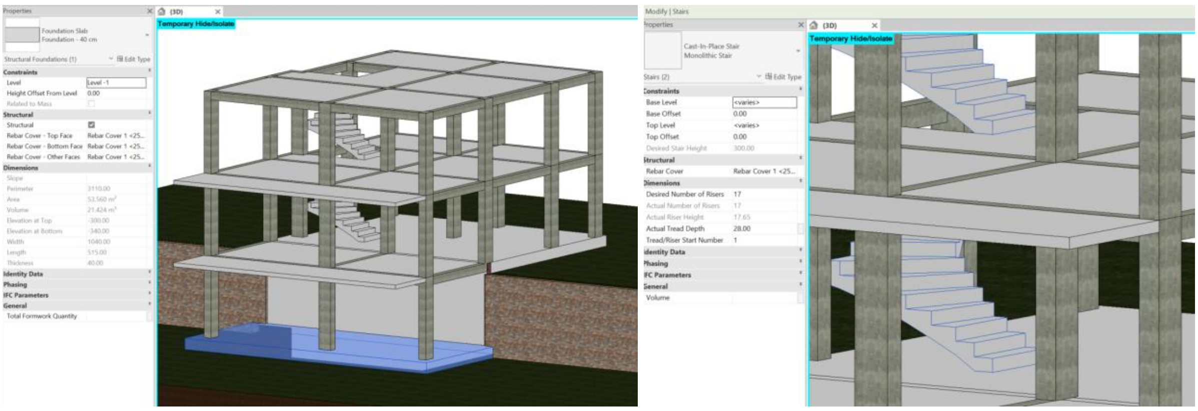

Fig. 11. Integrated parameters for foundation and stair elements in Revit

The Formwork Calculation script (DYN-02) effectively identified and quantified formwork surface areas and stair concrete volumes. Fig. 12 shows the automatically generated formwork surfaces in the Revit environment. From this visualization, it can be observed that specific scenarios, such as stair openings in slabs, correct formwork coverage of side surfaces, proper handling of connections between columns, beams, and slabs (without formwork at junctions), and accurate identification of formwork-exempt areas (e.g., upper and lower surfaces of foundations and columns), were effectively managed. Additionally, the calculated formwork areas were aligned closely with manual verifications, reinforcing the reliability and precision of the developed script in generating accurate project-specific quantities.

Further validation was conducted by examining the automatically generated Revit schedules using the Quantity Schedule Generation script (DYN-03). Fig. 13 demonstrates the detailed schedule of quantities produced for individual elements with examples of columns and architectural walls, confirming the accuracy and completeness of data extraction. This step critically verifies earlier script outcomes, facilitating error-free, rapid exportation of data for further cost management processes.

b) Architectural walls quantity

Fig. 13. Sample of automatically generated quantity schedule in Revit

Table 3 summarizes the quantity results for all modeled structural and architectural components. This comprehensive overview clearly illustrates that the Dynamo-based automated methodology delivers precise and consistent outputs for each building element type, significantly reducing time and minimizing potential human errors, typical of traditional methods.

Overall, the Dynamo-based scripts streamlined the QTO process efficiently, ensuring data integrity, accuracy, and reproducibility. Empirical validation using the case study conclusively demonstrated the potential of this automated workflow to significantly enhance construction project management and cost control practices. Future studies could further expand this approach by incorporating additional elements and exploring its integration with other construction management tools.

Table 3. Summary of QTO results

Element Category	Quantity Metric	Calculated Quantity
Foundations	Volume (m^3)	49.445
Columns	Volume (m^3)	13.050
Beams	Volume (m^3)	10.830
Slabs	Volume (m^3)	36.303
Shear Walls	Volume (m^3)	7.033
Stairs	Volume (m^3)	2.937
Architectural Walls	Area (m^2)	331.104
Doors	Count (units)	19
Windows	Count (units)	18
Total Formwork	Area (m^2)	568.700

5. Conclusions

This study presented a comprehensive Dynamo-based automated QTO workflow integrated with Autodesk Revit to enhance the accuracy and efficiency of construction project management. The implemented scripts (DYN-01, DYN-02, and DYN-03) effectively streamlined the processes of parameter creation, formwork area calculation, stair volume determination, and comprehensive schedule generation. Practical application to a real-world project validated the reliability, accuracy, and efficiency of the scripts, highlighting their capability to eliminate manual errors and significantly accelerate data processing. The Dynamo-based methodology presented herein offers a robust and replicable framework for precise and efficient quantity management, positively contributing to cost control and project management practices. Future research should explore its applicability in large-scale projects, diverse construction elements, and integration with advanced project management platforms.

Cost analysis of UWB and SLAM integrated building surveying technologies

Nezir Doğan[*1], Önder H. Bettemir[1]

[1] *İnönü University, Department of Civil Engineering, 44280 Malatya, Türkiye*

Abstract. Earthquake performance analyses of the damaged buildings which are classified as the medium damage level are carried out after the devastating earthquakes. Then the retrofit project is prepared by evaluating the earthquake performance analysis data and results, and the retrofit construction starts after the construction permit is obtained. Technical drawings of the structural and architectural elements are required to conduct earthquake performance analysis. However, it is quite common that buildings are constructed without completely complying with the approved static and architectural technical drawings or the aforementioned technical drawings might be lost long after their construction. For these reasons, a detailed building survey becomes mandatory. In this study, a cost analysis of the surveying of a building using UWB (ultra-wideband) indoor positioning sensors and SLAM (Simultaneous Localization and Mapping) based algorithms is performed. In the first phase of the study, 5 UWB sensors were placed in a suitable room of the building and positioning was performed using the multilateration method with these sensors. However, a SLAM-based tool was developed in the rooms where positioning accuracy deteriorated or position information could not be obtained in case of multipath effect and signal transmission failure due to obstacles such as furniture and walls in the building, and both positioning and mapping were performed with this tool. In addition, the effect of the placement pattern of the sensors on the cost and positioning accuracy was analyzed. The building survey was completed by considering the cost and technical feasibility of the implemented methods. The focus of the study is to examine in detail the cost of the survey work done with the integration of these two different technologies. Within the scope of the cost analysis, elements such as sensor and device purchases, equipment installations and software development were evaluated.

Keywords: Indoor positioning; Cost analysis; Multilateration; SLAM; Simulation.

1. Introduction

With the availability of the necessary sensors at affordable prices, the use of indoor positioning systems has become widespread. Indoor positioning systems can be used for different needs. Since system designs with different features and qualities specific to these applications are required, the selection of the indoor positioning system directly affects the system cost (Doğan & Bettemir 2024). Indoor location information increases efficiency in various construction applications such as control of the construction process, construction automation and the use of building information modeling (BIM) technology (Li et al., 2020).

Performance analyses of structures damaged after an earthquake are of great importance for the preparation and implementation of reinforcement projects. In order to perform the earthquake performance analysis, which is the first step of this process, the existing structure must have static and architectural projects. It is quite common for structures to be constructed without fully complying with the licensed static and architectural projects. In addition, it is quite common for projects belonging to buildings that have been built for a long time to be lost. For the reasons mentioned, it is mandatory to carry out a detailed survey study inside the buildings during the earthquake performance analysis process.

In this study, the additional cost that occurs when UWB and SLAM technologies are integrated and used in surveying studies is analyzed. UWB indoor positioning systems and SLAM-based algorithms are applied in an integrated manner in order to provide precision and efficiency in the surveying process. While UWB-based positioning systems provide location determination with the multilateration method, SLAM-based systems are activated in areas where location accuracy decreases due to reasons such as signal attenuation and multipath effects due to obstacles in the environment, location accuracy is improved and mapping is also performed. The effects of the sensor distribution used on cost and positioning accuracy are examined and equipment installation and software

golden light publishing

development processes are evaluated economically. In this way, it is aimed to design a system that provides high accuracy and is also cost-effective in surveying studies.

2. Literature review

GPS signals do not provide accurate positioning indoors due to obstacles in the environment. There are different technologies that can position indoors such as infrared, WiFi, UWB, Bluetooth, inertial navigation and magnetic technologies. UWB, Wi-Fi, Bluetooth and Zigbee are short-range and low-power protocol standards. Bluetooth is a wireless personal area network (WPAN) standard designed for short-range and low-cost devices over IEEE 802.15.1. UWB is suitable for multimedia connections requiring high bandwidth over IEEE 802.15.3. Zigbee is designed for reliable wireless monitoring and control networks over IEEE 802.15.04. Wi-Fi is designed to replace the extension of wired networks for inter-computer connections over IEEE 802.11 (Lee et al., 2007). WiFi technology is widely available in many environments, has a low cost due to the prevalence of existing infrastructure, and is not affected by complex non-line-of-sight (NLOS) environments with obstacles. WiFi-based indoor positioning systems do not require additional equipment as they measure the quality of the signals they receive from devices within the coverage area. Therefore, it is an advantageous system in terms of cost (Liu et al., 2009; Mrindoko & Minga 2016).

Infrared (IR)-based systems, radio frequency (RF)-based systems, and ultrasound-based systems are among the most widely used network techniques and systems. One of the most important advantages of infrared is that it has a wide range of use, as many devices have infrared features. Since the infrastructure is simple, the installation and maintenance costs are also low. However, its inability to pass through obstacles and the need for line of sight make infrared technology inapplicable in complex indoor scenarios (Zhang et al., 2010).

Ultrasonic-based indoor positioning systems have the ability to position with high accuracy at the centimeter level. It is also a low-cost system compared to other indoor positioning systems. However, ultrasound-based systems have lower stability than infrared-based systems due to the reflection effect. In addition, the need to synchronize these systems by associating them with RF technologies increases the cost (Zhang et al., 2010; Ijaz et al., 2013).

Mrindoko and Minga (2016) comparatively examined the fingerprint techniques, angle of arrival (AoA) and time of arrival (ToA) techniques used in indoor positioning systems according to criteria such as accuracy, adaptability and cost. The angle of arrival (AoA) determines the location of the target according to the angle of arrival of the signal to the receiver sensor. Technologies using the AoA method increase the cost because they require antennas that can calculate the angle. Reflections, multipath reflections and non-line-of-sight (nLOS) reflections due to objects located indoors cause changes in the direction of arrival of the signal and affect positioning accuracy. In cases where the signal speed is known, the distance between the receiver and transmitter devices can be determined using the transmission time of the signal. It is necessary to know the start time of signal transmission and requires time synchronization in all devices used.

Radio frequency systems are divided into systems that can estimate location using features such as RSSI, UWB, and RFID. RSSI-based indoor positioning systems are affected by errors caused by multipath effects and reflection and diffraction. RFID systems provide low-cost positioning that can position in NLOS environments. VLC-based systems can perform low-cost positioning using lamps or LEDs located in buildings. The emitted lights are detected by cameras (Kunhoth et al., 2020; Ijaz et al., 2013). Dabove et al. (2018) conducted outdoor tests using low-cost Pozyx, a product series that provides a positioning and tracking technology. First, it was aimed to determine the maximum range between a tag and a fixed device. The maximum range was determined as 40 meters. Secondly, the information obtained from the sensors was examined to evaluate the internal capability of the system. The sensor information obtained from the Tag and the MicroStrain IMU fixed on a total station was compared. The total station was used as a reference. It was concluded that the IMU sensors on the tag card had the same accuracy values as the MicroStrain.

In the indoor room test, four anchors with different heights were placed in the corners of a 6.44 m x 4.91 m room and positioning was tested with two different algorithms. The average 3-dimensional accuracy value was 100 ± 25 mm. In the narrow corridor test, 4 stations were placed in a 1.8 m x 6.8 m corridor. The standard deviation value increased compared to the room test. The absolute average accuracy of the range measurement values was approximately 150 ± 50 mm. The three-dimensional positioning accuracy was approximately 60 ± 45 mm. UWB-based systems provide high-precision location determination at a lower cost compared to other technologies, and UWB sensors consume less power compared to other technologies (Alışkan and Şahin, 2023). The 802.15.4a standardization group was established by IEEE for low-data-rate communication, and UWB is an important technology for this standardization. Since the use of antenna arrays increases the cost of the positioning system, AOA-based approaches are not suitable for UWB localization. In addition, due to the high bandwidth, the possibility of multipath tracking of UWB signals may increase and it will be difficult to estimate the angle accurately due to scattering from objects in indoor spaces. Thanks to the high time resolution (wide bandwidth) of UWB signals, time-based approaches in UWB localization provide high-accuracy positioning and are less costly than AOA-based approaches (Gezici et al., 2005). On the other hand, detection of multipath effect can be a feasible alternative if one of the received signals followed multipath, but detection of the signals that followed multipath can be infeasible if two or more signals followed multipath (Doğan and Bettemir, 2025).

Low-cost sensors such as smartphones and wearable devices have become widespread thanks to micro-electro-mechanical systems (MEMS). Accelerometers and gyroscopes in these devices are used for continuous monitoring of human activities such as gait detection. Positioning technologies such as GNSS are not reliable in indoor areas or in areas where the satellite signal is blocked. For this reason, PDR methods that can track user movements without the need for external infrastructure have gained importance (Basso et al., 2017).

Ruiz et al. (2011) aimed to increase the accuracy of indoor pedestrian positioning systems by tightly combining IMU and RFID measurements. This method, proposed as a solution to the inadequacy of GPS in indoor spaces, offers a low-cost and portable system. The 1% drift error of IMU was reduced to 1.5 meters with the help of RFID. The algorithm provided consistent accuracy regardless of walking speed or direction. The optimum cost-accuracy balance was evaluated using different RFID tag densities. As the density of RFID tags increased, location accuracy also increased. However, a distribution rate of 30 m² per 1 RFID tag was suggested to achieve an optimum cost-accuracy balance. The algorithm produced consistent results in different walking scenarios such as slow walking, fast walking or backward movement. Zero speed (ZUPT) and zero angular velocity (ZARU) updates reduced IMU-induced drifts and provided high accuracy (Ruiz et al., 2011). Bahl and Padmanabhan (2000) provide a solution to the problem of determining and tracking the location of users inside buildings with RADAR, a radio frequency (RF) based system. The RADAR system provides an effective solution for indoor user location and tracking. The average error distance was calculated as 2-3 meters with the empirical method. The radio propagation model reduced the installation costs but increased the error rate to approximately 4.3 meters. These results show that RADAR enables the development of location-aware services operating on RF-based network infrastructures. In the future, it is aimed to further develop the system by integrating user movement profiles and sensitivity to environmental factors. Zhang et al. (2006) conducted 1D and 2D localization experiments. In the 1D experiment, the receiver is placed 3 m away from the transmitter and then moved 2 cm away in the same direction to provide a precise displacement in one dimension. According to the value read from the oscilloscope, a shift of 64ps was detected between the two peaks. According to the detected shift value, the result is 1.92 cm. This indicates a difference of 0.8 mm from the true value of 2 cm. Experimental results show that Zhang et al. (2006) developed a positioning system based on UWB principles for low-cost indoor applications with subcentimeter accuracy. Doğan and Bettemir (2025) analyzed the error distribution of locationing with triangulation by differential sensitivity analysis. The results stated that the magnitude of the locatioıning error varies with respect to the position. Minimum location error is expected to be obtained at the center of gravity of the station points.

Randell and Multer (2001) developed a low-cost indoor positioning system that provides 8x8m coverage using one RF transmitter and four ultrasonic transmitters. Ultrasonic systems offer low-cost solutions, but they have disadvantages such as signal loss and signal reflections due to obstacles in the environment and interference from high-frequency sounds. Companies such as Intersense and AT&T have produced systems that can minimize these disadvantages. The average cost of commercial systems such as these is around $15,000. The system developed by Randell and Multer (2001) costs approximately $150 and provides 10-25cm accuracy. Yaman et al. (2021) designed 3 "Location Transmitter Electronic Cards", 1 "Location Receiver Electronic Card" and 1 "Location Receiver-Transmitter Electronic Card" as shown in Table 1, and this system; It is more economical than the system using 4 ready-made electronic cards and 1 smart device, the system using 1 electronic device and 1 smart device, and the systems using 1 ready-made electronic card and 7 electronic cards. The error level of the designed system was compared with existing studies and it was stated that it exhibited similar performance.

Table 1: Cost analysis of indoor positioning systems compiled from the literature

3. Method

3.1 Location estimation with multilateration

In indoor positioning, three distance measurements from known points are sufficient to determine the coordinates of an unknown point, while in the multilateration method, measurements are made from more points. The error values of the measurements are distributed with the least squares correction as shown in Equation 1 and the position is estimated.

$$\Delta\beta = (X^T X)^{-1} X^T \Delta Y \tag{1}$$

The vector expressed as ΔY in Equation 1 is the difference between the measured distance and the distances calculated for the estimated approximate location, as expressed in Equation 2. The explicit form of the X matrix for 2D positioning is expressed in Equation 3.

$$\Delta Y = \begin{bmatrix} d_1 \\ d_2 \\ d_3 \\ d_4 \\ d_5 \end{bmatrix} - \begin{bmatrix} \hat{d}_1 \\ \hat{d}_2 \\ \hat{d}_3 \\ \hat{d}_4 \\ \hat{d}_5 \end{bmatrix} \tag{2}$$

$$X = \begin{bmatrix} \frac{\partial \hat{d}_1}{\partial x} & \frac{\partial \hat{d}_1}{\partial y} \\ \frac{\partial \hat{d}_2}{\partial x} & \frac{\partial \hat{d}_2}{\partial y} \\ \frac{\partial \hat{d}_3}{\partial x} & \frac{\partial \hat{d}_3}{\partial y} \\ \frac{\partial \hat{d}_4}{\partial x} & \frac{\partial \hat{d}_4}{\partial y} \\ \frac{\partial \hat{d}_5}{\partial x} & \frac{\partial \hat{d}_5}{\partial y} \end{bmatrix} \tag{3}$$

The matrix X contains the partial derivatives of the distances with respect to the estimated position. The estimated distances are calculated as given in Equation 4.

$$\hat{d}_i = \sqrt{(\hat{x} - x_i)^2 + (\hat{y} - y_i)^2} \tag{4}$$

In Equation 4, $\hat{x}$ and $\hat{y}$ are the estimated coordinates of the point to be positioned and the index i represents the station points. The vector represented as Δβ contains the corrections to be made to the initial position values. In order to linearize the Euclidean distance equations, they are linearized with the first-order Taylor series expansion. The Taylor series expansion requires approximate initial position information. Initial position estimates are shown in Equation 5. The obtained Δβ vector is the correction made to the initial position estimate. The corrections are obtained after the least squares solution according to Equation 1. The corrections are added to the current solution obtained in the previous parameter estimation cycle as shown in Equation 6. The iteration continues until the correction values fall below the desired level.

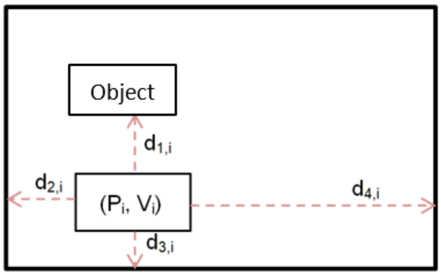
$$\beta_0 = \begin{bmatrix} x_0 \\ y_0 \end{bmatrix} \tag{5}$$

$$\beta = \Delta\beta + \beta_0 \tag{6}$$

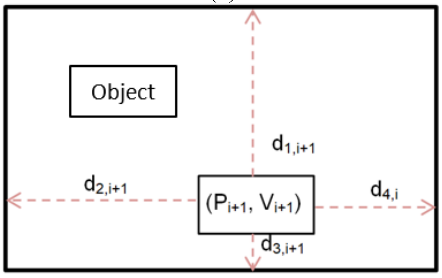
The approximate value is subtracted from the true value and the Euclidean distance of the obtained values is reported as the error value. The least squares adjustment will be applied 25 times for each point. The number of iterations is sufficient to ensure convergence.

3.2 Improving position accuracy with SLAM based algorithm

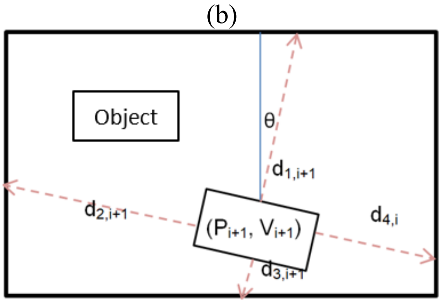
It is not possible to achieve continuous and high-accuracy positioning with indoor positioning systems. In order to prepare a high-accuracy and detailed interior survey, at least four distance meters as shown in Figure 1 will be placed on an autonomous vehicle. The vehicle will map the room by moving counterclockwise in the room, taking into account the distance defined as d3 distance, 50 cm from the wall, and making a full circle in the room. The location accuracy will be improved with the SLAM-based supporting algorithm as presented below.



(a)



(b)



(c)

Fig. 1. Measurements of the vehicle at time labels i (a) and i+1 (b) in a simplified spatial environment

Pi is the position vector at the ith time tag, Vi is the speed vector at the ith time tag, d1,i, d2,i, d3,i and d4,i are the distance readings obtained from the ultrasound sensors placed on the vehicle as presented in Figure 1 at the ith time. The situation when the vehicle moves for a period of Δt and the time is i+1 is presented in Figure 1.b. The progress shown in Figure 1 is exaggerated to make generalizations, the time interval is planned to be 1 second and the expected progress is 5 cm. In the case when the time period is i+1, the location is determined by indoor positioning and after the iteration is stopped, if the residual values calculated with Equation 2 are more than the threshold value, at least one of the signals will be considered to have come by following a multipath and the location obtained by indoor positioning will be corrected as specified in Equation 7. In Equation 7, the position vector at the i+1 time is estimated using the position and position vectors at the ith time.

$$\hat{P}_{i+1} = P_i + V_i * \Delta t \tag{7}$$

The prediction vector presented in Equation 7 will be highly accurate if the vehicle's forward speed remains constant, but there will be a high probability that it will deviate from the forward direction as a result of being caught on objects such as carpets etc. Therefore, the forward angle will be calculated from the direction perpendicular to the forward direction as presented in Equation 8.

$$\theta_{i+1} = \arccos\left(\frac{d_i + v_i \sin\theta_i}{d_{i+1}}\right) \tag{8}$$

It is possible to encounter situations where the distance between the object and the object is measured at time i and the distance between the object and the wall at time i+1 as indicated in Figures 1a and 1b. In this case, measurements numbered 1 and 3 will be evaluated together. If abnormal changes are detected in both measurements, measurements numbered 4 and 2, which are the forward direction, will be evaluated.

$$\theta_{i+1} = \arccos\left(\frac{d_i - v_i \cos\theta_i}{d_{i+1}}\right) \tag{9}$$

The signs of the sine and cosine functions in Equations 8 and 9 will be determined by taking into account the direction of the distance measurement and the sign of the angle. The position vector will be determined by taking into account the d4 and d2 measurements that are in the same direction as the direction of advancement.

$$\Delta x_{i+1} = d_i \cos\theta_i - d_{i+1} \cos\theta_{i+1} \tag{10}$$

If a sudden change is observed in the d1 and d3 measurements perpendicular to the direction of advancement, there is a possibility of an item or column protrusion.

4. Case study

The positioning accuracy was investigated when the sensor distributions were placed at $(x_1, y_1) = (5, 0)$; $(x_2, y_2) = (7, 0)$; $(x_3, y_3) = (10, 7)$; $(x_4, y_4) = (4, 10)$, and $(x_5, y_5) = (0, 6)$ as shown in Figure 2. In the case of a 1.0m x 0.3m column at point (5,5) of the room, the positioning accuracy of the blind spots relative to the sensors was investigated.

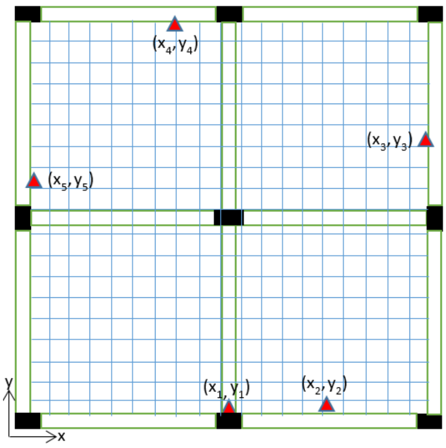


Fig. 2. Location of the columns and positions of the station points

The placement of sensors 1 and 2 on the same line and close to each other caused some points to be identified as blind spots by both sensors. Table 3 shows how many sensors identified a point as a blind spot for grid points created at 1 meter intervals.

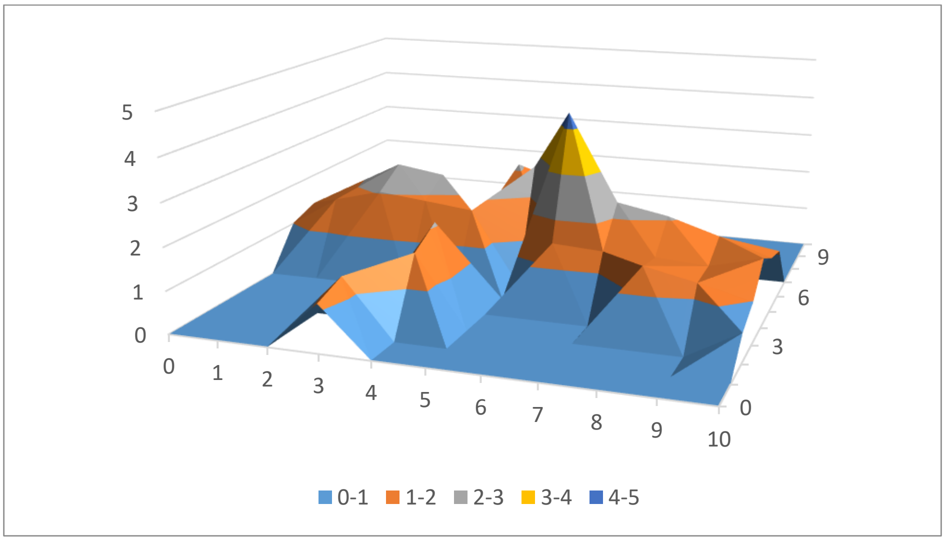

Fig 3. Positioning errors obtained as a result of simulation without considering the multipath effect

In order to determine the improvement provided by the proposed method, it is first assumed that the signals directly reach the receiving points and the distance values are computed accordingly when performing positioning with least squares adjustment. The error values of the positioning according to the position estimation without considering the multi-path tracking of the signals are visualized in Figure 3. The results are also tabulated in Table 4. The largest positioning error was 4.36m at (5,6) and the smallest positioning error was 0.00037m at (4,0).

Signals cannot reach blind spots directly, they follow reflected paths and reach the receiver. For this reason, positioning based on the assumption that the signal reaches the receiver directly will be incorrect. At these points, the analysis should be made by taking into account the length of the path that the signal will follow. The positioning errors obtained by neglecting the case where the signal reaches the receiver by following multiple paths are shown in Figure 4. The largest positioning error is 4.58m at (5,6), which is defined as a blind spot with respect to sensors 1 and 2. The next largest error was 1.04m at (4,10), which is also defined as a blind spot by sensors 1 and 2. The minimum error was 0.00037m at (6,1), where signals could be received without following multiple paths.

5. Conclusions

In this study, we focus on the cost analysis and positioning accuracy of the surveys of the buildings classified as medium damage level according to the locations of the sensors placed by using the integration of UWB sensor technology, indoor positioning methods and SLAM-based algorithms. High accuracy positioning is achieved at the points where the signals emitted from the UWB sensors can reach directly, but the positioning accuracy is reduced due to the multipath effect at the points where the signals cannot reach directly. In areas of the building where UWB signals are inadequate or do not reach at all, the SLAM algorithm is used to complete the missing areas in the measurements.

With the proposed algorithm, 31 out of 33 blind spots were successfully detected and positioning accuracies of the detected points are improved by implementing the proposed algorithm. Consequently, apart from the 2 unsuccessful points, important improvements were obtained in the analysis performed considering the multipath effect. Sensor placement has an impact on positioning accuracy, so the layout of the UWB sensors for high accuracy surveying was an important factor affecting the total hardware cost.

Understanding the key drivers of construction labor productivity in bricklaying

Abdirisak M. Abdillahi[1], Savaş Bayram[*2]

[1] Erciyes University, Graduate School of Natural and Applied Sciences, 38280 Kayseri, Türkiye
[2] Erciyes University, Faculty of Engineering, Department of Civil Engineering, 38280 Kayseri, Türkiye.

Abstract. Labor productivity in construction is crucial for project success. Despite its significance, productivity growth in the construction industry remains generally static. The building sector in Somaliland is fundamental to economic recovery and development, particularly following the devastation caused by the civil war. Understanding labor productivity is essential for improving the sector's contribution to economic advancement. This research collected data from 52 projects across four major cities in Somaliland: Berbera, Borama, Burao, and Hargeisa. A dataset of 532 cases of bricklaying activity was analyzed using descriptive statistics and non-parametric tests. Spearman's Rank Correlation, Kruskal-Wallis H, Mann-Whitney U, and Chi-Square tests were employed to examine relationships between productivity and various factors. Findings highlight the significant impact of resource availability, workspace conditions, and minimizing disruptions on labor productivity. This research provides actionable insights to improve productivity in the construction industry.

Keywords: Labor productivity; Drivers; Construction; Somaliland; Bricklaying

1. Introduction

Construction labor productivity (CLP) remains a critical concern in the global construction industry, with persistent challenges obstructing progress despite numerous efforts to improve it. Studies show that productivity growth in construction has either stagnated or declined in many countries, lagging behind other sectors in terms of innovation and efficiency (Van Tam, 2024). This issue is especially pressing in developing regions, where the construction sector is vital in economic development and post-conflict recovery. In Somaliland, construction is one of the most active and impactful industries, driven by the urgent need to rebuild infrastructure that was destroyed during the civil conflict. Building projects, particularly in urban centers, have become the backbone of urban renewal and national reconstruction efforts (Omar et al., 2020).

In construction, productivity is most commonly understood as labor productivity, typically defined as the ratio of output to a single input, labor. This form of partial productivity is widely used due to its practicality for task-specific assessments (Cevikbas, 2022). Labor productivity is especially significant because labor costs often account for up to half of a project's total expenditure (Buchan et al., 2012; Kaming et al., 1997; Zakeri et al., 1997). Consequently, a thorough understanding of labor performance is crucial for managing project costs and schedules effectively. As Ulubeyli et al. (2014) note, decisions related to labor allocation influence the overall time and budget of construction projects. Labor productivity metrics thus serve as benchmarks for contractors and managers in planning workforce needs, determining schedules, and estimating costs.

In recent years, research on CLP has intensified globally, reflecting a growing recognition of its impact on project success. Scholars have examined factors influencing labor productivity from various angles, including those of workers (Edwin & Calistus, 2023), engineers (Abdillahi & Kazaz, 2021; Attar et al., 2012), and broader stakeholder groups comprising clients, consultants, contractors, and suppliers (Alyew et al., 2020). These studies reveal a wide array of influences, from material supply and site conditions to communication practices and environmental constraints. Moreover, literature reviews by Momade et al. (2023) and Lee et al. (2023) show regional disparities in research priorities. While studies in North America and Europe focus on optimization techniques and advanced resource management, those in developing countries often address more fundamental challenges, such as labor shortages, site logistics, and informal project organization.

In the African context, including Somaliland, construction practices are often shaped by cultural norms, informal systems, and limited institutional support. Formal project management frameworks are weak or inconsistently applied, and much of the work relies on locally adapted methods of organization, negotiation, and

[*] Corresponding author, E-mail: sbayram@erciyes.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_438

leadership (Abdi & Hareru, 2024; Abdillahi et al., 2024). Understanding CLP in such a setting requires contextualized investigation grounded in local data and realities. To address this need, the present study explores the key drivers of construction labor productivity in bricklaying, one of the most common and labor-intensive activities in Somaliland's building sector. By grounding its findings in real-world data, this study contributes to a more inclusive understanding of labor productivity and provides practical insights for improving site performance under similar conditions.

The remainder of this paper is organized as follows: the next section presents the materials and methods used for data collection and analysis. This is followed by the results and discussion. The paper concludes with a summary of the main insights, their implications for construction management, and suggestions for future research.

2. Materials and methods

This study is based on a dataset collected by the researchers to explore the key factors influencing labor productivity in bricklaying. Data was gathered from 52 construction projects spread across four major cities in Somaliland, Berbera, Borama, Burao, and Hargeisa, over a five months from June to October 2024. The projects represented a mix of residential and commercial projects, providing a diverse and realistic snapshot of labor performance under varying site conditions.

Table 1. Description of variables used in the study

No	Variable	Type	Descriptions	Coding
1	Material Availability (MA)	Qualitative	Availability of materials needed for the work on-site	1 = Low Quantity, 2 = Medium Quantity, 3 = High Quantity
2	Weather Conditions (WC)	Qualitative	Weather condition on site	1 = Poor, 2 = Moderate, 3 = Good
3	Communication among Workers (CW)	Qualitative	Communication among workers on-site	1 = Poor, 2 = Medium, 3 = Good
4	Availability of Tools/Equipment (AT)	Qualitative	Availability of tools and equipment needed for work	1 = Low Quantity, 2 = Medium Quantity, 3 = High Quantity
5	Working Space Conditions (WS)	Qualitative	Working site conditions in terms of space	1 = Cramped, 2 = Adequate, 3 = Spacious
6	Rework Frequency (RF)	Quantitative	Number of reworks done by the crew in a day	Scale (0, 1, 2, etc.)
7	Accident Frequency (AF)	Quantitative	Number of accidents involving the crew in a day	Scale (0, 1, 2, etc.)
8	Working Hours (WH)	Quantitative	Number of hours worked by the crew in a day	Scale (e.g., 5, 6, 7, 8)
9	Gang Size (GS)	Quantitative	Number of laborers in the crew	Scale (e.g., 2, 4, 8, etc.)
10	Productivity (P)	Quantitative (Target)	Amount of work done per day per laborer per hour	$\frac{\text{Ammount of work done per day}}{\text{Number of labor perday} * \text{Work hour}}$

A total of 532 observations were recorded, each representing a daily productivity entry for a labor crew engaged in bricklaying. The dataset comprises 10 variables, including both qualitative and quantitative types. The target variable is labor productivity, defined as the amount of work completed per day per laborer per hour. The independent variables include material availability, weather conditions, communication among workers, availability of tools and equipment, and workspace conditions, all recorded as ordinal categorical variables. Additionally, rework frequency, accident frequency, working hours, and gang size were measured as continuous variables. The complete list of variables, their types, descriptions, and coding schemes is provided in Table 1. Descriptive statistics summarizing the data distribution are presented in Table 2, offering insights into the central tendencies and variability of each variable.

Table 2. Descriptive statistics of bricklaying data

Statistic	MA	WC	CW	AT	WS	RF	AF	WH	GZ	P
Count	532	532	532	532	532	532	532	532	532	532
Mean	2.68	2.50	2.63	2.94	2.56	0.22	0.14	7.22	6.72	23.91
Std	0.59	0.73	0.68	0.30	0.63	0.48	0.40	0.96	3.60	4.35
Min	1.0	1.0	1.0	1.0	1.0	0.0	0.0	5.0	2.0	12.5
Max	3.0	3.0	3.0	3.0	3.0	2.0	2.0	8.0	13.0	35.0

The current dataset serves as the foundation for the statistical analyses carried out in this study, aimed at identifying significant relationships between the selected factors and labor productivity in the context of bricklaying operations.

3. Results and discussion

Several methods are available for assessing the normality of data, including the Shapiro-Wilk test, Kolmogorov-Smirnov test, skewness and kurtosis analysis, and visual tools such as histograms, boxplots, P-P plots, and Q-Q plots. The Shapiro-Wilk and Kolmogorov-Smirnov tests are the most commonly used methods. The Shapiro-Wilk test is generally applied to smaller sample sizes ($N < 50$), while the Kolmogorov-Smirnov test is more suitable for larger samples ($N \geq 50$) (Yalçın & Bayram, 2023). In this study, the Kolmogorov-Smirnov test was used to assess the normality of the data. The results revealed significant deviations from normality, with p-values of 0.000, indicating that the data do not follow a normal distribution. Consequently, non-parametric tests were employed for further analysis to ensure accurate conclusions under the assumption of non-normality.

3.1. Correlation between productivity and key variables

Spearman's Rank Correlation was used to examine the strength and direction of relationships between productivity and the other variables. As shown in Table 3, several significant associations emerged. Working space conditions ($rs = 0.276$, $p < 0.001$) and tools/equipment availability ($rs = 0.201$, $p < 0.001$) displayed the strongest positive correlations with productivity, suggesting that improved site conditions and resource provision significantly enhance labor efficiency. Material availability ($rs = 0.146$, $p = 0.001$) and communication among workers ($rs = 0.088$, $p = 0.043$) also showed weaker but statistically significant positive relationships.

Table 3. Spearman's rank correlation between labor productivity and influencing variables (N = 532).

No	Variables	Spearman Correlation	p-value
1	Material Availability	0.146	0.0010
2	Weather Conditions	-0.118	0.0070
3	Communication among Workers	0.088	0.0430
4	Availability of Tools/Equipment	0.201	0.0000
5	Working Space Conditions	0.276	0.0000
6	Rework Frequency	-0.266	0.0000
7	Accident Frequency	-0.279	0.0000
8	Working Hours	-0.393	0.0000
9	Gang size	-0.052	0.2330

On the other hand, accident frequency ($rs = -0.279$, $p < 0.001$), rework frequency ($rs = -0.266$, $p < 0.001$), and extended working hours ($rs = -0.393$, $p < 0.001$) were negatively associated with productivity, reflecting the disruptive impact of unsafe or inefficient working conditions. Weather conditions ($rs = -0.118$, $p = 0.007$) also had a small but significant inverse relationship. Notably, gang size did not show a significant relationship ($rs = -0.052$, $p = 0.233$), indicating that crew size alone does not guarantee better performance. These results underline the importance of improving working conditions and minimizing disruptions on-site. They also support prior findings in the literature that emphasize workspace quality and resource availability as key productivity drivers (Alyew et al., 2020; Ulubeyli et al., 2014).

Fig. 1 illustrates the strength and direction of the relationships between productivity and the examined variables using a heatmap of Spearman's Rank Correlation coefficients. Positive associations are shown in warmer tones, while negative associations are depicted in cooler tones. This visual reinforces the statistical results in Table 3, highlighting the strongest positive correlations for working space conditions and tool availability, and the strongest negative correlations for working hours, accident frequency, and rework frequency.

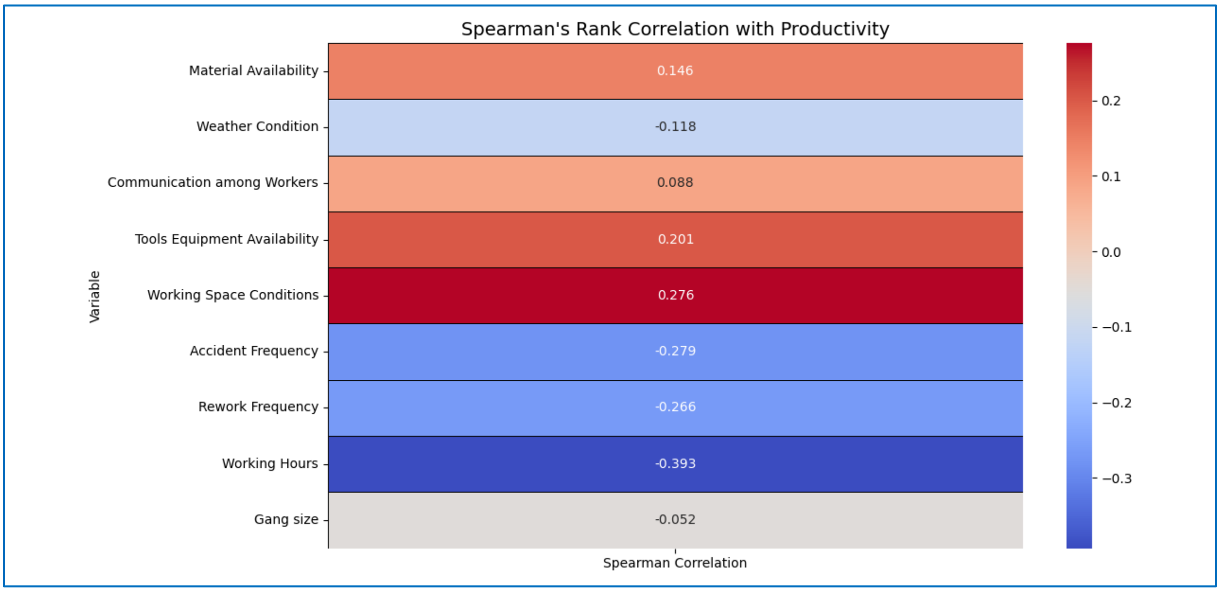

Fig. 1. Spearman correlation heatmap between productivity and influencing variables.

3.2. Group comparisons of categorical variables

To assess whether productivity significantly varied across different levels of key categorical variables, the Kruskal-Wallis H test was employed. As shown in Table 4, productivity differed greatly across all five variables tested. The strongest effect was observed for Working Space Conditions ($H = 43.011$, $p < 0.001$), indicating that laborers working in more spacious environments achieved considerably higher productivity than those in cramped or moderately sized spaces. Similarly, Tools Equipment Availability ($H = 25.161$, $p < 0.001$) and Material Availability ($H = 22.190$, $p < 0.001$) showed significant associations, which shows that access to necessary resources directly enhances work performance. Communication among Workers ($H = 23.724$, $p < 0.001$) was also a significant factor, reflecting the role of coordination and collaboration on-site. Lastly, Weather Condition ($H = 7.353$, $p = 0.025$) exhibited a smaller but statistically significant influence, indicating that productivity declines under poor weather conditions, a relevant concern in Somaliland's semi-arid climate, which presents frequent exposure to heat and dust, particularly on outdoor construction sites (Nelson et al., 2020). The influence of communication on productivity confirms Soekiman et al. (2011), who highlighted that poor communication on construction sites has a high effect on projects. These findings collectively underscore the importance of managing site environment, resource provision, and interpersonal dynamics to improve labor productivity.

Table 4. Kruskal-Wallis H test results

Variables	Kruskal-Wallis H	p-value
Material availability	22.190	0.0000
Weather condition	7.353	0.0253
Communication among workers	23.724	0.0000
Tools equipment availability	25.161	0.0000
Working space conditions	43.011	0.0000

3.3. Pairwise group comparisons

Following the Kruskal-Wallis results, Mann-Whitney U tests were conducted to compare productivity between the most contrasting groups (Level 1 vs Level 3) across selected categorical variables. These comparisons aimed to isolate the impact of moving from poor or limited site conditions to more favorable ones. As summarized in Table 5, all four variables demonstrated statistically significant differences in productivity between their lowest and highest levels.

Specifically, productivity was significantly higher under conditions of spacious working environments compared to cramped ones ($U = 3148.5$, $p < 0.001$), and when tools and equipment were highly available rather than scarce ($U = 262.5$, $p < 0.001$). Similarly, high material availability ($U = 3498.5$, $p < 0.001$) and good communication among workers ($U = 7939.5$, $p < 0.001$) were both associated with significantly higher productivity than their lowest categories. These results reinforce the importance of well-organized, well-equipped, and communicative work environments in maximizing labor output on construction sites.

Table 5. Mann-Whitney U test results for Level 1 vs Level 3 comparisons

Variable	Group Compared	Mann-Whitney U	p-value
Working space conditions	Cramped vs Spacious (1 vs 3)	3148.5	0.0000
Tools equipment availability	Low vs High (1 vs 3)	262.5	0.0000
Material availability	Low vs High (1 vs 3)	3498.5	0.0000
Communication among workers	Poor vs Good (1 vs 3)	7939.5	0.0000

3.4. Categorical associations

Chi-Square tests were conducted to explore potential associations between accident occurrence and key categorical variables, including resource availability, workspace conditions, communication, and rework. Given the practical and safety implications of accidents on construction sites, this analysis specifically examined accident frequency to categorical variables. Accidents are a critical barrier to productivity (Abdillahi & Kazaz, 2021). As shown in Table 6, only one statistically significant relationship was found. Weather Condition was significantly associated with accident frequency ($\chi^2 = 12.952$, $p = 0.0015$), indicating that poor weather may contribute to increased safety risks on construction sites.

No statistically significant associations were observed between accident frequency and other variables such as material availability, tool availability, working space conditions, communication among workers, or rework occurrence. While these factors are often considered influential in practice, the present data did not provide evidence of a strong statistical relationship. This may suggest that weather-related disruptions are the most immediate environmental concern for safety in the context of Somaliland's semi-arid construction sites.

Table 6. Chi-Square Test of Independence between Accident Frequency and Categorical Variables

Test	X^2 Value	Degrees of Freedom	p-value
Material vs Accident	0.986	2	0.6109
Weather vs Accident	12.952	2	0.0015
Communication vs Accident	0.446	2	0.8003
Tools and equipment vs Accident	1.162	2	0.5595
Space vs Accident	0.955	2	0.6204
Rework vs Accident	0.207	1	0.6489

4. Conclusion

This study investigates the key drivers of labor productivity in bricklaying within the construction sector of Somaliland, drawing on real-world data collected from 52 projects across four major cities. Using non-parametric statistical methods, the analysis revealed that factors such as working space conditions, availability of tools and materials, and communication among workers significantly enhance productivity. Conversely, disruptions, including frequent rework, extended working hours, and accidents, were found to negatively impact labor output.

The findings emphasize the central role of site conditions and resource availability in facilitating efficient labor performance. In particular, the consistent influence of workspace and tool access across multiple statistical tests underscores the need for construction managers to prioritize physical working conditions alongside technical planning. Notably, while many factors are assumed to affect safety and productivity, the data showed that only weather had a significant statistical association with accident frequency, highlighting the need for greater attention to environmental factors, particularly in semi-arid regions like Somaliland.

This study contributes to the growing body of productivity research by contextualizing findings in a post-conflict, low-infrastructure setting where formal project management frameworks are often absent. The practical implications are clear: improving basic site logistics, fostering team communication, and minimizing avoidable disruptions can yield measurable productivity gains even in resource-constrained environments.

The findings hold particular value for construction environments like Somaliland's, where informal labor structures and limited access to formal project management tools are the norm. By grounding the analysis in real-world conditions, this study demonstrates that meaningful productivity gains can be achieved not through high-tech solutions but through improvements in basic site organization, such as ensuring adequate workspace, maintaining tool availability, and promoting consistent crew communication. These are practical, low-cost interventions that local contractors and site supervisors can implement without systemic overhaul. Moreover, the results challenge assumptions common in highly industrialized settings, where factors like crew size and communication are typically strong predictors of productivity. In contrast, this study found that in Somaliland, these variables behaved differently, likely due to cultural norms, informal labor arrangements, and non-standardized communication practices on-site.

Future research should extend beyond bricklaying to explore productivity in other trades and across different project phases. Additionally, longitudinal studies tracking changes over time or intervention-based research testing specific productivity-enhancing strategies would further enrich understanding and application in the field.

Developing a virtual reality-based safety training tool for undergraduate civil engineering students

Umutcan Kılıç[1], İlyas B. Altun[1], Semra Çomu[*1]

[1] *Boğaziçi University, Department of Civil Engineering, 34342 İstanbul, Türkiye*

Abstract. Construction sites present numerous hazards, particularly for inexperienced individuals such as undergraduate civil engineering students completing mandatory site internships. Without adequate safety training, students may struggle to effectively recognize and respond to high-risk conditions, increasing the likelihood of accidents. This study proposes the development of an immersive, AI-powered Virtual Reality (VR) safety training tool integrating Unity, Convai, a VR headset, and motion controllers—to enhance civil engineering students' hazard recognition skills prior to exposure to real-world construction environments. The training module focuses on two critical risk sources commonly encountered on construction sites: falling from height and being struck by a moving object. Throughout the training, the students are accompanied by a voice-interactive AI-powered Non-Playable Character (NPC) who provides information regarding safety procedures and responds to their questions. Through a realistic and interactive simulation, students can observe the consequences of safe and unsafe behaviors and engage directly with an AI-powered NPC to ask safety-related questions. The anticipated outcomes of this study include enhanced hazard recognition, improved situational awareness, increased confidence in identifying risks, and the development of a proactive safety mindset among students. By demonstrating the potential of integrating AI-powered VR-based training into the civil engineering curriculum, this study aims to contribute to the broader goal of enhancing worksite safety by better preparing future civil engineers to understand and manage the complexities of real-world construction sites.

Keywords: Virtual Reality (VR) training; Artificial Intelligence (AI)-powered Non-playable Characters (NPCs); Unity VR Development; Construction Safety; Civil Engineering Education

1. Introduction

With high rates of occupational accidents and fatalities, the construction industry consistently ranks among the most hazardous sectors worldwide (International Labour Organization [ILO], 2023). In developing countries such as Türkiye, this risk is further amplified due to limited regulatory enforcement. Undergraduate civil engineering students are a particularly vulnerable group to these hazards, as they are often required to participate in mandatory internships or site visits without sufficient prior safety training. Their lack of practical experience and hazard awareness compromises their ability to recognize and respond effectively to unsafe site conditions, which might increase the likelihood of accidents during their early professional exposure. For instance, according to data from the Turkish Social Security Institution (SGK), nearly 25% of workplace injuries involve workers with less than one year of experience, a category into which many students fall (SGK, 2022). These statistics, when considered alongside the construction industry's widely recognized reputation for being hazardous, underscore an urgent need for innovative educational approaches that effectively equip students with relevant hazard recognition skills and safety awareness before they enter dynamic construction environments.

Traditional safety training is primarily theoretical and classroom-based. This approach often relies on crowded lectures given by an occupational health and safety expert and textual materials to communicate complex and dynamic site hazards. While it may be sufficient for conveying basic concepts, number of research indicated that traditional approaches fail to replicate the sensory and situational aspects of a real construction site, causing students and workers to struggle to translate what they learn in a classroom into practical situational awareness when confronted with active construction environments (Zhang et al., 2023). Furthermore, the lack of interactivity and engagement, which are often associated with traditional methods, can limit knowledge retention and can reduce students' motivation to internalize safety principles (Casey et al., 2021). Consequently, students may enter construction sites with limited risk awareness and hazard recognition, which will lead them to depend heavily on their observations and trial-and-error methods rather than proactive safety practices.

VR technology offers a promising alternative to traditional safety education methods. By immersing users in simulated environments, VR enables workers and students to experience realistic construction scenarios without exposure to actual danger. It allows them to observe, assess, and respond to hazardous conditions in a fully controlled and repeatable setting (Comu et al. 2021). This immersive approach enhances engagement and encourages active learning by allowing students to make decisions, see the outcomes of their actions, and receive immediate feedback. VR also accommodates a range of learning styles by combining visual, auditory, and kinesthetic elements, making it more effective than static teaching materials (Jena, 2016). According to Man et al. (2024), VR is significantly more effective than traditional methods in construction safety training, especially for enhancing behavior, skills, and experience, with its impact influenced by training context and worker experience.

Although several past studies have demonstrated the potential of VR-based safety training, they mostly relied on deterministic scenarios and predefined interactions that limit user input and adaptive learning (Akindele et al., 2024). In addition, most research investigating the integration of health and safety education into civil engineering curriculum has primarily focused on adapting traditional training content to better suit students' needs rather than reimagining the training method itself (Neto & Amaral, 2024). This study addresses these gaps by developing and evaluating a VR-based safety training tool specifically designed for undergraduate civil engineering students that incorporates AI-powered NPCs that students can communicate with using natural voice commands. The AI-powered NPC allows students to ask context-specific questions during training, receive verbal responses, and simulate real-time dialogue with a site supervisor or coworker. Because of its ability to replicate complex environments, dynamic risk factors, and authentic human interaction, the integrated VR-AI training system can significantly improve hazard recognition, situational awareness, and overall readiness among civil engineering students. By engaging with realistic site scenarios, students are expected to improve their hazard perception and response strategies before entering actual construction sites. This approach contributes to civil engineering education by promoting a proactive safety mindset and preparing students for the complexities of real-world construction environments.

2. Materials and methods

We developed the VR-based training tool using Unity, a cross-platform game engine widely used for immersive simulation design (Unity, 2024). We chose Unity for its flexibility, ease of use, and hyper-realistic graphics, which enabled us to rapidly develop a realistic construction environment. We designed the application to run on a standalone VR headset (HTC Vive Pro 2) with motion controllers (HTC Vive Controller), enabling full interaction within a virtual construction site. The virtual site was rendered in real-time using Unity's real-time rendering engine that ensured smooth visual feedback as users moved through the virtual site, which made interactions feel natural and allowed an experience as close as possible to the real world. To further increase realism and engagement, the system includes an AI-powered NPC with whom students can communicate using voice inputs through a microphone. This interactive NPC is powered by Convai, a conversational AI system integrated with Unity that combines speech-to-text (STT), large language models (e.g., GPT-4 and Gemini Flash), dialogue management, and neural text-to-speech (TTS) synthesis to enable realistic, voice-driven interaction with virtual characters (Convai, 2025). This integration allows adaptive learning where students can engage with the NPC to freely ask any questions that they might have. The system also includes a question filtering system to make sure that only questions relevant to the safety training module are answered.

The developed training tool simulates two of the most commonly encountered construction site hazards: falling from heights and being struck by a moving object. These scenarios were selected based on their frequency and severity in real-world construction sites (Kim et al., 2023). Within an interactive virtual environment, students are exposed to realistic situations where they are informed about these hazards and related safety practices. Each scenario presents both safe and unsafe behaviors, allowing students to observe the consequences of different actions when incidents occur. Safety recommendations and critical errors are highlighted before and after each scenario to reinforce the learning process. This scenario-based structure is intended not only to enhance hazard perception through consequence-based learning but also to support effective decision-making under realistic construction site conditions.

The training environment includes detailed 3D models of scaffolding, construction machinery and vehicles, construction materials, other workers, and other elements typically found on real construction sites. Figure 1 presents a screenshot of the virtual training environment as viewed from an aerial perspective. Throughout the training session, participants are accompanied by the AI-powered NPC. Figure 2 displays the AI-powered NPC's appearance inside the VR simulation. The AI-powered NPC offers verbal guidance and reminders to encourage reflective thinking during each stage.

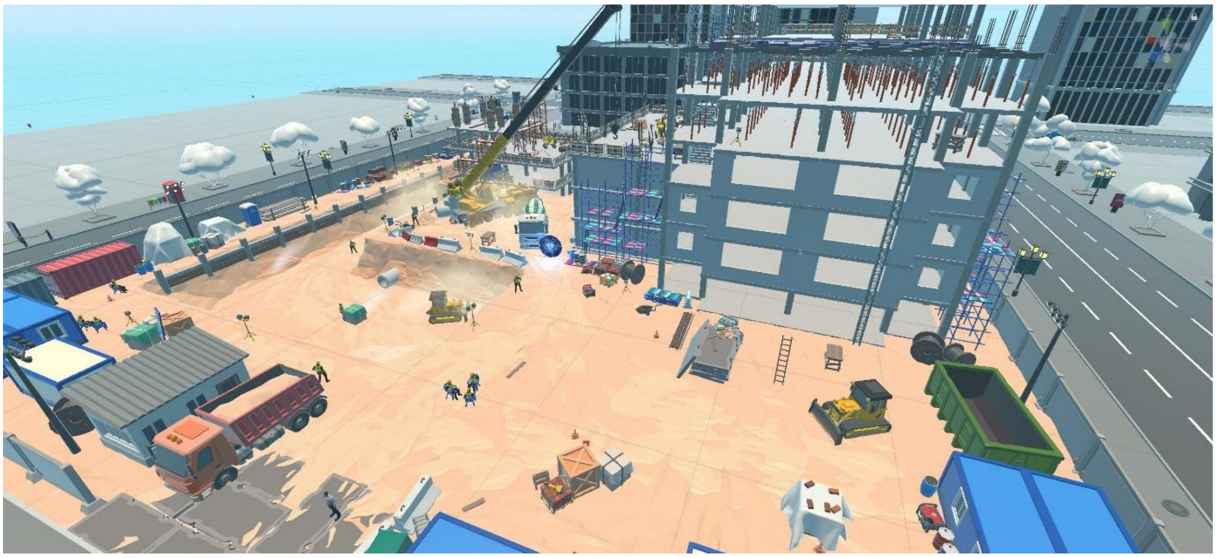

Fig. 1. Virtual training environment

Students can freely explore the virtual construction site and interact with various objects and workers. Hazards are integrated into the environment through scripted events developed in C# 8.0, while visual and audio cues enhance the sense of realism. The AI-powered NPC is designed to regularly prompt students to ask safety-related questions during the training. This immersive setup enables experiential learning by simulating real-world scenarios, reinforcing safe behaviors through observation and consequence-driven feedback, and encouraging active inquiry to deepen understanding.

The experiments were conducted with undergraduate civil engineering students who are in their freshman year and have not completed their mandatory site internships yet. Participation in the study was voluntary, and informed consent was obtained from all students prior to the experiment. A total of 7 students voluntarily participated in the study, and none of the students had prior experience in a real construction site. Following the VR training sessions, a survey was completed to evaluate the AI-powered VR-based safety training tool. Each session was conducted individually and lasted approximately 10 to 15 minutes per student. The overall goal of the experimental design was to measure the effectiveness of the AI-powered VR-based safety tool in improving construction safety competence of the students and also their opinion regarding the tool. The students were also instructed to ask at least one question related to the safety training and one unrelated question to evaluate the AI-powered NPC's response capabilities to different question types.

Fig. 2. AI-powered NPC guide

The survey was designed to capture quantitative feedback regarding the tool. The survey consisted of 12 close-ended statements rated on a five-point Likert scale (1 = Strongly Disagree, 2 = Disagree, 3 = Neutral/Uncertain, 4 = Agree, 5 = Strongly Agree). Table 1 demonstrates the Likert scale descriptions and corresponding intervals for analysis (Nyutu et al., 2020). Table 2 summarizes the 12 close-ended statements included in the survey, designed to assess students' perceptions of the VR-based safety training environment, including usability, engagement, realism, and perceived learning outcomes. The survey structure and content were informed by established practices in VR-based safety education and human-computer interaction design, as demonstrated in previous research (Abotaleb et al., 2022; Joshi et al., 2021; Xu & Zheng, 2020). In addition to the structured statements, participants were asked to provide qualitative feedback specifically regarding the AI-powered NPC, focusing on the relevance, clarity, and helpfulness of its responses to safety-related questions posed during the training. Survey responses were collected anonymously to ensure participant privacy and were used solely for research purposes. The collected data served to evaluate the overall effectiveness of the training tool and to identify specific areas requiring refinement, particularly in relation to the integration of AI-driven interaction and the realism of immersive training scenarios.

3. Results and discussion

Experiments were first conducted with seven first-year undergraduate students, who completed the AI-powered VR-based safety training session. Following the training, participants were asked to complete a survey consisting of 12 statements rated on a five-point Likert scale. The survey aimed to evaluate their perceptions of the training tool in terms of effectiveness, usability, realism, and educational value. Based on their context, the statements were categorized into three groups: (1) AI-powered VR-based Training Tool Related Statements, (2) Virtual Environment Related Statements, and (3) Learning Experience Related Statements.

Statements 1 through 6 comprise the first category of the post-training survey, focusing on participants' perceptions of the effectiveness, interactivity, and educational value of the AI-powered virtual reality (VR) training tool. Table 3 provides a summary of the descriptive statistics for each item. Based on the five-point Likert scale, which categorizes responses from "Strongly Disagree" (1.00–1.80) to "Strongly Agree" (4.21–5.00), the results reflect a generally positive evaluation of the training experience.

Among these six statements, only Statement 1, "The VR training improved my awareness of construction site hazards", received a mean score below 4.00 (M = 3.71, SD = 0.70), which falls within the "Agree" range (3.41–4.20). This suggests that, while students recognized the training's contribution to hazard awareness, their agreement was somewhat moderate. Similarly, Statement 3, "The AI NPC helped me better understand safety-related concepts", had a mean score of 4.14 (SD = 0.64), placing it near the upper boundary of the same range. These slightly lower ratings may reflect the current version of the training tool, which includes only two pre-defined scenarios: a fall-from-height incident and a being struck by a moving object incident. This limited scope likely reduced the diversity of hazardous events presented and restricted opportunities for meaningful dialogue and contextual learning with the AI-powered NPC.

Conversely, Statements 2, 4, 5, and 6 received mean ratings well within the "Strongly Agree" range. Notably, Statement 2, "The scenarios demonstrated clear consequences of unsafe behavior", achieved a high mean of 4.71 (SD = 0.45), indicating that the visual and narrative design of the scenarios effectively communicated the risks associated with unsafe practices. Statements 4 and 6 also performed strongly (both M = 4.57), suggesting that students found the AI NPC's responses to be both satisfactory and integral to the training's overall impact. Statement 5 received the highest mean score (M = 4.86, SD = 0.35), emphasizing that students overwhelmingly perceived voice-based interaction as a key factor in enhancing the naturalness and realism of the training environment.

These results highlight the value added by integrating conversational AI into immersive VR training settings. The strong agreement on interaction-related statements (4-6) suggests that students not only benefited from observing hazardous scenarios but also appreciated the opportunity to engage in a more personalized and responsive learning experience. This finding is consistent with previous research highlighting the positive role of AI-driven agents in improving user engagement and learning effectiveness across various educational domains (Lin et al., 2023).

Table 1. Five-point Likert scale descriptions and corresponding intervals

Likert-Scale Description	Likert-Scale	Likert Scale Interval
Strongly Disagree	1	1.00 – 1.80
Disagree	2	1.81 – 2.60
Neutral/Uncertain	3	2.61 – 3.40
Agree	4	3.41 – 4.20
Strongly Agree	5	4.21 – 5.00

Table 2. Survey content

ID	Statements
1	The VR training improved my awareness of construction site hazards.
2	The scenarios demonstrated clear consequences of unsafe behavior.
3	The AI-powered NPC helped me better understand safety-related concepts.
4	The AI-powered NPC's responses to my questions were adequate and satisfactory.
5	The voice interaction made the experience more natural and effective.
6	The training would have not been as effective if there was no AI NPC.
7	The training environment felt realistic.
8	I found it easy to navigate and interact within the virtual environment.
9	The scenarios reflected realistic construction site conditions.
10	I was able to focus and stay engaged throughout the session.
11	After completing the AI-powered VR training, I feel more confident about identifying hazards on a real construction site.
12	I would recommend this training tool to other civil engineering students.

In summary, while there is room to expand the scenario diversity to strengthen hazard awareness and conceptual learning, the current implementation of the AI-powered VR training tool was highly rated overall. The integration of natural voice interaction with a conversational agent appears to significantly enhance learner engagement, realism, and perceived training effectiveness, supporting the growing potential of such technologies in construction safety education.

The second category of the survey focuses on Statements 7 through 9, which assess students' perceptions of the virtual environment's realism, usability, and fidelity to actual construction site conditions. As shown in Table 4, the mean ratings for all three items fall within the "Agree" range (3.41–4.20), indicating a generally favorable reception of the virtual training environment.

Statement 7, "The training environment felt realistic", received a mean score of 3.43 (SD = 1.18), which, while indicating agreement, reflects the lowest mean in this category and shows considerable variation among responses. This variability may be influenced by students' differing levels of familiarity with immersive environments. Although the participants were first-year civil engineering students with no prior exposure to real construction sites, some may have had prior experience with VR technologies in other contexts (e.g., gaming or entertainment), which could have shaped their expectations and affected their perceptions of realism.

Statement 8, "I found it easy to navigate and interact within the virtual environment", achieved a higher mean score of 4.00 (SD = 0.76), indicating a consistent perception that the system was user-friendly and that the controls enabled seamless movement and interaction. This is a key aspect of effective VR-based training, as ease of use is essential for maintaining learner engagement and minimizing cognitive overload.

Statement 9, "The scenarios reflected realistic construction site conditions", received a mean score of 3.86 (SD = 0.99), suggesting that students generally found the training scenarios credible and aligned with what they imagine real site conditions to be. These perceptions are noteworthy given the students' lack of firsthand construction site experience and may again reflect the influence of prior exposure to digital or simulated environments. These findings are consistent with those reported by Xu and Zheng (2020), who observed that participants in their VR-based training, also developed with Unity, perceived the simulated environment as both usable and representative of real-world settings.

In sum, the results from this category suggest that the virtual environment effectively replicated core elements of a construction site, allowing students to engage in meaningful, risk-free safety training. Despite the absence of real-world experience, students were able to evaluate the tool's realism and usability, likely drawing on their prior familiarity with virtual platforms. This reinforces the value of immersive technologies in construction safety education, particularly for novices who have yet to access physical job sites.

Table 3. Survey results for AI-powered VR-based training tool related statements

Statement ID	Mean	Standard Deviation
1	3.71	0.70
2	4.71	0.45
3	4.14	0.64
4	4.57	0.73
5	4.86	0.35
6	4.57	1.05

Table 4. Survey results for virtual environment related statements

Statement ID	Mean	Standard Deviation
7	3.43	1.18
8	4.00	0.76
9	3.86	0.99

Table 5 presents the survey results for the third and final category of statements, which explores participants' overall learning experience. This category includes Statements 10 through 12, focusing on engagement, perceived learning outcomes, and students' willingness to recommend the training to peers.

Statement 10, "I was able to focus and stay engaged throughout the session", received a mean rating of 4.00 (SD = 1.07), indicating that students generally agreed that the training environment successfully maintained their attention. This finding is particularly important in the context of VR-based education, as previous studies have highlighted the risk of cognitive disengagement and sensory overload due to isolation in immersive settings (Abotaleb et al., 2022). The presence of an AI-powered NPC likely contributed to maintaining focus by fostering a more interactive and responsive learning environment, thus mitigating the typical shortcomings of VR training experiences.

Statement 11, "After completing the AI-powered VR training, I feel more confident about identifying hazards on a real construction site", also received a positive mean rating of 3.71 (SD = 0.16), indicating agreement among students, albeit with a narrow distribution of responses. Given that participants were first-year civil engineering students with no prior field experience, this result indicates the potential of immersive simulations to improve confidence and hazard recognition skills even among novices.

Statement 12, "I would recommend this training tool to other civil engineering students", received the highest mean rating in this category at 4.43 (SD = 0.49), falling within the "Strongly Agree" interval. This result strongly suggests a high level of satisfaction with the training experience and indicates students' belief in its value for their peers. Collectively, these findings reinforce the effectiveness of the developed AI-powered VR safety training tool in enhancing students' engagement, perceived preparedness, and peer endorsement.

Additionally, as part of the evaluation, students were instructed to interact with the AI NPC by asking at least one question relevant to the safety training and one unrelated question. All participants complied, asking exactly two questions each. For safety-related queries, all students reported receiving responses they deemed relevant and adequate. However, when it came to unrelated questions, the AI NPC responded to five out of seven inputs despite being designed to filter such content. It successfully identified only two unrelated questions and attempted to deflect them by humorously steering the conversation back toward safety training. While this behavior demonstrates some conversational flexibility, it also exposes a potential vulnerability in the system—namely, the risk of misinformation or unintended learning outcomes when off-topic dialogue is permitted.

This observation highlights the importance of implementing more robust content-filtering algorithms and topic-detection mechanisms in conversational AI agents, particularly in educational applications. Ensuring that the AI remains contextually aligned with training objectives is essential for maintaining educational integrity and avoiding distraction or confusion among learners. Overall, the results in this category affirm the pedagogical value of AI-integrated VR tools and highlight both their promise and the areas requiring further development to ensure safe, focused, and effective deployment in educational settings.

4. Conclusions

This study showcases the development and initial evaluation of an AI-powered VR-based safety training tool specifically designed for undergraduate civil engineering students. The developed tool addresses the limitations of traditional safety education, which often lacks interactivity, immersion, and practical applicability, by leveraging state-of-the-art technologies including Unity, VR headsets, motion controllers, and a conversational AI-based NPC. By simulating two of the most common construction hazards—falling from heights and being struck by a moving object in a virtual environment—the training tool aims to improve safety knowledge, hazard awareness, and proactive safety behavior among inexperienced civil engineering students before they enter real construction sites.

Table 5. Survey results for learning experience related statements

ID	Mean	Standard Deviation
10	4.00	1.07
11	3.71	0.16
12	4.43	0.49

Survey results collected from first-year civil engineering students indicate a high level of satisfaction with the training tool, its effectiveness, its usability, and its educational value. Notably, participants strongly agreed that the voice-interactive AI-powered NPC enhanced their safety training experience by making it more engaging and realistic. Moreover, the inclusion of consequence-based scenarios allowed students to internalize the importance of safe behaviors. Despite the limited number of scenarios included in the current version of the tool, the students expressed improved confidence in recognizing hazards and a willingness to recommend the tool to their peers, underlining its educational potential.

However, the study also identified a couple of areas for improvement. While the AI-powered NPC effectively responded to safety-related questions, its response filtering system requires further improvements to better identify and manage off-topic questions, preventing the risk of misinformation. This limitation is not only relevant to educational tools but should also be a key consideration for all applications integrating conversational AI to enhance user experience. Future iterations of the tool should incorporate a broader set of safety scenarios, more advanced AI filtering mechanisms, and a more diverse participant pool to strengthen its reliability, scalability, and generalizability.

In conclusion, the integration of VR and AI technologies in construction safety education showcases significant potential for transforming traditional methods. This study demonstrates that training tools, including not only virtual environments but also conversational AI agents, can play a critical role in equipping future civil engineers with the safety competencies necessary to navigate complex and hazardous construction sites. As civil engineering education continues to evolve in response to Industry 5.0 and Construction 5.0, tools like the one developed in this study will become essential components of modern civil engineering curricula.

The cost impact of using high fire-resistance materials in building claddings

S. Alperen Koçak*[1], Asude Göç[1], Hasan B. Başağa[1,2]

[1] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye
[2]Earhquake and Structual Health Application and Research Center, Karadeniz Technical University, Trabzon, Türkiye

Abstract. In this study, the impact of fire resistance of exterior cladding materials used in building construction on overall cost has been examined. Materials classified as A1, A2, B, and C were compared in terms of their fire resistance characteristics and associated costs. The primary objective was to determine whether the higher initial costs of fire-resistant materials are justified by their long-term benefits, particularly in terms of safety and reduced risk of damage in the event of a fire. The findings indicate that although fire-resistant materials—especially those in the A1 class—have higher initial costs, these are significantly outweighed by the long-term savings associated with reduced maintenance, repairs, and potential losses of life and property due to fire incidents. Furthermore, such materials offer additional value in critical infrastructures where fire safety is paramount, such as hospitals, schools, and other high-risk structures. The analysis also revealed that exterior cladding materials constitute a relatively small portion of the total building cost, making the selection of fire-resistant materials financially feasible without imposing a substantial burden on the project budget. In conclusion, it is recommended that materials with higher fire resistance be prioritized, particularly in densely populated areas and structures with elevated risk profiles. This approach not only ensures compliance with safety regulations but also helps protect human lives and property.

Keywords: Fire; Material; Cost; Cladding

1. Introduction

In recent years, large-scale fires have once again brought building safety to the forefront, especially in urban areas. These events have made fire safety an increasingly critical factor both in engineering design and in user awareness. Efforts to raise building standards and tighten regulations have led to fire resistance being considered one of the fundamental criteria in architectural design. While numerous factors influence a building's fire performance, one of the most impactful variables is the type of construction materials used. Specifically, during the onset and spread of a fire, the material type, its reaction, and its behavior play a decisive role.

Continuous developments in construction technologies have expanded the variety of materials used in building processes, thereby making it more feasible to meet safety criteria such as fire resistance. Today, thanks to innovative production techniques and advanced performance analysis tools, access to materials with high fire resistance or non-combustible properties has become more attainable. As a result, it is now easier to design buildings that comply with safety norms and sustainability principles alike.

In material selection, exterior cladding occupies a critical role in terms of fire safety. The spread of fire along a building's outer surface poses significant risks, especially in densely populated cities. Therefore, the fire resistance properties of exterior cladding materials have become an inseparable part of building safety. This importance is further underscored by real-world data, such as that from the Istanbul Fire Department's 2023 statistics, which report 6,456 residential fires, 290 factory fires, and 3,176 other building fires in that year alone. These figures clearly highlight the life-critical importance of using fire-resistant materials.

All these considerations demonstrate that material selection lies at the heart of fire safety strategies and directly impacts a structure's risk profile. Although fire safety standards and implementation principles vary from country to country, each nation has its own legal framework tailored to its specific conditions. In Turkey, the primary regulatory reference in this regard is the "Regulation on the Protection of Buildings from Fire." According to this regulation, exterior cladding materials must possess at least a Class C or higher fire resistance rating.

https://doi.org/10.31462/icearc2025_ce_mng_528

Despite their safety advantages, several economic and aesthetic challenges hinder the widespread adoption of highly fire-resistant materials. Especially when conducting cost-effectiveness analyses, decision-makers often opt for cheaper materials that offer less fire resistance. This situation necessitates a delicate balance between safety and economic sustainability. Consequently, material performance, in addition to cost, must be considered in fire safety-related decisions.

The literature addresses this issue from various perspectives. One group of researchers has argued that traditional construction materials do not provide sufficient fire safety for façades and thus called for the development of new-generation materials and application techniques. In this context, innovative solutions such as hybrid composite systems (Zhou, 2013) have gained prominence (Thevega et al., 2022). Another line of research experimentally analyzes the fire behavior of exterior cladding materials. These studies compare materials in laboratory settings in terms of ignition temperature, flame spread rate, and smoke production. The findings emphasize that, besides aesthetics and cost, fire performance should also be a key consideration in material selection (Hossain et al., 2021; McLaggan et al., 2021; Dréan et al., 2019).

A third approach involves retrospective analyses of fire incidents. Researchers adopting this method evaluate a building's fire performance based on post-event reports and on-site observations following large-scale fires. Such analyses offer concrete examples of risks posed by construction materials and often lead to questions about the adequacy of existing regulations (Yaman and Demirel, 2020; İnce, 2016).

Unlike previous studies, this research does not focus on a specific building typology. Instead, it addresses the relationship between fire safety and material cost from a broader economic perspective. Material unit prices are analyzed independently of building types, and in this context, the study explores how decisions can be made to ensure both fire safety and economic sustainability. The ultimate aim is to support decision-makers in selecting materials that are both fire-resistant and financially viable.

2. Aim of the study

This study analyzes the relationship between fire performance and cost based on the unit prices of façade cladding materials used in buildings. Fire safety, which has become a critical design component particularly in densely populated urban areas, is addressed in conjunction with economically sustainable solutions. In this context, the costs of materials with different fire reaction classifications are compared. The study aims to guide decision-makers in making optimal choices between fire safety and cost-effectiveness across various scales and types of construction projects. In this regard, it differentiates itself from the existing literature by offering a material-based and comprehensive economic assessment.

3. Methodology

This study was conducted to analyze the economic impact of façade cladding materials based on their fire resistance classifications and to evaluate the relationship between fire safety and cost-effectiveness.

The study was carried out in three main steps:

1. Identifying the fire classification categories to be considered within the scope of relevant regulations,
2. Selecting the façade materials corresponding to the identified fire classifications,
3. Conducting cost analyses of the selected materials.

3.1. Material fire classes

The fire resistance ratings of materials used in the construction sector are determined based on the classification system outlined in the Regulation on the Protection of Buildings from Fire. Each material is categorized according to this system, and its fire performance is evaluated accordingly. Under the relevant regulation, building materials are classified into seven categories—A1, A2, B, C, D, E, and F—based on their combustibility levels. In the scope of this study, only materials used in façade cladding that fall under the mandatory fire resistance classes A1, A2, B, and C were considered.

3.2. Material selection

A wide range of materials fall under the fire resistance classes considered in this study. During the selection process, both the fire resistance performance and the accessibility and common usage of materials in the industry were taken into account. The technical properties and application areas of the materials were examined in detail through literature review and market research. In this way, the material selection was carried out to reflect both the requirements of the regulations and the real-life conditions likely to be encountered in practice. The materials selected for the study and their corresponding fire resistance classes are presented in Table 1.

Table 1. Materials with classes

Material	A1	A2	B	C

Carbon-Based EPS				X

3.3. Final unit prices

This study examines the relationship between the fire performance and the cost of materials used in façade construction. In this context, the unit costs of selected materials were compared. However, to ensure a realistic comparison, the assessment was based on the completed state of façade applications. Therefore, for materials used solely as insulation, additional construction components such as plaster (item no 15.275.1111) and paint (item no 15.540.1601) were also included in the evaluation. Conversely, for materials used primarily as cladding, insulation applications—specifically stone wool (item no 15.341.3001)—were integrated into the cost analysis. The unit prices of the selected materials were obtained from the 2025 unit price lists published by public institutions, primarily the Ministry of Environment, Urbanization and Climate Change. The selected materials, their unit prices, and final unit costs are presented in Tables 2, 3, 4, and 5.

In this study, a representative building model was created to calculate the share of exterior cladding materials in the total building cost. In this model, a multi-story residential building with two apartments on each floor and a floor area of 25x20 m (500 m²) was considered. The total cost of this building was calculated based on the unit construction costs for the year 2025 published by the Ministry of Environment, Urbanization, and Climate Change of the Republic of Turkey. These costs were categorized into three different categories according to building height: less than 21.5 m, 21.5–30.5 m, and 30.5–51.5 m. Cost analyses for different building height scenarios were performed, considering these classifications.

In calculating the cost of the exterior cladding, the surface area of the building's façade was approximately determined. In this calculation, the building's perimeter was multiplied by the building height, and then a 15% reduction was made from the total surface area to account for openings such as windows and doors. This method was chosen as an approach that simplifies the area calculation but still allows for realistic results.

With this representative model, the share of exterior cladding material costs in the total building cost for various building heights was analyzed by comparing the unit prices of materials with different fire-resistance classes. The obtained data show that the total cost impact of fire-resistant cladding materials on the project is limited, and therefore, products providing high fire safety are economically feasible as well.

Table 2. A1-class materials

Material		Item No	Unit Price (TL)	Final Unit Price (TL)
Glass Mosaic Cladding		15.445.1001	886,10	886,10

5. Results and discussion

The ratio of the exterior cladding cost to the total building cost, based on building height and the exterior cladding, is provided in Table 6.

As the building height increases, the cost ratios of non-combustible materials generally decrease. This indicates that the use of non-combustible materials in taller buildings does not lead to a significant increase in cost. According to the data, the price difference between A1 and A2 class high fire-resistant materials and other materials decreases as the height increases. Specifically, in high-rise buildings, there is only a 0.20% difference between the most expensive materials chosen for aesthetic and safety purposes and the least expensive, widely preferred materials. Although there are materials with significantly different costs in the A2 class, economic solutions can still be found. This shows that the use of non-combustible materials, while necessary for safety in high-rise buildings, does not impose a substantial cost burden.

The selected materials, under the non-combustibility class categories, are presented in maximum, minimum, and average values in Fig. 1.

Table 6. The ratio of cladding costs to total building costs

Materials		>21,50 m	21,50-30,50 m	30,50-51,50 m
A1	Glass Mosaic Cladding	%2,23	%2,12	%1,89
	Ceramic Cladding	%2,61	%2,48	%2,21
	Seamless Natural Stone Cladding	%3,37	%3,20	%2,85

	Carbon-Based EPS	%4,31	%4,10	%3,65

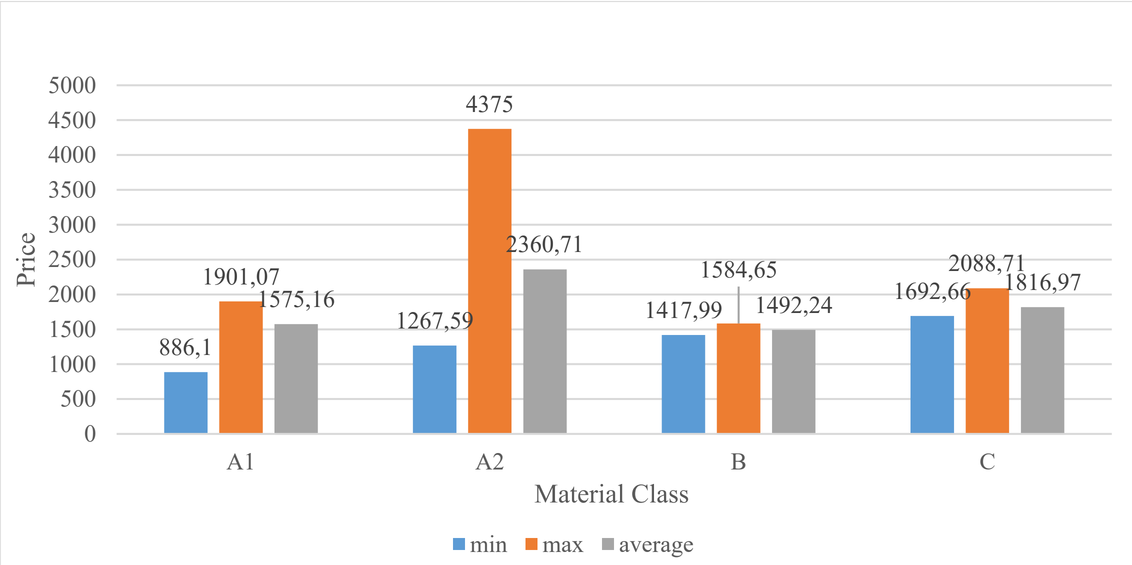

Fig. 1. Minimum, maximum, and average unit costs of cladding materials by class

When the selected façade cladding materials are examined according to their fire reaction classes, it is observed that the highest average cost is found in the A2 class, at 2,360.71 TL, followed by C (1,816.97 TL), A1 (1,575.16 TL), and B (1,492.24 TL) class materials. It is noteworthy that A1 class materials, which have the highest fire resistance, have a lower average cost compared to A2 and C class materials. This suggests that more fire-resistant materials are not always more expensive.

When the maximum and minimum cost ranges are examined, it is observed that the A2 class shows a wide distribution (4,375 TL – 1,267.59 TL), indicating variation in quality or production diversity within this class. In contrast, the B and C classes have narrower cost ranges, suggesting that the prices in these classes are more predictable.

According to the findings, high fire-resistant materials such as those in the A1 class have competitive average cost levels, and in some cases, are even more economical than lower-class materials. This result indicates that the impact of choosing superior materials for fire safety on the total project cost may be limited and could remain at an economically negligible level. Therefore, the selection of fire-resistant materials can be considered a reasonable choice not only in terms of safety but also in terms of sustainability. (Fig. 1)

A1 sınıfı malzemelerinin nihai birim fiyatları Fig. 2.'de gösterilmiştir.

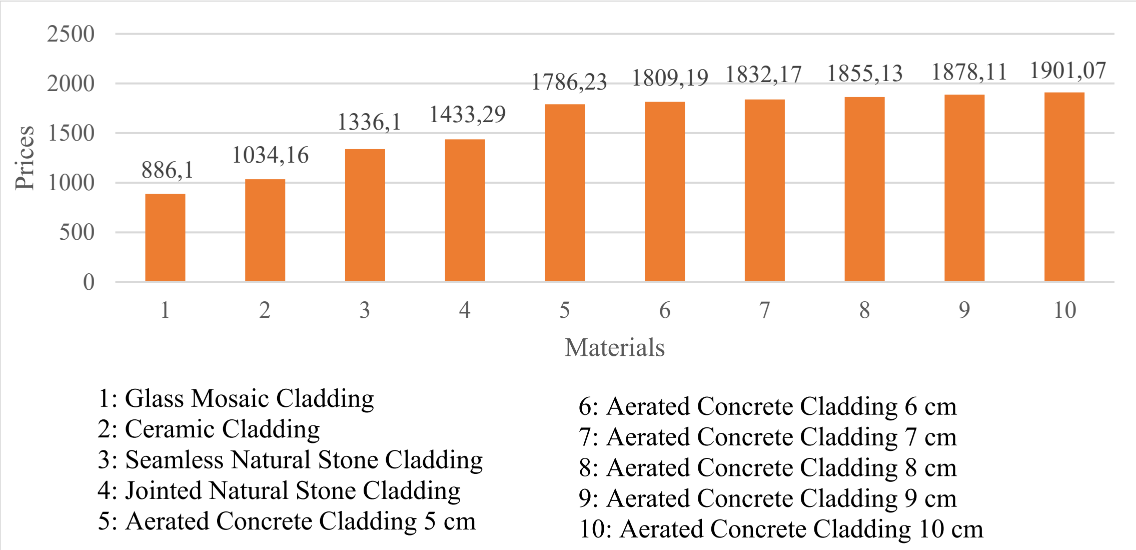

Fig. 2. A1-class materials

A1 class façade cladding materials include various building materials such as mineral-based products, natural stone, and ceramics. The unit costs range from 886.10 TL to 1,901.07 TL, with an average cost of 1,575.16 TL. This shows that A1 class materials, which offer the highest level of fire resistance, are available in a wide price range and can cater to different budgets.

When the data is examined, it is seen that the lowest-cost product is Glass Mosaic Cladding, at 886.10 TL, while the highest-cost product is Aerated Concrete Cladding (10 cm), at 1,901.07 TL. Decorative and aesthetically strong materials such as Ceramic Cladding and Natural Stone Cladding are priced at mid-range levels.

Overall, A1 class materials are notable not only for their fire resistance but also for their accessible cost structures. Thanks to the wide product range, a balance between aesthetics, technical performance, and budget can be achieved, making A1 class materials a rational choice for many projects. (Fig. 2)

The final unit prices of A2 class materials are shown in Fig. 3.

A2 class cladding materials have a very wide price range. The lowest cost is recorded as 1,267.59 TL for Cement-Based Cladding (1.5 mm), while the highest value is 4,375 TL for Electrostatic Powder-Coated Aluminum Sheet. The average unit cost of 2,360.71 TL indicates that this class generally falls into the medium-high cost group.

Stone Wool-based products (5–10 cm thickness) offer a balanced and performance-oriented option with prices ranging from 1,854.62 TL to 2,030.77 TL. As the thickness increases, the cost rise remains relatively limited, which indicates that the fire resistance can be increased while keeping costs under control in projects. On the other hand, Cement-Based Cladding products stand out with their low costs and emerge as an economic alternative within the A2 class.

However, materials developed with advanced technology and aesthetic concerns, such as Aluminum Sheet With Stone Wool and Electrostatic Powder-Coated Aluminum Sheet, show a rapid increase in cost. This observation demonstrates that the A2 class has a very wide product variety and that selections can significantly affect the cost based not only on fire performance but also on material type and design.

In conclusion, A2 class materials provide acceptable fire resistance performance, while their cost diversity offers flexible solutions for different projects (Fig. 3).

The final unit prices of B class materials are shown in Fig. 4.

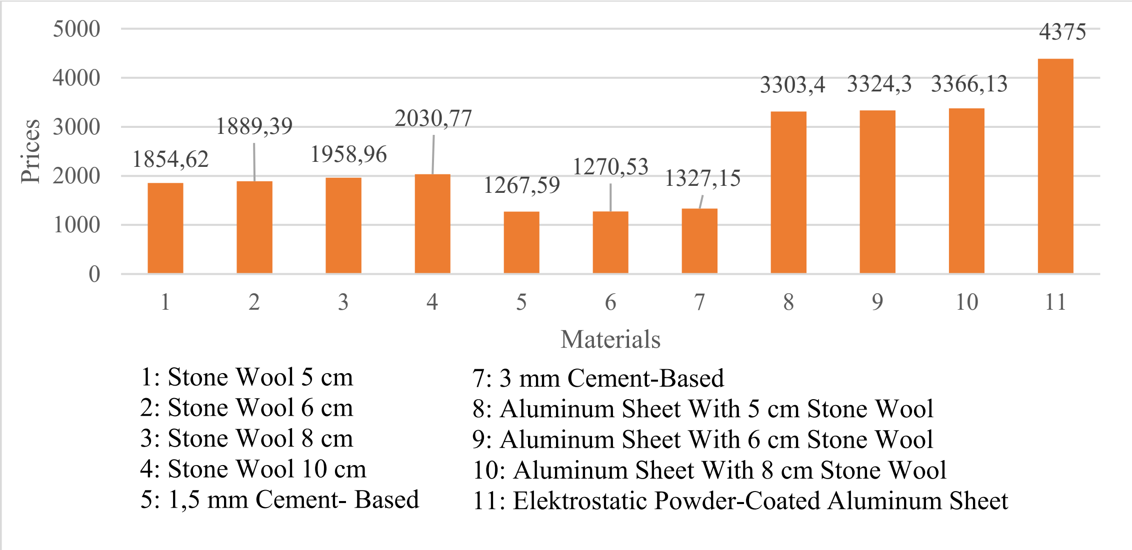

Fig. 3. A2-class materials

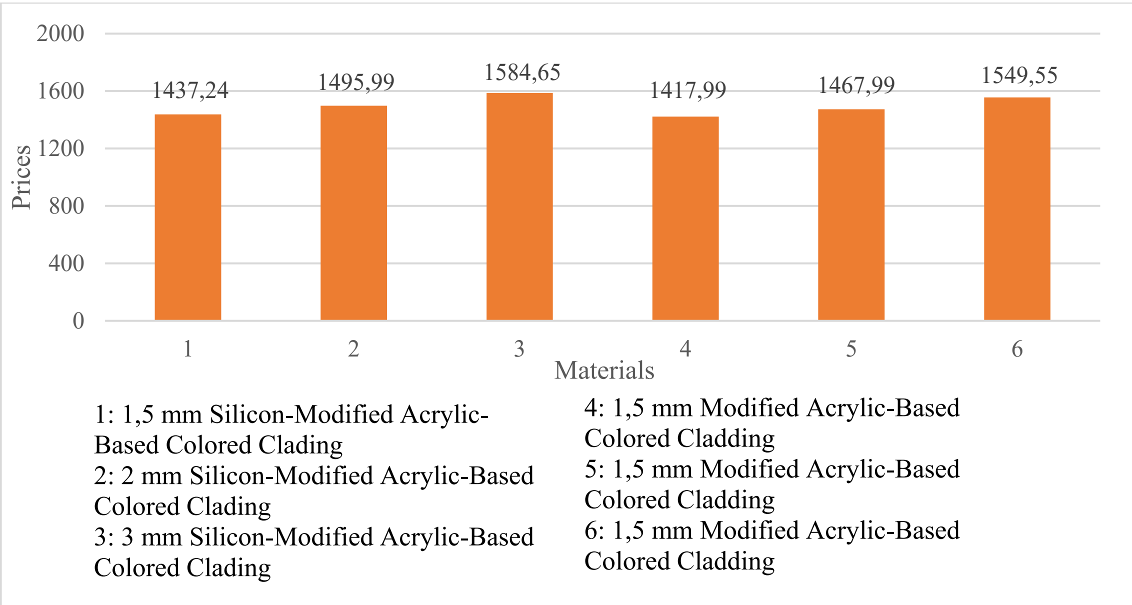

Fig. 4. B-class materials

B class cladding materials generally include acrylic-based and colored cladding solutions. The unit costs of materials in this class range from 1,417.99 TL to 1,584.65 TL, with an average value of 1,492.24 TL. This narrow price range indicates that the products are homogeneous both in terms of content and application, and that market prices have shaped within a certain balance.

According to the data, the lowest cost product is the 1.5 mm Modified Acrylic-Based Colored Cladding at 1,417.99 TL, and the highest cost product is the 3 mm Silicon-Modified Acrylic-Based Colored Cladding at 1,584.65 TL. As the thickness increases, the cost rises gradually, and it is also observed that silicon-modified products are sold at a higher price compared to standard acrylic coatings of the same thickness.

In conclusion, B class materials offer different technical specifications with limited cost differences and strike a balance between fire resistance and aesthetic expectations. However, in buildings where fire safety is a priority, the use of materials from this class should be carefully considered (Fig. 4).

The final unit price information for C class materials is shown in Fig. 5.

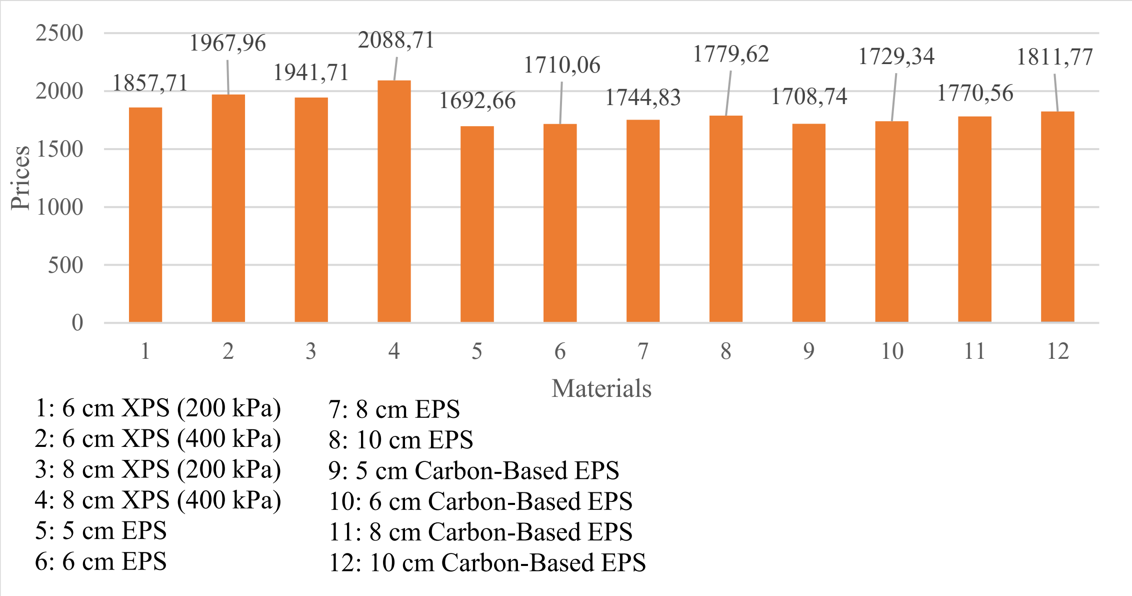

Fig. 5. C-class materials

C class cladding materials generally consist of low-density insulation products, particularly those based on XPS (Extruded Polystyrene) and EPS (Expanded Polystyrene). This class offers more limited performance in terms of fire resistance but is positioned in the mid-range in terms of cost. According to the data, the unit prices of the products range from 1,692.66 TL to 2,088.71 TL, with an average cost of 1,816.97 TL.

EPS and Carbon-Based EPS products typically offer low-cost options. Standard EPS with a thickness of 5 cm is priced at 1,692.66 TL, while the 10 cm thick version increases to 1,779.62 TL. Similarly, carbon-enhanced EPS prices rise with thickness, ranging from 1,708.74 TL to 1,811.77 TL.

On the other hand, XPS products, especially those with high pressure resistance, offer more costly solutions. A 6 cm thick XPS with a 200 kPa pressure resistance costs 1,857.71 TL, while the same thickness with a 400 kPa version is priced at 1,967.96 TL. When the thickness increases to 8 cm, the price reaches 2,088.71 TL.

In general, C class materials provide low-to-medium level fire performance, but their prices can approach those of some A1 class products. This presents a controversial situation in terms of fire safety, indicating that the cost-fire safety balance should be carefully reconsidered (Fig. 5).

6. Conclusions

This study compared cladding materials of different fire resistance classes and evaluated the effects of fire resistance levels on cost. The findings indicate that, although materials with high fire resistance appear to have higher initial investment costs, considering their contribution to building safety and human life, this cost difference is justified and necessary.

When building cost analyses are considered, it is evident that cladding materials have a small share of the total building cost. For example, there is only a 0.20% difference between the most expensive material of class A1 and the cheapest material of class C. Therefore, the choice of materials with higher fire resistance does not significantly impact the total project budget. This situation makes the use of higher-quality materials for fire safety also economically sustainable.

Additionally, while materials with lower fire resistance classes may offer cost advantages in the short term, they increase the total cost of ownership over time due to performance loss, maintenance, and repair needs. This creates risks for long-term building performance and user safety.

Especially in buildings with a high importance coefficient such as hospitals, schools, and public buildings, the use of class A1 fire-resistant materials should be preferred. In densely populated areas, these materials should become the standard. This approach not only ensures compliance with regulations but also fulfills the responsibility of protecting human life.

Estimation of construction material consumption with smart contract

Ali Uzunkaya*[1], Suat Topuz[1], Önder H. Bettemir[1]

[1] *İnönü University, Department of Civil Engineering, 44280 Malatya, Türkiye*

Abstract. Monitoring the remaining amount of the stocked material stored at the construction site is difficult and error prone when the intense and hurried work at the construction site is considered. Underestimating the construction wastes leads to ordering materials in short quantities while overestimating the wastes would lead to long term storage requirements of the material which may lead to deteriorate. In this study a smart contract based construction material quantity tracking frame system is proposed in order to prevent the aforementioned adverse consequences. The proposed system detects the required amounts of construction material from the quantity take-off data. The construction schedule is investigated to detect the time of the consumption requirement of the construction material. Proposed system determines the order time of the material to ensure the on time commencement of the construction activities. The waste amounts of the construction material are measured and the quantity of stock is updated by considering both the waste and the construction progress. The frame work detects any lack of construction material and updates the material order quantities and the corresponding payment amounts.

Keywords: Smart contract; Scheduling; Construction site management.

1. Introduction

Construction projects are complex processes that involve many dynamic factors from the planning to the completion stages and need to be continuously monitored. The material supply chain plays a key role in this process; the on time and within budget completion of the construction depends on the efficiency of suppliers and inventory management. It is very important that the required materials throughout the construction process are supplied at the appropriate time, in the right quantity and quality, and that these materials are stored and monitored properly. Incomplete, faulty or late delivery of materials to the construction site may cause delays in the construction process, while overstocked materials may cause contractors to make procurement payments earlier, and some of the materials that are stocked for a long time may be deteriorated due to the harsh environmental conditions and become unusable. Aforementioned situations may lead to an increase in costs. Therefore, proper procurement and inventory management is vital for the uninterrupted progress of the construction process.

Traditional procurement and inventory management methods are often based on manual data entry, human intervention and paper-based recording systems. Such processes are prone to errors and create many problems that reduce efficiency and slow down the process. Moreover, construction schedule may be updated according to the progress reports and the traditional methods require notification of the updated schedule to each department and any glitch may lead to the execution of the outdated construction schedule for procurement. Aforementioned event will lead to incorrect execution of the material procurement process and causing cost and time increases in the project. In this context, technology-based solutions, especially blockchain and smart contracts, contribute to the digitalization of procurement and stock tracking in the construction industry, creating a reliable and traceable material procurement and monitoring framework.

Smart contracts using blockchain technology offer powerful tools for the modernization of the supply chain in the construction industry (Li & Kassem, 2021). Smart contracts are reliable code snippets that can automatically initiate transactions under predefined conditions (Zheng et al., 2020). The entry or exit of a material into or out of a warehouse can be verified and recorded by smart contracts under these conditions. This structure allows transactions to take place securely and transparently, without the need for any human intervention. In addition, it accelerates decision-making processes and minimizes the margin of error by providing up-to-date and accurate information for all parties (Raffik et al., 2021).

In this study, the integration of an MS Excel-based inventory tracking system and blockchain-based smart contracts is analyzed. MS Excel offers flexible data processing and analysis solutions. With this feature, it is an

*Corresponding author, E-mail: 36223621016@ogr.inonu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_579

golden light publishing

ideal tool for creating a user-friendly procurement and inventory tracking system. It can also be preferred as a cost-effective solution in small and medium-sized projects. With this infrastructure offered by MS Excel, manual data entry, stock control and reporting processes will be facilitated and material stock movements will be made traceable. In this study, it is aimed to create a detailed roadmap for automating material procurement and stock tracking in the construction process with blockchain-based smart contracts. In the next section of the paper, the literature review is presented, followed by the methodology section, which describes the creation of a spreadsheet application file that enables the tracking of material order and stock status with a smart contract. In the last section of the paper, the results are discussed.

2. Literature review

Carrying out accurate and fast inventory management of assets in warehouses is a critical factor in terms of operational efficiency and cost control. However, manual counting has disadvantages such as high labor requirement, time loss and error risks. A semi-automated system (SAS) combines the advantages of existing manual and automated systems used in inventory counting. SAS automates many processes in the counting process, while it does not make the process completely unmanned and it requires warehouse workers. Increasing operational efficiency by reducing inventory counting time with a semi-automated system is an important factor (Cidal et al., 2019) Manual inventory counting in warehouse management requires a lot of labor and time and increases error rates (Tong, 2023). Tong aimed to improve warehouse inventory management processes by designing an intelligent system that speeds up the counting process, increases accuracy and minimizes human errors by using automation technologies. The system provides accurate counting and positioning of products with sensors, Radio Frequency Identification (RFID) and barcode technologies used in the warehouse. It makes the warehouse inventory counting process more accurate, fast and cost-effective. With the semi-automatic system, this process is made more efficient with less labor usage. The study also aims to develop a flexible and intelligent system that can be used in different warehouse conditions (Tong, 2023)

Currently, warehouse inventory management is usually carried out by manual operations or partial automation, and these methods increase limited data access, cost and labor requirements. The main objective of the proposed system by (Grmek at el., 2011) is to optimize the inventory management process by using the advantages of cloud infrastructure such as centralized data access, flexibility, real-time tracking and low cost. The prototype provides great convenience to businesses by automatically monitoring warehouse inventory, increasing data accuracy and providing users with quick access to inventory information (Grmek at el., 2011). The automatic data collection system developed by (Montaser, 2023) offers significant advantages in terms of data accuracy and speed, resource management, real-time monitoring, ease of decision making, security and risk management. This system increases data accuracy by reducing manual errors, provides real-time access to information through automated processes and facilitates managers to evaluate the project in a timely manner. In resource management, it prevents unnecessary waste by ensuring efficient resource utilization, while saving costs by shortening manual data collection time (Montaser, 2013).

Material losses, misplacement and inventory imbalances can increase the costs of construction projects and prevent their timely completion. In this context, RFID technology has emerged as an effective solution for automated material tracking systems. Kasim et al. explained the integration of RFID technology for material tracking in construction projects and emphasized the contribution of these systems to business processes. They aimed to reduce costs and ensure project efficiency by increasing the effectiveness of these systems (Kasim at el., 2019). Traditional inventory management methods can be time consuming and prone to human error. By providing automation of warehouse inventory management processes, it is aimed to increase efficiency, reduce costs and minimize human errors. Automation in warehouse management increases overall efficiency by enabling processes to be performed faster and more accurately. The benefits of automated warehouse inventory management include increased efficiency, error reduction, cost reduction and improved monitoring and control. Automation speeds up business processes by enabling inventory to be updated quickly and reduces reliance on manpower, resulting in more efficient use of labor. In addition, human errors are minimized thanks to automated data collection systems. Barcode and RFID technologies increase the accuracy of inventory data and improve the reliability of the data. Automation, which also has a positive impact on costs, reduces labor costs, performs certain tasks with robotic systems and enables optimization of stock levels with better inventory management; this reduces costs by preventing unnecessary stock accumulation (Hajibabaei, 2024).

Material management in construction projects is critical to the success of the project. Material tracking applications play a major role in effectively managing and controlling material movements. Traditional methods are often limited to manual operations, which can lead to errors, time loss and cost increase (Liwan et al., 2013). The construction industry is turning to technological innovations to overcome the challenges faced in materials management and supply chain processes. Material tracking technologies increase the efficiency of construction projects, reduce costs and make business processes more effective by automating processes. Young evaluated the performance of automated material location and tracking technologies in the construction supply chain and identified the potential advantages that these technologies can provide (Young, 2009).

Supply chain management is a critical area to improve the competitiveness of modern businesses. Rapidly changing market conditions and customer demands have led to the need to optimize inventory control and supply chain processes. Industrial automation tools and industrial internet of things (IIoT) offer many advantages in terms of supply chain control and inventory management. Thanks to IIoT, businesses can make faster and more effective decisions by accessing real-time data at every stage of the supply chain, while automation processes enable faster adaptation to changing market conditions. In addition, automated systems help optimize stock levels, reducing inventory costs and thus giving businesses a competitive advantage. Continuous monitoring and analysis of data provides an advantage in risk management by identifying potential problems in advance. IIoT provides better communication between different departments by improving data flow throughout the supply chain (Raffik et al., 2021). Material management in construction projects is a critical process that directly affects project efficiency and success rate. Difficulties in material tracking can lead to time loss, cost increase and quality problems. Therefore, it is necessary to establish an effective material tracking system. Innovative tools such as RFID, barcode and IIoT increase the speed of operations by making material tracking processes more effective. In addition, the training that employees receive about the system ensures the effective use of material tracking systems. Systems created with the participation of stakeholders provide better communication and coordination between all parties, making material management processes efficient. These systems keep costs under control while minimizing risks in projects by reducing material loss and waste (Liwan, 2015).

In the construction industry, materials management is critical for cost control and project efficiency. Keeping track of materials on site, providing timely access and positioning them in the right place are critical to the success of projects. RFID (Radio Frequency Identification) technology is used to make material tracking processes more precise. It increases the accuracy of material location estimates through reference RFID tags (Razavi, 2011).
Supply chain management (SCM) is important for the realization of objectives such as cost reduction, efficient use of time and optimal allocation of resources in construction projects. The complex and multi-stakeholder nature of projects in the construction industry necessitates the effective management of supply chain processes. Studer and Mello (2021) analyzed the main elements required for successful supply chain management in the construction industry and their impact on the success of the project (Studer, 2021).

The construction industry is known for its large number of stakeholders, unpredictable timelines and fluctuating material demands. Effective SCM is critical to ensure that projects are completed on time, within established budgets and in accordance with the required quality standards. Optimization in construction supply chain management can increase efficiency, reduce costs and improve overall project output. Golpîr and Tirkolaee investigated key strategies for optimization in construction supply chain management, exploring areas ranging from demand forecasting to inventory management, procurement strategies to logistics (Golpîra & Tirkolaee, 2021). In the construction industry, inventory management plays a critical role in ensuring that project deadlines are not exceeded, costs are reduced and materials are available when needed. Since construction projects are intertwined with fluctuations in material demands and project-specific needs, traditional inventory systems cannot adequately cope with the dynamic and complex nature of construction projects. (Kumar et al., 2024) developed a machine learning (ML) based intelligent inventory system designed to optimize inventory management in the construction industry. The proposed system utilizes advanced ML algorithms for accurate demand forecasting, real-time inventory tracking and automatic stock replenishment (Kumar et al., 2024).

Although the construction sector is one of the key components of economic growth and development worldwide, it faces significant challenges in terms of environmental and social sustainability. This sector struggles with sustainability issues such as depletion of natural resources, environmental degradation and social injustice. Construction projects can involve large consumption of natural resources, energy expenditure and negative impacts on the environment. Moreover, the production, transport and use of construction materials lead to greenhouse gas emissions, water pollution and waste generation. In this context, the concept of sustainable supply chain management (SSCM) stands out as a critical tool for balancing environmental, economic and social objectives in the construction industry. Sustainable supply chain management has been developed as an approach that aims to organize supply processes in the industry in a more efficient, environmentally friendly and socially just manner (Mohammadnazari & Ghannadpour, 2021). The construction industry, with its increasing complexity and size, needs the integration of digital technologies to meet the requirements for effective supply chain management and inventory control. Supply chain and inventory systems managed by traditional methods can lead to negative consequences such as inefficiency, errors and cost increases. Digital technologies improve the efficiency of these processes, enhance communication between supply chain participants and optimize resource utilization. The rapid development of digital technologies in recent years offers the potential to make supply chain management in the construction industry more efficient, transparent and optimized. This integration contributes to the timely completion of projects, reducing costs and minimizing environmental impacts (Güngör & Leindecker, 2024).

Supply chain visibility can be defined as the timely and accurate monitoring and reporting of all elements. Visibility enables all participants in the supply chain to see each other's activities and processes, enabling early detection and rapid response to potential disruptions. Supply chain visibility in industrial construction projects can improve overall efficiency and sustainability, as well as increasing on-time and on-budget completion of projects (Dharmapalan et al., 2021).

The UK construction industry is characterized by large-scale and complex projects and effective materials inventory management is critical to ensure projects are completed on time and on budget. However, traditional materials management methods in the industry are often characterized by inefficiencies, excess material purchases, inventory errors and disruptions due to manual processes. Nwankwo addresses the current state of materials inventory management in the UK construction industry, discusses the challenges faced and suggests improved approaches that can be developed through digitalization, artificial intelligence and other innovative technologies to address these issues. Since effective material management is a factor that directly affects the cost-effectiveness, on-time completion and quality standard compliance of projects, improvements in this area will contribute to productivity growth and sustainability in the sector (Nwankwo, 2023).

The construction industry deals with large-scale and complex projects, and the effectiveness of material management plays a critical role in the successful completion of projects. Material management covers the processes of procuring, storing, transporting and consuming materials in the right way, and failures in these processes can lead to failure to complete projects on time, cost increases and quality losses. Effective materials management not only optimizes the materials procurement process, but also contributes to factors such as labor productivity, occupational safety and environmental sustainability. Therefore, improving materials management practices can improve the overall performance of construction projects, enabling projects to be completed on budget and ensuring high quality standards (Yıldız et al., 2024). Literature review demonstrates the importance of the stock monitoring and management of construction materials stored at construction sites. In this study, a material stock monitoring and management framework is proposed by taking into account the capabilities of smart contract and IoT.

3 Methodology

In this study, it is aimed to monitor the material procurement and construction processes required for the construction of structural elements at the foundation and floor levels of a construction project with a detailed schedule. For this purpose, firstly, the quantity quantities of the construction items are calculated, the construction schedule is prepared by creating logical relationships between the work items, the construction definitions of the construction items are created to determine the required materials and equipment to be used for each construction item. The time when the materials and equipment will be needed is determined by evaluating the construction schedule and the calculated material and equipment data, and finally, the ordering process of the material is managed within the scope of the smart contract. The construction items included in the scope of the study are reinforcement steel detailing of foundation, installation of foundation formwork, pouring of foundation concrete, installation of scaffoldings for the formwork and placement of floor reinforcement. For each work item, information such as the materials used, order and delivery times and total completion times of the process were recorded, and the basic stages were structured in order to manage the project process effectively. The flowchart of the proposed material management framework is given in Fig. 1.

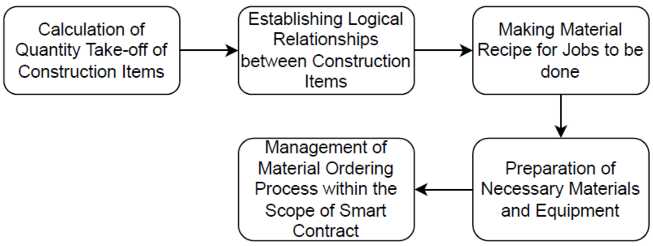

Fig. 1. Flowchart of the proposed material stock monitoring framework

Recent studies for accurate computation of quantity take-off of construction items exist in the literature (Ergen and Bettemir, 2022, Ergen & Bettemir, 2023, Ergen & Bettemir, 2024, Bettemir, 2018). With the correct establishment of semantic relationships including the dimensions and neighborhood of structural and architectural elements, the quantities of the work items are calculated and then the material requirement is calculated by multiplying the job definitions and their quantity take-off values. By defining the relationships between the activities, it is possible to prepare the construction schedule with the critical path method in MS Excel (Bettemir, 2018, Bettemir & Birgonul, 2023). In this way, when the materials are required is computed including the quantity of the corresponding material as presented in Figure 2.

	A	B	C	D	E	F	G	H	I	J	K	L
1	Activity	Material Name	Unit	Order Day	Delivery Date	Start date	Duration	Finish date	Input quantity	Quantity Used	Amount of required	Amount of lost
2	Rebar (Foundation)	Rebar	tonne	18.10.2024	23.10.2024	25.10.2024	4	29.10.2024	57,75	56,65	55	1,65

Fig. 2. Computation of quantities of material stock on MS Excel

The computations are conducted by defining the following equations defined in MS Excel.

Order Day = D1= F2 - 7

Delivery Date = E1 = F2 - 2

Required Reinforcement Amount is calculated by adding loss amounts to the quantity take-off value calculated in the beginning of the project. It is ensured that the material reaches the construction site before the start of the work by placing an order as many days before the required day defined in the construction schedule. The order amount is computed by considering 3% material waste. The total amount is calculated by the statement given below.

Amount of lost = 0.03* K2

Quantity Used = J1 = K2 + L2

Formwork board is a reusable building material. On the other hand, the formwork board brought to the construction site will suffer some loss during dismantling after use. The remaining material can be reused on the next floor. The use of formwork board based on the aforementioned situation is presented in Fig. 3.

	A	B	C	D	E	F	G	H	I	J	K	L

3	Formwork (Foundation)	Plywood	m2	23.10.2024	28.10.2024	30.10.2024	3	2.11.2024	154	154	140	14

Fig. 3. Calculation of the order time and amount of the formwork material

Material order date and the delivery date are determined by considering the start time of the corresponding activity which requires the relevant material. The formwork material is accepted to be wasted 10% at each usage.

Order Date = D1= F3 - 7

Delivery Date = E1 = F3 - 2

Amount of lost = 0.1* K3

Quantity Used = J1 = K3 + L3

Fresh concrete is not a material that can be stocked and cannot be produced at the construction site in accordance with the laws in force, but can only be purchased from the ready-mixed concrete plant. The fresh concrete material management table, which is created by taking into account the specified conditions, is presented in Fig. 4.

	A	B	C	D	E	F	G	H	I	J	K	L
1	Activity	Material Name	Unit	Order Day	Delivery Date	Start date	Duration	Finish date	Input quantity	Quantity Used	Amount of required	Amount of lost
4	Concreting (Foundation)	Concrete	m3	27.10.2024	3.11.2024	3.11.2024	3	6.11.2024	500	500	500	0

Fig. 4. Calculation of the order time and amount of the fresh concrete

The following statements are defined to the spreadsheet application. The waste amount is taken as zero since the waste of fresh concrete is a sign that the related work items such as formwork or scaffolding for the formwork or placement of the concrete is not done properly. The mentions issues are not expected to happen therefore the fresh concrete waste is taken as zero.

Order Day = D1= F4 - 7

Delivery Date = E1 = F4

Amount of lost = 0

Quantity Used = J1 = K4 + L4

The erection of scaffolding for the formwork is significantly similar to the manufacture of formwork. Since metal telescopic struts are commonly used in the erection of scaffolding for the formwork, the waste rate is lower than that of wooden formwork. The order of material quantity of formwork scaffolding is presented in Fig. 5.

	A	B	C	D	E	F	G	H	I	J	K	L
1	Activity	Material Name	Unit	Order Day	Delivery Date	Start date	Duration	Finish date	Input quantity	Quantity Used	Amount of required	Amount of lost
5	Scaffolding for the formwork (1.floor)	Scaffolding formwork	m2	31.10.2024	5.11.2024	7.11.2024	2	9.11.2024	2100	2100	2000	0

Fig. 5: Calculation of the order time and amount of the scaffolding for the formwork material

Order Day = D1= F5 - 7
Delivery Date = E1 = F5 - 2
Required Scaffolding Quantity
Amount of lost = K5* 0.03
Quantity Used = J1 = K5 + L5
The table created for tracking the order day of all work items is presented in Fig. 6.

	A	B	C	D	E	F	G	H	I	J	K	L
1	Activity	Material Name	Unit	Order Day	Delivery Date	Start date	Duration	Finish date	Input quantity	Quantity Used	Amount of required	Amount of lost
2	Rebar (Foundation)	Rebar	tonne	18.10.2024	23.10.2024	25.10.2024	4	29.10.2024	57,75	56,65	55	1,65
3	Formwork (Foundation)	Plywood	m2	23.10.2024	28.10.2024	30.10.2024	3	2.11.2024	154	154	140	14

Fig. 6: List of order date, order amount and type of material created automatically from the construction schedule and BOQ

In this study, a comprehensive timeline has been developed for the construction process, detailing material procurement, delivery schedules, start and finish dates for each task required throughout the project. Each task's procurement, delivery, and execution phases have been carefully planned to facilitate a structured progression in the project timeline, aiming to minimize delays.The project focuses on core construction tasks, including foundation and floor slab installations, arranged in a logical sequence to ensure structural stability. Each stage has been detailed to ensure materials are procured, delivered, and utilized at the appropriate times. This approach establishes a series of systematic steps intended to support efficient, uninterrupted progression throughout the construction process.

Materials required for each task have been ordered and scheduled to arrive on-site in advance of each phase. A variety of materials have been used, from essential reinforcement and formwork boards to ready-mix concrete and scaffolding. Delivery timelines were organized by accounting for lead times between order and delivery dates to ensure materials are on-site before installation begins, minimizing disruptions due to material delays and keeping each stage on track.

Throughout the project, workflows have been organized with a flexible, structured timeline based on material delivery schedules. Task durations were assigned by considering the difficulty and labor requirements for each task, with start dates and completion times recorded. This data has facilitated the correct scheduling of parallel or sequential tasks as needed, ensuring a logical flow from foundational work to upper-floor installations. The orderly sequence has not only streamlined time management but also ensured completion within the planned timeframe.
The proposed framework executes project management and workflow monitoring tasks. Each task was integrated into project management processes, allowing close tracking of procurement and delivery times, along with task start and completion dates. This recording of workflows has enabled consistent monitoring and adjustments as needed. Each phase has been checked step-by-step, with necessary adjustments documented throughout the project. This systematic approach prevented delays in subsequent stages by allowing prompt adjustments if a task requires more time or materials than anticipated.

4. Conclusions

The developed framework improves the overall project process and efficiency. The sequential and systematic application of construction elements contributed to completing the project within the planned timeframe. Every task was organized to maximize the efficient use of both labor and materials, ensuring effective allocation of the resources. Timely material delivery and labor optimization enabled project completion within the scheduled period. Detailed planning was conducted at each stage, with alternate procurement sources or process adjustments applied as needed to maintain efficiency. This method minimized unexpected delays and interruptions in the construction process.

Within this framework, tasks in the project were executed in a sequential, organized, and efficient flow, with the goal of maintaining rigorous planning and meticulous oversight throughout all processes. This ensured that construction activities at each level contributed cohesively to the overall structural integrity and resulted in a high level of structural coherence.

Abstract. The construction industry is one of the sectors with the highest number of occupational accidents worldwide. These accidents negatively affect the health and safety of the workers and the stakeholders in the sector economically and socially, causing a decline in labor productivity. In this context, spreading occupational health and safety awareness among stakeholders is critical to prevent accidents and make the work environment safe. The objective of the present study was to ascertain the measures of central tendency concerning occupational accidents in the construction industry. The research process involved the administration of questionnaires to stakeholders, which yielded data on accident details. The research findings indicated that the predominant category of occupational accidents was that of falls from height, with a notable concentration of incidents occurring during the morning hours. Furthermore, it was established that the majority of accidents resulted in injury. It is thought that the findings obtained will contribute to a deeper understanding of accidents in the construction sector and the development of safety culture in the sector. Moreover, it is anticipated that these findings will enhance stakeholder awareness regarding occupational health and safety, thereby facilitating the formulation of strategies to mitigate the material and moral ramifications of accidents.

Keywords: Construction Industry; Occupational Accident; Type of Accident

1. Introduction

Construction activities are one of the priority intervention areas in terms of occupational health and safety due to their structural complexity and physical risks. When the frequency and consequences of occupational accidents in different sectors around the world are assessed, the construction sector has a higher risk profile (Eurostat, 2024). Variable working conditions, multidisciplinary production processes, and operational intensity on site make the occurrence of accidents in this sector both more likely and more devastating.

A significant number of accidents in the sector result in serious injury or death, making occupational health and safety a problem that needs to be addressed not only nationally but also globally (Ayduran & Olcay, 2022; Birhane et al., 2022; Mosquera & Ileana, 2024). Working at height, moving equipment, outdoor weather conditions, and the simultaneous activity of subcontractor networks are the main sources of risk in the field (Alboga et al., 2023). Furthermore, managerial factors such as time pressure and cost-oriented decision-making processes can lead to postponement or neglect of necessary precautions (Forteza et al., 2017).

Sectoral statistics published in Turkey also support this picture. As demonstrated by data from the Social Security Institution (SSI), the construction industry ranks among the top in terms of both the frequency and severity of accidents (Gözüak & Ceylan, 2021; SSI, 2025). The high rate of fatal accidents in this sector makes it imperative to address safety precautions not only at the individual level but also at the institutional and systematic levels.

National and international literature similarly describes the types of accidents frequently encountered in the sector. Incidents such as falls from heights, equipment-related injuries, material falls, and collisions are the types of accidents that are emphasized in almost all studies (Müngen, 2011; Olcay et al., 2021; Williams et al., 2017). Structural problems such as inadequate supervision, irregular site layout, and poor safety culture are often at the root of these accidents. Conversely, the treatment of accidents as a purely technical issue may result in the oversight of the social and managerial components. Therefore, accidents need to be addressed multidimensionally in terms of time, type, and consequences (Halabi et al., 2022; Tixier et al., 2016). Traditionally, the approach to accidents has been mostly reactive, i.e., focused on post-incident response. Today, however, the need to quickly identify

*Corresponding author,E-mail: oalboga.mfbe19@iste.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_608

risks and design preventive precautions brings the proactive safety management approach to the forefront (Awolusi et al., 2022; Xu et al., 2023).

The effects of occupational accidents are not limited to the individual level. The economic losses, decrease in labor productivity, deviation in project deadlines, and damage to the reputation of the company directly affect all stakeholders in the sector (Elsebaei et al., 2022; Junjia et al., 2024). In this context, it is important to systematically analyze the structural causes of accidents and the conditions under which they occur to ensure that the precautions to be taken are targeted and sustainable.

Research indicates that different statistical methods are used to determine the causes and common types of accidents in the construction industry (Birgönül et al., 2016; Duman & Hamzaoğlu, 2011; Gürcanli & Müngen, 2013; Kang & Ryu, 2019; Williams et al., 2017; Zhang et al., 2020). Some studies in the literature have revealed that a significant portion of these accidents occur in building constructions (Baradan et al., 2016; Halabi et al., 2022). On the other hand, studies focusing only on a specific type of accident or outcomes such as fatalities have investigated the causes of these accidents (Assaad & El-adaway, 2021; Halabi et al., 2022; Olcay et al., 2021; Ünal & Aykaç, 2010).

Nevertheless, a significant number of studies in the relevant literature frequently depend on official records and secondary data sources (Assaad & El-adaway, 2021; Zhang et al., 2020). Such data is often insufficient to understand the actual dynamics of accidents on the ground. In contrast, primary data based on direct field experiences allows for a more detailed analysis of the contextual characteristics of accidents. Such information, obtained through surveys and similar data collection tools, not only describes the current situation but also contributes to the development of more effective and targeted preventive strategies. The studies developed in this context help us understand past accidents and have the potential to pave the way for data-driven, proactive policies to prevent similar incidents in the future.

The present study analyzes the times, types, and consequences of accidents within the framework of measures of central tendency in building construction. This analysis is based on the responses of industry professionals who have directly experienced occupational accidents. The findings of the study are anticipated to contribute to the development of a safety culture in the sector, raising stakeholder awareness and shaping strategies for occupational health and safety in a more targeted manner, taking into account the frequent recurrence of accidents in building construction.

2. Materials and methods

The present study is designed as quantitative research that aims to describe the type, time, and outcome occupational accidents that occur in building construction in the construction industry. The data for the research was obtained from professionals who have either directly witnessed or been involved in occupational accidents in the sector.

A questionnaire was utilised as a data collection tool. The questionnaire was administered to a total of 236 people working in different professional roles, such as project managers, construction site supervisors, labor inspectors, experts, and occupational health and safety specialists. Responses that were incomplete, contradictory, or insufficient for analysis were eliminated, and analysis was conducted on 203 valid responses. All participants were experienced personnel who had either witnessed or been involved in at least one occupational accident in their working lives.

The questionnaire form included questions on demographic information of participants and workers (including age, occupation and years of experience), time of the accident, accident type and outcome, and environmental conditions (including temperature). The questions were prepared in multiple-choice and ordinal scale format; the content was developed in line with expert opinions and simplified through the pre-test process.

The analysis process involved the utilisation of descriptive statistical methods, encompassing the calculation of measures of central tendency (mean, median, mode), standard deviation, and minimum and maximum values for both continuous and ordinal variables. Frequency and percentage distributions were presented for the categorical variables. A comparative analysis of accident types was conducted through graphical representation, with the variables of age, experience, and temperature taken into account. Additionally, an evaluation of accident frequency was undertaken, utilising a descriptive analysis across hourly time periods. The analysis was conducted utilising the Python programming language, and the findings were presented with graphical support.

3. Results and discussion

This section presents the main statistical findings on the type, timing, and outcome of accidents, as derived from the data obtained through the questionnaire. The analyses are based on measures of central tendency and descriptive statistical methods.

An analysis of the demographic profile of the respondents indicates that the majority possess a bachelor's degree, and that their professional experience is predominantly concentrated within the range of 0-10 years. A substantial proportion of the participants are construction site supervisors and occupational safety specialists. Table 1 presents the demographic information of the participants.

Table 1. Demographic information of the participants

		n	%
	Bachelor's Degree	149	73.40
Education Status	Master's Degree	50	24.63
	Doctorate (PhD)	4	1.97
	Site Supervisor	114	56.16
	Occupational Safety Specialist	37	18.23
Occupation	Project Manager	26	12.81
	Labor Inspector	15	7.39
	Expert	11	5.42
	0-10	159	78.71
	11-20	24	11.88
Experience (Year)	21-30	11	5.45
	31-40	7	3.47
	41-50	1	0.50

The results of the analysis of the distribution of accidents by time period demonstrate the presence of a pattern of concentration, particularly in the 10:01-12:00 and 14:01-16:00 periods (Fig. 1). These periods correspond to times of increased workload in the field and periods of reduced attention. The findings support studies in the literature suggesting that accidents occur more frequently in the middle hours of the working day (Akboğa, 2014; Ayhan & Tokdemir, 2020; Halabi et al., 2022). The result raises the need to reconsider preventive strategies such as work scheduling and the timing of breaks.

The analysis of accident types revealed that falling from a height was the most common type. Such accidents occur frequently in areas where temporary safety precautions are inadequate in building construction. Accidents such as falls of materials and equipment, as well as cuts and punctures, follow falls from height (Fig. 2). This distribution is in line with the patterns reported in national and international literature (Liu et al., 2020; Olcay et al., 2021; Williams et al., 2017). On the other hand, elevator falls, poisoning and explosions were the least frequently observed accidents in the study.The frequency of falls from height suggests that both the physical safety infrastructure on site and worker behavior should be more closely evaluated. Despite increased awareness and regulations, the persistence of fall-related accidents indicates possible gaps in enforcement, design adaptation, or training persistence.

Fig. 3 shows the distribution of occupational accidents by outcome, with each outcome category represented by descriptive abbreviations. According to the data, the most common accident outcome is minor injuries requiring treatment (MIN), with 58 cases, the highest frequency among all groups. This is followed by the group of 49 cases resulting in severe injury, occupational disease or permanent disability (Severe Injury - SEV). These two categories reveal that a significant proportion of accidents result in mild or serious health consequences. On the other hand, accidents requiring only first aid with no lost working days (First Aid, No Day Loss - FA1) and accidents requiring first aid with no lost working hours (First Aid, No Hour Loss - FA2) are less frequent with 35 and 27 cases respectively. This suggests that some accidents are survived with relatively less serious consequences. Fatality accidents (FAT) stand out as an important category with serious consequences with 35 cases. This distribution shows that although minor injuries are more frequent, severe consequences are also considerable and therefore preventive strategies for all types of accidents need to take a multidimensional approach.

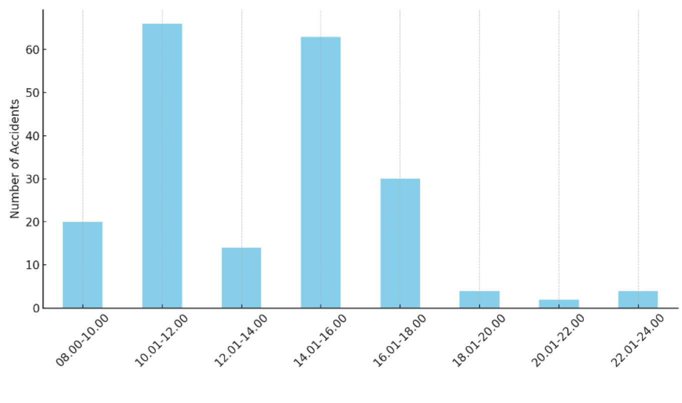

Fig.1. Distribution of Accidents by Time Interval

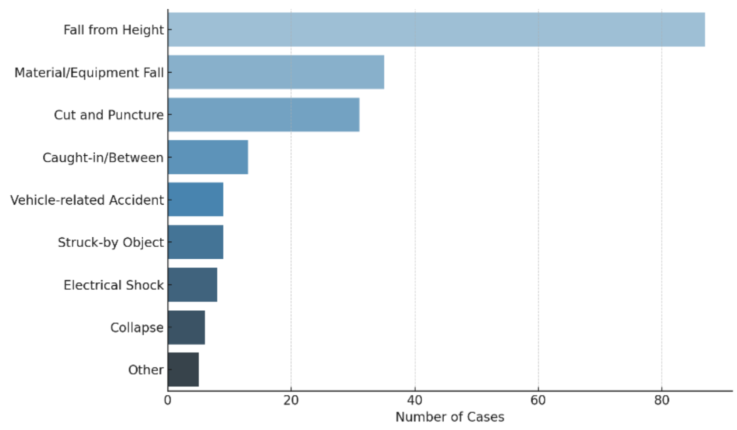

Fig. 2. Distribution of Accident Types

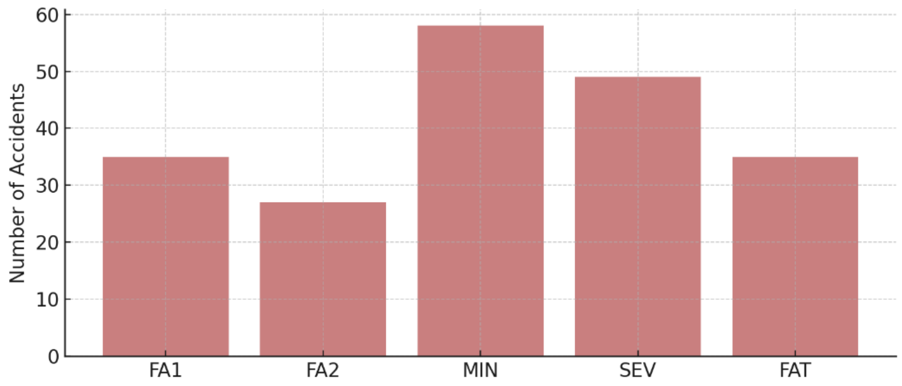

Fig. 3. Distribution of Accident Outcome

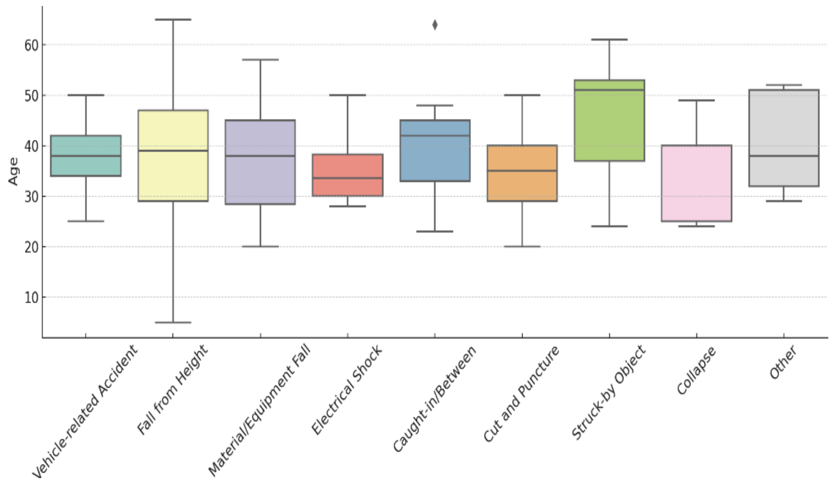
In the box graph showing the age distribution according to accident types, there are significant differences between age groups, especially in the "struck-by object" and "collapse" types. While the median age is 51 for "struck-by-object" accidents, it is 25 for "collapse-type" accidents. This difference indicates a concentration of certain accident types within either younger or older labor force groups. For common accidents such as "falling from height," the age distribution is more balanced, with a median of 39 and an average of around 38. These findings suggest that the age difference by accident type is an important variable to be taken into account in safety strategies. Similarly, it is also stated in the literature that types of accidents vary according to age groups (Kang & Ryu, 2019; Nai'em et al., 2021). In practical terms, age-sensitive safety training may help reduce incident rates in high-risk groups. This distribution is presented in Fig. 4.



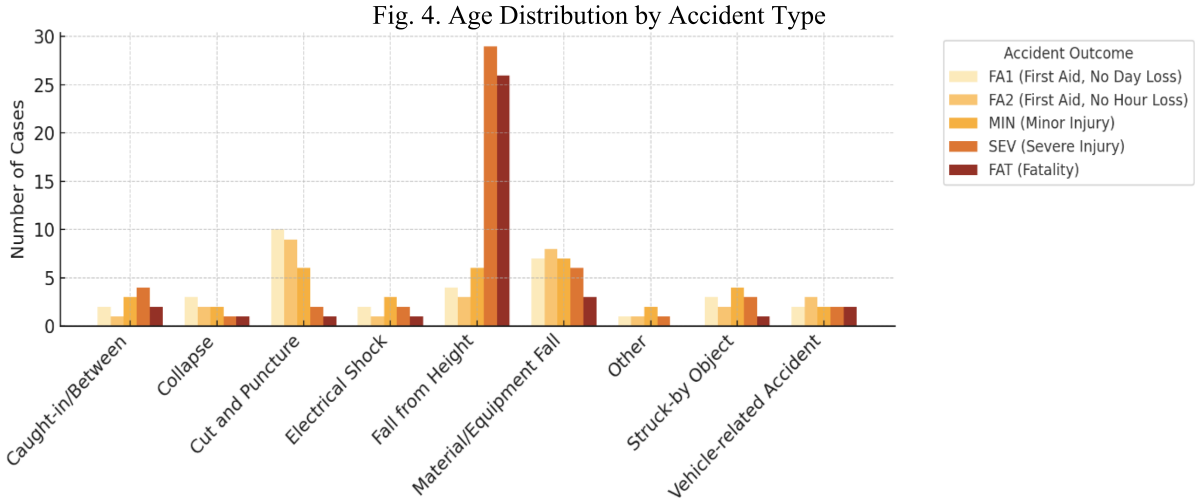


Fig. 5. Distribution of Accident Outcomes by Accident Type

Table 2. Statistics of Temperature by Type of Accident

Accident Type	**Mean Temp (°C)**	**Std. Deviation**	**Min Temp**	**Max Temp**
Collapse	26.00	9.06	16	39
Vehicle-Related Accidents	25.71	5.68	17	33

Other	19.60	10.33	7	33

Analysis of outcome distribution by accident type reveals that "fall from height" incidents are more prone to cause severe injuries and fatalities than other categories (Akboğa & Baradan, 2015; Halabi et al., 2022). Conversely, some accident types, such as "cut and puncture" and "caught-in/between," are limited to milder outcomes. This difference indicates that certain types of work are inherently higher risk and points to the need to diversify occupational safety measures according to the type of accident. This distribution is presented in Fig. 5.

An analysis of temperature distribution by accident type reveals that collapses and vehicle-related incidents predominantly occurred under high-temperature circumstances (mean >25°C). Conversely, "fall from height" accidents occurred in lower temperature conditions, with a minimum recorded temperature of -2°C. This finding suggests that low temperatures may increase the risk of falls by causing distraction, slippery surfaces, and difficulties in using equipment. These findings indicate that environmental conditions can also have an impact on the types of accidents and suggest that weather conditions should be taken more into account in safety planning processes (Kang & Ryu, 2019). The statistics on temperature distribution are presented in Table 2.

Fig. 6 illustrates the temporal distribution of occupational accidents within the construction sector, categorized by kind of accident. To facilitate a comprehensive observation and precise analysis of temporal patterns, the three most frequent time periods (mode values) for each accident type are determined and depicted as distinct bars in the display. The data indicates that specific categories of accidents are prevalent during particular periods of the day. Specifically, incidents including "Falls from Height," "Material/Equipment Falls," and "Cuts and Punctures" occur more frequently throughout the morning (10:01-12:00) and afternoon (14:01-16:00). This suggests that the likelihood of accidents escalates during periods of heightened physical exertion, while worker vigilance may diminish owing to exhaustion. Consequently, for certain categories of accidents, interventions (e.g. brief rest intervals, work rotations, enhanced field inspections, safety briefings prior to critical moments) can be more successfully formulated during high-risk intervals.

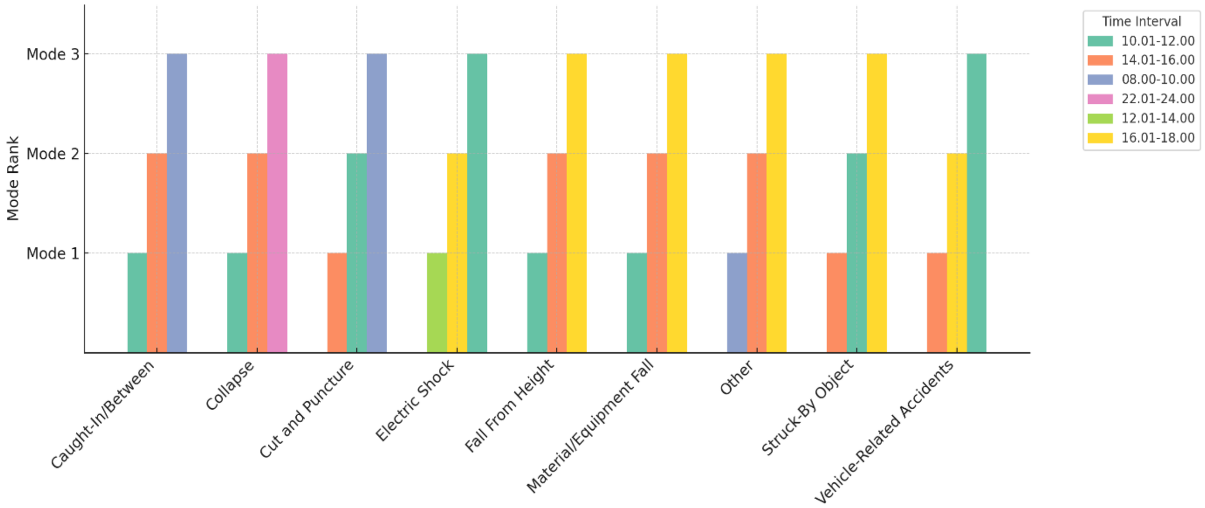

Fig. 6. Distribution of the Top 3 Most Frequent Time Periods by Accident Type

The results show that a significant number of incidents are associated with “falls from height”, with a notable concentration occurring in the morning hours. Analysis of the distribution of accident effects reveals that “minor injury” is the most common outcome, but there is also a significant frequency of major injuries and fatalities. Analysis of the age factor by type of accident revealed that certain types are associated with younger workers. In particular, accidents such as “collapse” are associated with younger workers, while accidents such as “struck by an object” are more prominent in older and more experienced groups. Mode-based analysis by time periods shows that occupational accidents are concentrated in specific time periods, allowing for the development of time-based preventive strategies. Taken together, these results emphasize the need for a multidimensional approach to safety planning that includes not only technical and environmental risk factors, but also demographic and task complexity considerations.

4. Conclusion

This study contributes to a deeper understanding of accident trends and high-risk conditions in the construction industry by providing a detailed analysis of occupational accidents in terms of time, type, and outcome. The findings, obtained through data based on direct field experiences, both shed light on the challenges faced in practice and generate concrete recommendations for improving safety culture. In particular, the concentration of certain types of accidents, such as “falls from height” in the morning hours reveals the importance of time management and on-the-job safety practices. Although most of the accidents result in minor injuries, serious injuries and fatalities are also prominent in certain circumstances.

The observed differences in age and experience based on accident type suggest that safety strategies need to be tailored to the employee profile. The increased vulnerability of young and less experienced workers to certain types of accidents highlights the importance of targeted training and mentoring programs. On the other hand, the exposure of experienced worker to more serious accidents in complex tasks shows that experience alone is not a protective factor; other factors such as equipment, organizational structure, and work planning should also be managed effectively. Moreover, it was observed that different types of accidents differed significantly in terms of severity of consequences. In particular, serious injury and death rates are higher in types such as falls from height, which suggests that accidents should be evaluated not only according to their frequency but also according to the severity of their consequences. This finding emphasizes the importance of developing accident type based preventive strategies.

The present study provides a multidimensional assessment of the types of accidents specific to the construction industry and how these accidents are shaped in environmental, temporal, and individual contexts and paves the way for proactive management of risks. The findings are expected to contribute to the development of occupational safety policies, improvement of practices, and data-based decision-making processes at the sectoral level. This research also demonstrates the effectiveness of analyses based on direct field experiences in better explaining the contextual dimensions of accidents. In this respect, the study serves as a reference for further research in both methodological and contextual terms. The findings suggest that types of accidents can be associated not only with individual or managerial factors but also with environmental conditions

However, some limitations of the study should also be considered. The sample may not be representative of all construction workforce groups, as it consists only of professionals with a certain sectoral experience. Future studies should recommend broader comparisons with data from different geographical regions and project types at different scales. In addition, the development of holistic modeling, including psychosocial and managerial factors regarding the causes of occupational accidents, will contribute more to the institutionalization of safety culture in the sector.

[2] Earthquake and Structural Health Application and Research Center, Karadeniz Technical University, 61080 Trabzon, Türkiye

Abstract. This study aims to provide a detailed comparative analysis of six AI platforms in the Architecture, Engineering, and Construction (AEC) Industry: Civils.ai, Kwant.ai, ArchiLabs, Nicky AI, Buildots, and Karmen. These AI platforms provide a variety of features, from project automation and construction site monitoring to resource optimization and AI-driven design. Their efficacy in tackling industry issues, including data processing, project efficiency, and workflow integration, will be assessed, and their specific advantages and possible overlaps will be identified. Key parameters, including launch year, supported file types, integration with programs, automation capabilities (functions/features), and price for users, are the focus of a qualitative comparison approach. Based on these key parameters, the analysis offers insights into how these AI platforms are used in the real world. The outcomes indicate notable differences in their functionalities; some concentrate on design automation, project collaboration, or predictive analytics, while others specialize in construction site management and real-time progress tracking. The study also identifies important areas for improvement, such as AI customization and interoperability, which may influence future developments in AI for AEC. This study conveys a systematic comparison of cutting-edge AI platforms, offering useful advice for corporate professionals looking to improve workflows and boost productivity with AI-driven solutions.

Keywords: AEC industry; AI platforms; Construction technology; Design automation; Workflow optimization

1. Introduction

The Architecture, Engineering, and Construction (AEC) industry has undergone a profound transformation, evolving from manual, labor-intensive practices to highly digital and intelligent systems. In the early 20th century, construction projects were predominantly managed through hand-drawn blueprints, physical models, and paper-based documentation, which often led to coordination errors, time inefficiencies, and increased costs(Eastman et al., 2011). The 1960s marked a pivotal turning point with the advent of computer-aided design (CAD), allowing for more precise and efficient drafting (Sacks et al., 2018). At the turn of the millennium, Building Information Modeling (BIM) revolutionized the industry by integrating 3D modeling with data-driven project management capabilities, thereby facilitating collaboration across disciplines and improving lifecycle coordination(Autodesk, 2024).

The emergence of Industry 4.0 further accelerated the digitalization of construction practices, introducing cyber-physical systems, Internet of Things (IoT) technologies, and cloud-based data exchange platforms(Oztemel & Gursev, 2020). These advancements transformed static digital models into dynamic, interoperable systems that support real-time decision-making. Most recently, artificial intelligence (AI) has emerged as a key technological enabler in the AEC industry, expanding the scope of digital transformation beyond automation toward intelligent decision support (Dattaa et al., 2021). AI applications are now being leveraged to enhance design generation, monitor construction progress, assess risks, and optimize resource allocation.

This technological evolution has given rise to a new generation of AI-driven platforms specifically tailored to the complex demands of construction environments. These platforms aim to improve productivity, increase safety, enable real-time collaboration, and provide greater transparency throughout the project lifecycle. Many platforms promote comprehensive solutions through their actual capabilities and applicability in diverse construction contexts. Despite their growing adoption, however, there remains a critical need for systematic evaluations of these emerging tools.

This study conducts a comparative analysis of six prominent AI platforms developed for the AEC industry: Civils.ai (2022), Kwant.ai (2018), ArchiLabs (2024), Nicky AI (2023), Buildots (2018), and Karmen (2024). The analysis is structured around key parameters including launch year, supported file types, integration with programs, automation features, and pricing models. By identifying each AI platform's features, this study provides valuable insights for AEC industry professionals and researchers aiming to leverage AI technologies for improved efficiency, coordination, and decision-making in construction projects.

2. Methodology

In this study, which examines AI platforms currently utilized in the AEC industry, Civils.ai, Kwant.ai, ArchiLabs, Nicky AI, Buildots, and Karmen were selected for analysis, respectively, as shown in Fig. 1. These AI platforms support the AEC industry's digital transformation by automating processes such as project design, project management, site monitoring, etc. With this context, the mentioned platforms were evaluated based on key parameters identified as launch year, supported file types, integration with programs, automation capabilities (functions/features), and pricing for users. When defining these parameters, the supported file types category refers to the typical file formats that the platforms can import and export. The integration with programs parameter denotes the software applications with which the platforms can interoperate during data exchange. It should be acknowledged that, as these platforms are continually updated and refined, the specific items listed under each parameter are subject to change.

This evaluation was structured to emphasize the AI platforms' technical features and contributions to the AEC industry. This approach aims to elucidate the current impact and future potential of AI platforms in the AEC industry. In the remainder of the study, each platform is discussed in sequence, and the information compiled for each platform is presented in table form. Data were compiled from official platform resources such as their own websites, LinkedIn accounts, and YouTube Channels.

a) Civils.ai b) Kwant.ai c) Archilabs d) Nicky AI e) Buildots f) Karmen

Fig. 1. AI platforms

3. Findings and discussions

3.1. Civils.ai

Civils.ai is an AI-powered platform designed to streamline data management in the construction industry, particularly for handling complex technical documents. Its primary purpose is to eliminate time-consuming manual tasks, such as searching through disorganized files and completing repetitive paperwork, while ensuring compliance and risk mitigation. It targets civil engineers, project managers, architects, and geoscientists who need to process large volumes of geotechnical and construction data efficiently (Civils-ai Construction AI, 2025). Table 1 presents the detailed features of the Civils.ai platform based on the specified key parameters.

Table 1. Detailing Civils.ai according to key parameters

Launch Year	Supported File Types	Program Integration	Functions/Features	Price
2022 (January)	PDF files Excel files AGS files Word files	Autodesk Procore SharePoint Power BI Microsoft Office	Data extraction (OCR/NLP) Generative design Predictive modeling Real-time monitoring Workflow automation Chat interface for automation	Basic: \$49/user/month Advanced: \$83/user/month

Civils.ai was launched in January 2022. It is designed to streamline data-intensive tasks, The platform employs advanced Optical Character Recognition (OCR) and Natural Language Processing (NLP) to extract structured information from diverse sources, including PDF borehole logs, geotechnical reports, CAD drawings, and site investigation documents. Civils.ai supports output generation in formats such as Excel, AGS, Word, and Power

BI dashboards, and integrates effectively with commonly used tools like Autodesk, Procore, SharePoint, and Microsoft Office—thereby embedding itself within standard AEC digital workflows. Technically, Civils.ai offers a range of functions spanning data extraction, generative design (generates design alternatives for structural optimization), predictive modeling (simulates soil behavior and assesses geotechnical risks), real-time monitoring (integrates with IoT for geotechnical data analysis), and workflow automation. This allows engineering teams to reduce manual labor, automate compliance checks, and simulate geotechnical behavior for informed decision-making. The platform emphasizes accessibility through its no-code workflow builder, enabling non-technical users to leverage AI capabilities without programming expertise (Civils-ai Construction AI, 2023). Additional features such as interactive mapping from location-tagged data, intelligent document search, and automated categorization of project files enhance productivity and reduce human error. Civils.ai is competitively priced, with a basic plan at $49/user/month (10 users with 12 month license period and 50 GB file storage) and an advanced plan at $83/user/month (10 users with 12 month license period and 100 GB file storage-2000 advanced AI workflow runs). Its adoption across multiple regions, including the United States, Hong Kong, Singapore, the European Union, the United Kingdom, Australia, New Zealand, and South Africa, demonstrates its global applicability and compliance adaptability in varied regulatory environments.

3.2. Kwant.ai

Kwant.ai is an AI-driven construction management platform designed to enhance workforce efficiency, improve on-site safety, and streamline compliance monitoring processes. Kwant.ai aims to overcome challenges such as manual reporting and delayed risk detection by delivering real-time site intelligence through integrated IoT devices and AI-driven analytics. It is designed for general contractors, project owners, insurance carriers, and brokers seeking to enhance productivity and safety on construction sites (Kwant, 2023). Table 2 presents the detailed features of the Kwant.ai platform based on the specified key parameters.

Table 2. Detailing Kwant.ai according to specified parameters

Launch Year	Supported File Types	Program Integration	Functions/Features	Price
2018	3D-BIM models Image files Excel files PDF files Files from the IoT sensor data	Procore Autodesk BIM 360 Autodesk Construction Cloud CMIC Checkr Primavera P6 Power BI Microsoft	Asset tracking Predictive analytics Real-time dashboards Workforce management Safety monitoring Fatigue management Heatmaps Fall detection Daily reports Chat interface for automation	*Pricing not publicly disclosed

Kwant.ai is introduced in 2018. By integrating IoT smart badges, environmental sensors, and 5D-BIM models, the platform enables continuous tracking of worker locations, activity levels, fatigue, and safety conditions while automating administrative tasks like timesheets, onboarding, and certification monitoring. A distinguishing feature of Kwant.ai is its fusion of real-time site intelligence with predictive analytics and multilingual LLM-based querying. Users can interact with the system in multiple languages through a built-in AI question interface, powered by OpenAI models and AWS integration, to generate instant reports, insights, and even customized data outputs. In addition, Kwant.ai's privacy-by-design approach ensures that no personally identifiable information is exposed during data collection or analysis, an essential feature for compliance-conscious organizations. Functionally, Kwant.ai supports predictive risk scoring, automated compliance monitoring, safety alert systems (e.g., fall detection, SOS), and asset tracking via IoT data. Its seamless integration with major AEC platforms such as Procore, Autodesk BIM 360, Primavera P6, and Power BI enables construction firms to embed Kwant.ai into their existing digital workflows without significant adaptation costs. The platform also contributes to productivity gains by reducing manual reporting time by an estimated 8–10 hours per week per site. While specific pricing is not publicly disclosed, Kwant.ai operates under a scalable subscription model based on peak workforce size, allowing firms to adapt usage to project demands. Having been deployed across major construction sites in the United States, Canada, and select regions in Asia and Africa, Kwant.ai demonstrates both technical robustness and global adaptability.

3.3. Archilabs

Archilabs is an AI assistant developed to revolutionize architectural design and planning by automating CAD/BIM tasks. Its purpose is to simplify complex workflows, allowing architects to focus on creativity rather than repetitive tasks, using natural language processing to translate commands into actionable outputs. It is intended for architects, designers, and planners working with BIM tools like Revit and SketchUp (Archi Lab, 2023). Table 3 shows the detailed features of the Archilabs platform based on the specified key parameters.

Table 3. Detailing Archilabs according to specified parameters

Launch Year	Supported File Types	Program Integration	Functions/Features	Price
2024 (April)	CAD/BIM models 2D sketches Excel files TXT files Render files Python scripts	Autodesk Revit Autodesk BIM 360 Autodesk Construction Cloud Rhino SketchUp ArchiCAD Vectorworks Dynamo Grasshopper	AI-based generation with Python Generative design Visualization Compliance checking Automating repetitive tasks Chat interface for automation	Ideation: Free Architecture/Design: $1,000/idea Development: Custom pricing AI Toolset: $2,500/month

Archilabs, launched in April 2024, is developed with a focus on eliminating inefficiencies in traditional design tools like Autodesk Revit. Archilabs allows users to interact with complex CAD/BIM environments using plain English prompts, automatically converting these into executable Python scripts. This AI-driven approach facilitates rapid modeling, compliance verification, data conversion, and visualization, considerably reducing the time and expertise required for manual tasks. At the core of Archilabs is its AI Co-Pilot, which interprets natural language inputs such as “add windows to the north wall” or “check building code compliance” and translates them into actionable commands within Revit, Rhino, SketchUp, or ArchiCAD. The platform also features a Python Generator for automating API-based operations, an AI-enhanced editor for Excel/CSV/TXT files, and generative design capabilities that propose optimized layouts. Distinct from many other platforms, Archilabs also includes an AI-powered Revit tutorial generator, enabling users to receive customized, step-by-step learning guides tailored to their project context, thereby supporting both task execution and continuous professional development. The system architecture ensures a scalable and responsive user experience that accommodates evolving project demands. Archilabs supports a wide range of input and output formats, including CAD/BIM files, 2D sketches, project specs, and structured data files (Excel, CSV, TXT), enhancing interoperability across different design and project documentation tools. Output capabilities include annotated floor plans, model updates, compliance reports, and interactive dashboards, all accessible via web and mobile interfaces. Integration with platforms such as Autodesk BIM 360, ArchiCAD, Dynamo, and Grasshopper positions Archilabs as a powerful automation layer within existing BIM ecosystems. Pricing is structured flexibly, offering a free plan for ideation, a $1,000 one-time project fee for architecture and planning use cases, a custom pricing model for development, and a $2,500/month full-access plan for firms seeking enterprise-level AI toolsets. Although currently based in the United States, Archilabs is designed for global scalability and is accessible worldwide via cloud applications.

3.4. Nicky AI

Nicky AI, proposed in 2023, is an AI-powered administrative assistant developed specifically for construction project teams seeking to streamline communication, document management, and routine workflow administration. Unlike other AI platforms, Nicky AI is tailored to the needs of construction professionals, addressing common challenges such as submittal tracking, request for information (RFI) management, and email handling through intelligent automation and voice-activated interaction. It intends to reduce administrative workload, enabling faster project coordination and fewer errors (Sibay, 2024). Table 4 demonstrates the detailed features of the Nicky AI platform based on the specified key parameters.

Table 4. Detailing Nicky AI according to specified parameters

Launch Year	Supported File Types	Program Integration	Functions/Features	Price
2023	Emails Text messages PDF files Excel files Voice commands	Gmail Outlook Procore Microsoft Excel	Voice-enabled AI for tasks Workflow automation Email management Document control Real-time updates RFI management	*Pricing not publicly disclosed

The platform ingests unstructured data from multiple sources, including emails, text messages, PDF documents, submittals, RFIs, and even spoken commands, and transforms them into structured outputs such as automated cover sheets, workflow reports, email responses, project updates, and Excel exports. These functionalities are accessible via Nicky AI's web and mobile applications, making it a highly portable and responsive tool for on-site and remote users alike. A standout feature of Nicky AI is its voice enabled interface, which allows users to issue natural language commands (e.g., "Show me the approved electrical panel") to instantly retrieve documents or project information. This capability significantly reduces search time, particularly in fast-paced site environments. Moreover, its email automation feature enables users to draft and send context-aware communications through integrations with Gmail and Outlook, thereby enhancing professional correspondence while reducing manual workload. In terms of workflow efficiency, Nicky AI automates the generation of submittal cover sheets, maintains task lists, and delivers real-time notifications for pending actions or project changes. It also provides document control functionality, organizing information extracted from unstructured files such as PDFs and submittals into integrated platforms like Procore and Excel. These tools collectively yield substantial time savings, estimated at over three hours per day per user, by eliminating repetitive administrative labor and enabling professionals to refocus on higher-value activities such as project coordination and field supervision. While the pricing structure for Nicky AI is not publicly disclosed, it follows a subscription-based model that is likely customized based on team size and project complexity. Headquartered in New York City, the platform is primarily focused on the U.S. construction market, though its cloud-based architecture ensures broader accessibility.

3.5. Buildots

Another AI-driven platform, Buildots, launched in 2018, is a computer vision-powered construction management platform that revolutionizes site monitoring through full integration with BIM models, project schedules, and AI analytics. Developed to bridge the gap between digital plans and on-site execution, Buildots enables real-time, objective oversight of construction progress by combining 360-degree imagery, automated data processing, and predictive insights. It targets contractors, project managers, and site supervisors managing large-scale construction projects (Buildots, 2025). Table 5 demonstrates the detailed features of the Buildots platform based on the specified key parameters.

Table 5. Detailing Buildots according to specified parameters

Launch Year	Supported File Types	Program Integration	Functions/Features	Price
2018	360-degree camera footage BIM models BCF files	Autodesk BIM 360 Autodesk Construction Cloud Procore Revizto Navisworks MS Project Primavera P6 Power Project	AI-powered progress tracking Predictive Analytics Issue Management Delay Reduction Gap analysis Gantt view powered by AI Digital twin-based visualization	*Pricing not publicly disclosed

At the core of the platform is a helmet-mounted 360-degree camera system, which captures site conditions passively during routine site walks. The captured footage is automatically synchronized with BIM models and construction schedules to generate an as-built 4D timeline of project execution. This allows for AI-powered progress tracking, in which computer vision algorithms compare current site conditions against planned milestones to detect deviations, identify misalignments or missing installations, and generate visual, actionable reports. The result is a continually updated model of project reality, providing a clear, verifiable basis for informed decision making. Buildots' automated gap analysis feature enhances quality control by flagging discrepancies between planned and actual progress, significantly reducing the need for manual inspections. Its predictive analytics engine offers early warnings about potential delays and bottlenecks, enabling project teams to take preemptive action before minor issues escalate. All identified issues are exported in BCF (BIM Collaboration Format), with precise BIM location tagging and linked visual evidence, ensuring seamless issue tracking and resolution in platforms such as Autodesk BIM 360, Procore, and Revizto. Accessible via web and mobile interfaces, the Buildots Control Center also empowers field personnel to view task-specific dashboards, receive real-time notifications, and manually update progress when needed. This mobile access enhances collaboration between office-based teams and on-site staff, further streamlining the construction management workflow. Buildots supports input formats such as 360-degree video, BIM models, and project timelines, and generates outputs including predictive reports, gap analyses, and actionable metrics. It integrates seamlessly with a wide range of AEC software platforms, including Autodesk Construction Cloud, Procore, Navisworks, MS Project, and Primavera P6. While pricing is not publicly disclosed, the platform is offered as a customized subscription based on project scale and configuration.

3.6. Karmen

Karmen is a specialized AI automation assistant designed to reduce the administrative burden of data entry, document handling, and communication tracking in construction projects. By minimizing manual data entry and reducing administrative errors, Karmen ensures timely project updates and enhances cost control. The platform is tailored for use by project managers, administrative staff, and subcontractors involved in construction projects (Karmen, 2025). Table 6 presents the detailed features of the Karmen platform based on the specified key parameters.

Table 6. Detailing Karmen according to specified parameters

Launch Year	Supported File Types	Program Integration	Functions/Features	Price
2024 (August)	Emails Text messages Invoices PDF files Excel files	Microsoft Suite Outlook Procore Excel SAP CMIC Oracle Autodesk	Data entry automation Project matching Real-time updates Invoice processing RFI management	*Pricing not publicly disclosed

Geared toward project managers, coordinators, and administrative staff, Karmen leverages AI to extract structured information from unstructured sources, including emails, text messages, invoices, PDFs, and purchase orders. Automatically enters this data into project management and enterprise resource planning (ERP) systems such as Procore, Excel, SAP, CMIC, and Oracle. A central feature of Karmen is its project-matching engine, which intelligently associates incoming communications with specific subcontractors or projects. This automated categorization streamlines documentation workflows and ensures traceability across a wide range of project inputs. By integrating with tools from the Microsoft Suite, Outlook, Procore, and Autodesk, Karmen creates a unified interface where teams can process and review information efficiently without switching between platforms. Karmen's real-time update functionality enables proactive management by notifying users of emerging risks such as potential change orders that could affect schedule or budget, thus allowing timely decision making. In addition, the platform automates invoice processing to reduce the likelihood of approval errors and supports RFI and change order management to improve visibility into contract modifications. Users can access a centralized dashboard to control or confirm extracted data before final submission, reinforcing accuracy and compliance. While Karmen's availability outside the U.S. has not been explicitly confirmed, its compatibility with globally adopted platforms and standard file formats suggests high adaptability for international construction teams. Finally, pricing details are not publicly disclosed.

4. Discussions

A comparative analysis of six AI platforms including Civils.ai, Kwant.ai, Archilabs, Nicky AI, Buildots, and Karmen reveals that the benefits of artificial intelligence tools have increased across various functions in the AEC industry. While each platform shares the common objective of improving productivity, minimizing manual effort, and enhancing decision-making accuracy, they cater to diverse operational phases and user needs across the projects.

A key similarity across all platforms is their strategic use of AI to automate repetitive, time-consuming tasks. From extracting structured data from unorganized files (Civils.ai, Karmen), to automating administrative workflows (Nicky AI), and tracking site progress via computer vision (Buildots), these platforms together demonstrate how construction management is evolving toward digital workflows and real-time decision-making.

However, significant functional and domain-based differences also emerge. Civils.ai, Archilabs, and Buildots primarily support technical design and analysis processes. While Civils.ai focuses on geotechnical data extraction and modeling, Archilabs emphasizes natural language–based BIM interaction and generative design for architectural planning. These tools are tailored for engineers, architects, and planners operating at the early stages of a project. Buildots offers a unique solution through AI-driven 4D progress tracking, combining helmet-mounted 360-degree camera data with BIM models and schedules. This approach enables precise detection of deviations, improving scheduling accuracy and issue resolution.

In contrast, platforms such as Kwant.ai, Nicky AI, and Karmen are more aligned with site-level operations and administrative management. Kwant.ai integrates AI and IoT devices to enable real-time worker monitoring and predictive risk analytics. Nicky AI serves as a digital administrative assistant with voice-enabled interaction for email and document management. Karmen supports document automation and ERP integration, especially for financial documents like invoices and change orders.

5. Conclusions

In this study, which examines AI platforms used in the AEC industry, the analysis shows that AI tools in this industry are becoming more specialized and technically advanced. Instead of providing general-purpose solutions, today's platforms are designed to support specific tasks by integrating AI into areas such as design, project administration, safety checks, and tracking construction progress. While common themes such as automation, integration, and time savings are evident across all six platforms, their diversity underscores the need for contextual platform selection. Firms must assess their technological maturity, project scale, and operational priorities when adopting these tools. Platforms like Civils.ai and Archilabs are ideal for design-centric organizations, whereas Nicky AI and Karmen are more suited to administrative optimization. For large-scale construction projects with tight deadlines, platforms like Buildots and Kwant.ai offer valuable real-time tracking and risk prediction capabilities. As AI technologies continue to develop, future platforms will likely become more compatible with each other, able to understand and combine different types of data such as text, voice, images, and sensor readings, and offer smarter predictions.

Implementing IDS-based information validation in BIM: A practical application

Bayram A. Temel*[1]

[1] Karadeniz Technical University, Department of Civil Engineering, 61080 Trabzon, Türkiye

Abstract. This study presents an application scenario developed to demonstrate the applicability of the Information Delivery Specification (IDS) standard in automating information validation processes within Building Information Modeling (BIM) projects. In this example, the fire resistance ratings (FireRating) of wall and door elements in a BIM model were validated using IDS-based rules. The validation process was structured in three main stages. First, an IDS file was created using Solibri IDS Editor, defining information requirements related to the selected elements. Second, this file was imported into Solibri Office, where the relevant elements were automatically filtered and verified using classification-based methods. Third, the detected data inconsistencies were reported to stakeholders using the BIM Collaboration Format (BCF) to facilitate feedback. The findings indicate that the use of IDS enables the early identification of data deficiencies and may offer advantages in terms of time efficiency and systematic control compared to manual validation processes. This study provides a practical example of how IDS can be implemented and aims to serve as an introductory reference for users unfamiliar with its use in BIM workflows.

Keywords: Information delivery specification (IDS); Building information modeling (BIM); Information validation; Exchange information requirements (EIR); BIM collaboration format (BCF)

1. Introduction

Building Information Modeling (BIM) has brought significant transformations to project processes within the architecture, engineering, and construction (AEC) industries by enabling the digitalization of design coordination, project management, and facility operations (Pauwels et al., 2017). At its core, BIM represents the physical and functional characteristics of building elements in a structured and accurate digital environment (Eastman et al., 2011). This structured information enhances decision-making efficiency throughout the project lifecycle and plays a critical role in applications such as design validation, clash detection, energy efficiency analysis, and maintenance management (Volk et al., 2014).

However, manually checking the accuracy and completeness of information in BIM models can lead to significant time losses, human errors, and information inconsistencies, especially in large-scale projects (Succar, 2009). Moreover, the use of different software platforms and multidisciplinary teams in projects often results in non-standard data exchanges (buildingSMART International, 2024). Such issues can cause quality losses and increased costs in project delivery processes.

To address these challenges, the Information Delivery Specification (IDS) was developed by buildingSMART International. IDS enables the automatic, transparent, and standardized validation of BIM data by transforming project information requirements (Exchange Information Requirements - EIR) into a machine-readable format. Designed in alignment with the ISO 19650 series, IDS enhances efficiency in information management processes and supports cross-platform interoperability within the openBIM framework (ISO 19650-1, 2018).

In this study, the concept of Information Delivery Specification (IDS) is examined in detail, and its role and significance in structured BIM data validation are explained. Furthermore, the contributions of IDS to information management processes in the AEC sector are evaluated, and its potential applications within BIM workflows are discussed. In this context, a practical application using the Solibri IDS Editor is presented in the following sections to demonstrate the practical use of IDS.

*Corresponding author, E-mail: bayramali.temel@ktu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_661

2. Information Delivery Specification (IDS)

The construction industry is undergoing a significant transformation driven by digitalization. At the center of this transformation, BIM not only enables the digital representation of physical designs but also facilitates the management of information required throughout the entire lifecycle of buildings (Eastman et al., 2011).

However, in BIM applications, the absence of required information or the provision of incorrect data can lead to major disruptions and increased project costs. As a result, clearly, understandably, and verifiably defining which information should be present on which elements has become a critical necessity in modern projects (Pauwels et al., 2017).

In response to this need, the IDS was developed. IDS explicitly defines the information that must be present in BIM models and allows the automatic validation of this information through software tools (buildingSMART International, 2024).

IDS is a standard that specifies, in a machine-readable and human-understandable format, the information that must be associated with specific model elements. In simple terms, IDS enables automated checks for questions such as:

- "Does this door have fire resistance information?"
- "Is the thermal transmittance of this wall correctly defined?"

Summarizing this structure, IDS systematically answers the following three fundamental questions:

- What? → Which elements will be checked?
- For what? → Which information is required?
- How? → According to which rules will it be evaluated?

Traditionally, information requirements in BIM projects have been specified through lengthy textual documents, contract appendices, and technical specifications. However, this approach has introduced several challenges, as summarized in Table 1.

Table 1. Common problems in traditional information requirement definitions

Problem	Description
Ambiguity	The required information was not clearly defined.
Interpretation Differences	Each team could interpret the textual requirements differently.
Manual Validation	Information validation was performed manually, resulting in time consumption and human errors.

For instance, if a contract merely states, "Doors must be fire-resistant," this phrase leaves significant ambiguity:

- Which doors?
- According to which fire-resistance standard?
- Based on which testing methods?

IDS addresses such ambiguities by defining information requirements in a clear, measurable, and machine-verifiable manner. When rephrased using IDS principles, the statement becomes objective, unambiguous, and instantly verifiable across different software environments.

An example of an IDS definition is given Table 2.

Table 2. Example of an IDS requirement definition

Element	Property	Requirement
IfcDoor	FireRating	≥ EI60 standard

An IDS file organizes information requirements within a clearly structured framework. The core components of this framework are illustrated in Fig. 1. This systematic structure standardizes information demands, facilitates interoperability between different platforms, and ensures objective measurement of information accuracy.

The Entity facet specifies the type of IFC entity to which the IDS rule applies, ensuring that validation checks are only performed on relevant elements. For example, a rule regarding thermal transmittance would apply specifically to IfcWall and IfcWindow entities.

The Attribute facet refers to fundamental metadata associated with an IFC entity, such as its GlobalId and Name.

The Classification facet enables validation based on standardized classification systems such as OmniClass, Uniclass, or COBie. This approach ensures structured data organization within the BIM model. For instance, a classification rule may require that all structural beams are correctly categorized under a predefined standard.

The Property facet concerns measurable or definable attributes assigned to an element. These properties align with IFC schemas and BIM project requirements. For instance, an IfcDoor could have a Width property that must be at least 900 mm to meet accessibility standards.

The Material facet verifies whether elements have the correct material definitions, which is critical for sustainability assessments, structural integrity evaluations, and compliance with environmental regulations. An IDS rule might, for example, ensure that IfcSlab elements utilize C30/37 concrete for structural strength.

The PartOf facet defines the relationships between elements, ensuring that grouped components meet specific requirements. For instance, a IfcDoor located within a fire compartment (IfcSpace) must have a fire rating that matches the safety classification of that compartment.

Fig. 1. Facets of IDS (Dias, 2024)

The IDS validation process operates in two main stages: Applicability and Requirements. In the Applicability stage, the specific elements to be checked are defined (e.g., "Only external walls will be checked."). In the Requirements stage, the attributes or properties that the selected elements must possess are specified (e.g., "Each external wall must have a ThermalTransmittance value of ≤ 0.30 W/m²K."). In essence, IDS translates information requirements into a machine-readable language and enables automated model validation according to these defined rules.

The concept of IDS aims to standardize the definition of information requirements within BIM workflows. However, integrating the IDS framework into real-world sectoral practices poses challenges due to technical limitations within the current software ecosystem.

Currently, the number of software tools capable of generating and utilizing IDS files remains limited. Solibri IDS Editor, supported by buildingSMART International, and some solutions offered by ACCA Software, allow for the creation of IDS rules. Nevertheless, most of these tools serve only specific functions and may not adequately support integrated data management in large-scale, multidisciplinary projects.

Moreover, widely used design platforms such as Autodesk Revit and Graphisoft ArchiCAD are not currently capable of directly producing or validating IDS files within their native environments. This limitation primarily stems from the restricted alignment of these platforms' data modeling approaches with open data standards like IFC. Specifically, proprietary platforms such as Revit require users to export data for subsequent processing, which introduces additional steps to ensure compatibility with IDS rules (Volk et al., 2014).

Currently, the use of IDS in BIM projects typically involves a two-stage workflow. In the first stage, BIM models are exported using open data standards such as IFC. In the second stage, the exported models are validated against IDS rules using verification tools like Solibri Office.

While this two-stage approach offers certain advantages in terms of data integrity, it also introduces additional coordination and time management challenges during project execution. Particularly in large-scale and international projects, the integration of data from various platforms into the IDS validation process requires meticulous planning and effective data management strategies.

In conclusion, for IDS to achieve broader adoption across the industry, design authoring tools must evolve to natively support IDS-compliant data generation. Accordingly, buildingSMART International and various software developers are actively working to enhance IDS compatibility in future software releases.

3. IDS setup and implementation using Solibri solutions

In this study, Solibri's IDS Editor platform was used to define IDS rules, while Solibri Office software was employed to perform information validation on the BIM model. The Solibri IDS Editor is an online platform that enables the creation of IDS specifications, whereas Solibri Office is a robust verification tool designed for quality control and data validation in building information models. Both tools operate in full compliance with the Industry Foundation Classes (IFC) standard (Solibri, 2024).

As part of the study, an information validation procedure was carried out to identify critical data deficiencies related to fire safety within wall and door elements of the BIM model. In particular, the FireRating property, which represents a building component's resistance to fire, plays a vital role in ensuring both design accuracy and building safety.

The validation process consists of three main stages:

1- *Definition of IDS Rules:* Separate IDS specifications were created for each element group (walls and doors) using the Solibri IDS Editor (2024). At this stage, the element type to be validated (IfcWall, IfcDoor), relevant classifications (e.g., Fire Compartment, Fire Doors), and the property to be checked (FireRating) were defined.

2- *Importing into Solibri Office and Automated Validation:* The defined IDS file was imported into Solibri Office, and the BIM model was validated against the rules. All relevant elements in the model were scanned to verify compliance with the IDS criteria.

3- *Error Detection, Issue Creation via BCF, and Feedback:* For entries that failed to meet the validation criteria, issues were created within Solibri Office using the BIM Collaboration Format (BCF). These issues were then communicated to responsible stakeholders (e.g., architects), enabling correction of erroneous data in the authoring software and contributing to overall data quality improvement.

This case study clearly demonstrates how the IDS approach can be effectively utilized in project information management processes and how it contributes to enhancing the quality of BIM model data.

3.1. Fire safety check

In this case study, the aim is to verify whether the fire compartment walls contain the FireRating property. To apply the IDS rules correctly—targeting only fire compartment walls—the walls were classified within Solibri as either belonging to a fire compartment or not, as illustrated in Fig. 2.

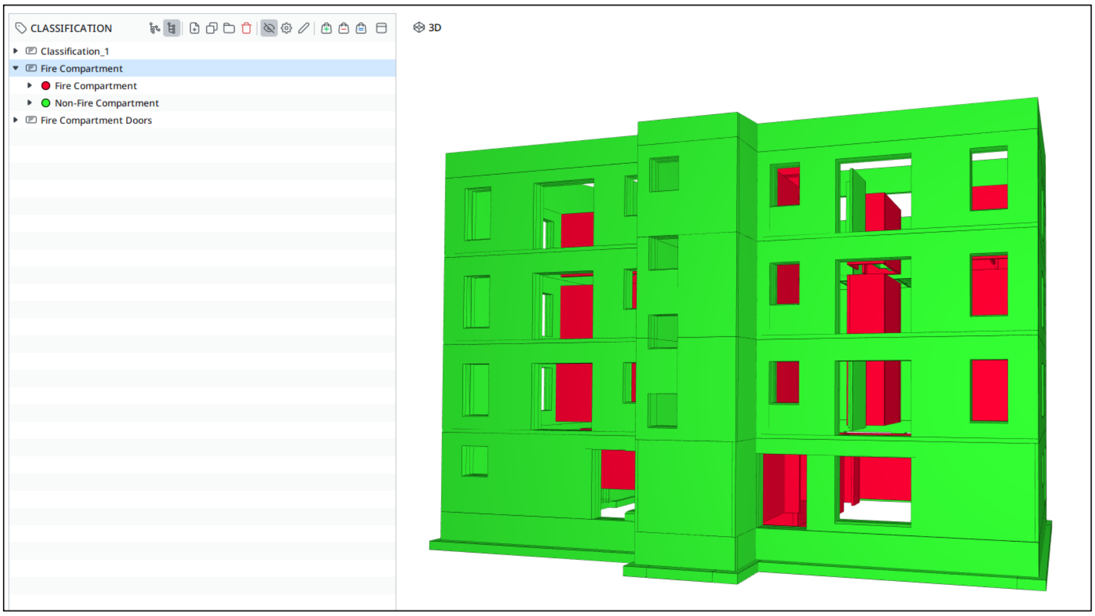

Fig. 2. Classification of walls based on fire compartment status within Solibri

Then, the creation of the IDS was initiated using the Solibri IDS Editor (Solibri, 2024). Initially, it was intended to verify whether the fire compartment walls include the FireRating value. As shown in Fig. 3, the IFC schema selected for IDS creation is IFC4. In the applicability section, the Entity facet of IDS was used, with its value set to IfcWall, this filters all wall elements from the model. Since the goal is to check only the walls that are part of the fire compartment, a classification was applied as a second applicability condition, and its value was defined based on the previously created classification within Solibri.

In the requirement section, the Property facet was used, and the value was set to FireRating, as this is the property to be checked. The data type was automatically assigned according to the IFC schema. Additionally, under the requirement section, a list of acceptable values for the FireRating property such as EI90, EI60, and EI120, was defined. This ensures that during validation, only these specific values are accepted; any deviation from them will be flagged as an error.

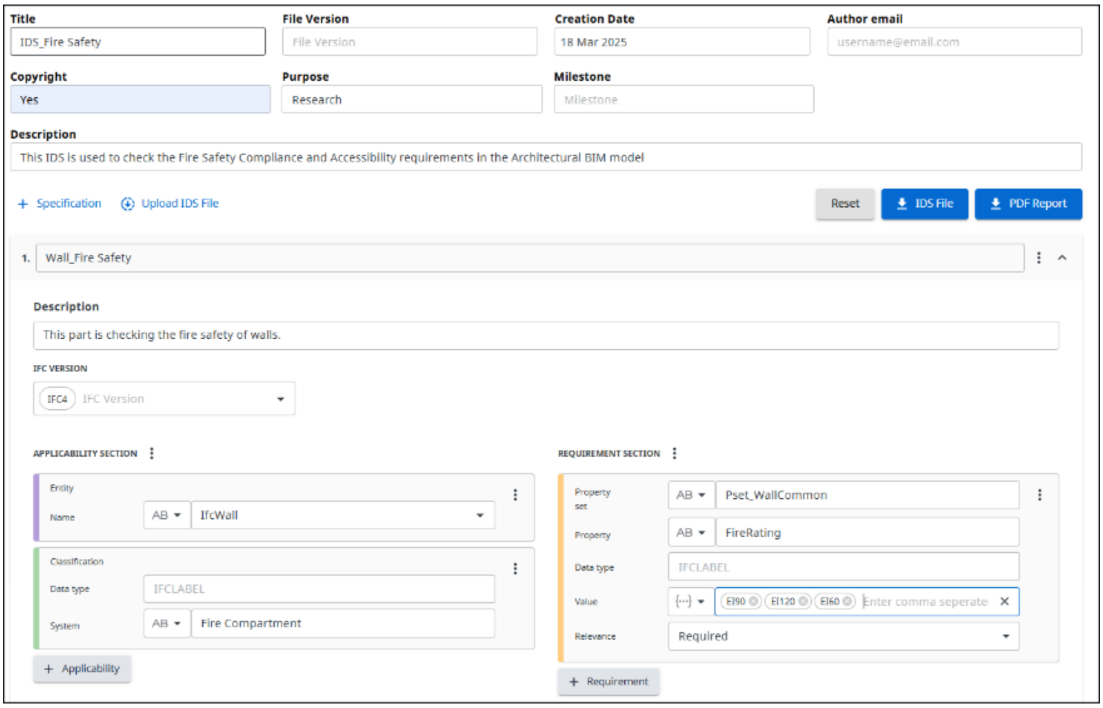

Fig. 3. IDS configuration for fire safety validation of walls using the Solibri IDS Editor

After creating the specification for the fire safety of walls, the next step is to define the requirements for the fire safety check of doors. As shown in Fig. 4, like the approach used for walls, the doors were first classified within Solibri as Fire Doors and Non-Fire Doors.

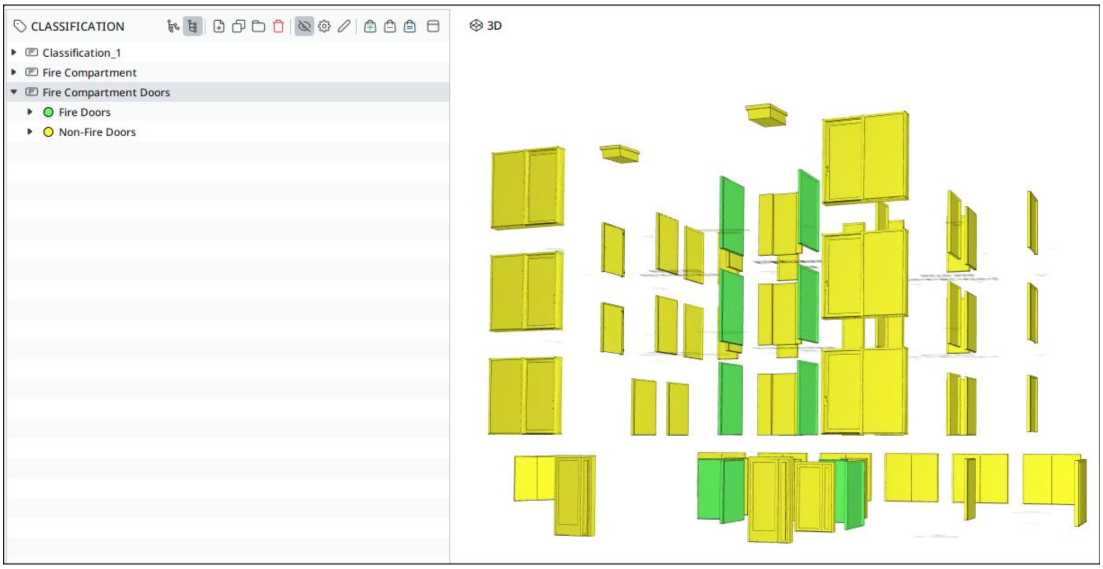

Fig. 4. Classification of doors based on fire safety criteria within Solibri

As shown in Fig. 5, another specification was added within the Solibri IDS Editor to perform the fire safety check for doors. The IFC schema selected for validation is IFC4, as the BIM model conforms to this schema. In the applicability section, the Entity facet was used, and its value was set to IfcDoor, thereby filtering all door elements from the model. Since the goal is to check only the doors that are part of the fire compartment, a classification was applied as a second applicability condition, and its value was defined based on the previously created classification within Solibri.

In the requirement section, the Property facet was selected, and the value was set to FireRating, since this is the property to be validated. The data type was automatically assigned based on the IFC schema. A list of acceptable values for the FireRating property such as EI30 and EI60 was defined so that during validation, only these values are accepted. Any deviation from the predefined list will result in an error.

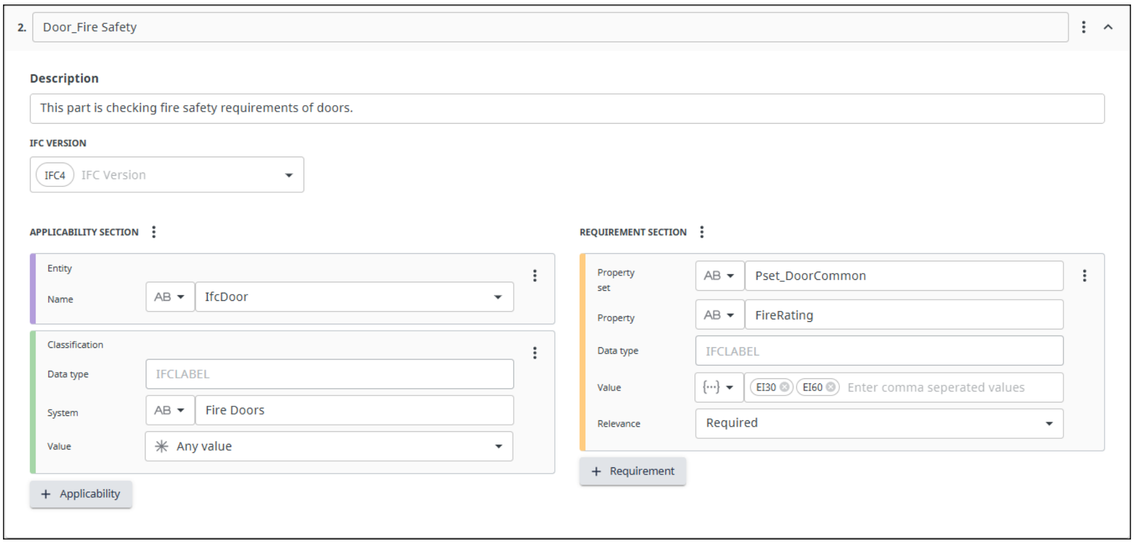

Fig. 5. IDS configuration for fire safety validation of doors using the Solibri IDS Editor

After creating the IDS using the Solibri IDS Editor online service, the resulting IDS file was downloaded. The specifications defined for the fire safety of walls and doors are summarized as follows:

```

After downloading the IDS file from the Solibri IDS Editor online service, it was uploaded into Solibri Office to validate the information content of the BIM model against the defined IDS requirements.

As shown in Fig. 6, the fire safety check for the doors was successfully completed, with no errors detected during validation.

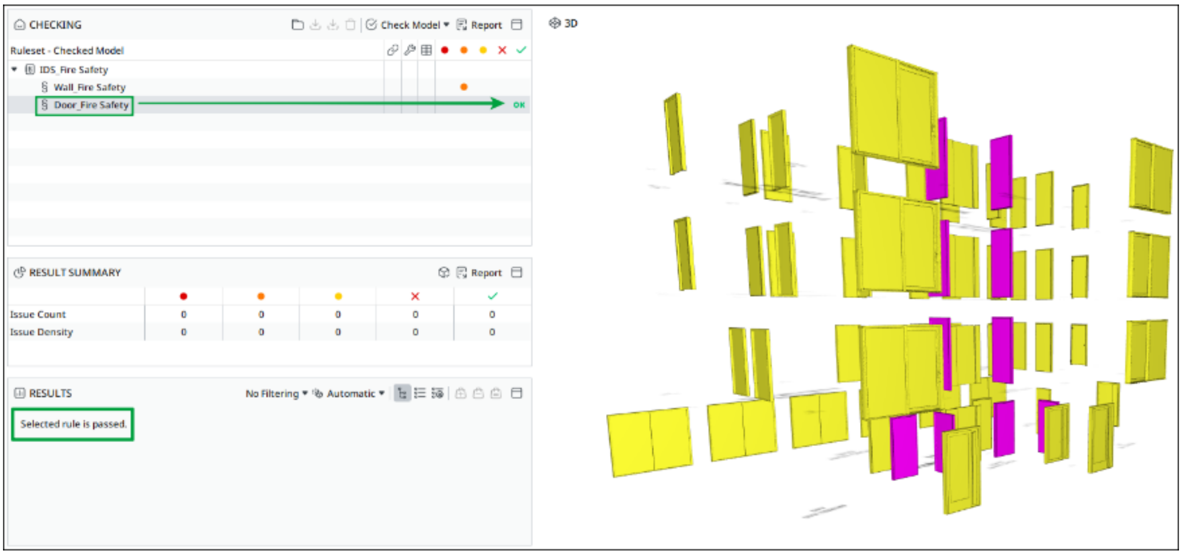

Fig. 6. Validation results of door fire safety requirements against IDS in Solibri Office

On the other hand, as shown in Fig. 7, Solibri Office identified errors related to the fire safety of certain walls during the IDS-based validation process. Specifically, two errors were detected, both resulting from the use of values that do not match the predefined acceptable values specified in the IDS.

Two issues related to the data entry errors were created in Solibri Office and exported in BCF in Figs. 7 and 8. Thess issues were then forwarded to the architect to correct the erroneous values for the relevant elements, allowing the architect to update the information in the BIM authoring tool with the appropriate values.

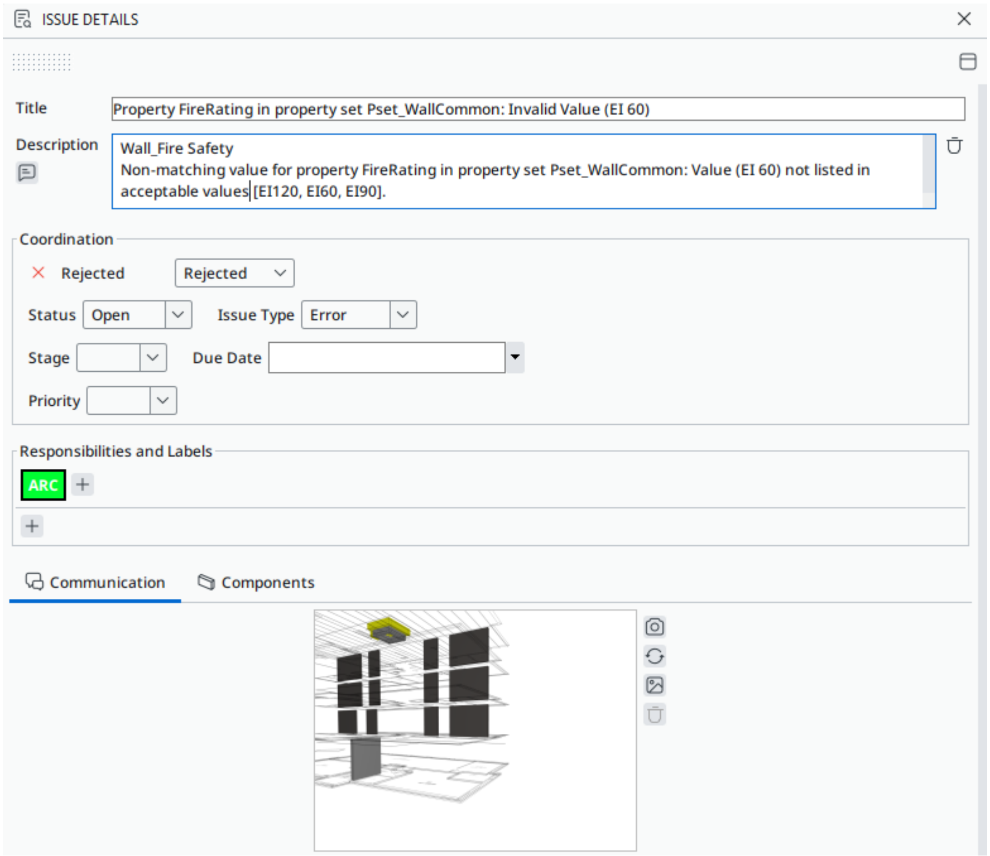

Fig. 7. Creating an issue in Solibri Office for inaccurate fire rating data (e.g., EI 60) using the BCF format

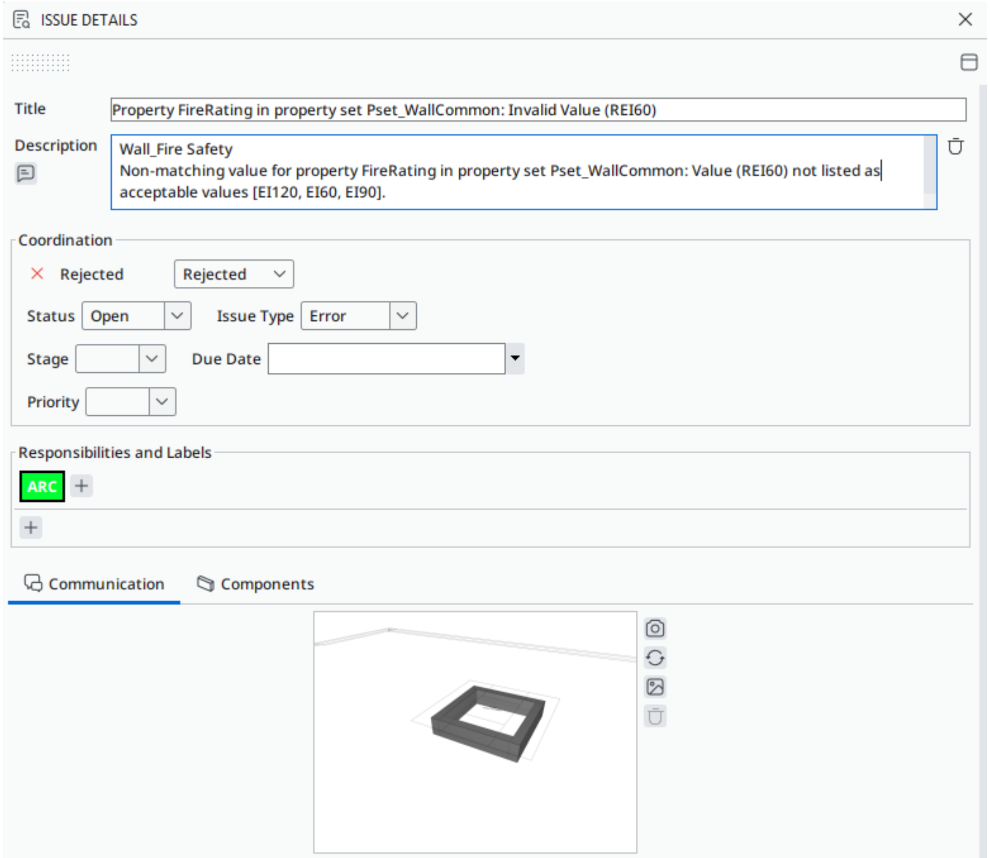

Fig. 8. Creating an issue in Solibri Office for inaccurate fire rating data (REI60) using the BCF format

4. Conclusions

This study presented an example scenario illustrating the application of the IDS approach, which was developed to ensure information accuracy in BIM projects. The increasing complexity of information management and model coordination in contemporary projects necessitates systematic and standards-based data validation. In this context, IDS provides significant support to project information workflows by enabling the automatic verification of defined information requirements across model elements.

To demonstrate this applicability, a scenario was developed in which the FireRating properties of wall and door elements in a BIM model were validated. IDS rules were defined using the online Solibri IDS Editor, and the generated IDS file was imported into Solibri Office to conduct the automated validation process. Detected inconsistencies were reported to stakeholders using the BIM Collaboration Format (BCF), enabling an effective feedback mechanism. The findings suggest that the use of IDS allows for the early identification of data deficiencies and may provide advantages in terms of time efficiency during the validation process. This application demonstrated that IDS has the potential not only to ensure data integrity but also to support risk mitigation, improve design decision-making, and enhance interdisciplinary coordination.

The ability to define information requirements in a standardized format and to validate them automatically is becoming essential for achieving the digital transformation goals of the AEC industry. This study offers a practical scenario to demonstrate how IDS can be applied, providing a clear and accessible example for users who may be unfamiliar with the concept.

[2] *Erciyes University, Department of Civil Engineering, 38039, Kayseri, Türkiye*

Abstract. Disputes occurring in the construction industry cause quantifiable damages, like delays in project timelines, cost increases, quality degradation, and incalculable effects, like loss of trust among concerned stakeholders and deteriorated business relationships. Resolving conflicts at the initial phase is instrumental in maintaining project continuity and reducing temporal and monetary losses. The legislative change enacted in 2020, which gave contractors the discretion of submitting applications to the Directorate of High Technics Board (DHTB) directly, afforded a significant administrative framework for the speedy resolution of disputes in public works projects. The present research conducts a comparative analysis of the efficiency of the modified application to the DHTB used by contractors and that of the judicial process of the Court of Cassation. The results are that both the Court of Cassation and the DHTB have the same approach in solving disputes, except that the DHTB provides a faster and less expensive means of dispute resolution. The significant limitation of this research is that the analysis is conducted based on two case studies alone. It is recommended that future research explore the impact of DHTB decisions on dispute resolution practices using larger population samples and both quantitative and qualitative approaches.

Keywords: Construction disputes; Dispute resolution mechanisms; Early-stage dispute management; Comparative legal analysis; Public construction projects

1. Introduction

Construction disputes have been technically referred to as legal and technical disagreements that develop between parties through the process of project delivery, construction, and design. These disputes are essentially caused by defective or insufficient realization of contractual duties, differing interpretation of contract conditions, or unforeseen circumstances (Fenn et al., 1997; Sarı et al., 2021). The construction industry, with its numerous stakeholders, prolonged project durations, and intricate technical specifications, is prone to result in the occurrence of disputes (Kumaraswamy, 1997; Sarı et al., 2024). Additionally, communication inefficiencies, scope changes in the project, and ambiguous contractual terms greatly enhance the likelihood of disputes in mega-projects (Mitkus & Mitkus, 2014).

Disputes arising in construction projects cause delayed timelines, cost overruns, and a decline in quality, thereby inflicting real economic damages on the industry (Assaf & Al-Hejji, 2006). Especially in large projects, such delays put added financial strains on contractors and employers, dramatically heightening the duration required for the fulfillment of a project (Koushki et al., 2005). Likewise, research in Jordan found that disputes result in higher project costs, major variations in completion schedules, and dissatisfaction experienced by both employers and contractors (Sweis et al., 2008).

Early resolution of construction disputes is known to be a crucial way to avoid the possible escalation of conflicts that could adversely affect project goals. Alternative Dispute Resolution (ADR) techniques like negotiation, mediation, adjudication, and arbitration enable prompt and cost-effective resolution of conflicts in the construction industry while emphasizing the importance of maintaining interpersonal relationships (Cheung et al., 2002). Signing detailed and unambiguous contractual terms at the beginning of a project and maintaining effective communication channels minimizes the possibility of conflict and improves the continuity of the project (Yates & Epstein, 2006). Currently, in addition to conventional methods, emerging technologies such as Building Information Modeling (BIM), blockchain, and smart contracts are also essential tools for the early identification and resolution of conflict (Kalogeraki & Antoniou, 2024). These technologies accelerate data exchange between the parties, enhance transparency, and contribute to faster advancement in resolution procedures.

In Turkiye, judicial and administrative bodies have important roles in the resolution of disputes arising from construction projects during their execution phases. In this context, the Court of Cassation and the Directorate of High Technics Board (DHTB) under the Ministry of Environment, Urbanization, and Climate Change are noted as two main bodies in resolving technical and contractual disputes occurring in the course of project execution. The Court of Cassation is the supreme judicial body for the settlement of legal disputes stemming from construction contracts, including developing case law on contractual provision interpretation, contractor-employer performance relations, determination of construction defects, consideration of time extension and variation claims, payment of progress payments, return of performance bonds, and contract termination (Sarı et al., 2025). The decisions of the Court of Cassation define the rights and duties that govern subcontractors, employers, and contractors, thus promoting legal certainty within the sector.

Conversely, DHTB functions as a distinct administrative entity tasked with the resolution of technical and contractual conflicts arising within public construction initiatives. The technical assessments and contractual interpretations provided by DHTB serve an advisory role and lack legal enforceability for judicial bodies and involved parties; however, its decisions regarding unit prices hold binding authority following applicable regulations.

In 2020, there was a regulatory change that permitted contractors to approach the DHTB directly, hoping to settle disagreements at the preliminary phases through the application of technical expertise. This has been a great boost for DHTB in resolving disputes. DHTB is now a neutral technical authority to be accessed not only by administrative authorities but even contractors, thus acquiring a more central position in the resolution of technical and contractual disputes in public works contracts. In particular, in technically complex disputes, DHTB provides fast and impartial opinions, opening up the possibility of settlement between the parties before their escalation to judicial proceedings. Nonetheless, since DHTB's decisions are mostly non-binding, they do preserve the parties' freedom of action but also possibly limit the finality of dispute resolution. Therefore, DHTB's increased role must be maintained in delicate equilibrium with the principles of the rule of law.

The current state of research literature available on construction dispute resolution is predominantly concentrated on ADR techniques, judicial proceedings, and the incorporation of technology. Research investigating the use of institutional systems to enable early-stage dispute resolution is significantly lacking. The 2020 amendment, under which contractors could submit directly to DHTB, has created a mechanism akin to conventional ADR methods (e.g., mediation and arbitration), whereby parties can seek solutions from an administrative technical authority before the courts. This innovation is a significant alternative for the early resolution of disputes in public construction projects. Yet, no systematic research on the impact of this regulatory reform on sectoral practice, early resolution of disputes, and settlement promotion between parties can be found in the literature, indicating a broad research gap.

This research aimsto assess the efficiency of allowing contractors to make direct applications to the DHTB in comparison with the conventional judicial resolution mechanism as determined by the Court of Cassation. Despite the wealth of in-depth studies on other ADR approaches, there is a notable lack of studies that investigate comparative roles of administrative technical organs and judicial bodies in terms of dispute resolution effectiveness. The research aims to uncover the real-world contributions of DHTB's expertise-based early-stage dispute settlement mechanisms compared to the Court of Cassation's dispute settlement results in terms of time, expenses, and settlement dynamics. In this way, it hopes to make an original contribution to academic literature and supply practitioners with a comparative assessment of the procedural efficiency of DHTB and the Court of Cassation.

2. Materials and methods

Case study analysis is a qualitative research method that enables an in-depth examination of a particular event, phenomenon, or decision-making process within its contextual framework. This method is widely utilized across disciplines such as psychology, anthropology, sociology, political science, education, clinical sciences, social work, and administrative sciences (Baron & McNeal, 2019; Miles-Keogh, 2015). In the fields of construction law and dispute resolution, case study methodology is employed to thoroughly understand the procedures adopted by decision-making bodies and the reasoning logic underpinning their rulings. Particularly in the prediction and resolution of construction disputes, previous studies have utilized case analysis to perform detailed evaluations of each case and identify key factors influencing the decisions of judges or arbitrators (Arditi et al., 1998; Arditi & Tokdemir, 1999; Chaphalkar et al., 2015; Mahfouz & Kandil, 2012).

Case study methodology, especially within the framework of interpretivist qualitative research paradigms, aims to achieve a deep understanding of the context and dynamics of specific events. In this study as well, this specific qualitative approach was preferred, considering the objective of analyzing each decision within its unique contextual features. Case study analysis provides an effective methodology for comprehensively understanding the dispute resolution processes and the legal and technical reasoning underlying decisions in the field of construction law (Hemanth Sai Kalyan et al., 2022). Similarly, studies predicting the outcomes of disputes in Public-Private Partnership (PPP) projects between public authorities and private sector participants have demonstrated that case study methodology serves as an effective tool for data collection and evaluation (Zheng, 2021).

Given the significant importance of the unique circumstances surrounding each case in construction law disputes, case study analysis is considered a superior method compared to other qualitative approaches for revealing the reasoning patterns and decision-making mechanisms across different cases.In this context, the case study method will be employed to conduct an in-depth examination of the decisions rendered by two different institutions (the 15th Civil Chamber of the Court of Cassation and DHTB) in terms of both procedural and substantive aspects. In this study, each decision will be analyzed separately as a case under the following thematic headings:

- Subject of the Dispute
- Procedural Rules Applied
- Evaluation Criteria and Use of Evidence
- Legal and Technical Grounds Underpinning the Final Decision

Through this framework, case study analysis will offer a detailed examination not only of the textual content of the decisions but also of the logical structures underlying the decision-making processes.

3. Results and discussion

In this study, two construction dispute cases arising from public works contracts based on lump-sum turnkey agreements in Türkiye have been examined. In each case, the contractors sought additional payments from the contracting authority for some items of work they alleged were not included within the contractual scope. An analysis of the judicial and administrative decisions related to these disputes shows that, despite the structural and authoritative differences between the Court of Cassation and the Directorate of High Technics Board (DHTB), there are significant similarities in their interpretive approaches (Table 1). Surprisingly, both were found to heavily depend on expert testimony from technical experts and utilized the same reasoning strategies when deciding whether the contested works fell under the original contract. These findings suggest a convergence between judicial and administrative systems' decision-making reasoning for the resolution processes of public works disputes in Türkiye.

To begin with, both rulings expressly declare the nature and extent of the agreements. The Court of Cassation expressly declares:

"*... a contract was executed between the parties on 18.07.2011 for the construction of the District Police Headquarters and Lodging Building at a fixed lump sum of 2,124,000.00 TL + VAT...*", thus affirming the lump-sum contractual structure. Similarly, DHTB notes:

"*... a construction work contracted under a lump-sum turnkey contract on 08.05.2017 under the Public Procurement Law No. 4734 and the Public Procurement Contracts Law No. 4735...*", confirming the same contractual framework.

In both cases, the contractors made similar claims. In the case before the Court of Cassation, the contractor requested payment for the fitting of a generator that was allegedly not covered by the contractual agreement, with the decision stating:

"*...regarding the purchase of a 150 KW generator, the technical specifications did not define the generator's features, it was absent from the room lists, and no payment was foreseen in the bill of quantities, thereby seeking to recover the generator's cost outside the contractual scope...*". In the Directorate's decision, the contractor claimed:

"*...in a petition dated 18.09.2017, the contractor summarized that for Poz Y.16.062/09 works of the Ministry of Environment and Urbanisation, debris generated from borehole drilling was transported over 12 km whereas the contract assumed up to 60 meters; hence, an additional transport cost was sought for the distance exceeding 60 meters...*".

Both decision texts strongly emphasise the binding nature of project documents and contractual annexes. The Court of Cassation underlined that:

"*...the contract was based on a lump-sum turnkey price, and Article 8 of the contract listed the annexes, with the implementation projects qualifying as part of the contract documents. Since the 150 KW generator was included within the implementation project, it cannot be considered as an extra work item. Thus, the trial court's ruling in favour of the claim was erroneous...*".

Similarly, the Directorate's assessment stated:

"*...Article 6 of the contract stipulates that 'this is a lump-sum turnkey contract based on the implementation projects and room lists included in the tender documents, and the total contract price offered by the contractor covers the entire work.' Furthermore, Article 39 of the General Specifications for Construction Works prescribes that 'for lump-sum turnkey contracts, payments are made based on progress percentages as foreseen in the tender documents, under the principles outlined in the contract and its annexes'...*".

Table 1. Comparison of Court of Cassation and DHTB Decisions on construction disputes

No	Criterion	Court of Cassation Decision	Excerpt (Court of Cassation)	DHTB Opinion	Excerpt (DHTB)	Similarity / Difference
1	Type and Nature of Contract	Lump-sum turn-key contract; annexed documents are essential	"...a lump-sum turn-key contract of 2,124,000 TL + VAT was signed..."	Lump-sum turn-key; based on technical specifications and item lists	"...this is a lump-sum turn-key contract as defined..."	Similarity
2	Subject of Dispute	Whether generator work was contractually included	"...claimed payment for generator work excluded from the original scope..."	Whether hauling of pile waste was within contractual scope	"...a dispute arose as the contractor requested payment for hauling over 60 meters for surplus material (pasa)..."	Similarity
3	Project Documentation and Annexes	Implementation drawings and quantity lists are integral parts of the contract	"...since the 150 KW generator was part of the implementation project..."	Technical specs and project definitions are binding	"...the contract includes all works defined in the project and specification..."	Similarity
4	Normative Legal Basis	Art. 355 et seq. of the Turkish Code of Obligations; Articles 22–23 of the GSC	"...Articles 355 et seq. establish the work contract; Articles 22–23 of the GSC apply..."	General Specification Article 39	"...payments are made according to Article 39 of the General Specifications..."	Similarity
5	Outcome and Legal Effect	Court ruling reversed; retrial to be conducted	"...the decision was REVERSED in favor of the defendant..."	Advisory technical opinion given to administration, not binding	"...the Board unanimously issued this non-binding opinion..."	Difference

Consequently, both parties founded their arguments on the General Specifications for Construction Works, though citing different articles: the Court of Cassation relied on provisions related to the price of additional works, whereas the Directorate put forward payment procedures in the event of lump-sum contracts. Both approaches, however, refer to mutual dependence on the same normative framework, indicating an integrated legal framework for the adjudication of technical disputes.

The fundamental structural difference between the two judgments is in their binding effects. The Court of Cassation, holding that there was both a failure of proof in the expert report and a grave error of law on the part of the trial court, ruled that the judgment at first instance be annulled:

"*...since the implementation project envisaged the construction of a 150 KW generator, this work cannot be classified as extra. Therefore, the court's acceptance of the claim was incorrect. Accordingly, the appeal of the defendant is upheld, and the judgment is REVERSED in favour of the appellant...*".

This implies that the Court not only evaluated the expert evidence but also addressed the substantive questions directly, thus rendering a binding judicial decision that calls for a retrial. On the other hand, the decision of the Directorate is a non-binding technical view addressed to the administrative authority. As stipulated clearly:

"*...regarding the additional claims for the 'Annex Building Construction Work,' it was concluded that the transport of debris beyond 60 meters falls within the contract price. According to Article 16 of Decree Law No. 644 on the Organization and Duties of the Ministry of Environment and Urbanisation, this evaluation was adopted unanimously in the meeting held on 11.01.2018...*".

This explains that the conclusions of the Directorate, while having force, do not carry the force of a judicial ruling, and therefore, the contracting authority is afforded discretion to implement the recommendations.

One of the important points of convergence observed in both institutions' rulings is how they deal with the normative value of contract documents. Important also is the acknowledgment by the Court of Cassation and the DHTB of execution drawings, technical specifications, and bills of quantities as basic and defining components of the contract to indicate that dispute resolution is concerned not just with the work's completion itself but with addressing whether the scope defined has been exceeded. This statement illustrates the significance attached to the principles of foreseeability and contract discipline.

In the same vein, the perspective regarding the General Specifications for Construction Works also strengthens inter-institutional coherence. Both institutions view the Specification as not merely a guide to be followed, but as a binding requirement that incorporates the terms of the contract and delineates the roles of the contracting parties. This method is designed to provide both legal certainty and uniform application by demanding a systematic interpretation of the documents in case of technical disputes. Besides, ascertainment of dispute between the contracting parties is founded not merely on technical proof but also adherence to contractual agreements and general system coherence; in this case, the assessment process is done on the grounds of 'legitimate demand' and not merely on 'work done'. This practice enhances the doctrine of contractual fidelity between the administrative organization and the contractor. Both decisions dismissed the claim against the project description of the work on technical grounds, i.e., while the Court of Cassation decision states that 'if there is a generator in the application project, this work is within the scope of the contract', the DHTB decision states that 'material transported in the works described in the bored piling exposure is covered in the contract price'. When assessing the contractor's requests, both institutions consider not only the fact of completion of the work but also its conformity with the requirements established in the contract and technical documentation; moreover, they give contextual and document-based explanations for the rejection of requests outside the contractual agreement.

This methodology holds significant importance for safeguarding both legal integrity and technical rigor. Despite their specific natures, it can be claimed that the Court of Cassation and DHTB judgments share a common framework, especially concerning contractual interpretation, conformity with technical documentation, and enforcing normative texts; such a framework is fundamental to ensuring the consistency of the legal and technical framework in public projects. This common knowledge works towards a more equitable resolution of disputes and an explicit definition of the boundaries regarding the rights and responsibilities of stakeholders in the industry.

DHTB is a specialized organization that has been in operation since 1927 and has a high level of institutional experience in the settlement of technical disputes regarding public works. The Board's evolution over time reveals that, drawing on its expertise developed over the years, it has transcended its original role of providing technical advice to contracting authorities. Remarkably, the addition of Article 2 to the Public Procurement Contracts Law No. 4735 by Article 31 of Law No. 7221, which entered into force on February 14, 2020, paved the way for both the contracting authority and the contractors to make applications to the DHTB. This amendment has reshaped the DHTB, shaping it from a traditional administrative advisory committee into an efficient first-instance mechanism for dispute resolution, facilitating the impartial, technical, and speedy resolution of disputes occurring in construction works. The ability to conduct examinations within a considerably shorter time and at a lesser expense than the judicial process enhances the possibility of the DHTB to get involved at an early phase, thereby safeguarding public administrations and contractors from lengthy and expensive litigation. In this regard, the DHTB is a solutions platform that balances the stakeholders, is founded on technical competency, and aligns with the legal framework.

In the present research, the case analysis approach has been applied in order to examine critically the contextual variables, rational reasoning, and decision-making processes that support the judgments of the Court of Cassation and DHTB. Due to the ability of case analysis to allow an in-depth exploration of each case in its specific context, it has been possible to conduct a comprehensive comparison of decision texts with both procedural and substantive elements. Yet, while the case analysis approach is beneficial insofar as it affords detailed qualitative data, it is worth noting that the research findings may be restricted in terms of their generalizability. Thus, conclusions drawn will be regarded as applicable to specific contexts, and interpretations arrived at will be envisioned in terms of applicability only to the qualities of the two judgments examined and to analogous controversies involving construction contracts. This limitation is embraced within the methodological rigor of the study, in light of a recognition that findings are not directly applicable to more comprehensive judicial processes.

4. Conclusions

The current study aimed to make a comparative examination of the interpretative approaches taken by the Court of Cassation and DHTB in two construction dispute cases arising out of public works contracts that were lump-sum turnkey agreement-based in Türkiye. The present study makes a new contribution in examining the impacts of the 2020 amendment of the regulations that allowed contractors to apply directly to the DHTB as a right, on dispute resolution processes.

The results indicated that despite variations in institutional and jurisdictional frameworks, the two institutions employed the same interpretative approaches in addressing technical disputes. The convergence witnessed is a sign of harmonization among the rational frameworks employed in judicial and administrative decision-making in public building disputes in Türkiye. Specifically, following the establishment of the contractor's right to make direct applications, the DHTB has begun to work as an effective alternative dispute settlement process at the early stages. As such, DHTB provides a technically viable solution platform for the speedy, economic, and preservation-of-continuity resolution of disputes without resorting to formal judicial process. In addition, the DHTB process eliminates the lengthy timetables, cumbersome bureaucratic red tape, and prohibitive expense usually involved in litigation before the Court of Cassation, and thus presents disputing parties with an alternative method that is more feasible and accessible for conflict resolution.

Further research is suggested to enhance the examination of DHTB decisions using larger samples and both quantitative and qualitative methods. Further research is also needed to quantify the effect of contractor applications on settlement rates, the decrease in litigation frequency, and the overall effect of DHTB decisions on dispute resolution culture in the construction sector.

Abstract. In developing countries, the construction industry plays a crucial role in economic growth but faces significant challenges, including inefficiency, poor working conditions, low quality, and frequent accidents. In recent years, Building Information Modeling (BIM) has emerged as a powerful tool to improve efficiency, productivity, and coordination in construction projects. Despite its proven benefits and widespread adoption in developed nations, the uptake of BIM in Morocco has been limited, primarily restricted to specific stages like design and surveying in a few major projects. This study aims to explore the current state of BIM adoption in the Moroccan construction industry by examining the knowledge, experiences, and attitudes of various stakeholders, including architects, engineers, project managers, and technicians. A comprehensive survey was conducted using Google Forms, targeting a diverse group of professionals across different age groups and professional backgrounds. The findings reveal a mixed level of familiarity with BIM, with a significant portion of respondents acknowledging its potential benefits but also highlighting challenges such as resistance to change, lack of awareness, and high implementation costs. The study identifies key barriers to BIM adoption and underscores the need for targeted education, training, and investment to foster wider acceptance of BIM practices. By addressing these challenges, the Moroccan construction industry can leverage BIM to enhance project management, reduce costs, and improve overall quality and safety in construction projects. The insights from this study provide guidance for policymakers, educators, and industry leaders to promote BIM integration and maximize its benefits in the Moroccan context.

Keywords: Building information modeling (BIM), Civil engineering; Construction industry; Morocco; Project management efficiency

1. Introduction

According to the World Bank, there are 135 middle- and low-income economies classified as developing countries. These nations experience significant knowledge gaps and are marked by infrequent and limited technological innovation. Within these developing countries, the construction industry remains labor-intensive (World Bank, 2015a; 2015b; 2015c). Various challenges in construction within developing countries result in delays, substandard site environments, poor working conditions, low quality, and frequent accidents. The inefficiency in this sector highlights a significant opportunity for development. As construction can optimize the use of human and material resources, it is often regarded as a key driver for economic growth and achieving development objectives (Latiffi et al., 2013) and (Giang & Pheng, 2011).

Similar to other industries, construction companies leverage a variety of information and communication technology (ICT) solutions to enhance project delivery. Research indicates that the integration of ICT applications can significantly increase the efficiency and productivity of construction projects (Latiffi et al., 2013). One notable ICT application is Building Information Modeling (BIM). Invented in the 1970s by Professor Charles M. Eastman, BIM is based on a procedure that organizes all task information. It has become a practice, and even a requirement, in many countries across different continents. BIM is a strategy in construction aimed at improving productivity and profitability through the use of various collaborative tools. It provides a universal platform for working consistently and collaboratively (Idrissi Gartoumi et al., 2021). Traditionally, checking, controlling, and rectifying

[*] Corresponding author, E-mail: fahd.jehhad@etu.uae.ac.ma

https://doi.org/10.31462/icearc2025_ce_mng_700

discrepancies has been a time-consuming process. BIM addresses this by offering an information-rich design in the form of mock-ups that can be automatically updated (Czmoch & Pękala, 2014). It begins at the design phase and serves as a foundational information resource throughout construction and project supervision, encompassing time, budget, facility management, and environmental considerations (Montiel-Santiagoet al., 2020) and (Cheng et al., 2016). Although originally developed for the building industry, BIM has successfully penetrated various sectors of the construction industry, making a positive impact throughout the life cycle of infrastructure projects. BIM has gained significant traction, proving its value on numerous real-world projects. During the COVID-19 pandemic, BIM played an important role in global efforts to enhance hospital infrastructure. However, its adoption in Morocco remains limited. In practice, the implementation of BIM in Morocco has been slow. BIM is primarily used in a few major projects and is often confined to specific stages like design and surveying. Therefore, the aim of this study is to explore the knowledge and adoption of BIM among different stakeholders in construction and public works in Morocco. The perspectives and experiences of various professionals will be examined, including architects, BIM managers, project managers, construction directors, construction engineers, civil engineers, and technicians, across different age groups. This study seeks to understand the current state of BIM implementation, identify barriers, and highlight opportunities for enhancing BIM adoption in the Moroccan construction industry.

2. Materials and methods

To investigate the knowledge and adoption of Building Information Modeling among various stakeholders in the Moroccan construction industry, a comprehensive questionnaire was developed and administered via Google Forms. This approach facilitates efficient data collection while leveraging modern technological solutions. The questionnaire is structured into six sections, each designed to capture insights from professionals in the field, including engineers, architects, surveyors, and other relevant roles. Below is a detailed description of each section: Section 1 concerned demographics, aiming to gather basic demographic information to contextualize the responses. It includes gender to understand gender representation among respondents, age to analyze trends and attitudes across different age groups, profession to identify the professional backgrounds of participants, allowing for a comparative analysis of BIM knowledge and adoption among different roles. Sections 2-5 concerned respectively the knowledge of BIM to assesses the familiarity and experience of respondents with BIM in section 2, project management practices in section 3 to explore the effectiveness of project management within the Moroccan construction sector, Section 4 examines perceptions of BIM's potential benefits, it also addresses barriers and potential benefits associated with BIM implementation and the last section is for open-ended comments allowing respondents to share any further thoughts or insights not captured in previous sections, providing qualitative data that enriches our analysis (Table. 1).

Table 1. Overview of each section and its corresponding subsections, along with their purposes

Section	Subsection	Description
Demographics	Gender	Collecting information on the gender of respondents to analyze representation.
	Age	Gathering age data to explore trends and attitudes across different age groups.
	Profession	Identifying professional backgrounds to compare BIM knowledge among various roles.
Knowledge of Building Information Modeling	Familiarity	Assessing how familiar respondents are with BIM on a scale.
	Experience	Determining if participants have worked on projects utilizing BIM.
Project management practices	Effectiveness	Evaluating the effectiveness of project management practices in the Moroccan construction sector.
	Use of digital tools	Investigating the frequency of digital tool usage in construction projects.
Optimization of coordination and communication with BIM	Coordination	Assessing beliefs about BIM's ability to enhance project coordination.
	Communication	Exploring how BIM can improve communication among project stakeholders.
	Challenges	Identifying key challenges faced regarding BIM adoption in the construction industry.
	Opportunities	Highlighting perceived opportunities that BIM offers for the industry.
Additional Comments		Providing an open-ended space for respondents to share further insights or thoughts.

3. Results

To account for the diversity in construction professionals, the questionnaire included an assessment of the distribution of respondents by both their professional profiles (Table. 2) and gender (Fig. 1). There was a noticeable gender imbalance among participants, with 74.3% being male and 26.7% female. This disparity reflects the ongoing gender imbalance in the Moroccan engineering sector, where approximately 42% of engineers are women and 58% are men. The age range of participants varied significantly, from 20 to 66 years old, with an average age of 30.6 years. Upon examining the demographic characteristics of the participants, also their familiarity with BIM technology was analyzed, as shown in Table. 1 of the Materials and Methods section. The findings indicate varying levels of familiarity with BIM among respondents: 40% reported being very familiar with using BIM in the context of construction projects, 20% were somewhat familiar, 11.4% were quite unfamiliar, and 5.7% were very unfamiliar, with the remaining respondents expressing a neutral stance. Additionally, 62.9% of the participants used BIM in at least one construction project, while 37.1% had not, underscoring the growing need for wider adoption of this technology in the industry (Fig. 2). These results highlight an increasing trend in the adoption of BIM across different construction project profiles, as depicted in Fig. 2. The data suggest that while there is a significant portion of professionals who are well-versed in BIM, a substantial number still lack familiarity, indicating an opportunity for further education and training to enhance the effective implementation of BIM practices across the Moroccan construction sector.

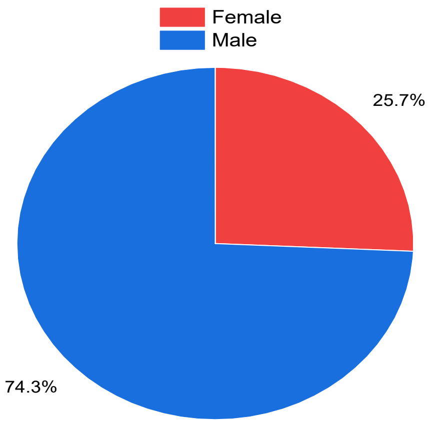

Fig 1. Sexe distribution of this study's participants in Morocco

Table 2. Different professions of participants in the present study

Profession	Count	Percentage (%)
Technician	5	14.29
Civil Engineer	10	28.57
Architecture	8	22.86
Topographical engineer	5	14.29
Project director	7	20%

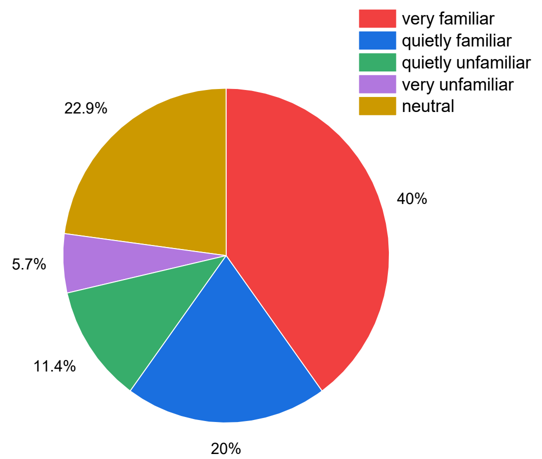

Fig 2. Familiarity rate distribution of BIM knowledge across different age, sex and profiles

To evaluate the extent of BIM management practices in the Moroccan construction industry, a question designed to determine the perceived effectiveness of BIM's usage was included. The responses indicated that approximately 74.3% of participants were satisfied, reporting that BIM was either "very effective" or "effective" in enhancing their overall project outcomes. In contrast, the remaining participants were either neutral, lacking sufficient knowledge to judge its effectiveness, or considered it ineffective. These results are further supported by the fact that over 70% of respondents reported using digital tools, such as project management software and applications, within their construction projects, whereas the rest relied solely on conventional methods. Even among those with limited knowledge of BIM, there was a consensus that BIM could significantly optimize the coordination process in project planning. Specifically, 51% of respondents highlighted that the most critical role of BIM in project management is facilitating real-time collaboration among various project stakeholders. Additionally, 26% identified the centralization on information as the primary benefit of BIM, while the remaining respondents believed that BIM tools greatly enhance the visualization and tracking of a project's status. When assessing the challenges associated with implementing BIM for project management and optimization, the survey revealed that 46% of participants were primarily concerned about the resistance to transitioning from traditional methods to newer, more optimized approaches. Meanwhile, 29% pointed out a significant lack of awareness regarding the importance of BIM in the Moroccan context. The remaining respondents expressed concerns about technical difficulties and the high costs associated with implementing BIM technology (Table. 3). These findings suggest that while there is a growing recognition of the benefits of BIM in improving project management practices, there are also notable barriers to its widespread adoption, including cultural resistance, inadequate knowledge, and financial constraints. Addressing these challenges through targeted education, training, and strategic investment could further enhance the adoption and effectiveness of BIM in the Moroccan construction industry.

Table 3. BIM effectiveness in optimizing and managing construction projects: insights from different profiles

Parameter	Response	Percentage
Perceived effectiveness of BIM	Very effective/effective	74.3%
	Neutral/No knowledge Not effective	25.7%
Use of digital tools versus conventional methods	Digital tools	70%
	Conventional tools	30%
Perception of BIM benefits	Real time collaboration	51%
	Centralization on information	26%
	Enhancement of visualization and tracking	23%
Challenges in BIM adoption	Resistance to change	46%
	Lack of awareness of BIM benefits	29%
	Technical and implementation costs	25%

4. Discussion

BIM offers more than just improved building modeling, it also enhances the design of infrastructure compared to traditional methods, which were limited to simple lines without detailed properties. With BIM, each element in the design has parameterizable values and interacts with other elements, allowing us to identify and address potential issues before project execution, something that was not possible with conventional approaches (Latiffi et al., 2013). Interoperability and automated electronic data delivery are crucial for maximizing the effectiveness of BIM in project management. Interoperability ensures that different software platforms and tools used across various stages of a project can seamlessly exchange and interpret data. This capability is essential in a BIM environment, where multiple stakeholders, from architects and engineers to contractors and facility managers, need to collaborate and share information in real-time. Automated electronic data delivery further enhances this process by streamlining the flow of information, reducing the likelihood of errors, and ensuring that all team members have access to the most up-to-date data. Together, these features significantly improve coordination, increase efficiency, and help prevent costly mistakes and delays in construction projects (Montiel-Santiago et al., 2020). In the present study, a section of additional comments was added at the end to establish more insights: BIM fundamentally transforms the way construction projects are managed and executed. It offers a centralized model where all project data is stored, facilitating easy access and retrieval of information. This centralized approach allows for better project tracking, enabling early detection of potential issues, which is a significant improvement over traditional methods that lacked this level of integration and detail. The enhanced data management capabilities of BIM are crucial for efficient project execution and are particularly beneficial in managing the complexities of modern construction projects. In addition to better data management, BIM supports project management by providing tools for controlling all technical aspects across different phases of a project's lifecycle. This includes design, construction, and maintenance, ensuring that each phase is well-coordinated and executed efficiently. The integration of BIM into project management practices enables improved planning, resource allocation, and risk management, ultimately leading to projects that are completed on time and within budget. However, the implementation of BIM in Morocco faces several challenges. One significant hurdle is the resistance to upgrading existing workflows and methodologies. This resistance is often rooted in the need for a cultural shift within construction companies, which may be accustomed to traditional, often informal, ways of working. The construction sector in Morocco, still largely characterized by artisanal and informal practices, may find it challenging to adopt the digitalization and organizational changes required for effective BIM implementation. Furthermore, the lack of highly qualified professionals in BIM is another barrier that could hinder its widespread adoption. Without a skilled workforce, the effective use of BIM could be compromised, potentially damaging its reputation and leading to a lack of confidence among senior management in its benefits. This emphasizes the need for comprehensive training and education programs to build the necessary competencies within the industry. Despite these challenges, there are substantial opportunities for BIM to revolutionize the construction industry in Morocco. The introduction of BIM could significantly enhance collaboration among various stakeholders, such as architects, engineers, contractors, and project managers. By facilitating better communication and coordination, BIM reduces errors that often arise from misinterpretations of traditional plans, leading to more efficient and effective project execution. BIM also offers significant advantages in cost and schedule management. Its ability to provide three-dimensional visualization of projects enables early detection of design conflicts and quick resolution of issues, thereby avoiding costly delays and optimizing resource management. This not only improves project timelines but also contributes to cost savings, making projects more economically viable. Furthermore, the adoption of BIM could encourage the standardization of construction processes in Morocco. By promoting common standards for modeling and information exchange, BIM could lead to more consistent and high-quality project outcomes, even when multiple companies are involved. This standardization could be a significant step towards modernizing the Moroccan construction industry.

5. Conclusion

While the adoption of BIM in Morocco presents certain challenges, particularly related to cultural resistance and the need for skilled professionals, the potential benefits are significant. By addressing these challenges through strategic initiatives in training, technology integration, regulatory development, and government support, BIM can lead to more efficient, sustainable, and economically viable construction projects.

To fully leverage the benefits of BIM in Morocco, several strategic actions are recommended. Training and awareness initiatives must be prioritized, investing in comprehensive programs to equip engineers, architects, and project managers with the necessary skills. Furthermore, the integration of BIM with emerging technologies such as the Internet of Things (IoT) and Artificial Intelligence (AI) offers opportunities to enhance project management through real-time monitoring and predictive analytics.

It is equally crucial to establish a regulatory framework that defines specific standards for BIM implementation, ensuring data security, quality consistency, and alignment with international practices. Additionally, promoting the long-term benefits of BIM, such as improved asset lifecycle management, easier maintenance, and greater sustainability, that will foster a deeper and more enduring adoption.

Finally, government involvement is fundamental. By establishing clear legal frameworks and policies, inspired by successful models in Anglo-Saxon countries, public authorities can stimulate the modernization and digitalization of the Moroccan construction sector.

The successful adoption of BIM could thus transform the Moroccan construction industry, aligning it with global standards and practices, and ensuring its competitiveness in the international market.

[2] *Istanbu University, Department Of Architecture, 34100 Istanbul, Türkiye*

Abstract. LEED (Leadership in Energy and Environmental Design) certification is a worldwide rating system for green buildings. LEED certification is essential in the architectural design of buildings that aim to reduce environmental impacts and promote energy conservation. LEED-certified buildings benefit the environment and occupants by saving energy. Additionally, green buildings have the answer to issues like global climate change and depletion of energy resources. Therefore, LEED certification has environmental, economic, and social benefits. The application of energy-saving measures at Istanbul University Hasdal Campus is a good example of sustainable construction with increased energy efficiency. Not only do they help the university attain its sustainability objectives, but they also contribute to the development of an environmental awareness in a wider population. The main objective of this study is to examine the compatibility of the energy and sustainability strategies implemented in Istanbul University Hasdal Campus with LEED certification, and to explore how a healthcare campus can be designed in a high-risk seismic city through the lenses of sustainability, energy efficiency, and resilience. More specifically, the study aims to measure the conformity of energy efficiency procedures to LEED requirements. To this end, this research seeks to generate implications for planning more efficient energy management and conservation measures in university campuses. In future research, a more holistic evaluation of sustainability is recommended by incorporating components such as water efficiency, material circularity, and waste management. Comparative analyses involving different certification systems—such as LEED, BREEAM, and WELL—applied to the same healthcare project can reveal their methodological distinctions and practical implications. Additionally, long-term modeling of the environmental and economic impacts of energy infrastructures in public investments, particularly in high-risk urban areas, may support the development of more resilient, inclusive, and cost-effective planning strategies.

Keywords: LEED certification, Energy efficiency, Sustainable buildings, Energy conservation, Disaster-resilient buildings.

---

1. Introduction

Istanbul is situated at the western terminus of the North Anatolian Fault Line and is considered one of the world's megacities with the greatest seismic risk. The city's geographical setting, geological conditions, fast demographic expansion, and unplanned urbanization amplify the threat of earthquake-induced damage (Eraybar et al., 2010). In Parsons (2004) study, the probability of the occurrence of an earthquake of magnitude 7.0 or larger in Istanbul region and the Marmara Sea during 2004-2034 was calculated as 38% based on a time-independent model, whereas the time-dependent model incorporating the effect of stress transfer provided the probability as 53 ± 18%. For Istanbul specifically, this probability was calculated as 41 ± 14% (Parsons, 2004).

Istanbul University is the oldest institution of higher learning in Turkey, dating back to the Sahn-ı Seman Madrasahs established following Mehmed II's conquest of Istanbul in 1453 (Günergün & Kadıoğlu, 2006). The contemporary university creation process was finalized with the founding of Darülfünun in 1900 and the subsequent University Reform of 1933. The university has played a pioneering role in the development of higher medical education and health care in Turkey, and, above all, in the health sector, represented by institutions such as the Istanbul Faculty of Medicine. The current building stock of the university is comprised of a combination of historically significant structures as well as educational and healthcare facilities that were built in the mid-20th century. Earlier research attests that a high proportion of the cultural heritage structures in Istanbul have considerable seismic-related hazards (D'Ayala & Ansal, 2012; D'Ayala et al., 2008). As a result, harmonizing the physical structure of Istanbul University with modern seismic codes has become a vital need for protecting cultural

* Corresponding author, E-mail: mahmutsari@ahievran.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_702

heritage as well as maintaining institutional services' provision on a continuous basis. The geographical location of the Hasdal Campus of Istanbul University is endowed with serious strategic and locational advantages.
Hasdal is situated on the European side of Istanbul city, close to the TEM Motorway (O-2) corridor, and has a good link to the city center. The developed transport system in the region is a factor that supports the accessibility of the campus in terms of emergency management and logistics activities following disasters. It is reported to have a closed solid waste landfill in the Hasdal region previously, and the region has been subjected to large-scale rehabilitation activities since then (Ozcan et al., 2007). Research has indicated that there has been soil stability in the region and environmental hazards have been significantly reduced. Moreover, the adverse environmental effects have been mitigated through sustainable practices, such as controlled methane gas extraction and energy generation. The mentioned characteristics have played a major role in selecting the Hasdal region as a green and resilient campus area for Istanbul University's education and health services.

The Hasdal site is located on the European side of Istanbul, the northwestern region of the city, and is characterised by having geologically stable ground conditions (Kundak & Handan, 2005). Based on high-resolution seismic hazard studies carried out all over Istanbul, it is explained that the stiffness of the ground is greater in the northern parts - among them Hasdal - than in the southern coastal parts near the Marmara Sea, and thus earthquake waves will be less amplified (Kalkan & Gülkan, 2023). The results indicate that, in comparison to Istanbul's high-risk coastal zones, the Hasdal region demonstrates superior seismic performance characteristics.

Istanbul University Hasdal Campus has been master-planned as part of a strategy to revitalize the current vulnerable building stock and reinforce healthcare infrastructure to mitigate the impact of future catastrophes. Situated in the Hasdal area in the northwestern sector of Istanbul, the campus is known for being close to key roadways, stable ground conditions, and far from active fault lines. It encompasses a series of healthcare facilities, schools, laboratories, emergency response and disaster management spaces, parking, and central energy systems. The project has been designed using a modular and staged planning approach, with the inclusion of sustainable energy technologies like photovoltaic panels and trigeneration system. The main goal of this research is to investigate the campus plan of a medical facility based in a city with severe seismic hazards, with a specific reference to the case of Istanbul University Hasdal Campus. The study will adhere to sustainability, energy efficiency, and resilience guidelines, as well as to confirm the degree to which it conforms to the conditions set by the LEED (Leadership in Energy and Environmental Design) certification scheme.

2. A case study: Istanbul University Hasdal Campus

Istanbul University Hasdal Campus was planned through a phased settlement and construction process (Table 1). The planning of the campus was staged in three principal phases to facilitate uninterrupted healthcare services, enhance operational capacity following a disaster, and to systematically organize the different medical specialties.

- **Blocks A, A1, A2:** Operating theaters, intensive care units, emergency services, and outpatient clinics
- **Block B:** Clinical specialties such as pediatric surgery, ENT, ophthalmology, and general surgery
- **Block C:** Faculty building
- **Blocks H1, H2, and H:** Technical elements, mechanical areas, and medical storage units.
- **Block H Utility Gallery:** Mechanical and electrical infrastructure systems
- **Block I:** Technical and clinical support units
- **Block G:** Main block at a later stage of construction

The next phase includes the opening of more clinical centers specialized in different fields, such as pediatrics, infectious diseases, cardiology, internal medicine, and oncology.

- **Block D:** Infectious Diseases and Childhood Health
- **Block F:** Pulmonary disease, cardiology, internal medicine, oncology
- **Block E:** Faculty building
- **Block J:** Newly established clinical units

Phase three includes state-of-the-art treatment and research centers:

- **Cardiovascular Center:** Evaluation, management, and recovery services for cardiovascular conditions.
- **Oncology Institute:** Research and education in oncology
- **Chronic Diseases and Treatment Center:** Diagnosis and rehabilitation of chronic conditions
- **Proton Therapy Center:** Proton radiation therapy
- **Faculty of Dentistry:** Dental education and clinical practice
- **Nuclear Medicine Unit:** Treatment and diagnostic imaging unit

Table 1. Istanbul University Hasdal Campus Phases, blocks and functional distribution

Phases	Blocks	Functions
PHASE I	**Block A**	Operating Rooms, Intensive Care Units, Laboratories, Emergency Service Units
	Block A1	Outpatient Services, Patient Examination Areas
	Block A2	Outpatient Services, Patient Examination Areas
	Block B	Pediatric Surgery, Otorhinolaryngology (ENT), Ophthalmology, Audiology, General Surgery, Urology, Orthopedics, Thoracic Surgery, Cardiovascular Surgery, Dermatology
	Block C	Faculty Building
	Block H1	Technical Units, Mechanical Areas
	Block H2	Technical Units, Mechanical Areas
	Block H	Medical Storage, Technical Support Areas
	Block H Utility Gallery	Mechanical and Electrical Infrastructure Gallery
	Block I	Clinical Support and Technical Areas
PHASE II	**Block G**	Main Block Under Advanced Construction
	Block D	Pediatric Health, Infectious Diseases, Neurology
	Block F	Pulmonology, Cardiology, Internal Medicine, Oncology, Dermatology, Nephrology
	Block E	Faculty Building
	Block J	New Clinical Units
PHASE III	**Cardiovascular Center**	Cardiovascular Diagnosis, Treatment, and Rehabilitation Center
	Oncology Institute	Oncology Research, Treatment, and Training Center
	Chronic Diseases and Treatment Center	Diagnosis and Rehabilitation Center for Chronic Diseases
	Proton Therapy Center	Proton Therapy Treatment Center
	Faculty of Dentistry	Faculty of Dentistry – Education and Clinical Application Center
	Nuclear Medicine Unit	Diagnostic Imaging and Therapeutic Unit

The first phase covers the main health services units and support infrastructures:

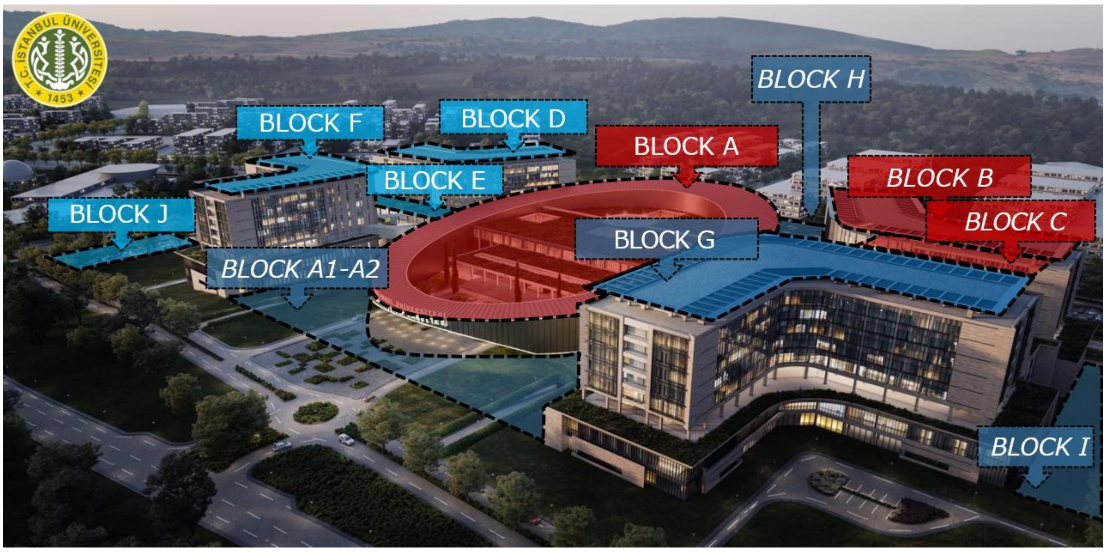

Fig. 1. Layout of Istanbul University Hasdal Campus Blocks

Table 2. Energy infrastructure and project specifications

Category	Description
General Project Information	**Total Area – Phase I:** 451.167 m² **Total Area – Phase II:** 202.344 m² **Total Approximate Area:** 653.511 m² **Total Bed Capacity:** 1.678 beds **Number of Operating Rooms:** 50 **Number of Outpatient Clinics:** 117 **Parking Capacity:** 2.129 vehicles
Photovoltaic Panel Application	A rooftop photovoltaic system with an approximate capacity of 480 kW will be installed on Blocks B, G, F, and D. Each roof will accommodate 210–230 panels, ensuring a minimum production of 120 kW per block. Panels will be south-oriented for optimal solar gain, and no energy storage system is planned. The payback period for the system is estimated at approximately 4.5–5 years.
Trigeneration System	Trigeneration system will be installed in Block H4, supplying electricity, heating, and cooling across the entire campus. The system aims to achieve 30–40% higher energy efficiency compared to conventional systems.
Integrated Energy Strategies	The integrated use of photovoltaic panels and the trigeneration system will reduce carbon emissions and improve energy efficiency across the campus.

This phased and functional structure of the campus reflects Istanbul University's goals of sustainability in health services, expertise-based organisation and high resilience after disasters.

The campus structure aligns with the objectives of healthcare sustainability, organizational structure based on specialization, and high post-disaster resilience by Istanbul University. Istanbul University's Hasdal Campus has been planned with dual consideration for seismic resilience and as a pioneering concept that integrates innovative design principles for sustainability, energy efficiency, and continuity of functioning. This campus goes beyond the traditional campus scheme by aiming to operate as an edifice complex that can facilitate rapid recovery during disasters, acquire a level of energy autonomy, and integrate green technologies for the environment. As a component of the project energy policy, it includes the simultaneous production of electricity, heat, and cold by a trigeneration system, and electricity from solar energy by photovoltaic panels. Project features and campus energy infrastructure are described in Table 2. The campus is built on a total area of 653,511 m² and comprises 1,678 inpatient beds, 50 operating rooms, 117 outpatient clinics, along with parking for 2,129 vehicles (Figure 2).

Fig. 2. Istanbul University Hasdal Campus Construction Site

Fig. 3. Photovoltaic panels and trigeneration system in Istanbul University Hasdal Campus

In accordance with sustainable energy goals, it is suggested that photovoltaic panels be mounted on Blocks B, G, F, and D to a total installed capacity of approximately 480 kW (Figure 3). The installation would comprise around 210-230 panels per block in order to produce a minimum electric output of 120 kW per block. The system is meant to satisfy a major part of the daily electricity requirement directly using the energy from the sun. The solar panels face the south direction to absorb more solar radiation and increase the output energy. The system has no energy storage capacity since the power that will be produced will be used instantly. The payback period for the installation has been estimated at around 4.5 to 5 years. This project is supposed to enhance the environmental sustainability objectives of the campus through carbon emission reduction and additional contribution to energy security during cases of post-disaster scenarios.

With a view to developing energy efficiency and continuous energy supply during crisis periods, trigeneration system is going to be installed in Block H4 (Figure 3). The system will be designed to produce electricity, heat, and cold at the same time. Implementation of trigeneration systems in hospitals results in significant energy conservation and carbon emission savings because of the constant need for electricity, heating, and cooling throughout the year (Ziher & Poredos, 2006). When compared to traditional methods of separate production of energy, trigeneration systems decrease primary energy consumption by a great extent and enhance operational energy efficiency in hospitals. Besides, by providing a solution to the cooling issue, the systems meet the energy profile of the facility throughout the year. Within this system, trigeneration is central to providing energy supply security in the case of emergencies. During normal operations, the system is able to fulfill a significant proportion of campus electricity and HVAC requirements, while during the occurrence of a disaster, it will offer extended energy support for maintaining the provision of health services. Consequently, the trigeneration system will assist Hasdal Campus in realizing its vision of establishing a disaster-resilient campus framework in addition to supporting environmental sustainability by reducing carbon emissions.

3. Discussion

LEED (Leadership in Energy and Environmental Design) is a globally recognized green building certification system that evaluates and rates the design, construction, operation, and maintenance of sustainable buildings(Cole, 2005). The LEED system assesses a building's performance across environmental, social, and economic sustainability metrics under various categories: Sustainable Sites, Water Efficiency, Energy and Atmosphere, Materials and Resources, Indoor Environmental Quality, Innovation, and Regional Priority. Projects earn certification levels based on the number of points achieved in these categories: Certified (40–49 points), Silver (50–59 points), Gold (60–79 points), and Platinum (80+ points). Achieving LEED certification allows buildings to increase energy efficiency, reduce operational costs, minimize environmental impacts, and improve occupant health. Moreover, LEED-certified buildings have been shown to provide economic benefits, including increased market value and higher occupancy rates (Bond & Devine, 2016).

The design and implementation processes of the Istanbul University Hasdal Campus demonstrate strong alignment with the LEED certification framework due to their focus on environmental sustainability and energy efficiency. The strategic development of the campus as a disaster-resilient facility, combined with the integration of a trigeneration system and photovoltaic panels in the energy infrastructure, significantly enhances its potential to score highly in the "Energy and Atmosphere" and "Sustainable Sites" categories.

The geographic location and soil characteristics of the Hasdal region offer advantages in minimizing environmental risk, contributing positively to the "Sustainable Sites" category in LEED evaluations. The campus's modular building system and phased planning strategy support credit acquisition in the "Regional Priority" and "Innovation" categories. Additionally, the design of operational continuity in emergency scenarios—particularly crucial for healthcare services—aligns with LEED's environmental management and resilience criteria.

The photovoltaic panel application directly contributes to the "Energy and Atmosphere" category. With approximately 480 kW of installed capacity and south-facing orientation, these panels are expected to meet a significant portion of the campus's daily energy demand using renewable sources. The planned trigeneration system at the Istanbul University Hasdal Campus also significantly contributes to energy efficiency. It has the potential to substantially reduce primary energy consumption compared to standalone electricity production and separate HVAC systems (Ziher & Poredos, 2006). This energy efficiency supports direct credit acquisition under the "Optimize Energy Performance" and "Fundamental Commissioning and Verification" criteria within the "Energy and Atmosphere" category. Improvements in total energy consumption and operational efficiency are key parameters that can earn high scores under LEED. However, the LEED credits for "Renewable Energy Production" and "Green Power and Carbon Offsets" are specifically tied to the use of fully renewable energy sources. Nonetheless, improvements in energy production efficiency, reductions in carbon emissions, and enhanced energy autonomy at the campus support continued indirect point acquisition under the LEED framework. The trigeneration system offers significant advantages for LEED certification due to its high energy efficiency, reduced carbon emissions, and uninterrupted energy supply during emergencies.

4. Conclusions

The aim of this research was to investigate the use of a healthcare campus plan in a city having high-risk characteristics, specifically the case of the Istanbul University Hasdal Campus. The research sought to align this plan with the concepts of sustainability, energy efficiency, and resilience, as well as how well it adheres to the standards set by the LEED rating system. Case study methodology was used to examine the geographic location of the campus, earthquake-resistant design objectives, phased planning process, and energy systems infrastructure, with the project features assessed based on the benchmarks stipulated by LEED standards.

The results show that Hasdal Campus has a high degree of compliance with the LEED system, specifically in the "Energy and Atmosphere," "Sustainable Sites," and "Innovation" categories. The use of photovoltaic panels, supported by a very efficient trigeneration system, increases the campus's energy efficiency, while the modular planning approach allows for ease in maintaining flexibility and ensuring continuity of operations in the event of post-disaster situations.

Future studies need to strive for in-depth analyses of health care facilities in urban high-risk areas, especially with regard to sustainability criteria; make comparative analyses of various green building rating systems, i.e., LEED, BREEAM, and WELL, applied to the same projects; and simulate long-term environmental and economic effects of energy infrastructure. Furthermore, incorporating sustainability strategies into decision support systems for major public investments with cost-benefit analyses will lead to the further evolution of more inclusive and resilient planning strategies.

Sketch-to-BIM: A comparative analysis for automated truss design in Dynamo

Feyzullah Yavan*[1], Reza Maalek[1], Atefeh Aali[1]

[1] *Institute of Technology and Management in Construction (TMB), Department of Digital Engineering and Construction (DEC), Gotthard-Franz-Straße 3, 76131 Karlsruhe, Germany*

Abstract. The advent of digital technologies and artificial intelligence has transformed designers' capability and allowed them to reveal their potential to achieve optimal designs. However, in the initial design explorations, many designers, similar to artists, rely on freehand sketches, which must then be converted to digital designs for information modeling, structural analysis, and engineering optimization. Such a fragmented approach results in time inefficiencies, compatibility errors, and a lack of opportunity for design explorations. Thus, to address these challenges, this paper presents an integrated workflow for converting hand-sketched truss designs into digital structural models within building information modeling (BIM)-based software environments, referred to as Sketch-to-BIM (StB). This unified framework employs Dynamo's visual programming capabilities and involves several interconnected stages: (i) exploring different methods available in the open literature (e.g., Harris corner detection, Skeletonization method, Heat map technique, and Deep Learning (DL) techniques) for geometry extraction, which includes node and element recognition from sketches; (ii) converting the identified nodes and elements into parametric designs in Dynamo; and (iii) testing and comparing these sourced methods on the proposed workflow. The results showed that the proposed methodology is successful in solving test problems, and each feature extraction method provides different trade-offs in both execution time and accuracy. Overall, the current manuscript created a valuable foundation for upcoming studies on StB workflow, and the findings can be utilized to discuss and determine the most effective approach based on the use case.

Keywords: Computer vision; Deep learning; Dynamo; Feature extraction; Image processing

1. Introduction

Current industry practices typically involve: (i) manual creation of structural models in Computer-Aided Design (CAD) software; (ii) separate optimization tools, which are usually coded as part of the research, for sizing, shape, and topology optimization; (iii) Finite Element Method (FEM) analysis software like Robot Structural Analysis (RSA) for final validation; and (iv) iterative refinement through multiple software platforms. Multiple research studies were proposed to enhance this workflow. In this regards, scholars have developed a parametric modeling framework through Dynamo and RSA for FEM analysis within Visual Programming (VP) environment for model creation and optimization to enhance structural design and optimization workflow. This line of research was also followed with employing Python libraries and RSA Application Programming Interface (API) for FEM analysis to further enhance proposed workflow with different constraint conditions such as reliability of structure and different Metaheuristic Algorithms (MAs) (Yavan, Maalek, & Maalek, 2024; Yavan, Maalek, & Toğan, 2024; Yavan & Maalek, 2025). However, while these methods improved the engineering design process compared to textual programming (e.g., Python, C#, etc.) and manual methods, parametric modeling in a VP environment is very demanding in terms of technical expertise and possesses a steep learning curve. In this respect, while VP tools such as Dynamo can enhance and ease the engineering design process by automating structural model complexities, the designer must obtain strong programming skills in addition to their civil engineering background in order to effectively employ them (Kossakowski, 2023). On the other hand, the integration of automation to find the optimal design rather than a good enough option is essential to create cost-effective and structurally efficient models (Kubicki et al., 2018). In response to these challenges, this study focuses on developing the structural model from hand-drawn sketches. This approach eliminates the necessity for parametric modeling in VP, textual programming-based modeling, and even manual modeling, which is time-consuming and prone to error (Joffe et al., 2024). Recent studies have focused on innovative methods to convert hand-drawn sketches into structurally analysed models. In the referenced study (Joffe et al., 2024), a computer vision-based framework that enables the

* Corresponding author, E-mail: feyzullah.yavan@kit.edu

https://doi.org/10.31462/icearc2025_ce_mng_736

automatic conversion of hand-drawn beam diagram sketches was introduced. In their study, the YOLOv5 (You Only Look Once) (Redmon et al., 2016) was used to detect objects such as beams, supports, and the loads with 99.1% mean average precision. The numerical values were determined using a Deep Learning (DL) model with 99.0% accuracy, and after determining the relationships between the elements with Multi Layer Perceptrons (MLPs) (Rosenblatt, 1957) with 95.1% to 99.5% accuracy, the structural analysis was performed using OpenSees (Mckenna et al., 2010). Their system could correctly analyse 45% of test images entirely and 55% partially.

In a separate study, (Hutchinson et al., 2007) introduced 2DSketchFEA, an innovative sketch-based tool for two-dimensional Finite Element Analysis (FEA). This system enabled users to draw structural models by using conventional engineering symbols directly. Their system integrates sketch recognition, geometric meshing, FEA, and result visualization within a single sketch-based interface, without the need to use traditional command-line or menu-driven modeling environments, and is easy to use by those with minimal CAD or FEA experience. In a similar study, (Jeong et al., 2024) proposed a way to automate the conversion of sketch-based architectural data to BIM models using ResUnet (Z. Zhang et al., 2018), which is a DL-based sketch recognition model to distinguish architectural sketches from redundant data. This data was eventually converted to a BIM model using Autodesk Revit and Dynamo for automated model creation. In another study, (Peschel & Hammond, 2008) introduced STRAT (A Sketched-Truss Recognition and Analysis Tool), which could find all the unknown forces in a truss and avoid the complexity and time-consuming process of performing manual calculations or using CAD-based software for structural analysis. In their study, full truss recognition was done with an accuracy of 70%. Other scholars have also worked on the interpretation and conversion of sketches into digital representations (Ahmed et al., 2014; Aoki et al., 1996; de Klerk et al., 2019; C. Li et al., 2022; Weber et al., 2010).

Despite the previous work on the structural analysis of models converted from sketch to digital model, there is still a need to extend this approach to other systems, such as trusses. For this purpose, this paper performs a comparative analysis of the success rates of 4 different methods, namely the Harris corner detection algorithm (Harris & Stephens, 1998), Skeletonization method (T. Y. Zhang & Suen, 1984), Heat map technique (Cheng & Schwartzman, 2017), and DL techniques with YOLO (Redmon et al., 2016), in sketch recognition and digital model conversion. Numerous industries have made extensive use of these techniques for various objectives. Harris corner detection finds corners and feature points in a sketch by detecting variations in intensity. In the literature, this method has been applied for tasks such as image restoration in occluded environments (Dong & Liu, 2013) and human activity recognition (Babiker et al., 2017). In the skeletonization process, binary shapes are converted into simplified lines, or so-called skeletons. This technique has been applied in a variety of fields, including skeleton-based morphing between sketching images (Tan, 2010) and the retrieval of 3D objects from sketch inputs (X. Zhao et al., 2019). The Heat map approach is used in computer vision to determine the possible location or a part of an object. This technique has been applied in the literature for doing tasks like analyzing the accuracy of human sketches (Thibhodee & Viyanon, 2021) and even in the medical sciences to evaluate the fidelity of compressed Computed Tomography (CT) scans (Lee et al., 2011). YOLO is a DL method to analyse and extract structural relationships in images. Scholars have employed different versions of YOLOs for tasks such as image and color recognition (X. Zhang et al., 2018), facial mask detection during COVID-19 (Loey et al., 2021), and multivehicle detection (Diwan et al., 2023; X. Li et al., 2018). To achieve better outcomes, several researchers have also combined some of these techniques. For instance, (Wang et al., 2022) combined Harris corner detection method and an improved version of YOLO, namely YOLOX (Ge et al., 2021), for camera calibration.

The significance of this study lies in providing a comparative analysis of the methods available in open literature for feature extraction and addressing the gap in the current structural design workflow by suggesting a fully integrated pipeline that is capable of converting hand-sketched truss designs to digital models in a BIM environment. This approach eliminates the necessity for manual and parametric modeling and advanced technical knowledge on software platforms. It also makes the traditional time-consuming design and analysis workflow more efficient with Dynamo; hence, this study not only enhances automated geometry extraction but also provides a scalable and intuitive framework that can improve creativity and productivity in architectural and structural engineering designs.

2. Methodology

For the present study, a Dynamo workflow presented in
Fig. 1 was prepared, and a comparative analysis of different feature extraction methodologies, namely Harris corner detection, Skeletonization method, Heat map technique, and DL technique, was performed for the Sketch-to-BIM (StB) concept. The problem was approached through two different methods: (i) generating more artistic sketches without any pre-specification and letting the algorithms understand the connection points for Group 1 examples; (ii) marking the nodes in sketches to ease feature extraction for Group 2 examples shown in Fig. 2. For this purpose, two different test examples were prepared, as one group was identical to the other, with connection points specified by round ball-like drawings, as presented in the Experimental Design section.

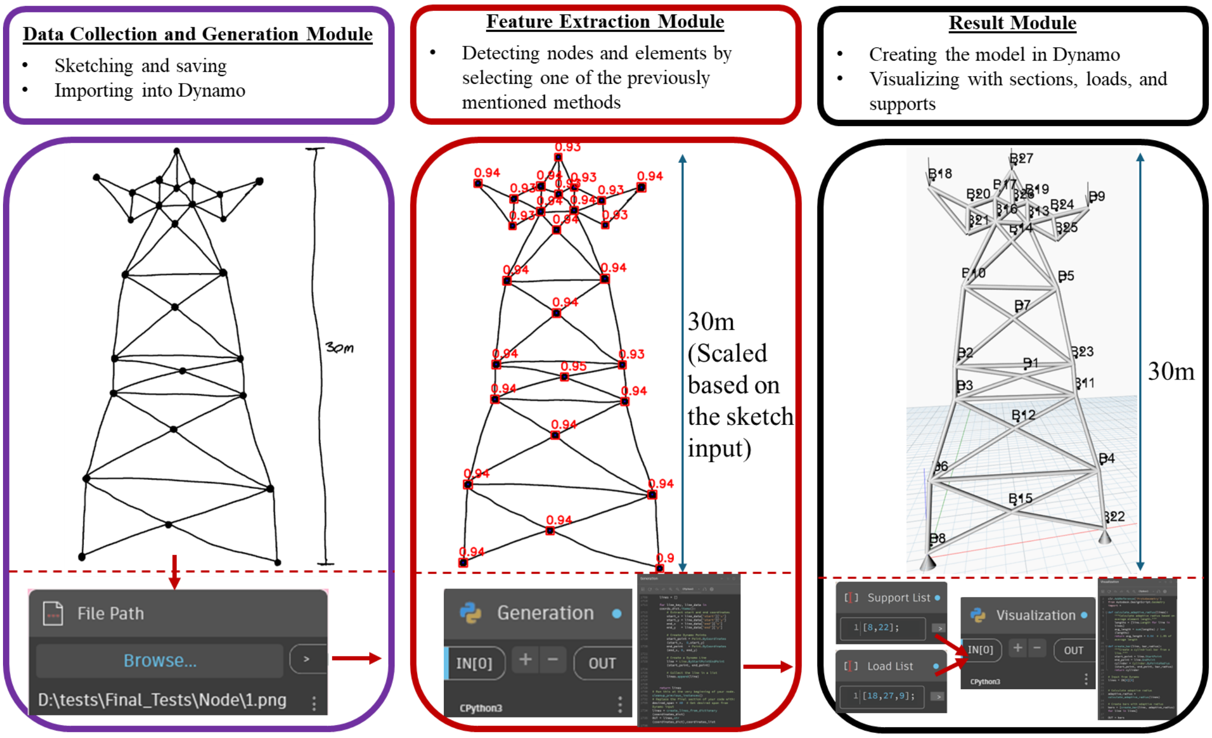

Fig. 1. The Sketch-to-BIM process is divided into sections as importing hand-drawn sketches to Dynamo, extracting geometric features, and displaying visualization outcomes.

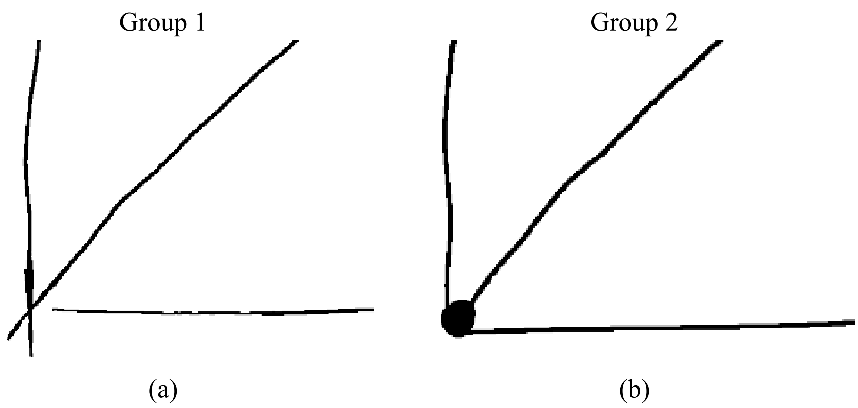

Fig. 2. The two different test examples: (a) Test example without node specification (example from Group 1); (b) Test example with node specification (example from Group 2).

2.1. Feature extraction

In the proposed method, the connection points, i.e., nodes in the present truss example, were first extracted from sketches. To achieve this, previously mentioned 4 different methods were employed, and the outcomes were presented in the Results section. For feature extraction, a common first step is to convert the input image into grayscale and then into a binary image. In our use case, this translates into the truss elements, drawn as lines, separating from a contrasting background. This preprocessing stage includes: (i) convolving the image with a kernel that gives more weight to central pixels, effectively blurring the image slightly to diminish noise (Mafi et al., 2019); (ii) median filter which uses a 5x5 window size utilized for removing salt-and-pepper noise (Justusson, 2006); (iii) enhancing the contrast through adaptive histogram equalization; and (iv) image binarization using the global Otsu's thresholding method (Otsu, 1979) for small object removal, which is basically based on labeling the components and then discarding those whose area (pixel count) is below a given threshold (Haralick & Shapiro, 1985), and morphological operations such as dilation and closing (Soille, 1999). Following image preprocessing, the subsequent steps included node detection, which will be explained thoroughly in the upcoming section, and clustering. Given that multiple connection points may be identified due to drawing artifacts, such as discontinuity, a process to segment these connection points into one node was necessary. To this end, the unsupervised clustering method, Density-Based Spatial Clustering of Applications with Noise (DBSCAN), was employed, which does not require specifying the number of clusters in advance, can find clusters of arbitrary shapes, is robust to noise, and can identify outliers (Schubert et al., 2017). The clustering process took place with epsilon (eps): 50 parameters. Then, cluster centers using the mean position of points within each cluster were computed, and cluster weights based on the number of points in each cluster were determined.

2.1.1. Harris corner detection

The first considered method for feature extraction is the classical Harris corner detection, which is implemented using the OpenCV library (OpenCV: Harris Corner Detection; Ye et al., 2009) and "cv2.goodFeaturesToTrack" function. It is used to locate potential corners based on parameters such as quality level, minimum distance, block size, etc. The script marks each detected corner on a copy of the original image for visualization. Next, circles representing nodes are drawn around each cluster center, with the radius scaled by the cluster weight to emphasize clusters with more detections, as presented in
Fig. 3b.

2.1.2. Skeletonization method

This method is mainly designed for the Group 1 examples shown in Fig. 2a to be able to detect the nodes, even though the node in the sketch is not clear. To detect nodes and lines from the hand sketch image, the skeletonization technique from "scikit-image" was employed by converting the image to a one-pixel-wide representation while preserving the overall structure of the drawing, and then analyzing the local connectivity of each pixel in that skeleton. Specifically, a small neighbor kernel is convolved over the skeleton, yielding a numerical score that indicates how many neighboring pixels are also part of the skeleton. Pixels with a connectivity value exceeding a certain threshold are labeled as branch points, and those with a specific connectivity count are labeled as endpoints, similar to the referenced study (Aastrup Olsen et al., 2011), in which the same method was employed for detecting end and intersection points in vascular/vein images . This combined skeleton-based approach gives closely spaced branch/endpoints as a single "node," shown in
Fig. 3c.

2.1.3. Heat map detection

The third method is a simpler version of the second approach, where skeletonization is not needed while using similar principles with the Harris method, and is specifically designed for Group 2 examples, where nodes are specified with round drawings that clearly state where the nodes are. This approach utilizes pixel density analysis and peak detection, as presented in
Fig. 3e, to identify regions of high pixel concentration in images, and the methodology employs the same principles explained in (Zhao et al., 2022) by using density map generation and peak detection. For density map generation, a zero-initialized array matching the input image dimensions is created, and binary pixels of interest are mapped to value one in their corresponding positions. Then, Gaussian smoothing is applied with a controllable sigma parameter. The smoothing operation creates a continuous density field around pixel clusters. Consequently, the density map is normalized to the range [0,1] using min-max normalization, which ensures consistent interpretation of density values across different images. The final stage involves identifying and visualizing regions of high pixel density by detecting the local maxima, using the "peak_local_max" algorithm from the "skimage.feature" library with parameters such as minimum distance between peaks, absolute threshold, etc. For visualization, the original image was displayed alongside the density heatmap and detected peaks marked with blue circles. The methodology provides a robust approach for identifying regions of high pixel concentration, which are nodes in this scenario.

2.1.4. Deep learning technique

This method combines DL based node detection techniques to analyze and extract structural relationships (nodes) in images. The system employs a YOLOv8n DL model for initial node detection, implementing a sliding window with 416×416 pixels and a 75% overlapping ratio between adjacent windows, showing the detections with over 50% confidence, which can be found in
Fig. 3d. Since creating annotated datasets for computer vision tasks typically involves extensive manual effort, for training the model, a synthetic dataset generator of graph-like structures with varying visual styles, presented in
Fig. 3d, was created. The step-by-step process includes: (i) initialization by setting parameters such as image size and node box size; (ii) shape generation by automatically creating predefined shapes (regular, X, T, V, star); (iii) node validation by computing intersection angles and annotating valid nodes; (iv) realism enhancement by applying waviness, noise, and thickness variations to the lines; (v) annotation by converting node positions into YOLO annotations, then saving images and labels; and (vi) visualization by randomly selecting samples for visual quality assurance. The system implements a multi-style generation approach with configurable parameters for visual variation and structural diversity. The generated data has 416×416 pixels for image resolution and consists of PNG images. Each image contains 4 to 8 nodes, placed using a grid-based distribution with a minimum separation of 80% of the cell size and margins preserved at twice the maximum node size. Connectivity is

guaranteed through the generation of a spanning tree, with additional random edges added to meet a minimum of four connections per image. Node placement is validated based on distance to prevent overlap. Post-processing steps include style-specific adjustments such as adding random noise and applying a Gaussian blur with style-dependent sigma values to enhance the natural appearance of the images. Also, the most common connection types, such as K, X, T, V, etc., were separately created and added to the sample group to ease the detection process, as presented in
Fig. 3d. In total, 21,000 images with corresponding annotations in YOLO format were generated to train the DL model.

2.2. Path analysis and line extraction

The system implements a path-finding and analysis approach by identifying intersection points between skeleton lines and cluster boundaries found by the previously mentioned methods. Then the algorithm traces skeleton paths and labels connected regions in the skeletonized image, presented in
Fig. 3a, where pixels are connected to clusters while validating paths for intersection with other clusters and preventing redundant path detection between cluster pairs. Each labeled component represents a continuous path between node clusters, specifying a linear element of structure as shown in
Fig. 3a. Subsequently, the “Generation” node shown in
Fig. 1 integrates computer vision, DL, geometry processing, and user-driven scaling to create an interactive, end-to-end pipeline for extracting and adjusting structural components from a hand-sketched image. First, it attempts to automatically read a dimension line from the source image and numeric annotation by employing Artificial Intelligence (AI). If the script successfully identifies this dimension line from the sketched image shown in
Fig. 1, it calculates a scale factor by comparing pixel distance to the real measurement, thus automatically converting the structure’s pixel geometry into real-world units. If automatic scaling is not viable, due to user preference, the code switches to a manual mode and launches a PyQt-based Graphical User Interface (GUI) shown in
Fig. 4. Within this interface, a user can pick reference connections or a known span to define the structure’s scaling. The GUI provides real-time visual feedback, displaying node position and element lengths, and a calculated scale factor. Subsequently, the user’s chosen scale factor is applied to all relevant coordinates. Finally, the script integrates with Dynamo (through the clr reference to ProtoGeometry) by converting the scaled coordinates into Dynamo-native geometry objects for further parametric modeling. The visualization module, shown in
Fig. 1, was prepared to number the nodes, create sections for structure, and provide the supports and force representation on the Dynamo. The result is a flexible framework that adapts to varying quality of source images while maintaining precise control over final geometry.

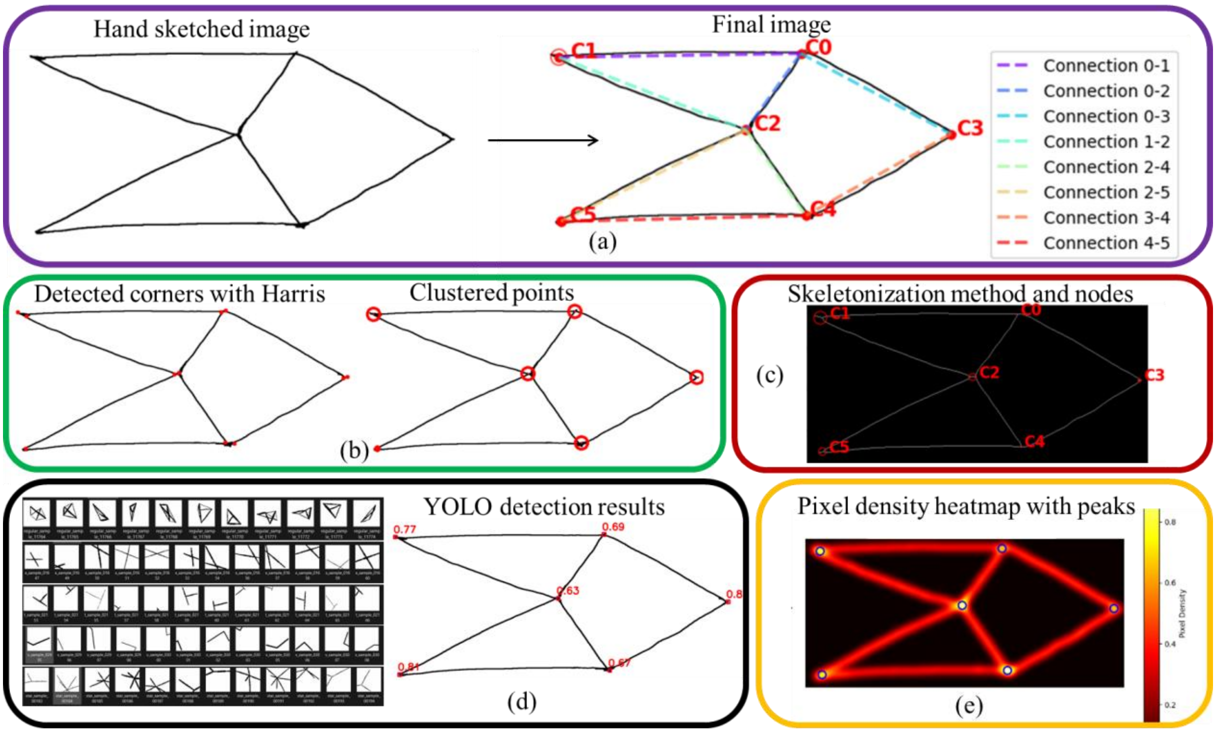

Fig. 3. Overall representation of employed methods: (a) showing the objective of the workflow and path finding; (b) Harris corner detection process (c) image skeletonization and cluster results; (d) synthetic data created to train the YOLO and the results gathered with trained model along with confidence levels; (e) Heat map technique with detected nodes

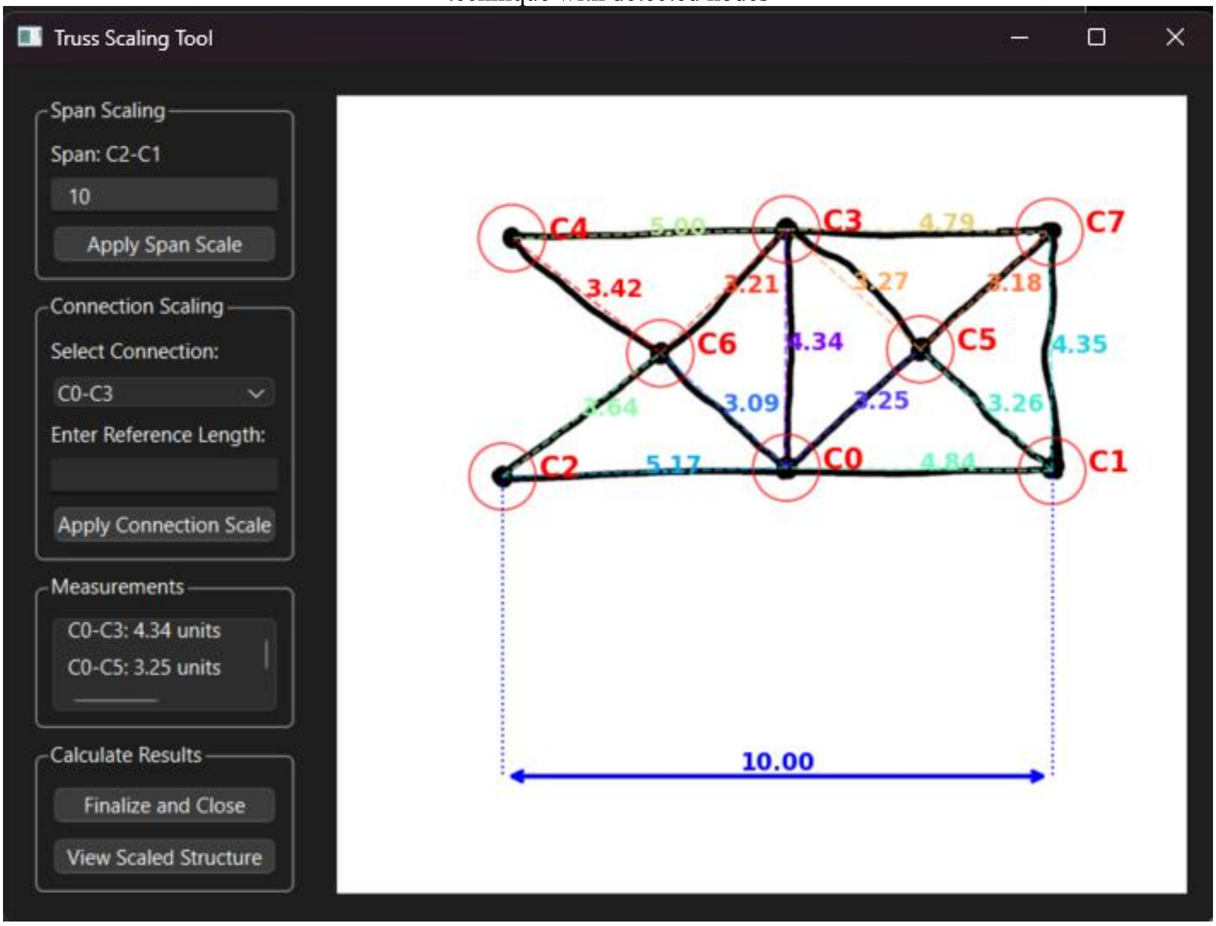

Fig. 4. Truss Scaling Tool GUI. The left-hand panel lets the user scale a hand-sketched truss in two ways: by specifying a span length (here C2 – C1 = 10 units, shown with blue dashed guides) or by entering a reference length for any single member. Detected nodes are marked with red circles, and the automatically calculated member lengths appear alongside each bar. After the desired scale is applied, the Finalize and Close or View Scaled Structure buttons generate a dimension-consistent digital model.

3. Experimental design

As discussed in the methodology section, the most important step for this methodology is detecting the connection points (nodes) for the structure. As such, the effectiveness of four methods—namely, Harris corner detection, Skeletonization method, Heat map technique, and DL technique—was tested on 10 different hand-sketched truss examples presented in Table 1. For comparison, each example was implemented in the previously mentioned workflow, and the results, such as any missing nodes, connections, or false-positive nodes, were counted as errors along with each specific algorithm's runtime. To provide extensive and robust experimental results, different drawing styles were implemented with varying line thicknesses. For instance, example 4 from Group 1 was created to challenge the algorithms with drawings that are misconnected, not connected at all, or overly connected. Example 3 represents small, imperfect drawings with varying line thicknesses within the same sketch. Example 9 was created to test curved drawings, while Example 6 tests both curved and unattached node connections. Example 7 evaluates the detection of more rounded L-shaped connections, and example 10 tests sketches with many node connections at varying distances, specifically challenging for the clustering algorithm. Initially, a fifth feature extraction method using Large Language Models (LLMs) was considered; however, during the experimental design, models such as ChatGPT 4o, o3 mini, o3 mini high, Claude 3.5, and Gemini 2.0 failed to produce meaningful results. Thus, the comparison of future and advanced LLMs remains as a topic for future study.

Table 1. Test examples

No	Group 1	Group 2
1		2		3		4		5		6		7		8		9		10		
4. Results

As summarized in Table 2 and

Fig. 5, each feature extraction method provided different trade-offs in both execution time and accuracy. Notably, all methods performed worse with Group 1 examples, except the Skeleton method, with average error rates approximately 79% higher than Group 2 examples when the Heat map detection technique was excluded. Moreover, Table 3 provides visual comparisons of the four methods across 4 different structural examples selected during the tests. The overall execution time from sketching to optimized FEM model took approximately 500 seconds which is promising for future studies to enhance design workflow and add optimization step to this process. These findings demonstrate that a hybrid approach combining multiple detection methods or training more comprehensive DL model, since it maintained the most consistent performance for most of the cases despite the short training and data creation time spent on the technique, for fixing all weaknesses with current model could further enhance both reliability and speed, thereby improving the overall automation process for converting sketches into structurally valid models.

5. Conclusions and discussion

The present study focuses on the development of a hybrid workflow that converts hand-drawn truss designs into digital models on a BIM platform while assessing the ability of different methods, namely Harris corner detection, Skeletonization, Heat map analysis, and Deep learning-based YOLO detection, to extract features. During the process, features such as AI-based dimension specification using image inputs and an advanced GUI have been added to the workflow. These achievements are the starting point for a larger Augmented Reality (AR)-based project where users define structures in a real-world environment, similar to scenes in science fiction movies, by using Virtual Reality (VR) glasses, voice commands, and sketches, which results in a streamlined design and optimization workflow. The findings of this study demonstrated that the Sketch-to-BIM (StB) framework significantly enhanced and sped up the design process. From an accuracy standpoint, Heat map detection had low error rates for Group 2's well-defined nodes, yet provided by far the highest error rates for Group 1 examples. Deep learning detection, despite its higher computational demand, maintained its detection accuracy across both groups, providing the best performance for Group 2 examples. These findings provide valuable insights for the authors regarding the future direction to enhance the methodology by incorporating AI-based optimization, speech-to-structure techniques, more robust feature extraction, and enhanced capabilities with sketches, such as load and support definitions. The workflow can also be further improved by merging several feature extraction methods to complement their strengths and bypass their weaknesses or by training more advanced machine learning models to improve feature detection precision. Adding a systematic error detection mechanism would make the detection of nodes more robust, and expanding the dataset to include a greater variety of hand-drawn samples would make the proposed approach more broadly applicable. Overall, the present study performs a comparative analysis among four different methods by converting hand-drawn sketches into digital models. The results outline the strengths and limitations of each approach and exhibit their potential for reducing the design time, increasing accuracy, and bridging the gap between digital modeling and hand sketching, which lays out the foundation for prospective future studies on the StB workflow.

Türkiye's climate change mitigation efforts: Evaluating the role of GBCs in the construction sector

Zulfiqar Ali*[1], Gözde Tantekin-Çelik[1]

[1] *Cukurova University, Engineering Faculty, Department of Civil Engineering, 01250 Adana, Türkiye*

Abstract. Climate change is a pressing global issue demanding immediate action to minimize its harmful effects. Türkiye, identified as the 14th largest CO_2 emitter worldwide (EDGAR, 2024), urgently requires sustainable urban development strategies. This study explores how Türkiye's construction sector can reduce carbon emissions by adopting green building certifications (GBCs). A review of global climate policies reveals that Türkiye's current efforts fall short of addressing this challenge stating, "critically insufficient". To bridge this gap, the study proposes prioritizing Green Building Ratings as a key tool to combat climate change. Successful implementation of this approach could position Türkiye as a meaningful contributor to global climate action. By evaluating Türkiye's existing, green-certified buildings, the research demonstrates that adopting advanced construction practices would not only reduce emissions but also accelerate progress toward Sustainable Development Goal 11 (SDG-11), which focuses on sustainable cities. The study enhances awareness among policymakers, construction experts, and stakeholders, emphasizing that eco-friendly buildings serve as long-term and effective solutions in combating climate change. Ultimately, integrating GBCs into national strategies can drastically lower the sector's carbon footprint, aligning Türkiye's climate objectives with international sustainability targets.

Keywords: Türkiye; Climate crisis; Construction sector; Green building certification systems

1. Introduction

Emissions from the building sector, including both direct and indirect sources, account for approximately one-third of global greenhouse gas emissions (IEA, 2024). To mitigate the environmental impact of emissions from the building and construction sector, sustainable frameworks such as Green Building Rating Systems (GBRS) have emerged. These include Leadership in Energy and Environmental Design (LEED), EDGE, Building Research Establishment Environmental Assessment Methodology (BREEAM), DGNB, HQE, Green Star, and several others. These rating systems aim to achieve net-zero emissions by promoting sustainability within the construction industry. Building certification systems predominantly adopt conventional production approaches and regulatory frameworks tailored to specific geographic regions within the construction sector to enhance resource efficiency in new developments, achieve net-zero emissions during operations, and ensure indoor air quality surpasses regulatory (Kokatnur et al., 2025; Leite Ribeiro et al., 2025).

To align with the global sustainability goals for 2030 and 2050, the construction industry plays a crucial role as it is one of the largest consumers of natural resources and energy. Addressing the climate crisis and energy challenges, Green Building Rating Systems (GBRS) serve as an effective solution to improve energy efficiency in the building sector while reducing carbon emissions and enhancing indoor environmental comfort (Ribeiro et al., 2025). The building sector must prioritize energy efficiency and shift from conventional to renewable energy sources. Liu (2022) analyzed energy consumption statistics alongside economic growth and population trends to advocate for increased renewable energy use. The study found that a 1% rise in renewable energy consumption could lead to a 0.144% reduction in carbon emissions. However, a 1% increase in population and economic growth would result in carbon emissions rising by 1.51% and 0.961%, respectively (Liu et al., 2022).

Each country has established its own Green Building Council under the World Green Building Council (WGBC) to promote sustainable development and advance sustainability in the construction industry (WGBC, 2024a). Türkiye, situated at the crossroads of Asia and Europe, is implementing climate change policies to reduce emissions by 41% by 2030. The country is advancing its energy transition by shifting to renewable energy sources (Gül et al., 2025).

The analysis of retrospective studies highlights the existing research gap concerning the role of GBRS at both regional and national level (Anyanya et al., 2025; Eminel & Salgın, 2025). This study focuses on evaluating the

* Corresponding author, E-mail: 2021913104@ogr.cu.edu.tr

https://doi.org/10.31462/icearc2025_ce_mng_768

influence of Green Building Rating Systems (GBRS) around the world, particularly in developing regions. The primary emphasis is on Türkiye, aiming to explore how GBRS can help address the challenges of climate change. The central research question explores how carbon emissions in the construction sector can be mitigated through the adoption of GBRS.

2. Materials and methods

This study examines Türkiye's greenhouse gas emissions in comparison with those of other countries, emphasizing emissions from the construction sector and highlighting the role of buildings in climate change. It also addresses the application of green building certifications in Türkiye. Furthermore, the study analyzes the implications of measures starting at the building scale and extending to the national scale through an exemplary scenario. Details of the databases used and the analyses conducted are presented below.

1. Global Emissions Dynamics. In this study, to examine global emission dynamics, data from the Emissions Database for Global Atmospheric Research (EDGAR), a widely utilized source in scientific research (EDGAR, 2024) has been used to enable cross-country comparisons of emission trends, identify decoupling patterns between emissions and GDP/population growth, and determine high-impact sectors.

Within the scope of this study, CO_2 emissions of year 2023 have been analyzed at both the national and sectoral levels, with a particular focus on the building sector. Emissions per capita, Gross Domestic Product (GDP) by country, and population-based emissions have been examined accordingly. The results of Global Emission Dynamics are depicted in sections 3.1 and 3.2.

2. Climate Policy Compliance Assessment. Using progress reports from the UNFCCC and Nationally Determined Contributions (NDCs), quantitative metrics track national adherence to net-zero commitments (UNFCCC, 2024). Indicators include emission reduction rates, policy implementation timelines, and sectoral decarbonization targets, benchmarked against global climate goals by employing the Global Climate Action Portal (Global Climate Action) and Climate Action Tracker Portal (Climate Action Tracker, 2025). Climate Policy Compliance Assessment results are mentioned in section 3.3.
3. Energy Performance of Green Buildings in Türkiye. An inventory of 802 certified sustainable buildings in Türkiye spanning LEED, BREEAM, DGNB, EDGE, YES-TR and BEST certifications is analyzed to evaluate energy efficiency outcomes (B.E.S.T | ÇEDBİK; BREEAM Projects; EDGE Buildings; LEED; YES-TR). Metrics include energy consumption intensity (kWh/m²), renewable energy integration rates, and certification-specific benchmarks. Moreover, the results are described in sections 3.4 and 3.5.
4. Türkiye's Progress toward SDGs. To evaluate the progress of countries in achieving the Sustainable Development Goals (SDGs), an OECD tool is applied specifically to Türkiye's regions and cities. This tool measures how far they are from achieving the 17 SDGs outlined in the United Nations' 2030 Agenda (OECD, 2025). Results are mentioned in section 3.6.
5. Scenarios for reduction in GHGs.Opting the literature supported options how to reduce the GHGs emissions from building and construction sector mainly in the perspective of Türkiye to support the adoptability of GBRS, a data of Edge rating system is used along with the data of energy consumption in a residential household of 100m^2 for 4 persons in Türkiye and the findings are mentioned in section 3.7.

The reason for focusing on EDGE rating system is access to data. Because EDGE provides data on energy saving, emissions savings and water consumption of every building. While other rating systems don't give access to data except giving details like category of buildings.

The methodology computes the macro-scale emission of countries specifically Türkiye with micro-scale built-environment emissions, while embedding Türkiye NDCs to reveal actionable insights. By triangulating EDGAR's global data, Türkiye's building-specific metrics, and UNFCCC compliance reports, the study promotes a comprehensive approach to adopting green building certifications as a strategic measure for addressing climate change.

3. Results and discussion

This section presents a detailed analysis of global GHGs emissions and from building sector, renewable energy integration and Türkiye's mapping with SDGs. Moreover, discusses the research findings while systematically evaluating the outcomes to align with the study's aims and objectives.

3.1. Global comparison of CO_2 emissions & climate action ratings

The analysis of global CO_2-equivalent emissions has identified the top 27 highest-emitting countries based on 2023 greenhouse gas (GHG) emission statistics, as illustrated in Fig. 1 and Table 1 (EDGAR, 2024). Notably, Table 1 serves as a key reference, providing an in-depth breakdown of emissions from the building sector, per capita emissions, and GDP-based emissions. Additionally, it presents demographic insights, including total population figures and urbanization trends, both current and projected.

Additionally, the research is focused on the Eurasian country of Türkiye. Türkiye became a member of the Kyoto Protocol in 2009 and approved the Paris Agreement in 2015 to act against global climate change. According to the 2023 greenhouse gas (GHG) emission statistics, Türkiye is ranked 14th globally for total emissions. When looking at emissions per capita, Türkiye is ranked 7th in the world, which is most alarming and concerning climatic situation. However, when emissions are measured based on the country's total land area, Türkiye records 773.60 tons of CO_2 equivalent per square kilometer (tCO_2e/km^2). With this value, Türkiye is not among the top 50 countries in terms of emissions per land area (EDGAR, 2024).

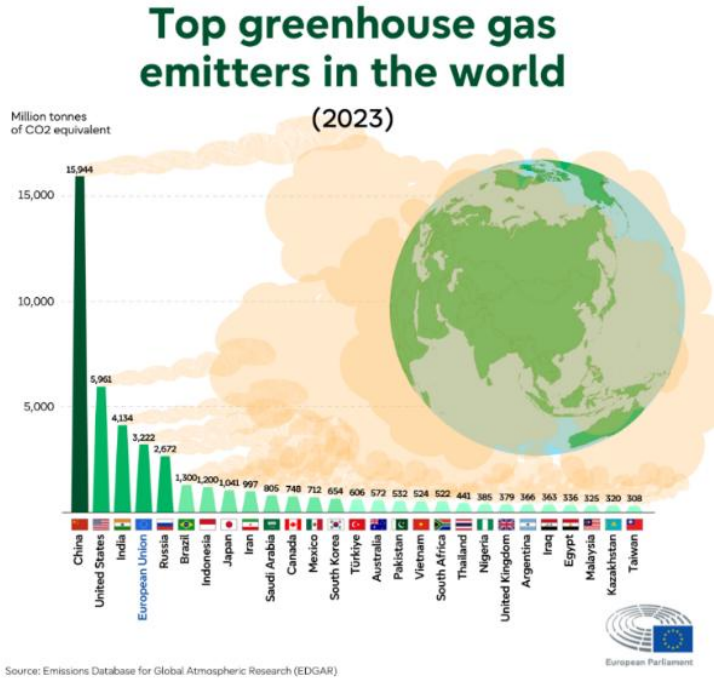

Fig. 1. Global top GHGs emitter 26 & EU27 countries

3.2. Emissions from the building sector

Analyzing sectoral CO_2-equivalent emissions, the Building Sector emerges as a key contributor, with China leading the emissions chart, followed by the USA, Russia, and India. Türkiye ranks 9th in this sector, as illustrated in Fig. 2 (EDGAR, 2024). In terms of global population statistics for 2023, Türkiye holds the 14th position, maintaining the same emission levels. However, when considering urban population dynamics, the country's ranking shifted from 14th to 13th due to a 5% increase between 2023 and 2024. This ranking is expected to remain unchanged in the near future (EDGAR, 2024; Urbanization, 2024). Projections by the World Bank indicate that Türkiye's urban population will rise to 80.25% by 2030 and further to 86% by 2050 as shown in Fig. 3.

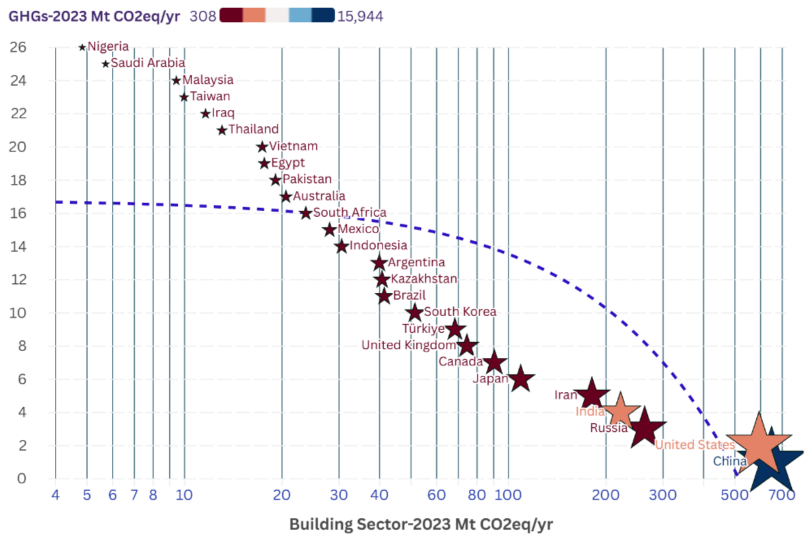

Fig. 2. Global emissions from the building sector

Fig. 3. Urban population statistics

3.2.1. Role of building sector in greenhouse gas emissions
The buildings and construction sector stands one of the biggest contributors to global greenhouse gas emissions, accounting for an astonishing 34% of total emissions. The environmental impact is further exacerbated by the production and utilization of energy-intensive materials such as cement, steel, and aluminium, each leaving a substantial carbon footprint (UNEP & GABC, 2024). Furthermore, an in-depth assessment of embodied carbon emissions in the construction sector, based on the International Energy Agency (IEA) report (IEA, 2023) reveals the embodied emissions from construction subsectors like residential, non-residential and industry as illustrated in Table 2.

Table 2. Embodied carbon emissions from the construction sector

Sectorial Emissions	Embodied Emissions (%)
Residential (direct)	5
Residential (indirect)	10
Non-residential (direct)	2
Non-residential (indirect)	8
Buildings construction industry	6
Building Construction other materials	2
Other construction industry	5
Other	63
Total	100

However, Operational Carbon emissions which stem from heating, cooling, and lighting, constitute a significant portion of a building's total environmental impact. Projections indicate that these emissions currently account for 75% of total building-related emissions, with expectations to decline to 50% in the coming decades through enhanced energy efficiency measures and technological advancements. Moreover, according to Energy Performance of Buildings directive building materials can be classified into three primary categories (non-renewable, transitional and renewable materials) based on their decarbonization potential (European Commission, 2025). By prioritizing the use of renewable and transitional materials, alongside innovative design and sustainable green building construction practices, the built environment can significantly reduce its carbon footprint and contribute to a climate-resilient future. Strategic policies, coupled with advancements in green building technologies, will be essential in accelerating the shift towards sustainable and energy-efficient buildings worldwide.

3.3. Energy use in the building sector & renewable energy trends
At this stage, the total final energy consumption of the country will be evaluated, with a focus on usage trends for renewable energy. The analysis will primarily target the residential and construction sectors. mainly associated with the residential and construction sector.

3.3.1. Total Final Consumption (TFC) in residential sector

In most countries, heating and cooling account for the largest portion of residential energy consumption (UNFCCC, 2024). While air conditioners, appliances, and lighting predominantly rely on electricity, heating and cooking still depend heavily on combustible fuels such as natural gas, oil, coal, and biomass. Transitioning these energy intensive applications to electricity particularly by replacing conventional fossil fuel-based heating systems with advanced energy efficient systems is a critical step toward reducing CO_2 emissions (Sghiri et al., 2025; Tang et al., 2025).

In the case of Türkiye, the building sector remains heavily reliant on natural gas, which constitutes 59% of the country's total final energy consumption (TFC), as illustrated in Fig. 4 (UNFCCC, 2024). This significant dependence underscores the urgent need for strategic electrification and energy-efficient solutions to enhance sustainability and mitigate environmental impact.

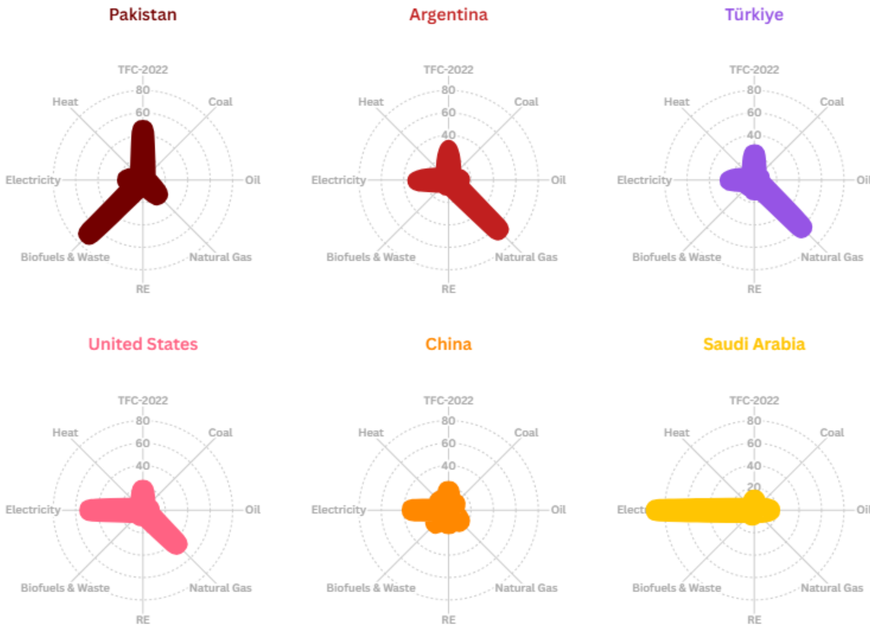

Fig. 4. Total final consumption in building sector

3.3.2. Role of modern renewables

As nations strive to lower CO_2 emissions and reduce reliance on imported fossil fuels, renewable energy is emerging as a crucial component of the global energy transition. While renewables are predominantly utilized for electricity generation, their applications extend to residential and commercial heating. Additionally, biofuels are increasingly being explored as a viable solution to decarbonize sectors of transportation that are otherwise difficult to electrify. It is important to distinguish modern renewable energy sources from traditional biomass usage, such as burning wood, agricultural residues, or dung for cooking and heating practices that have significant health and environmental consequences. Unlike these conventional methods, modern renewables contribute to a cleaner and more sustainable energy mix.

According to Sustainable Development Goal-7.2, the share of modern renewables in final energy consumption has been analysed over the period from 2000 to 2021. Fig. 5 highlights trends in renewable energy consumption across the world’s 27 highest-emitting countries. Notably, Argentina, Pakistan, Egypt, Kazakhstan, and Türkiye have experienced declines of approximately -1%, -6%, -13%, -20%, and -30%, respectively. Furthermore, the adoption of modern renewable energy in the residential sector is examined (IRENA, 2025). As illustrated in Fig. 6, Türkiye ranks 10th among the highest-emitting countries, with the share of renewable energy usage in the residential sector's total energy consumption being approximately 12%. It is evident that Türkiye needs to increase its investments in renewable energy.

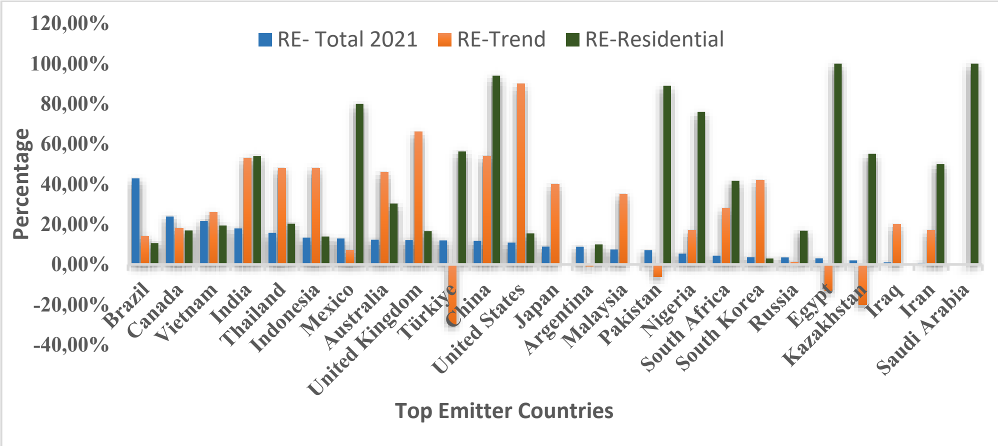

Fig. 5. Share of renewable energy in TFC 2021 statistics and country-wise trend

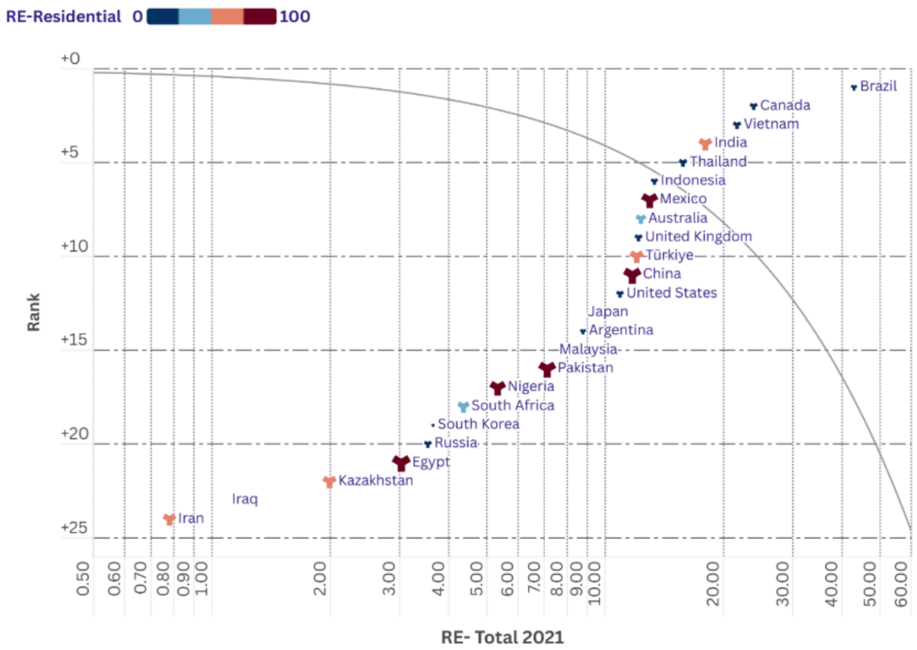

Fig. 6. Percentage of renewable energy in residential sector

3.4. Role of green building certifications in reducing emissions

Under the framework of the World Green Building Council (WGBC), each country operates its own Green Building Council, striving to advance sustainability in the built environment. Complementing these efforts, various rating systems are employed globally to assess buildings based on their climate resilience and sustainability performance, as illustrated in Fig. 7. A critical aspect of sustainable building practices involves evaluating the role of Green Building Regulations (GBRs) concerning energy efficiency, consumption patterns, and renovation strategies, particularly in mitigating greenhouse gas (GHG) emissions from the construction industry. According to the Energy Performance of Buildings Directive (EPBD), approximately 75% of buildings in the European Union are classified as energy inefficient. Furthermore, as per 2022 statistics, the annual building renovation rate remains alarmingly low at just 1% (European Commission, 2025).

However, GBRS drive carbon reduction by significantly improving energy efficiency. These systems establish rigorous criteria that prioritize enhancing energy efficiency, encouraging low-carbon materials, water and waste reduction, enhancing indoor environmental quality (IEQ) and passive design and lifecycle carbon accounting and net-zero pathways (European Commission, 2025; Xian et al., 2025). By adopting these measures, buildings can reduce their operational carbon footprint by up to 50%, significantly cutting emissions over time (WGBC, 2024b).

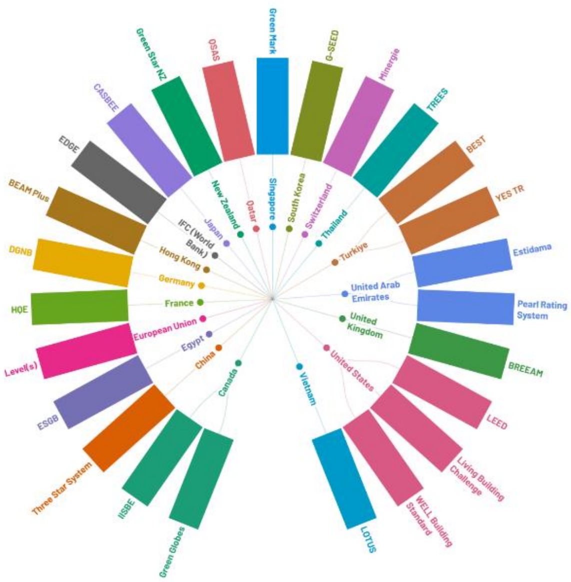

Fig. 7: Green building certification systems

Türkiye, like many other countries, has developed its own building certification systems YES-TR and BEST (B.E.S.T; YES-TR) as illustrated in Fig. 7. These systems aim to reduce the environmental impact of the built environment by addressing local needs, conditions, and regulations. While they share similarities with other international certification systems, they are specifically tailored to Türkiye's unique local context (YeS-TR).

3.5. Türkiye's status

Analysing Türkiye's climate action policies, as illustrated in Fig. 8, reveals a multifaceted scenario encompassing progress and challenges. While Türkiye has made strides in certain areas, there is a pressing need to accelerate the adoption of renewable energy sources to meet its 2035 targets. However, Türkiye's Nationally Determined Contribution (NDC) falls behind its existing policies and demonstrates insufficient progress in aligning with the Paris Agreement's 1.5°C temperature target. The Climate Action Tracker (CAT) classifies Türkiye's climate policies, targets, and financial commitments as "Critically Insufficient," indicating that its efforts remain far from the necessary benchmarks to curb emissions effectively (Climate Action Tracker, 2025).

At COP29, Türkiye introduced its Long-Term Strategy (LTS) (Ministry of Climate Change, 2025), reaffirming its previously declared goal of achieving net-zero emissions by 2053. The action plan for the Building and Services sector emphasizes the integration of Green Building Ratings (GBRs) as a key adaptation measure to combat climate change. If Türkiye successfully implements this strategy, it will mark a significant contribution to the global fight against climate change.

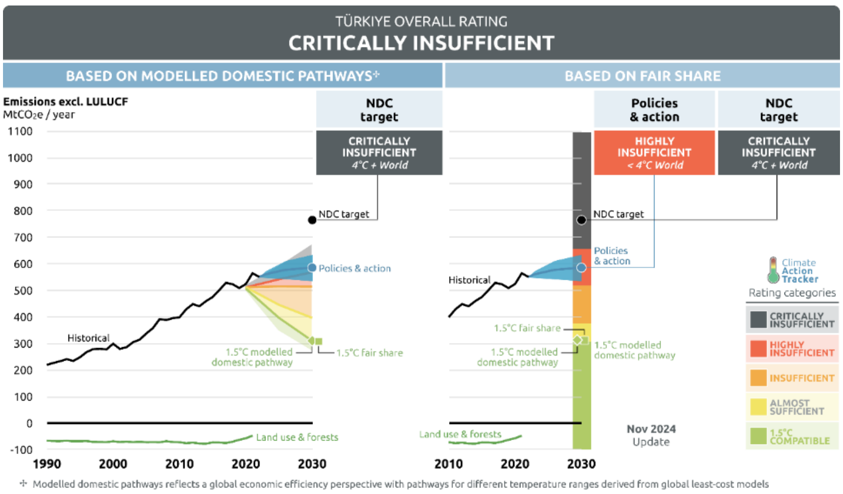

Fig. 8: Climate action tracker – Türkiye statistics

3.5.1. Türkiye's construction sector and green building certifications

About the Türkiye's construction sector, Statista reported the fluctuating trend of construction permits from 2002 to 2024 and residential building developments from 2015 to 2023 respectively. The industry peaked in 2017 with 139.555 new residential buildings, while in 2023, 120.113 new buildings were constructed (Statista-Türkiye, 2025). According to Turkish Statistical Institute, from 2002 to 2024, Türkiye issued 7.528 million construction permits, distributed as Buildings: 2.5 million (33.33%), Residential Buildings: 2.14 million (28.51%), and Two-and-Dwelling Buildings: 1.49 million (19.85%). Despite these numbers, the proportion of green-certified buildings is still quite small (TURKSTAT, 2025b). In the Turkish construction and building sector, several international and national green building rating systems are in use. These include LEED, BREEAM, DGNB, EDGE, WELL, BEST, and YES-Tr. However, due to limited availability of data from some of these systems, this section only includes information about buildings certified under LEED, BREEAM, EDGE, BEST and YES-TR. There are 802 certified buildings in total (B.E.S.T; BREEAM; EDGE Buildings; LEED; YES-TR) as illustrated in Table 3, with the majority (35.54%) being newly constructed buildings and certified residential buildings constitute merely 8.23%, as shown in Fig. 9.

Table 3: Green building certifications in the Turkish construction sector

Certification	Type	Number of Units	%
LEED	International	600	74.82
BREEM	International	72	8.97
EDGE	International	3	0.37
WELL	International	0	0
DGNB	International	0	0
BEST	National	23	2.87
YES-TR	National	104	12.97
Total		802	100

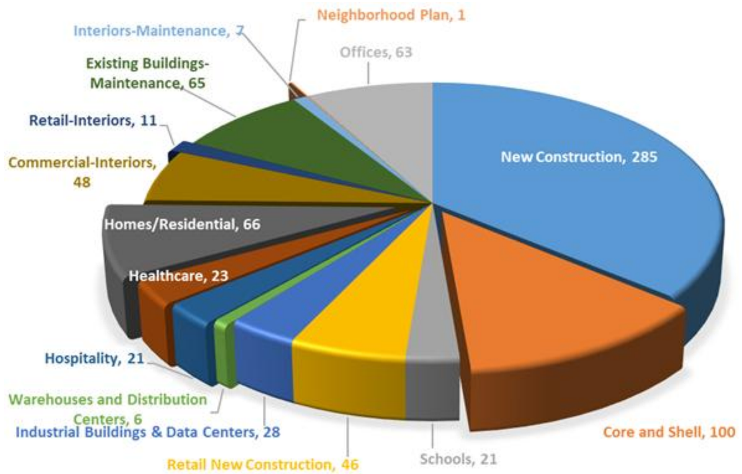

Fig. 9: Classification of Türkiye certified buildings

To assess Türkiye's performance in green building standards, LEED scoring system about Türkiye, scores highest in Energy & Atmosphere, alongside notable ratings in Indoor Environmental Quality (IEQ), Water Efficiency, Material Resources, and Sustainable Sites (LEED). These scores emphasize Türkiye's potential to enhance its sustainability credentials through focused policy and investment in green buildings. Furthermore, an analysis of the EDGE rating system quantifies potential reductions in emissions through green building certifications. Per square meter of construction, EDGE-certified buildings can achieve 0.15% saving in energy consumption, 0.17% saving in water consumption, 0.25% reduction in embodied energy material usage and 0.95% annual reduction in CO_2 emissions (tons) (EDGE Buildings, 2025). Moreover, BREEAM framework offers the sustainability solutions by making built environment resilient towards net zero emissions through life cycle analysis (LCA). In regional perspective of Türkiye, BREEAM can be effective to achieve net zero emissions from the built environment by making it more sustainable and resilient for people. The national certification system mainly YES-TR and B.E.S.T focus on less energy usage including eco-friendly materials and offer healthier indoor spaces. B.E.S.T standards can help compare local building performance with European practices. YES-TR can also focus on building energy efficiency; water use and innovation to improve the health and comfort of people inside buildings.

If Türkiye adopts a Green Building Rating System (GBRS) like YES-TR, B.E.S.T or other internationally recognized certifications in the construction sector, it could significantly lower greenhouse gas emissions. Over the past two decades, Türkiye has issued 7.528 million construction permits, yet only 802 buildings have received green certification as the illustrated in Table 5 and Fig. 10. In 2023 alone, 120,113 residential buildings were built, but just 55 were certified highlighting the urgent need for a strategic shift toward sustainable construction practices.

3.6. Türkiye's progress toward SDGs

Organisation for Economic Co-operation and Development (OECD) is working with more than 100 countries around the globe to help in the shaping of regional public policies and innovation in the societies against the 2030 agenda by comparing the performances of countries.

Eurasian country Türkiye is a member of OECD which is further comprised of multiple regions including Ankara, Central Anatolia-East, Central Anatolia-Middle, Central Anatolia-West & South, E Anatolia-E, E Anatolia-W, Eastern Black Sea, Eastern Marmara-North, Eastern Marmara-South, Istanbul, Izmir, Mediterranean-E, Mediterranean region-Middle, Mediterranean region-West, Middle Black Sea, N.E. Anatolia-E, N.E. Anatolia-W, Northen Aegean, S. Aegean, S.E. Anatolia-E, S.E. Anatolia-W, Southeastern Anatolia-Middle, Southern Marmara-West, Thrace, W. Black Sea-ME and Western Black Sea-West within the boundary. To assess Türkiye's regional progress towards SDGs, an OECD Tool has been utilized to enable subnational governments to evaluate current standing concerning the 2030 Agenda. The OECD tool which comprises more than 100 indicators working in approximately 600 regions and 600 cities to measure the distance from SDGs (OECD, 2025).

As depicted in Fig. 10, Türkiye's national score for SDG-11 (Sustainable Cities and Communities) stands at 66, with regional variations: Middle Black Sea leads with a score of 76, Ankara follows at 70, while Southeast Anatolia East lags at 50, indicating a critical need for urban sustainability interventions. In contrast, for SDG-7 (Affordable and Clean Energy), Türkiye scores 34 out of 100, with Izmir leading at 51, Ankara at 34, and the Western Black Sea registering zero, a concerning indicator for energy sustainability efforts.

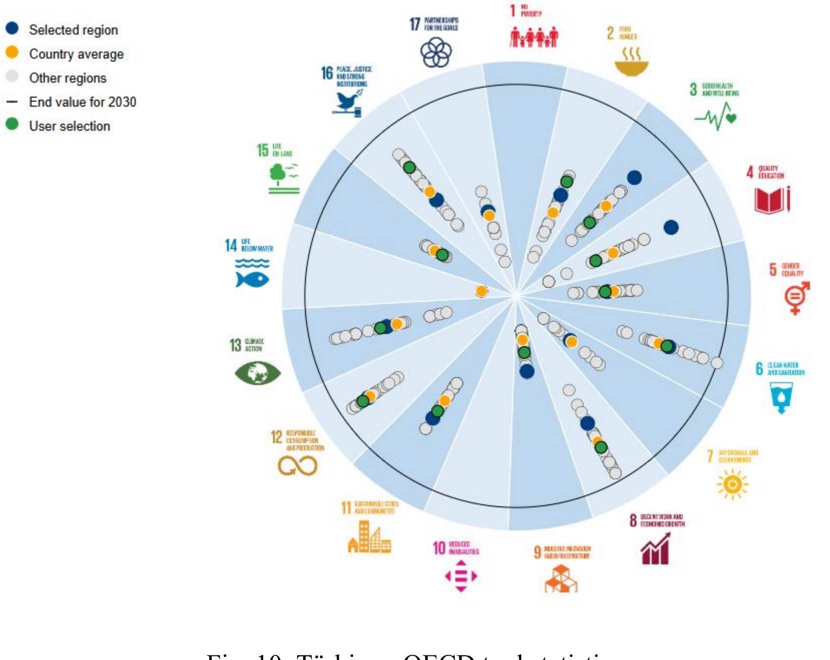

Fig. 10: Türkiye - OECD tool statistics

3.7. Analysis of the scenario for reducing greenhouse gas emissions

Türkiye's energy consumption patterns highlight critical challenges in reducing its carbon footprint. Consumer right association in Türkiye reported that an average four-member household having a net area of 100m^2 in Türkiye consumes 1,500 m^3 of natural gas annually, with monthly averages of 125 m^3, increasing to 250 m^3 in winter. Additionally, the average monthly electricity consumption for a four-member household stands at 230 kWh (Tüketici Hakları Derneği, 2025). However, natural gas accounts for 59% of energy consumption, signalling an urgent need to transition towards renewable energy sources in the residential sector. But alarmingly, the trend of renewable energy use in the building sector is insufficient, undermining efforts to meet the 2030 sustainability goals as depicted in Fig. 6.

To estimate the impact of GBRS in regional context of Türkiye, two approaches are formulated using data enlisted in Table 4 to estimate the emissions reduction. The Approach-I is about to calculate savings per m^2 by using the EDGAR emissions data and the Approach-II is to calculate the saving in emissions by using the Türkiye population and the EDGAR emissions data comprised of methodologies enlisted in Table 5.

Table 4: Emissions reduction by using GBRS

Data	Value	Unit	Reference
Total Population	85,664,944		(TURKSTAT-2025a)
a 4-person household of area	100	m^2	(Tüketici Hakları Derneği-2025)
Annual emission per person	7.01	ton CO_2eq/yr	(EDGAR - 2024)
Emissions Saving	0.95	% per m^2	(EDGE Buildings-2025)
Energy Consumption	0.15	% per m^2	(EDGE Buildings-2025)

Table 5: Key methodologies

Step	Methodology	Purpose
Residential Area	Per Capita Scaling	Total built environment based on Population data
Energy Consumption	Sectoral Energy Demand Modeling	Quantify natural gas and electricity use.
Emissions calculations	Emission Factor Approach according to IPCC guidelines	Convert energy to CO_2 emissions. - 1.9 kg CO_2/m^3 for natural gas, - 0.4 kg CO_2/kWh for electricity
Green Certification Savings	Efficiency Improvement Modelling + Energy Consumption Savings	Model direct and energy-related savings. - Edge Data
Total Savings	Integrated Emissions Reduction Framework - direct and indirect savings	Aggregate impacts for policy/climate strategy.

3.7.1. Approach-I

Baseline for Building: for a 4-person household of area 100-m^2

a. Annual Emission per Person: $Ep = 7.01 - \text{ton } CO_2eq/yr$
b. Annual Emission – Building: $Eb = 4 \text{ x } Ep = 28.04 - \text{ton } CO_2eq/yr$
c. Emission Intensity (per m^2): $I = Eb/100m2 = 0.2804 - \text{ton } CO_2eq/m2/yr$
   Maximizing Savings with EDGE Green Certification System
d. Emissions: 0.95% per m^2
e. Energy Consumption: 0.15% per m^2
f. Saving per m^2 = $0.95\% \text{ x } I = 0.0026638 - \text{ton } CO_2eq/m2/yr$
g. Total saving for 100 m^2 building: $Semission = 100 \text{ x } 0.0026638 = 0.26638 - \text{ton } CO_2eq/m2/yr$
h. Energy (related emission) savings: $Senergy = 0.15\% \text{ x } Eb = 0.04206 - \text{ton } CO_2eq/yr$
i. Total Saving per Building: $Stotal = Semission = 0.26638 - \text{ton } CO_2eq/yr$
j. P_{total} = 85,664,944 (assuming 4 people in 100 m^2 building)
k. $N_{buildings}$: $Nb = \frac{Ptotal}{4} = 21{,}415{,}236.00$ (assuming every building will be green-certified)
l. $S_{national}$: $Sn = Nb \text{ x } Stotal = 5{,}704{,}856.9 \text{ ton} - CO_2eq/yr$
m. $EnergyS_{national}$: $ESn = Nb \text{ x } Senergy = 900{,}766.1 \text{ ton} - CO_2eq/yr$

By opting the green building certification, around 5.704 Mtons-CO_2eq can be saved per annum.

3.7.2. Approach II

a. Population: 85,664,944
b. Average area per person: 25 m^2 (from 100 m^2 for 4 people)
c. Total residential area: $TRarea = 85664944x25 = 2{,}141{,}623{,}600 \text{ m2}$
d. Total households: $Thouses = \frac{85664944}{4} = 21416236$
e. Total Consumption Natural gas $= 21416236x1500 = 32.12 \text{ billion m3/yr}$
   Electricity $= 21416236x2760 = 59.11 \text{ billion kWh/yr}$
f. Emission factors:
   Natural Gas = 1.9 kg CO_2/m^3
   Electricity = 0.4 kg CO_2/kWh
g. Total Emissions: Natural gas $= 1.9\, kg \frac{CO2}{m3} x32.12 billion \frac{m3}{yr} = 61.028\, MtonsCO2/yr$

$$\text{Electricity} = 0.4\, kg \frac{CO2}{kWh} x59.11\ billion \frac{kWh}{y} = 23.64\, MtonsCO2/yr$$

h. Total residential emissions: Electricity + Natural Gas = $84.668\ \text{MtonsCO2/yr}$

i. Opting Green building certification

Emission-Savings: 0.95% /m^2. $Savings = 0.95\%\ x\ 84.668 \frac{MtonsCO2}{yr} = 804{,}346 \frac{tonsCO2}{yr}$

Energy Consumption Savings:

$$\text{Natural Gas} = 32.12\ \text{billion m3}\ x\ 0.15\% = 48.18\ \text{million m3}$$
$$\text{Electricity} = 59.11\ \text{billion kWh}\ x\ 0.15\% = 88.665\ \text{million kWh}$$

Emissions Savings:

$$\text{Natural Gas} = 48.18\ \text{million m3 x 1.9kg/m3} = 91{,}542\ \text{tons CO2/yr}$$
$$\text{Electricity} = 88.665\ \text{million kWh x 0.4kg/kWh} = 35{,}466\ \text{tons CO2/yr}$$

Total Energy (related) savings = 127,008 tons CO_2/yr

By utilizing the green building certification in Türkiye might save the 804,346 tons of CO_2 annually or might save the 127,008 tons of CO_2 per annum from energy consumption in residential sector to support national climate goals.

4. Conclusions

Türkiye's climate action trajectory presents a blend of achievements and critical gaps, requiring a concerted effort to accelerate progress toward sustainability. While policy frameworks, international collaborations, and strategic initiatives offer a foundation, the nation must enhance its renewable energy adoption, green building certifications, and emissions reduction strategies to align with global climate objectives.

One important step toward sustainable development in Türkiye is using local and international green building certification systems. As of 2025, the limited number of buildings with green building certification have been identified, and it has been observed that the proportion is very low. The long-term importance of green buildings in the fight against climate change and to progress to achieve the 2030 UN SDGs which should be understood by all stakeholders and property owners, and it is recommended that practices be encouraged through government support which can help developers to design buildings with less energy consumption, eco-friendly materials, and healthier indoor spaces.

The strategic adoption of these global sustainability frameworks holds significant potential for Türkiye. By fostering sustainable urbanization, the country can establish a robust foundation for reducing its environmental footprint to achieve the 2030 climate targets. Aligning Türkiye's national policies and regulations with these internationally recognized certification systems will enable continuous innovation and improvement in the construction sector, reinforcing its commitment to climate action.

In the future, Türkiye's success in sustainable urban development will depend on how well it can improve its policies, increase financial support, and strengthen its laws and regulations by embedding sustainability into its core development strategies, Türkiye can drive long-term economic, environmental, and social benefits, contributing meaningfully to the global climate agenda and setting a precedent for responsible urban growth.

Acknowledgments

This study has been conducted as part of the first author's PhD thesis research. With deep gratitude, the author acknowledges YTB (Yurtdışı Türkler ve Akraba Topluluklar Başkanlığı - Presidency for Turks Abroad and Related Communities) for generously providing a scholarship, which has enabled the continuation of doctoral studies at Çukurova University in Adana, Türkiye.

Proposal of a framework for data acquisition for Digital Twin of building façade

Merve Kaya*[1], Önder H. Bettemir[1]

[1] İnönü University, Department of Civil Engineering, 44280 Malatya, Türkiye

Abstract. The construction sector is one of the cornerstones of developing economies and it has great importance for economic development. However, traditional construction methods pose serious limitations in terms of efficiency and quality. Therefore, the sector needs to be aligned with technological advances in order to increase efficiencies of construction and management processes. These developments provide benefits to the sector in terms of minimizing personnel mistakes, while increasing construction speed and ensures occupational safety. Technological developments also assisted process monitoring and detection of unanticipated mistakes. Earthquakes are important events that affect the structural integrity as well as proper functioning of roof and building façade which interferes with the energy consumption dynamics of buildings. Even if the building is in service after the earthquake, failures of infrastructure system such as heating, electricity, water and communication networks may occur. In addition windows, doors and roofs, especially those in contact with the building façade, are likely to be affected by the earthquake, worsening thermal insulation and increasing heat losses. Therefore, it is necessary to inspect such buildings at frequent intervals. In this study, a framework system including an autonomous ground vehicle algorithms and software that performs non-destructive testing and collects data on the building exterior is proposed to reduce building inspection costs and guarantee the integrity and accuracy of the collected data. The vehicle will be capable of navigating autonomously around the building with a maze algorithm based algorithm and maps the building exterior. The vehicle will be equipped with an optical camera, thermal camera, ultrasonic distance sensors, servo motors for vertical and horizontal scanning from different angles, 2D laser scanner, 9 dof IMU and GPS receiver and Radio Frequency transmitter for real-time data sharing. At night, exterior of the building will be monitored with thermal camera at regular intervals so that early detection of possible heat losses and installation failures will be possible. The developed system will detect the condition of the building infrastructures in a short time with minimum human labor and will accelerate the necessary measures to ensure the effective operation of the heating systems, thus energy will be used effectively.

1. Introduction

Digital transformation is the realization of fundamental changes by integrating digital technologies into business models, processes, organizational structures and systems. Digitalization involves changing socio-technical structures using digital technology and affects the social and technical aspects of structures (Yoo et al., 2010; Fichman et al., 2014). Digital transformation, digitalization and digital innovation are interconnected and enable organizations or industries to make major changes in the way they do business (Fichman et al., 2014). Organizations make the decision to engage in digital transformation by combining their internal needs with external factors such as the proliferation of digital technologies and increased competition. Changing ways of doing business and the evolution of customer expectations make it imperative for organizations to move towards digitalization. This change provides significant advantages, such as maintaining competitive advantage in the sector, increasing efficiency, reducing costs, mitigating risks and engaging with the market. Many different sectors such as industry, health, education and construction have embarked on digital transformation. The construction industry faces chronic problems such as long project durations, high costs, inefficiency, lack of information and communication gaps. The integration of digital technologies is crucial to overcome these problems and create a sustainable, efficient and collaborative building production process for stakeholders. At this point, digital twin technology stands out as one of the building blocks of digital transformation in the construction industry.

The construction industry is one of the most information-intensive sectors where information must be readily available, accurate, complete and in an understandable format. A huge amount of data is generated from a

https://doi.org/10.31462/icearc2025_ce_mng_773

construction project throughout its lifecycle, and the success of the project depends on the insights gained through effective management and analysis of this data. Research emphasizes that knowledge management is an integral part of construction projects and the importance of the processes by which knowledge is generated, communicated and interpreted. However, the literature has mostly focused on the design and construction phases, which account for only 30-40% of the total project cost. The major cost, which is 60-80% of the total cost, is incurred during the operation and utilization phase (El jazzar et al., 2020). The design and management tools used in construction projects have evolved over time from paper drawings to CAD, Building Information Modeling (BIM) and Geographic Information Systems (GIS) (Hasan et al. 2022). In recent years, important steps have been taken in information management thanks to BIM. BIM has transformed the construction industry from 2D-based systems to 3D-object-based systems, making the information needed throughout the project lifecycle more accessible. However, the BIM cannot fully capture the data generated during the operation and utilization phase. To address this shortcoming, Digital Twin technology, one of the key elements of Industry 4.0, comes to the fore.

In the context of the digital twin, the earliest mention of the 'twin' concept is in aerospace. Its general philosophy dates back to NASA's Apollo project in the 1960s (Shafto et al. 2010; Negri et al. 2017; Boschert et al. 2018). However, at that time, the 'twin' was a physical system (Zhuang et al., 2018). The digital side was not included in the title of 'twin' in this period. The term digital twin was first coined by Grieves in 2003 during a lecture on product lifecycle management (PLM) (Grieves, 2014). The first Digital Twin application was implemented by NASA in the Apollo program in 2010 to reflect the state of the spacecraft. The definition of the Digital Twin has evolved over time, focusing on three main components: physical environment, virtual environment, and the data that connects these two environment. Based on the work of Kritzinger et al. (2018), the level of integration of these components is classified as Digital Model (manual data flow), Digital Shadow (automatic one-way data flow), and fully integrated Digital Twin (two-way data flow). Existing BIM applications in the construction industry generally fall into the Digital Shadow subcategory and changes to the digital models do not affect the physical environment. A fully integrated Digital Twin should be able to enable bidirectional data exchange between both physical and virtual environments.

2. Materials and methods

Maze solving algorithms aim to solve a maze autonomously without external intervention. Various algorithms have been developed in this regard, depending on the type of maze. Left/right hand rule, depth-first search, width-first search, Dijkstra's algorithm and A* search algorithm are some of them. The left-hand or right-hand rule, also known as the wall-following algorithm, is widely used in maze solving. In this algorithm, the robot starts by placing its hand on a wall and then proceeds by always following the wall in that direction. It is suitable for simply-connected mazes, where all walls are connected to each other or to an external boundary. If there are loops in the maze, the robot may return to the same place or may not reach the exit. In the left hand rule, the robot moves forward by placing its hand on the left wall and prioritizes turning left at the junctions. In a maze using this method, the robot can encounter eight basic situations: left turn only, right turn only, right or left turn, straight ahead and left or right turn, straight ahead or left turn, straight ahead or left turn, straight ahead or right turn, straight ahead or right turn, reaching the end of the maze and dead end.

Suthar and Shukla (2023) designed, implemented and analyzed the performance of a robot that autonomously solves loop-free mazes using infrared (IR) sensors and the Left-Hand-Wall Algorithm. The developed robot is equipped with an Arduino Uno microcontroller, L298N motor driver, two DC motors, three IR sensors and a 7.4V Li-ion rechargeable battery. The IR sensors enabled the robot to be steered by detecting the contrast between the black maze lines and the white background. The motor driver and Arduino Uno processed the data from the sensors to determine the robot's movements and direction changes. As a result of the experiments, it was observed that the robot completed the maze with 70% success.

Suryanarayana and Akhila (2021), developed a Maze Solving Robot that uses the wall following algorithm (left hand rule) by measuring distance with ultrasonic sensors. In the study, 6 path detection sensors were used. Two sensors act as path sensors and detect the robot's deviations, helping to keep it on track. Two sensors allow the robot to turn left or right. One sensor is used for forward direction detection, while one sensor is used to determine when the end of the maze has been reached. As the robot moves forward, it exhibits the following behaviors: Finds the next intersection by following the line, detects the type of intersection and changes direction at the intersection. These processes continue cyclically until the end of the maze. Using the data from its sensor, the Arduino determines the direction of movement according to a specific algorithm. First it checks the left path, if there is no left path, it evaluates the forward direction. If there is no forward path, it checks the right path. If there is no right path, it makes a 'U' turn and continues to try possibilities until it is determined that all sensors are on the black surface. When all IR (Infrared) sensors of the robot are on the black surface, it stops the movement. IR sensors work by detecting the color of the surface. When the sensor is on a dark surface, the surface absorbs the rays and the IR receiver does not receive any rays. This sends an active high signal to the Arduino. On light-colored surfaces, most of the reflected rays are detected by the IR receiver because these surfaces reflect the beam. This is how IR sensors detect the black path.

Khaleel and Oleiwi (2024), developed a decision-making algorithm for autonomous mobile robots to move through a maze without hitting walls. Ultrasonic sensors are used to avoid obstacles and the robot moves flexibly according to the measured distances. The algorithm starts with determining the starting point, activating the ultrasonic sensor, servo motor and DC motors. When the robot starts, the ultrasonic sensor measures the distance and this sensor scans its surroundings by rotating between 0 and 180 degrees through the micro servo motor. To make the measurements more stable, the robot waits three seconds before moving. If the distance is 20 cm or less, the robot stops the right DC motor and turns to the left. If the distance is more than 20 cm, the left DC motor is stopped and the robot turns to the right. The distance of 20 cm was chosen because it is compatible with the robot's height. To complete the 300 cm long maze, the robot stopped 10 times and checked its surroundings with an ultrasonic sensor moving between 0-180 degrees. If it encounters an obstacle, it continues on its way in an unobstructed direction. If there is no obstacle, the robot stops and reaches the target point. The central control of the system is provided by the Arduino Uno microcontroller. The movement of the robot is provided by two DC motors controlled by an L298N motor driver. The robot reached the target point in 60 seconds by moving at a speed of 5 cm/sec. It is stated that the developed algorithm is highly suitable for autonomous mobile robots to avoid collisions with wooden walls and offers the fastest solution compared to similar studies.

Pandian et al. (2012) developed a maze solving robot (MSR). The robot consists of three subsystems: the drive system, the sensor system consisting of various sensors and the control system. The developed robot aims to find the shortest route in the maze using an algorithm called LSRB. In the LSRB algorithm, the robot reaches the target from the starting point in two stages. Four basic motion decisions are defined here: L (left), S (straight), R (right) and B (return). In the search phase, at each intersection, the robot evaluates these movements in a certain priority order and records them in the decision book. In the journey phase, this sequence of decisions is optimized to obtain a shorter and more efficient path. For example, while solving the maze, the decision sequence is “LBLLBSR”, this sequence is optimized and reduced to “SRR”. Thus, the robot efficiently determines the shortest path to reach the goal.
