(3) *Comparison through cross background context application*. For deeper analysis, selected GBRT was applied to the building assessment. JIS building becomes a comparative tool in this research, where the assessment of JIS with selected GBRS will be compared. The comparation will be limited on the presence or absence of certain point and analysing the relationship between GBRS with the design result. With this, the analysis of similarities, differences, strengths, and weaknesses of GBRS is expected to be clearer.

2.2 Jakarta International Stadium (JIS) as a case study

Jakarta International Stadium (JIS) is an 82,000-capacity football stadium located in Tanjung Priok, North Jakarta. There is an interesting background of JIS, as the building is standing in a district with the largest number of people under the poverty line compared to other districts in Jakarta. Thus, the construction of JIS is one of the efforts to accelerate urban development in the district. The construction of JIS was primarily carried out by local workers and experts (Azzahra, 2022), and it received the highest level of recognition, Platinum, from the Greenship certification. Stadium typology is considered as the case study in this comparative study since stadium construction is counted as a mega-structure that involves major investment, but in contrast shows in many cases become a threat once the event is over. The construction of the stadium as a mega-structure is mentioned to comprise a large amount of carbon footprint and often becomes a financial burden both for the owners and the local community around the stadium after the event due to the lack of utilization and maintenance (Francis et al., 2023;Azzali, 2019). These addressing that sustainable stadium construction is highly directed to all aspects of sustainability, as viewed from the standpoint of the entire rating system.

The study about the comparison between Greenship and LEED within the performance of JIS was previously done by Hanif (Hanif, 2022), one of stakeholders from JIS construction, PT. Jakarta Propertindo. The data obtained in the study regarding JIS and its sustainable tool and performance in achieving Platinum Greenship considered to be valid data that can be used in this paper. Moreover, the result of the comparative analysis towards Greenship and LEED in the study was considered to be useful in extending wider comparative study.

Jakarta International Stadium (JIS) is an 82,000-capacity football stadium located in Tanjung Priok, North Jakarta. There is an interesting background of JIS, as the building is standing in a district with the largest number of people under the poverty line compared to other districts in Jakarta. Thus, the construction of JIS is one of the efforts to accelerate urban development in the district.

Greenship certification is carried out in two phases, namely design recognition (DR), where the assessment is carried out to see how the building complies with the green building principle, and the final assessment (FA) phase through on-site evaluation to see the overall performance of the building. The ratio between DR and FA is 77%

and 23%, which means that differences may occur after FA, but are less significant to the total score. Table 1 shows the performance of JIS in each assessment criterion during DR and FA. On the FA, all of the criteria received a score above 50%, where ASD received 59%, energy performances received 85%, water performances received 81%, material received 71%, indoor comfort performance received 70%, and environmental management performance received 77%. The final score obtained has a slight difference with the DR stage, where DR stage of JIS show the results of 81.8% (Hanif, 2022). The difference can occur because there are several indicators in FA that have not reached the maximum in the on-site evaluation.

Fig. 1. Jakarta International Stadium (StadiumDB, n.d.)

Table 1. Greenship Assessment of Jakarta International Stadium

Greenship Assessment Criteria	**Max. Score (DR)**	**JIS's Score (DR)**		**Max. Score (FA)**	**JIS' Score (FA)**

3. Result and Disussion

3.1 General characterization of GBRT: Overview of LEED, DGNB, SBAT and Greenship

Table 2 presents general information on four major Green Building Rating Systems (GBRS) likely to influence indicator formulation and weighting. LEED, one of the pioneers, is not limited to national use; its global adoption spans over half the countries worldwide. DGNB, though newer than SBAT for Stadia, is implemented in over 30 countries. According to Kouka et al. DGNB aligns most closely with the European Green Deal among European GBRS, suggesting its adaptability beyond national boundaries (Kouka et al., 2024).

SBAT emerged earlier than Greenship (GS) and several GBRS in developed countries (Zarghami & Fatourehchi, 2020a), yet records of its application and updates are scarce. GS, Indonesia's national GBRS, is the most recently established among the four, with a lower number of applications than DGNB. Green building adoption in emerging countries lags behind developed nations due to perceived higher risks in sustainable construction (Nguyen et al., 2023). Nonetheless, GS saw a notable increase in 2024, with 40 new certified buildings (Mardhiyana et al., 2023).

DGNB and SBAT were initiated by government institutions, while LEED and GS were developed by non-governmental Green Building Councils. Despite this, both LEED and GS are officially recognized. LEED is accepted for building tax incentives in the U.S., and GS is similarly recognized by regional governments in Indonesia, with government support seen in public project certifications (GBCI, n.d.).

However, GS and SBAT have experienced significantly slower updates than LEED and DGNB. GS has not been updated for over a decade, and SBAT Regular has remained unchanged for more than 20 years. SBAT for Stadia is its most recent update, prompted by the World Cup. As Fenner & Ryce (2008) note, continual evolution of GBRS is vital to sustain momentum in sustainable development and reach new markets (Fenner & Ryce, 2008).

Table 2 also compares the assessment criteria categories. LEED and GS emphasize key design and construction factors affecting sustainability outcomes. In contrast, DGNB and SBAT are structured around the three pillars of sustainability—economic, social, and environmental. DGNB further includes Technical, Process, and Site Quality categories, which complement its core evaluation areas. This topic is explored in detail in the "Comparison of Categories" section.

Table 2. Comparison of General characterization of LEED, DGNB, SBAT and Greenship (table edited).

	LEED	**DGNB**	**SBAT**	**GS**
Year	1998	2007	2001	2010
Origin	USA	Germany	South Africa	Indonesia

Number of certified buildings	>190.000	>10.000	-	146
Average project (yearly)	7.307	588	-	40

3.2 Comparison of categories

The GBRS categories were compared by grouping into several categories by the similarities. Category comparison is made by identifying and aligning the indicators and grouping based on the common topics. It should by highlighted that comparison is not limited only to the same category name, but to the context of the indicators. This was done since there are different approaches of GBRS's category (LEED and GS, DGNB and SBAT), resulting different title but covering the same context. After that, we also analysing what topics are emphasized in each GBRS by marking indicator with the high score. The result of the comparison is shown in

Fig. *2*.

The Common Categories; As a final, the indicator of LEED, DGNB, SBAT, and GS was grouped into eleven topics: Site, Energy, Water, Material and Resources (MR), Indoor Environment Quality (IEQ), Waste, Management, Innovation, Social, Economy, and Technical Quality. In the grouping process, even though according to literature occupants' health and comfort is included as social aspects, but it is found that several GBRS only assess social aspect only up to health and comfort. Since this paper aims to have deeper analysis in GBRSs' differences and strengths, social aspect that also cover empowerment, inclusion and governance was excluded on the separated group. All GBRS share four common topics categories in Site, Energy, Water, MR and IEQ. According to Nevado-Pena et al., three out of four common topics such as site (land use), Energy, Water, and MR referring to environmental dimensions of sustainability (Nevado-Peña et al., 2015). Meanwhile only IEQ refers to social aspects of sustainability (Illankoon et al., 2017). From that, even though with the same goal towards sustainability development, it shows that each GBRS have the common concern in environmental aspect but different extension in the social and economic aspects.

Prominent Strength of LEED; Among six categories in LEED, a high score category owned by Energy, Location and Transportation included in Site, and Indoor Environmental Quality. This is in line with LEED's aims, as according to the official website of LEED (USGBC, n.d.), 60% of LEED indicator is related to the environment (climate change, water source, and biodiversity), 20% to human health, and the rest is green economy and community. Zimmermann et al. (Zimmermann et al., 2019) address this case by describing LEED and 'Green Building' certification rather than 'Sustainable Building' certification, even though LEED has correlated their indicator with the UN's Sustainable Development Goals. Originating from the developed country become a factor in the environmental aspect's suppression in LEED. Developed countries such as US, can be identified as a country that has reached the economic stability by the GDP value as well as the assurance in the social aspect. These results formulated GBRS has addressed the environmental aspect as a priority instead of social and economic aspect, as it is pointed out by Zarghami and Fatourehci (Zarghami & Fatourehchi, 2020). With the high existences of LEED as the global GBRS, it can be taken to note that LEED is suitable for the project that focus to minimize the environmental impact rather than to reach out as sustainable development approach.

Greenship's Notable Strength; Unlike international GBRS, national-based GBRS shows different criteria formulations. Sharing the same parent organization as LEED, GS highlights similar categories but prioritizes Water over Indoor Environment Quality and even Site development. This emphasis stems from Indonesia's serious water issues, despite its high rainfall and coastal geography. Problems like water supply-demand imbalance, erosion from palm oil plantations, poor sanitation, mining contamination, groundwater over-extraction, and increased flooding (USAID, 2021) led to GS focusing on Water Conservation (WAC) as a prerequisite, stressing water metering, usage calculation, and Water Use Reduction. Even in the Appropriate Site Development (ASD) category, GS emphasizes Storm Water Management to encourage rainwater reuse instead of burdening city drainage systems.

Moreover, while GS indicators appear similar to LEED, there are notable adjustments to prerequisites and the addition of new indicators, influenced by technological differences and local culture. For instance, "Environmental Tobacco Smoke Control" is mandatory in LEED but a high-value (non-mandatory) indicator in GS, reflecting Indonesia's strong smoking culture (Nua, 2024; Salsabila et al., 2022). Similarly, "Renewable Energy" is treated as a bonus in GS due to challenges like expensive solar power investments in developing countries (Pristiandaru, 2023) and Indonesia's reliance on imported solar panels due to limited local production (Thomas, 2019).

Stand-Out Aspects in DGNB; Despite DGNB originated from a developed country, they emphasize all the pillars as equally by providing equal weight to each pillar namely Environmental Quality which includes indicator in Site, Energy, and Water, Socio-Cultural and Functional Quality which includes Indoor Environment Quality, and Economic Quality. The perspective used by DGNB creates this rating system is not just a 'Green Building' rating system, but a 'Sustainable Building' rating system. Initiated from Guidelines for Sustainable Building (GSB) by The Ministry of Transport, Construction and Urban Affairs Germany, lead the GBRS developed by Germany to stick with the sustainable principle. According to

Fig. *2*, the indicators in DGNB are only missing in two categories: Waste and Innovation. However, this does not mean that they are not considered. The discussion of this finding takes place later in Waste and Innovation categories discussion.

DGNB also shows another unique side through the category 'Technical Qualities' which is only found in DGNB. This category specifically encourages building envelope quality, in-building technology, reuse of site potential, and mobility infrastructure. This category is mentioned to "strongly influence the other sustainability qualities in the early planning phase" and "determines the degree to which the planned quality is implemented during execution' (Federal Ministry for the Environment, 2016). Technical categories also can cover the reliability, durability, flexibility, and adaptability of the system (Illankoon et al., 2017).

SBAT Noticeable Strength; SBAT has general points for assessing green buildings with the main categories using triple bottom line of sustainability. The formulation of SBAT indicators projects the conditions of its home country in the consideration of indicators. By using a sustainable approach in the formulation of indicators such as that used by the DGNB, it provides an explanation that may not be available in other GBRS. In the Location category, which reflects the issue of food security in South Africa, "Food garden" is a separate indicator.

The Different Extension towards Economic and Social Sustainability; In the Economy category, promoting local contractors, materials, components, and furniture is explicitly mentioned, along with considerations like Efficiency, On-going Cost, and Capital Cost—elements absent in GS and LEED. These align with Munasinghe's (2004) elements of economic sustainability: growth, efficiency, and stability, showing that SBAT and DGNB address both environmental and economic "Green" performance.

For the social aspect, LEED and GS do not assess design inclusivity, unlike DGNB and SBAT for Stadia. DGNB emphasizes "Barrier-free design" to promote inclusivity, while SBAT adds categories like "Social-Participation Control" and "Social-Education, Health, and Safety," reflecting South Africa's high social inequality (World Bank, 2022). This shows the relevance of social considerations, especially in large community buildings like stadiums. Education-related health issues, like HIV/AIDS control, are only found in SBAT for Stadia, highlighting the link between local health conditions and building certification—an approach other GBRS could adopt.

The lack of social and economic assessments in LEED and GS undermines a full sustainability approach, as sustainable buildings should balance the triple bottom line (Illankoon et al., 2017). Studies also show LEED's weakness in this area (Doan et al., 2017; Zarghami & Fatourehchi, 2020; Ferreira et al., 2023). Meanwhile, government-developed GBRS like DGNB and SBAT address sustainability more comprehensively (Mardhiyana et al., 2023), suggesting that LEED and GS could improve to better suit developing countries' needs.

The Differences in Waste Category Assessment; It is noticeably found that in the Waste category, only SBAT gives separate space for waste assessment. GS assess waste from the BEM category, the 'Basic Waste Management' indicator as it promotes domestic waste management for building operations becomes a prerequisite. Both show differences with other GBRS from developed countries. LEED assess waste in MR category, with the aim to managing waste related to the construction activity. Meanwhile, DGNB did not put 'waste' in any title of the indicator. Instead, DGNB discussed it in the 'PRO2.1 – Construction site/construction process' instead. Where in the mentioned indicator, waste is discussed together with noise, dust, and negative impacts to soil and groundwater during the construction process.

It is interesting since international and developed country's GBRS such as LEED and DGNB assess waste in the indicator to the construction process only, while GBRS from developing countries such as SBAT for Stadia and Greenship assess waste up to the operation phases. Even in GS, indicators for waste during construction are not mandatory, and the priority is taken by waste management during the sage of the building. Positively, LEED, DGNB, SBAT for Stadia and GS promotes adaptive reuse of old structure as one of the ways to fulfil the indicator, which is one of the efforts to run the circular economy (Potting et al., 2016).

The differences in Waste assessment can be triggered by differences in waste management conditions in the country of origin. It is reported that South Africa has been working in the waste and recycling landscape by funding and technical expertise, but the progress has remained slow in the non-packaging waste stream including in construction and demolition waste and organic waste (Godfrey & Oelofse, 2017). In Indonesia's case, it is reported that waste management is still not optimal and sustainable condition (Kusumaningrum et al., n.d.). Different from the condition in the US, where the US already implemented the Environmental Protection Agency (EPA) and 3R (reduce, reuse, recycle) and implemented the recycling program with a goal of utilizing solid waste up to 50% (Kerenhapukh et al., 2021). A Similar condition within Germany, where a waste management policy has been adopted for more than 20 years successfully increasing people's awareness to separate waste and implement disposal technology, leading to 14% of raw materials used by the German industry are from recovered waste (Nelles et al., 2016). The contrasting conditions between the countries of origin of the GBRS may give some insight into the indicators listed. Where the indicators are a directive towards the improvement of the conditions that are still lacking in the country.

Spaces for Innovation Activity in GBRS; Regarding the opportunity to innovate in design, despite the condition of the country, LEED and SBAT for Stadia encourage innovation in assessing green buildings as we can see in

Fig. *2*, Innovation technology. But while DGNB does not have a specific category for innovation, it integrates innovation as a bonus option in the overall certification, mentioned as the "Innovation Area" segment in the guidelines (Fig. 3). As for GS, the term 'innovation' is not mentioned directly in the handbook. What is included is an encouragement to 'use innovative technologies' to achieve targets on water efficiency only. The innovation activity promoted by GBRS in line with a statement by OECD (Organisation for Economic Co-operation and Development) where innovation in the form of creation of new products, processes and technologies, as well as the diffusion and application in green development is helpful to achieve green growth (OECD, 2011). Therefore, the addition of separated indicators for innovation is recommended for GS to catch up with the current condition.

3.3 Comparison through cross background context application

This section compares GBRS—GS, LEED, DGNB, and SBAT—based on JIS performance. In case of SBAT, the analysis adjusted to the SBAT for Stadia version, tailored for stadium projects. Notably, the 'Occupants Comfort' indicator becomes 'Spectators Comfort', where daylighting is replaced with shading; other indicators remain unchanged.

Based on the LEED assessment, JIS falls short in MR, Energy, and IHC categories. Similarly, DGNB and SBAT for Stadia highlight gaps in economic and social aspects, particularly in inclusive design. However, JIS satisfies the Water and Site categories across the systems.The MR shortfall in JIS is linked to lifecycle assessment, which GS does not explicitly include. DGNB does incorporate this, particularly regarding demolition waste—an aspect absent in GS and SBAT. Despite national waste management differences, post-occupancy scenarios, as noted by Fregonara et al. (2018), are critical for long-term sustainability, especially for large-scale facilities (Fregonara et al., 2018).

Stadium-specific assessments in GS and SBAT for Stadia shows differ in focus. JIS meets GS's 'Thermal Comfort' criteria through energy-saving envelope design, aligned with LEED and DGNB. Conversely, SBAT for Stadia prioritizes passive cooling via roof shading. The unique 'Spectators Comfort' indicator in SBAT for Stadia, replacing 'Daylighting', reflects the needs of semi-open stadiums, where excess sunlight can impact occupant comfort and health. Research supports roof shading as more effective than natural ventilation (Guo & Sun, 2024; Conradie, 2018), highlighting SBAT's critical evaluation of social sustainability aspects.

Further, JIS shows deficiencies in meeting the economic and social indicators emphasized by DGNB and SBAT. These systems assess not only environmental but also community and long-term economic impacts. In JIS's context—built in a dense urban area requiring relocation—DGNB's 'Quality of Indoor and Outdoor Spaces' and SBAT's 'Participation and Control' indicators stress community integration. Similarly, economic indicators examine building longevity, cost-effectiveness, and societal value—essential for projects with high public investment and social implications.

Nonetheless, GS performs well in Water and Site Development, consistent with its high standards in these areas. Meanwhile, the unique SBAT category of 'Spectators Comfort'—focused on lighting—has limited impact on overall assessment.

Ultimately, JIS meets over half the criteria in LEED, DGNB, and SBAT. However, its shortcomings reflect the differing priorities among GBRS, shaped by their regional origins. While all aim for sustainability, each system applies distinct strategies based on local contexts.

4. Conclusions

Green Building Rating Systems (GBRS) have been developed by many countries and organizations around the world to assess, evaluate and certify the performance of green buildings. Some GBRS have been adopted in different sites around the globe, some GBRS have been developed for a specific country, and some of them are specially made for special occasions. This study address to compare GBRS from different backgrounds, to identify the similarities, differences, strengths and weaknesses of each GBRS.

As the result of the comparison, it shows that all GBRSs are similar in their focus on environmental aspects, addressing categories such as site, energy, water, MR, and social aspects through IEQ. However, differences in their backgrounds lead to variations in the indicators they evaluate, presenting both strengths and opportunities for improvement. From this research, it can be suggested for stakeholders in the construction field to choose locally developed GBRS as a green building reference to access regionally specific sustainability issues. In addition, it is expected that the wide use of regional GBRS can lead to the development of GBRS periodically, especially in improvement areas found at several points. That way, the goal of future sustainability can be achieved.

Acknowledgments

The research described in this paper was part of Sustainable Building Production with assistance from Professor Nilüfer Taş and Professor Mürat Taş.

A review on artificial intelligence extensions integrated into architectural drawing programs and their applications

Yahya Melikoğlu*[1]

[1]Harran University, Department of Architecture, 63000 Şanlıurfa, Turkey

Abstract. Artificial intelligence is creating a significant transformation in the field of architecture by offering advantages such as accelerating design processes, reducing the margin of error and producing creative solutions. Artificial intelligence technologies integrated into architectural software not only facilitate design processes, but also provide more sustainable, economical and innovative solutions. In order to examine the role of AI in architectural design, this study provides a comprehensive overview of AI extensions and design-based AI applications integrated into architectural drawing programs. The aim of the study is to analyze in detail the functions and usage areas of artificial intelligence in software such as AutoCAD, Revit, Rhino+Grasshopper, Fusion 360, Sefaira, Lumion, Enscape, Twinmotion and SketchUp. In addition, the transformative effects of AI in areas such as parametric design, energy efficiency analysis and sustainability-oriented modeling are highlighted. As a methodology, a literature review and technical review of existing software features were conducted. In this process, the effects of AI on generative design, data analytics, energy simulations and visual presentation processes were evaluated. It has been observed that AI-supported extensions make the design processes more efficient and effective, while at the same time improving the design quality. The results of the research show that artificial intelligence is faster in architectural design processes, encourages innovation and offers designers more flexible, functional and aesthetic solutions. The study predicts that the integration of artificial intelligence into architectural software will have a wider application area in the future and will make significant contributions to the discipline of architecture.

Keywords: Artificial Intelligence (AI); Architectural Design; Desing Program, Architecture

1. Introduction

With the influence of digitalization, architectural drawing and modeling programs have undergone a profound transformation over the past forty years. Initially limited to producing two dimensional drawings, computer-aided design (CAD) programs have evolved into multifunctional tools encompassing three dimensional modeling, building information modeling (BIM), parametric design, energy simulation, and visualization (Eastman et al., 2011). This evolution has reshaped both architectural education and professional production processes.

Contemporary architectural practice now encompasses not only aesthetic and functional design but also sustainable, economical, and technologically innovative solutions marking a shift toward a multidimensional design process (Yang et al., 2025). One of the primary driving forces behind this transformation is the integration of artificial intelligence (AI) technologies into design workflows. The use of AI in architecture has become increasingly visible alongside the digitalization of design processes, enabling designers to make faster, data driven, and optimized decisions. As architectural practice has shifted from traditional drawing methods to digital modeling, drawing software has likewise transformed from being merely two-dimensional drafting tools to becoming integrated platforms equipped with three-dimensional modeling, analytical, and simulation capabilities. These platforms (Revit, AutoCAD, Rhino+Grasshopper) now not only support drawing production but also offer intelligent systems that guide user decisions, propose alternative solutions and analyze various scenarios simultaneously (Li et al., 2024). In this context, AI-supported extensions and plugins have significantly transformed conventional design practices.

However, despite this rapid technological advancement, several questions remain inadequately addressed: How is AI integrated into architectural software? What specific functions do these AI extensions perform? What types of contributions do they make to the design decision-making process? These unresolved issues highlight a substantial knowledge gap in both academic literature and professional practice (Jang & Lee, 2025). A systematic

* Corresponding author, E-mail: ymelikoglu2@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_390

assessment of the nature, functions, and advantages of AI tools integrated into architectural software is therefore necessary.

With the development of digital design tools, AI powered extensions now go beyond merely facilitating production processes they enable complex functions such as generating alternative solutions, conducting performance analyses, and integrating sustainability criteria. Yet, the existing literature on how these technologies are integrated into various software platforms, what contributions they offer, and in which contexts they are most effectively used remains limited. Most studies focus on individual software programs or tools and fail to provide a comprehensive evaluation.

The primary aim of this study is to systematically examine AI extensions integrated into commonly used architectural drawing and modeling software and to explore their multifaceted contributions to the architectural design process. Through an evaluation of software platforms such as AutoCAD, Revit, Rhino+Grasshopper, Fusion 360, Sefaira, Lumion, Enscape, Twinmotion, and SketchUp, the study details the scope of AI-supported functions in relation to design workflows, analysis, visualization, and performance optimization. The research focuses on the following central questions:

- What functions do AI extensions perform in architectural drawing programs?
- How do these technologies contribute to subdomains such as sustainability, energy efficiency, and visualization?

Within this framework, the study seeks to contribute to the existing literature while also offering a technical and conceptual perspective on the future of architectural design. It emphasizes that the integration of AI into architectural software represents not only a technological innovation but also a paradigm shift that is transforming the culture of design. The analysis will evaluate the technical functions, areas of application, and representation in the literature of these software programs and extensions, and will discuss their impact on architectural practice. Without relying on surveys or applied data, this study, conducted through a literature based approach, aims to present a comprehensive overview of AI integration in architectural software and to lay the groundwork for future critical inquiry.

2. Theoretical Background of Artificial Intelligence Integration in Architectural Drawing Programs

Artificial intelligence (AI), while generally referring to the development of computer systems that mimic human intelligence, in the context of architecture, entails a redefinition not only of computational capacity but also of the creative process itself. In architecture, AI transcends traditional design processes and functions as a tool that supports multi-layered workflows such as parametric design, generative algorithms, data analytics, and optimization. This transformation directly influences the architectural thought system at both cognitive and productive levels

2.1. The Definition and Role of Artificial Intelligence in Architecture

Architecture has historically evolved as a design practice grounded in intuition, experience, and cultural values. Today, however, the computational power offered by AI enables the reconstruction of this practice in digital environments through data driven approaches. AI, particularly through areas such as machine learning (ML), deep learning (DL), generative design, and algorithmic thinking, is becoming one of the guiding components of the design process (Oxman, 2017). In this context, the architect is no longer merely a designer but a strategist who co-directs the design process alongside algorithms.

2.2. Conceptual Foundations of AI Integration

Generative design allows AI algorithms to automatically produce various design alternatives based on predefined input parameters. This approach is exemplified in software such as Autodesk Revit, where the "Generative Design" module offers designers a range of optimal solutions aligned with specific goals such as energy efficiency, spatial utilization, or aesthetic coherence. This significantly facilitates decision-making, especially during early design stages (Turrin et al., 2011). In Rhino + Grasshopper environments, AI based plugins such as Wallacei and Opossum utilize evolutionary algorithms to test design variations and recommend optimized solutions. These tools not only accelerate the design process but also exceed human capacity in solving complex, multi variable problems.

2.3. Generative Design Approach and Computational Thinking

The integration of AI into architectural software is not only a technical instrument but also a new mode of thought. Accordingly, the design process is increasingly reduced to a problem solving algorithm, and the designer becomes a "cognitive operator" who manages this algorithm. Machines should be considered not merely as tools, but as "collaborative designers"a vision that has become increasingly tangible with today's AI integrations (Vartiainen, 2021).

Furthermore, generative AI models such as Midjourney and DALL·E can directly influence the formal articulation of design, allowing AI to operate not only in the background as a support tool, but also in the foreground as a "designer" capable of form generation. This challenges the traditional human-centered paradigm of architectural theory and prompts a critical reassessment of authorship in design.

3. Examination of Architectural Drawing Software and Integrated AI Extensions

As architectural design processes undergo transformation through digital technologies, they are evolving beyond traditional CAD (Computer Aided Design) tools into systems that integrate data driven, computational, and adaptive structures. In this evolutionary process, artificial intelligence (AI) has emerged not merely as an auxiliary module within architectural software but as a generative system actively participating in decision-making. Designers now work alongside systems that not only generate geometric forms but also simulate performance, conduct optimization, and propose alternative solutions. In this context, the integration of AI into architectural software has fundamentally altered the nature and operation of the design process.

With the rapid advancement of technology, architectural design processes have shifted from form based visual production toward a structure grounded in data driven analysis, automation, environmental simulation, and performance based decision support systems. Within this transformation, AI particularly through various modules and extensions integrated into drawing and modeling software significantly enhances both the efficiency and quality of the design process. These platforms, which have replaced traditional drafting tools, now function as intelligent systems capable of analyzing architectural problems in multidimensional ways and proposing optimal alternatives.

This section examines nine major software programs commonly used in architectural design: AutoCAD, Revit, Rhino+Grasshopper, Fusion 360, Sefaira, Lumion, Enscape, Twinmotion, and SketchUp. Each program is evaluated under separate subheadings in terms of its mode of AI integration, the algorithms employed, functional advantages offered to the user, and its representation within the academic literature.

3.1 AutoCAD ve Autodesk Assistant

AutoCAD is a widely used 2D and 3D drafting software in the fields of architecture, engineering, and construction. Its artificial intelligence integration is primarily realized through systems such as Autodesk Assistant and MyInsights. These systems analyze user behavior to predict the most frequently used commands, detect drawing errors in advance, and accelerate the drafting process by offering suggestions (Maheshwari & Agrawal, 2024). The "Smart Blocks" feature, integrated into the latest versions of AutoCAD, enables the automatic placement and adjustment of objects by recognizing them.

3.2 Revit ve Generative Design

Autodesk Revit is a building information modeling (BIM) oriented software that is particularly used in planning building functions through AI supported generative design tools. With its Generative Design module, Revit generates a wide range of design alternatives based on user defined criteria (such as circulation, lighting, and space efficiency) and performs performance analyses to suggest optimal solutions (Turrin et al., 2011). In this process, AI participates directly in decision-making both visually and numerically.

3.3 Rhino + Grasshopper: Wallacei, Opossum, Dodo

Rhino is a powerful CAD software that enables free form modeling. Through its Grasshopper plugin, it facilitates a transition into parametric design processes. AI supported extensions such as Wallacei, Opossum, and Dodo generate optimized designs using evolutionary algorithms and machine learning. These tools are particularly effective in solving complex, multi variable design problems in areas such as form exploration, structural stability, and light analysis (Ekici, 2022). The Rhino/Grasshopper combination serves as a robust generative design platform in both architectural and industrial design domains.

3.4 Fusion 360: AI-Supported Design Focused on Fabrication

Fusion 360 is an integrated CAD/CAM/CAE software developed by Autodesk. While it is widely used in mechanical engineering and product design, it is also preferred for the detailed fabrication of architectural components. The Generative Design module within Fusion 360 produces solutions that offer the most durable form using minimal material, in accordance with structural requirements. In this context, AI undertakes the role of simulation supported generative optimization (Shrestha et al. 2021).

3.5 Sefaira: Energy Performance and AI-Supported Simulation

Sefaira is a software primarily used for building energy modeling, natural lighting analysis, and environmental assessments. Compatible with both SketchUp and Revit, it employs artificial intelligence to analyze factors such as energy consumption, daylight efficiency, and thermal comfort in real time. Sefaira's AI based simulation engine provides performance feedback during the early stages of the design process, facilitating the development of sustainable solutions (Komatina et al., 2024).

3.6 Lumion: Real Time AI-Supported Visualization
Lumion is a powerful rendering software used for visualizing architectural projects. Artificial intelligence is particularly involved in tasks such as material recognition, scene lighting, and automatic adjustment of environmental details based on weather conditions. New plugins like AI Artist Styles allow visual outputs to be transformed into either artistic or photorealistic representations according to user preferences (EIN Presswire, 2025).

3.7 Enscape: Real Time Presentation and Lighting Analysis with Artificial Intelligence
Enscape operates in integration with software such as Revit, Rhino, ArchiCAD, and SketchUp to provide real-time rendering and virtual reality (VR) experiences. Artificial intelligence contributes primarily through automatic enhancements in light distribution, shadow analysis, and material interactions (Moldovan, 2024). Additionally, it features a system infrastructure that learns users' frequently applied visual settings and recommends them in future scenes.

3.8 Twinmotion: AI Supported Rapid Visualization and Interactive Scene Generation
Twinmotion is a visualization platform based on Unreal Engine. With AI support, many scene elements such as the automatic arrangement of environmental components, traffic density simulation, and weather scenario modeling can be generated without manual user input. Additionally, features such as sound synchronization and human movement animations are also automated by artificial intelligence (EIN Presswire, 2025).

3.9 SketchUp and Veras AI
SketchUp is a practical modeling tool commonly used for architectural concept design. Its functionality can be expanded through various plugins. In particular, Veras an AI-supported rendering engine enhances drawn objects with artistic or photorealistic renderings. Based on the user's stylistic preferences, Veras provides suggestions and generates scene specific variations through generative artificial intelligence (EvolveLAB, 2025).

Each of the software and plugins discussed in detail above illustrates how artificial intelligence is integrated into the architectural design process and the specific functional domains in which it contributes. The AI capacity, intended use, and the level of design support provided by each program vary considerably. This diversity necessitates that architects select the most appropriate digital tool based on project specific needs, thereby making design decisions more strategic. The comparative table below (Table 1) summarizes the modes of AI integration in the mentioned software and presents their contributions to the design process alongside their functional focus areas.

Table 1. AI Extensions in Architectural Drawing Software and Their Key Application Areas

Software	AI Extension / Module	Key Application Area
AutoCAD	Autodesk Assistant, Smart Blocks	Automated command suggestions, error detection
Revit	Generative Design	Plan variations, design optimization
Rhino + Grasshopper	Wallacei, Opossum, Dodo	Parametric modeling, evolutionary algorithms
Fusion 360	Generative Design	Fabrication oriented component design
Sefaira	AI based energy simulation	Daylighting, energy efficiency analysis
Lumion	AI Styles, Smart Lighting	Scene automation, realistic visualization
Enscape	AI Light Adjustment, Auto-materials	Lighting simulation, rendering optimization
Twinmotion	AI Landscape/Environment Builder	Interactive scene creation, environmental animations
SketchUp	Veras (EvolveLAB)	Conceptual visualization, AI-powered rendering

4. Application Areas and Advantages of AI-Supported Design Processes

The integration of artificial intelligence technologies into architectural drawing software represents not merely a technical transformation, but a holistic paradigm shift that reshapes the theoretical structure of architecture, decision-making processes, and professional practice. Traditionally guided by intuition, experience, and aesthetic judgment, the architectural design process has evolved into a data driven, computational, and automation-supported form. AI-assisted software stands at the core of this transformation, acting as an interactive solution partner for architects in tasks such as form generation, analysis, scenario development, and presentation preparation.

In this section, the contributions of AI integration to architectural design processes are evaluated under five main application areas: generative design and optimization, energy performance and sustainability analysis, visualization and presentation, decision support systems, and collaborative/learning environments (Table 2). These areas enhance both the technical and creative capacities of architects, enabling the development of more sustainable, rapid, error-free, and high quality projects.

Generative Design and Optimization: One of the most prominent areas where AI stands out in architectural processes is generative design. This approach allows for the creation of numerous design alternatives according to predefined goals and facilitates the identification of the most optimal solution. Tools such as Revit's Generative Design module, Wallacei and Opossum in Rhino+Grasshopper, and Fusion 360's generative design infrastructure are prominent in this field. For instance, when designing an office plan, the user can define criteria such as spatial efficiency, daylight duration, and user density, and the system generates optimized solutions based on these inputs. This enables the architect to make performance based decisions alongside aesthetic considerations (Turrin et al., 2011). These systems not only generate forms but also encourage the user to understand the mathematical rationale behind design decisions. In this way, AI transforms architectural design from a purely graphical process into a data-driven problem-solving practice.

Energy Performance and Sustainability Analysis: Sustainability has become one of the core principles of contemporary architecture and is considered a parameter that must be addressed from the earliest design stages. AI-supported simulation software provides substantial ease in this regard. Tools like Sefaira analyze performance data related to natural lighting, energy consumption, shading, and thermal comfort, offering real time feedback to architects on the environmental impact of their designs. In this way, energy modeling can be conducted even before construction, and cost performance forecasts can be developed. Furthermore, the system can test different design scenarios based on user inputs to determine the most efficient form. This process yields results that are significantly faster, more accurate, and measurable than traditional trial and error methods.

Visualization, Presentation, and Communication: Architecture not only involves designing but also effectively communicating the design. AI supported visualization software offers time and quality advantages to architects in this regard. Platforms like Lumion, Enscape, and Twinmotion can automatically adjust lighting conditions, optimize material reflections, and create scenes based on environmental factors using AI algorithms to produce highly realistic renderings. Additionally, generative AI extensions such as Veras contribute creatively to the design process by transforming basic sketches into meaningful conceptual designs. These systems serve as effective communication tools, especially in early design stages, when conveying ideas to clients or juries. The visual qualities of a design can thus be tested not only in terms of form but also perceptually and psychologically (Turrin et al., 2011).

Decision Support Systems and Error Reduction: AI has enabled the development of systems that can suggest commands based on user behavior, detect drawing errors in advance, and reduce repetitive tasks. Features like Smart Blocks and MyInsights in AutoCAD enhance the architect's efficiency while significantly reducing the margin of error, especially in large scale projects. These systems continuously monitor the user to learn common mistakes, offer suggestions, and automate the process. As a result, the architectural production process becomes not only faster but also improved in terms of quality and consistency. These software tools, which evolve from mere information users to systems that learn and develop, can be considered digital design partners providing cognitive support.

Table 2. Application Areas of AI-integrated Design Software in Architecture

Application Area	Software Examples	AI Contribution
Design & Modeling	Revit, Fusion 360, Rhino + Grasshopper	Producing alternative solutions, parametric optimization
Energy & Sustainability	Sefaira, Revit Insight	Performance analysis, energy modeling, environmental scenario generation
Visualization & Presentation	Lumion, Twinmotion, Enscape, Veras	Real-time visualization, lighting and material adjustment, render optimization
Decision Support / Error Reduction	AutoCAD (Smart Blocks, Assistant), Revit	Error detection, command suggestion, data-driven design guidance
Collaboration & Education	Hypar, Grasshopper	Real-time multidisciplinary teamwork, parametric design education

Collaboration, Educational Use, and Interdisciplinary Integration: Cloud based AI supported platforms (e.g., Hypar) enable multi-user interaction, turning design into a collective process. These environments allow users from different disciplines to work simultaneously on the same project while also facilitating the educational transmission of parametric thinking. Especially for architecture students, such platforms are highly functional for experiencing AI-based modeling strategies and developing algorithmic thinking skills. Thus, architectural education is transformed from a static knowledge transmission process into an experiential and generative learning environment.

Given all these contributions, the integration of artificial intelligence into architectural software should be considered not only as a technical support element, but also as a paradigm shift that rebuilds the philosophy of design. Architectural design now relies not only on human creativity, but also on the capacity of machine intelligence to generate and analyze unlimited variations. Thanks to this integration, the architect can make more holistic, data-driven and future sensitive design decisions, and establish stronger links between user needs, environmental factors and technological possibilities.

5. Conclusions

The integration of artificial intelligence into architectural drawing software is reshaping not only how architects design but also how they think, analyze, and communicate spatial ideas. As demonstrated throughout this study, AI supported design tools have become central to a wide range of architectural processes spanning from generative form finding and environmental simulations to real time rendering and decision support. These tools not only accelerate the production process but also enhance the quality, adaptability, and sustainability of architectural outcomes.

The comparative review of widely used programs such as AutoCAD, Revit, Rhino+Grasshopper, Fusion 360, Sefaira, Lumion, Enscape, Twinmotion, and SketchUp reveals a landscape where AI is no longer a supplementary feature, but a core engine behind intelligent design solutions. AI algorithms today can simulate complex behaviors, optimize spatial configurations based on performance data, suggest context aware modifications, and even render visually compelling outputs with minimal human input. This shift enables architects to move beyond traditional trial and error methods, embracing predictive and data driven approaches that reduce error margins and encourage design innovation.

Beyond its practical benefits, AI’s growing influence is gradually redefining the professional identity of the architect. The role is expanding from that of a sole creator to a strategic decision maker who collaborates with intelligent systems. In this new paradigm, creativity is augmented not replaced by computation, and design becomes a process of human machine synergy. However, this transformation also brings challenges. Issues such as algorithmic transparency, data ethics, and the risk of over automation must be critically addressed. Furthermore, architectural education must evolve to incorporate AI literacy, equipping future architects not only with design sensibilities but also with computational fluency.

Looking ahead, the architectural profession stands at the threshold of a digitally enriched future, where artificial intelligence will play an increasingly decisive role in shaping spatial experiences. Future research should focus on developing open source, context aware, and user friendly AI design tools that support inclusive, sustainable, and culturally responsive architecture. In this evolving landscape, architects who embrace the collaborative potential of AI will be better positioned to navigate complexity and drive meaningful innovation in the built environment.

Assessing the knowledge of BIM professionals and the need for theoretical BIM education

Gökçen Ö. Ezgi[1], Salih Ofluoğlu*[2]

[1] *Mimar Sinan Fine Arts University (Department of Informatics) – Yazılım 3D, Istanbul, Türkiye*
[2] *Antalya Bilim University (Department of Architecture), Antalya, Türkiye*

Abstract. Building Information Modeling (BIM) has emerged as an indispensable tool within the Architecture, Engineering, and Construction (AEC) industry, offering powerful capabilities for digital project planning, coordination, and management. Despite its growing use, many professionals engaging with BIM software often lack a comprehensive theoretical understanding of its underlying concepts, workflows, standards, and broader benefits. This missing knowledge hinders the effective use of BIM, as familiarity with software tools alone is insufficient for leveraging its full potential. A solid grasp of theoretical foundations can empower professionals to better coordinate complex projects, reduce design and construction errors, improve interdisciplinary collaboration, manage data efficiently, and make informed decisions across all project phases. To investigate this knowledge gap, the present research utilizes a structured survey targeting BIM professionals in Türkiye. The study focuses on their conceptual understanding of core themes such as data management, interoperability, standard compliance, and lifecycle integration. The results reveal a substantial disconnect between practical software use and theoretical knowledge, with many participants depending primarily on informal learning pathways. This dependence often results in inefficiencies, miscommunication, and limited project performance and quality. The findings emphasize the urgent need for structured and standardized education in BIM theory at both academic and professional levels. Incorporating comprehensive BIM theory into curricula and certification programs can enhance strategic thinking, workflow coordination, and long-term project outcomes. Ultimately, closing this knowledge gap is vital for cultivating a more capable, collaborative, and forward-thinking workforce equipped to lead digital transformation within the rapidly evolving AEC industry.

Keywords: Building Information Modeling; BIM; Theoretical BIM Education; Knowledge-based BIM Education; Digital Construction

1. Introduction

The construction industry plays a pivotal role in shaping economic activity and supporting numerous other industries. To enhance its efficiency and long-term value, the industry increasingly relies on digital tools and data-driven processes. One of the most transformative developments in this context is Building Information Modeling (BIM). The ISO 19650-1 standard refers to it as a "shared digital representation used to facilitate the entire life cycle of a building." Sinclair (2014) defines BIM as "the process of managing information in a three-dimensional model containing data related to a building's construction." This process serves as a tool applicable not only during the design phase but also throughout the construction phase and beyond.

BIM should not be considered merely as a software application. It represents a paradigm shift from traditional workflows by promoting a shared data environment where architects, engineers, contractors, and other stakeholders collaborate more effectively. Unlike conventional methods, where each party relies on separate and often incompatible tools, BIM fosters integration and communication across disciplines. It serves as a bridge between the architecture, engineering, and construction industries, enabling visualization before the construction phase, identifying potential issues early, and supporting time- and cost-efficient project delivery.

Recognized as a next-generation approach, BIM enhances productivity and streamlines the building delivery process (Qian, 2012). Its multidimensional framework—ranging from 3D modeling to 7D facility management and beyond—combined with information integration technologies, allows stakeholders such as government agencies, property owners, construction managers, and designers to access and manage comprehensive project data throughout the lifecycle (Li et al., 2014). Ultimately, BIM is a collaborative, multidimensional methodology that spans a wide professional domain.

* Corresponding author, E-mail: salih.ofluoglu@antalya.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_391

With BIM becoming mandatory for large-scale construction projects in many countries, it is crucial for all industry stakeholders to develop a clear understanding of this technology. However, the successful adoption of BIM is often hindered by the high costs associated with skill development, training programs, and management processes. Studies indicate that these challenges represent some of the most significant barriers to widespread BIM implementation (Khosrowshahi & Arayici, 2012; Succar et al. 2013; McGraw Hill Construction, 2014) . To overcome these obstacles, acquiring fundamental BIM skills through structured education is essential. This not only reduces adoption costs but also enhances career opportunities for architecture, engineering, and construction professionals.

BIM is particularly critical for the Turkish construction industry, which must align itself with global advancements. Understanding the current state of BIM adoption in Türkiye and implementing effective strategies for its integration are key priorities. However, BIM education in Türkiye remains limited and lacks standardization at the academic level. There is a pressing need to develop comprehensive BIM training programs covering theoretical foundations, terminologies, methodologies, and the necessary digital infrastructure.

Recognizing these gaps and the urgency for action, the Ministry of Environment and Urbanization took a significant step by issuing the memorandum titled "Inclusion of Building Information Modeling (BIM) Courses at Undergraduate/Graduate Levels," on October 8, 2021 (T.C. Çevre ve Şehircilik Bakanlığı, 2021). Through this initiative, the Ministry launched efforts to develop innovative national strategies and related regulations aimed at the digital transformation of the Turkish construction industry. The memorandum states that it is planned for all construction and operation processes, from the design phase to the end of a building's lifecycle, to be conducted using BIM. Furthermore, it emphasizes that one of the most critical steps to ensure BIM integration in public institutions, organizations, and the private industry is for universities to train academics in these fields, update their curricula, and educate qualified technical personnel. Through the decision formalized by this memorandum, the importance of adopting the BIM concept at an early stage is also supported and prioritized by public institutions.

Building upon these efforts, a significant regulatory development was introduced with the amendment to the Regulation on Planned Areas (T.C. Resmi Gazete, March 11, 2025). According to this amendment, for projects designated by the Ministry, it has become mandatory to store project documents, drawings, calculations, and reports related to construction permits in a digital environment in accordance with BIM standards. These documents will be recorded, reviewed, approved, and archived electronically within the Ministry's or authorized bodies' digital infrastructure systems, eliminating the requirement for printed documents during these procedures. This legislative change marks a pivotal step toward accelerating the widespread adoption of BIM in Türkiye, further solidifying its role in the country's ongoing digital transformation in the construction industry.

2. Research Rationale

The research rationale of this study centers on the critical need to integrate a theoretical foundation of Building Information Modeling (BIM) into architectural and engineering education as well as professional training programs, especially within the Turkish construction industry. As explained in the earlier section, BIM represents a transformative innovation in the construction industry, facilitating interdisciplinary collaboration through a shared three-dimensional modeling environment. Despite its increasing global adoption, BIM education in Türkiye remains inadequate, lacking widespread standardization and comprehensive theoretical coverage. This insufficiency is reflected in the limited understanding of BIM concepts, terminologies, logic, innovations, and its adaptable infrastructure among professionals, which hinders effective BIM utilization and adoption in practice

This study identifies that while BIM software skills and process-specific training are common, there is a significant gap in imparting the conceptual and theoretical knowledge necessary for a holistic understanding of BIM. Such theoretical knowledge is essential not only for grasping BIM's operational tools but also for fostering critical thinking, organizing information logically, and adapting to technological advancements in the field. The absence of this foundational knowledge can lead to suboptimal BIM implementation, increased errors, and inefficiencies in construction projects

Moreover, the demand for BIM-competent personnel worldwide has surged, yet the shortage of individuals with adequate BIM theoretical knowledge remains a major barrier to BIM adoption. This gap is particularly pronounced in Türkiye, "where BIM education is still new and not yet well-organized. Thus, establishing the necessity for a structured, conceptual BIM education tailored to the industry's needs is vital for enhancing BIM competence, reducing adoption costs, and improving career prospects for graduates and professionals in architecture, engineering, and construction disciplines.

This research further rationalizes that a theoretical BIM education grounded on internationally recognized standards and learning outcomes, such as those published by buildingSMART, would provide a robust framework for curricula development (buildingSMART, 2018). By aligning educational content with these outcomes, it becomes possible to systematically address the educational deficiencies identified through both literature reviews and empirical data gathered via industry-wide surveys. These surveys assess current theoretical BIM knowledge among Turkish construction professionals, revealing critical gaps in areas such as BIM maturity levels, standards, information exchange requirements, common data environments, and BIM execution plans.

In summary, the research rationale is based on the recognition that effective BIM adoption and utilization in the Turkish construction industry require a foundational theoretical understanding that is currently lacking. This study aims to fill that gap by demonstrating the need for conceptual or knowledge-based BIM education, identifying the critical content areas for such education, and providing a basis for future curriculum development and sectorial capacity building. The study's findings and methodology can serve as an essential reference for educators, professionals, and policymakers aiming to enhance BIM competence and promote innovation in the construction industry.

2. Materials and Methods

2.1. BIM Education Types

The increasing importance of Building Information Modeling (BIM) in architecture, engineering, and construction has led to the emergence of diverse educational strategies aimed at equipping future professionals with both conceptual and practical competencies. BIM education typically follows two parallel pathways: academic programs centered on conceptual foundations and professional training that emphasizes technical application. Each pathway serves different purposes and caters to distinct audiences, yet both contribute to the widespread implementation and understanding of BIM.

Academic programs often approach BIM as a multidisciplinary concept and seek to embed it within architecture, engineering, and construction curricula. At many universities, particularly at the postgraduate level, BIM is incorporated not only as a software tool but as a process-oriented framework involving standards, information workflows, and lifecycle thinking. Cardiff University, for instance, offers a master's degree in Smart Engineering focusing on infrastructure modeling, incorporating subjects such as information requirements, project delivery plans, and data environments (Cardiff Univ., n.d.). Similarly, the University of Minho's BIM A+ program emphasizes information management, collaboration, 4D–6D modeling, and sustainability analysis across six specialized courses (Univ. of Minho, n.d.). These programs reflect a pedagogical commitment to aligning technical skills with conceptual knowledge and collaborative workflows.

Private institutions also contribute significantly to the development of BIM competencies. The Zigurat Institute's "Global BIM Management" master's program, delivered entirely online, serves industry professionals seeking leadership roles in digital construction. This program presents BIM not just as a modeling tool, but as a holistic management strategy, with topics including coordination, cost planning, and asset management (Zigurat Institute, n.d.). The Graphisoft BIM curriculum, designed for educators, offers a comprehensive instructional package focusing on design collaboration, sustainability, and documentation using ArchiCAD (Graphisoft, n.d.).

In Türkiye, universities and continuing education centers have started offering programs with increasing depth. The "Architectural and Urban Informatics" master's degree at Mimar Sinan Fine Arts University (MSGSU) introduces students to BIM from a theoretical standpoint, emphasizing the relationship between design and information systems. This curriculum includes courses on sustainable modeling, project integration, and GIS-BIM interoperability, offering students both theoretical and practical grounding (MSGSU, n.d.). Complementary to this, MSGSU and ITU's continuing education centers provide certification programs for BIM operators and specialists. These shorter, modular programs focus on project delivery, document control, software proficiency, and model coordination, aiming to meet the immediate needs of professionals (ITU SEM, n.d.). For example, the MSGSU SEM BIM Operator course blends theoretical instruction with applied learning, addressing ISO standards, sustainability analysis, and HVAC modeling tools.

Comparative reviews of international and Turkish programs reveal a strong emphasis on software training and industry-specific needs, while deeper conceptual content remains underrepresented. A cross-analysis of 11 programs found that over 90% covered topics such as BIM software, standards, collaboration, and data environments. However, more abstract elements like BIM maturity levels, schema development, and data security were included in less than 20% of the programs (Şen, 2022). These findings underscore the continued prioritization of tool-based instruction over conceptual integration, despite growing recognition that a balanced curriculum should cover both. Researchers such as Wu and Issa (2014) have shown that while industry professionals value software skills, long-term BIM effectiveness requires understanding the processes and frameworks that underlie the technology. This sentiment is echoed by Sacks and Pikas (2013), who argue that conceptual fluency is more sustainable than tool mastery alone, given the evolving nature of BIM platforms.

Nonetheless, many institutions face challenges in transforming curricula. Surveys show that over 70% of BIM educators in the U.S. are adjunct or contract-based faculty, largely due to resistance from tenured faculty to adopt new technologies and revise established courses (Joannides et al., 2012; Sharag-Eldin & Nawari, 2010). Most instructors were trained in CAD environments, creating a generational gap in BIM fluency (Suwal et al., 2014). These obstacles point to a need for professional development initiatives that can align teaching capacity with industry expectations. Collaborative efforts like Li et al. (2013) industry-supported design workshops and curriculum development seminars of Suwal (2013) have proven to be successful models for advancing BIM instruction.

At the policy level, countries that have mandated BIM usage in public projects, such as the United Kingdom, Norway, and Singapore, have observed a direct increase in BIM training programs and national standard-setting initiatives. The UK's 2011 Government Construction Strategy, which mandated BIM Level 2 for public projects was a catalyst for educational reform and professional certification in the country (Government, 2012). Organizations like the BIM Academic Forum (UK), the Academic Interoperability Coalition (US), and New Zealand's NBEWG (New Zealand National BIM Education Work Group) have also supported the development of standardized curricula and learning outcomes in response to national strategies.

In conclusion, the current landscape of BIM education reveals a dynamic yet imbalanced emphasis: while software training and industry-driven content dominate course offerings, foundational understanding of BIM's conceptual underpinnings remains limited. This gap emphasizes the need for educational models that treat BIM not merely as a technical tool but as a collaborative, data-driven methodology that reshapes the construction process. As the demand for digitally literate professionals grows, both academic institutions and industry actors must work together to ensure that BIM education evolves in both depth and scope.

2.2. buildingSMART BIM Training

buildingSMART is an internationally recognized non-profit organization that leads the development of openBIM standards and promotes interoperability in the built environment. In response to persistent confusion surrounding BIM processes and terminology, buildingSMART established a global Professional Certification (pCERT) Program, aiming to standardize BIM-related competencies and provide a consistent benchmark for evaluating industry professionals worldwide.

Central to this initiative is a framework of Basic Learning Outcomes, grouped into five thematic areas encompassing 28 specific competencies. These outcomes include foundational knowledge such as defining BIM, understanding its necessity, recognizing key openBIM standards and ISO19650 terminologies (e.g., EIR, BEP, CDE, COBie), and interpreting BIM maturity levels from Level 0 to Level 3. The curriculum also highlights the value of BIM in contrast to traditional project delivery methods, focusing on its role in improving collaboration, information accuracy, and lifecycle management, while mitigating the risks of poor information handling (buildingSMART, n.d.).

A key component of the certification process is the Body of Knowledge (BoK), which outlines the educational content to be covered in formal training. Upon completing a certified course, participants must pass a standardized online exam developed by buildingSMART to obtain the official buildingSMART Professional Certification. This certification program is also actively implemented in Türkiye through buildingSMART Türkiye, the Turkish chapter of buildingSMART International (buildingSMART Türkiye, n.d.). The same Body of Knowledge, translated and localized for Turkish professionals, forms the basis of training and examinations offered within the country. Notably, this research study was conducted between June 2021 and January 2022, just before the implementation of the education program by buildingSMART Türkiye.

Globally, the buildingSMART certification is increasingly recognized as a mark of BIM competence. In Germany, for example, the certification is often referenced in public procurement documents and is used as a formal credential in professional qualification frameworks. Similarly, in countries like the UK, Norway, and the Netherlands, the certification aligns with national digital construction strategies and is supported by both public authorities and large private firms as a reliable indicator of openBIM proficiency. Its alignment with ISO 19650 and international interoperability frameworks adds further value for professionals working in multinational or collaborative digital environments.

In summary, buildingSMART's education and certification program plays a transformative role in elevating BIM literacy across the AEC industry. By offering a structured, internationally accepted framework that blends conceptual clarity with technical precision, and through national chapters like buildingSMART Türkiye, it enables professionals to engage meaningfully in digital workflows, both locally and globally.

2.3. Methodology

This study employs a survey-based research design to assess the necessity of Building Information Modeling (BIM) education in the Turkish construction industry and to evaluate the extent to which professionals comprehend core BIM concepts. Given the critical importance of informed and capable stakeholders for the successful implementation of BIM processes, the research focuses on measuring foundational knowledge among practitioners currently involved in BIM-related roles.

The survey instrument was developed in alignment with the buildingSMART Professional Certification Program, specifically drawing from the open-access document Phase 1: Individual Qualification – Overview and Sponsorship Plan. In particular, the survey questions were structured according to Section 3.6 of this document, which outlines 28 Basic Learning Outcomes grouped under five competency categories: (1) understanding what BIM is and why it is necessary, including its terminology; (2) recognizing the benefits of BIM over traditional project delivery; (3) understanding the project information development cycle and related key terms; (4) acknowledging the need for open and interoperable solutions; and (5) assessing an organization's capacity to work with BIM. While the survey questions are structured according to these categories, they do not entirely encompass the full scope of their content.

The primary goal of the survey was to determine whether professionals actively engaged in BIM-related roles possess a basic level of conceptual knowledge as defined by buildingSMART. The survey also sought to reveal whether there is a need for further structured, knowledge-based education in Türkiye. While the survey addresses fundamental concepts, it may contain content that exceeds the expected expertise of individuals who have never received formal BIM education or participated in structured BIM processes.

Due to limitations caused by the COVID-19 pandemic, the survey was distributed in digital form via Google Forms to facilitate participation. The link was sent through email, and follow-up reminders were issued at 10-day intervals for non-respondents. The final version of the questionnaire consisted of 20 multiple-choice questions, each with a single correct answer, mirroring the structure of buildingSMART's actual certification exam (Table 1). In addition, two open-ended questions were included: one to gather participants' views on the value of theoretical BIM education, and the other to collect their suggestions. To obtain a realistic measure of BIM knowledge within the industry, the survey specifically targeted construction professionals who have experience with at least one BIM project. Participants were selected from individuals holding the roles of BIM Manager or BIM Operator, which are among the most essential positions within BIM teams. According to Baldwin (2021), BIM Managers oversee internal BIM teams, supervise CAD/BIM processes, ensure project compliance with the BIM Execution Plan (BEP), lead quality control, and coordinate among disciplines. BIM Operators are responsible for producing and managing model data, performing analyses and documentation, and supporting coordination and reporting tasks.

To achieve a balanced dataset, the sample was designed to reflect a 1:2 ratio of BIM Managers to BIM Operators, representing a typical BIM team structure consisting of one manager and two operators. In consideration of the limited extent of BIM adoption in Türkiye, the survey was sent to a total of 90 professionals. Ultimately, 40 valid responses were collected. Among the respondents, 12 (30%) identified as BIM Managers and 28 (70%) as BIM Operators. While gender distribution data was collected (12 BIM Managers: 7 male, 5 female; 28 BIM Operators: 14 male, 14 female), this was not used in the analysis, as gender was not within the scope of the research objectives.

Table 1. Survey Questions

No	Question
Q01	Which of the following is not one of the primary factors promoting the use of BIM?
Q02	Which of the following is not covered by the BS 1192 standard, which is described as a Code of Practice?
Q03	Which of the following is the full form of the term EIR?
Q04	Which of the following is not one of the components of an EIR?
Q05	The sharing of information produced by organizations in a structured format—based on agreed standards, methods, and procedures—with project teams through a Common Data Environment (CDE) is considered to fall under which level of BIM Maturity?
Q06	Which of the following is the BIM Maturity Level that was mandated by the government in the UK in 2016?
Q07	In project processes, which of the following must the Appointing Party determine first?
Q08	At which stage within project processes is it recommended to establish the Common Data Environment (CDE) in organizations?
Q09	Which of the following is not one of the sub-information areas of the Common Data Environment (CDE)?
Q10	Which of the following is not considered part of the openBIM category?
Q11	Which of the following standards focuses on the use of assets in operational processes within BIM workflows?
Q12	Which of the following cannot be given as an example of the benefits of BIM adoption?
Q13	Which of the following is not one of the main challenges in BIM adoption?
Q14	Which of the following best describes the concept of openBIM?
Q15	Which of the following is not true about buildingSMART?
Q16	Which of the following is the plan that explains how the information management aspects of appointments will be carried out by the delivery team in response to the EIR requirements?
Q17	Which of the following is not a part of an information model?
Q18	Which of the following is the name given to the information model during project delivery processes?
Q19	Which of the following is the guideline primarily used by advanced technical users or software developers, defined as a methodology for identifying and documenting business processes and information requirements—that is, standard BIM activities?
Q20	Issues related to spatial coordination, site inspections, or clashes that arise can be easily communicated using which of the following, instead of a long email chain?
Q21	Have you received any conceptual training on the theories, standards, and protocols related to BIM? Do you consider such training necessary? Why?
Q22	Other comments and suggestions

3. Results and Discussion

The survey identifies the topics that are lacking or not well understood in the industry by individually evaluating the 20 multiple-choice questions designed to measure the general level of BIM knowledge among participants (Table 2).

Most BIM Operators have 1–5 years of experience. The majority of BIM Managers, on the other hand, have 4–5 years of experience. These durations reflect the participants' working time under the specified titles. It was found that 80% of the participants had previously received some form of BIM education. In response to the open-ended question about the type of training, most participants cited graduate-level programs, individual certification programs, and in-house training. Undergraduate-level education appeared to be the least common.

When evaluating the responses of all participants, the overall average success rate remained around 50% and did not exceed the average threshold. For the 12 participants with the title of BIM Manager, the average success rate was determined to be 57.9%. For those with the title of BIM Operator, the average success rate was 47%.

As part of determining and evaluating the success rates of the survey questions, the success rates of all 20 multiple-choice questions designed to assess BIM knowledge were examined in the graph presented in Fig. 1. As shown in the graph, 10 of the survey questions (marked in green: questions 1, 4, 6, 7, 9, 14, 15, 17, 18, and 20) were answered correctly by 50% or more of the participants. The remaining 10 questions, however, fell below the 50% success threshold, which is considered the average level of BIM proficiency for the Turkish construction industry (marked in red: questions 2, 3, 5, 10, 11, 12, 13, 16, and 19).

Following the evaluation of all survey questions, the distribution of success rates between participants with the titles of BIM Operator and BIM Manager was also examined in detail. The two resulting graphs (Fig. 2 and Fig. 3) indicate that the overall average was slightly lower by the responses of participants in the BIM Operator role.

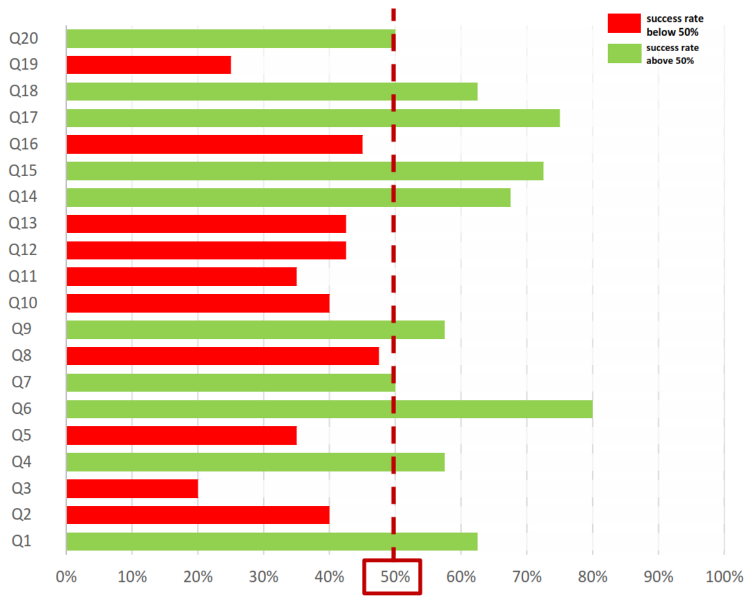

Fig. 1. Correct response rate for the survey questions

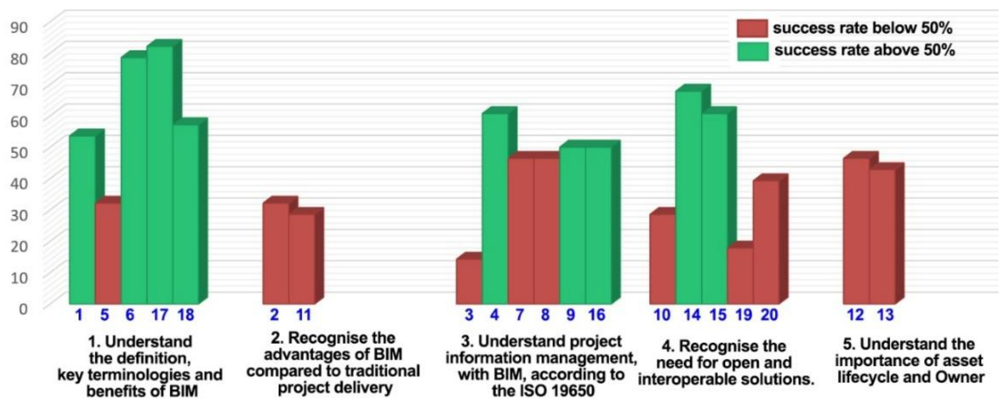

Fig. 2. Graph showing the success rates of survey questions among participants with the role of BIM Operators

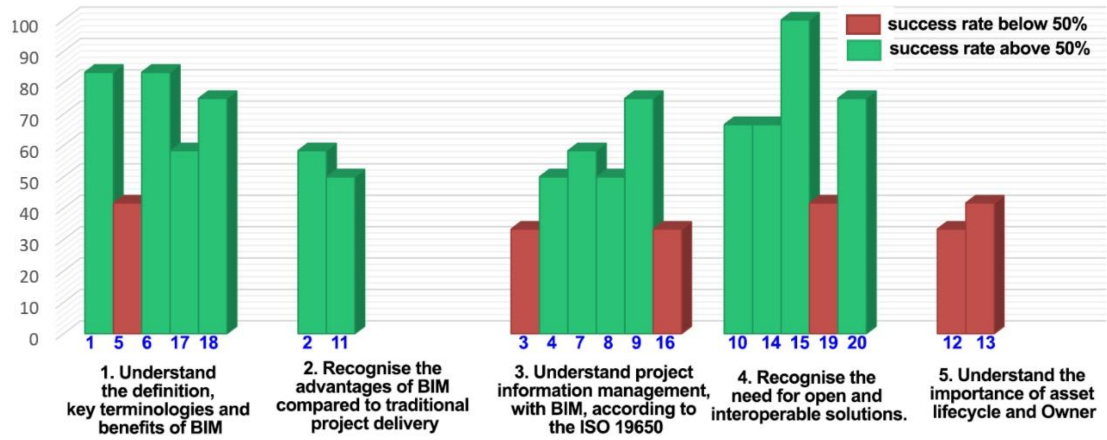

Fig. 3. Graph showing the success rates of survey questions among participants with the role of BIM Managers

3.1. Survey results by topics

When all the collected data is examined, it is observed that the questions with a success rate above 50% fall under the following topics: drivers of the BIM concept, Exchange Information Requirements (EIR), BIM Maturity Levels, Common Data Environment (CDE), openBIM, buildingSMART, Information Model, Project Information Model (PIM), and BIM Collaboration Format (BCF).

The topics that fell below the 50% success rate were identified as follows: BIM Standards, Exchange Information Requirements (EIR), BIM Maturity Levels, Common Data Environment (CDE), openBIM, Benefits and Challenges of BIM Implementation, BIM Execution Plan (BEP), and Information Delivery Manual (IDM).

Among all the collected data, it was observed that four topics appear both among those with a success rate above 50% and among those below 50%. These topics are: Exchange Information Requirements (EIR), BIM Maturity Levels, Common Data Environment (CDE), and openBIM. This indicates that participants do not demonstrate full competency in these areas, yet the topics also cannot be classified as clearly lacking. These four ambiguous areas should be treated with the same level of importance as those below the 50% success threshold and should be addressed further.

Considering these findings, it becomes evident that BIM lacks conceptual clarity in various processes where it is applied within the industry. While the existence of knowledge is reflected in success rates close to the average, the evaluation of participants' understanding based on the Basic Learning Outcomes reveals notable deficiencies. These shortcomings can be attributed to factors such as misinterpretation of terminology, lack of awareness of up-to-date information, and a practice-oriented approach focused solely on problem-solving during implementation phases.

In light of these issues, identifying the deficient areas—whether in academic institutions or within firms—and developing theory-based BIM training programs tailored to those needs would help address the gaps in current educational systems. The wide range of educational sources, such as academic programs, certifications, and software training, which professionals rely on to build their competencies, may be contributing to conceptual confusion within the industry. Therefore, defining BIM terminology and its theoretical foundation, and offering a structured conceptual BIM education to the industry is essential. The knowledge gaps revealed through the survey and the feedback provided by professionals from the Turkish construction industry strongly support this need.

As with any discipline, the most effective way to learn and apply knowledge in the field of BIM is not through superficial solutions but through a solid conceptual foundation. A theory-based BIM education is one of the essential building blocks for constructing such a foundation.

3.2. The value of theoretical bim education through the review of the open-ended question

Out of the 40 professionals who participated in the survey, 35 responses supported the necessity of a conceptual BIM education, with several participants stating that this survey helped them recognize their own knowledge gaps and emphasized the importance of conceptual training, which is considered one of the positive outcomes of the study. Among all comments, only one participant stated that they had not received any conceptual BIM training and did not find it necessary. Although personal details were not disclosed, it was noted that this participant had previously received BIM training, had over five years of experience working as a BIM Operator, and provided responses at around the average level. In four responses, participants chose not to answer this specific question. These individuals' overall survey scores were either average or below average.

Participants responded to the final open-ended qualitative question, which asked: "Have you received any conceptual education regarding the theories, standards, and protocols related to BIM? Do you think such training is necessary? Why?"

Upon reviewing the responses, it was observed that the comments clustered around certain themes. These themes, insights, and participant opinions were analyzed by grouping respondents into two categories: those who had previously received BIM training and those who had not. Among participants who had not received any prior BIM education, the most frequently mentioned issue was the existence of conceptual confusion regarding BIM within the industry. These participants expressed the view that a theory-based BIM education is necessary in order to resolve this confusion.

- *"BIM does not only mean modeling. One must also learn its underlying structure and processes."*
- *"I believe training is necessary to eliminate conceptual confusion."*
- *"... such training is necessary. Otherwise, it's hard to understand why a large amount of information needs to be integrated into the model."*

Based on the comments provided by the participants, it is apparent that a theory-based BIM education is considered beneficial for understanding standards. A few of the relevant comments received in this regard are listed below:

- *"I believe receiving such training would be beneficial for understanding BIM within the framework of standards and protocols."*
- *"I have not received a qualified education regarding theory, standards, and protocols. I have only participated in general informative sessions. Confronted with the survey questions, I realized how much I lacked knowledge and how necessary such training is."*
- *"While working on a project that follows BIM standards, I believe it is essential to be familiar with the standards and protocols in order for the process to run smoothly. In this regard, receiving such training would have been valuable."*

At this point, the inclusion of standards as a core topic in a theory-based BIM education is supported as a factor that would have a positive impact. Participant feedback also suggests that a theory-based BIM education would be beneficial for promoting the use of BIM within the framework of interoperability, enhancing its applicability, and improving its management.

- *"I believe such training is necessary for professional BIM use and coordination."*
- *"I haven't received conceptual training, but I see it as essential. This way, the logic behind the work can be understood, and a common language can be established among collaborators."*
- *"Since conceptual training forms the basis of communication, it is essential for a healthy and clear data exchange."*
- *"I haven't received any conceptual training. I think it's necessary in order to better understand BIM-related resources and to apply them in projects. It will also accelerate BIM processes."*
- *"... I believe BIM theory should be gradually and accessibly integrated into the industry. Especially since the benefits gained from practice give more meaning to its theory, I think a balanced adaptation process is needed."*

Among the participant comments, there are also remarks indicating that this study has raised awareness regarding the need for a theory-based BIM education. Some of these comments include:

- *"I struggled a lot while answering the questions. I haven't received training on these kinds of conceptual topics, but I now realize there's so much I didn't know."*
- *"Through this study, I realized that I need to receive such training."*
- *"... I haven't received any training. However, after completing this survey you prepared, I've come to understand that such education is essential. ... Simply knowing a few software programs is not enough to be part of the BIM system. Just as a building needs a foundation, regulations and theoretical knowledge are the foundation of every system."*

When examining the responses from participants who had previously received BIM training, it is observed that topics related to BIM processes, workflows, and the management of these processes come to the forefront.

- *"It is necessary to receive training; BIM processes and management are a form of project and process management independent of software tools."*
- *"In order to properly understand and manage BIM processes, all project stakeholders must have knowledge of its theory, standards, and protocols. This knowledge can be acquired through training."*
- *"Since both the concepts and workflow models are very new to most professionals in the field, I absolutely believe that training is necessary."*

Another point on which the comments from participants who had previously received BIM training tend to cluster is sectoral needs, goals, and expectations. Within this context, some participants expressed the belief that the goals to be determined for the industry can be achieved through proper training.

- *"I believe that training will lead to more informed, more economical, and more efficient construction processes."*
- *"Yes, I consider training necessary. If the concepts are not well understood, I don't think BIM implementations can reach a level that meets goals and expectations."*
- *"I have mostly received technical training, but I also believe conceptual training is necessary. I think it's essential to understand the concepts and standards in order to properly define the needs."*

4. Conclusions

This study has confirmed that Building Information Modeling (BIM) is not only a technological shift but also a transformative process that necessitates the redefinition of education within the construction industry. A key argument throughout the research is that without proper training, particularly at the conceptual level, the full potential of BIM cannot be realized. An in-depth examination of both international and national BIM education programs, alongside a detailed analysis of existing standards such as BS-PAS 1192 and ISO 19650, has revealed substantial gaps in the theoretical content currently being delivered. Topics such as BIM Maturity Levels, Exchange Information Requirements (EIR), Common Data Environment (CDE), openBIM, and the BIM Execution Plan (BEP) were consistently underrepresented in existing curricula, despite being critical for effective BIM implementation.

Using the buildingSMART Professional Certification's Basic Learning Outcomes as a reference, a structured survey was developed and administered to 40 professionals working as BIM Operators and BIM Managers in the Turkish construction industry. The results revealed that most participants were unable to achieve a success rate above 50% on key conceptual questions, and the feedback clearly indicated a demand for structured, theoretical BIM training. Notably, many professionals acknowledged through the survey that they had previously underestimated the importance of conceptual education, and realized their own knowledge gaps during participation. The comments collected from industry professionals, who acknowledged the survey as a turning point in recognizing their educational needs, add further weight to the study's conclusions.

The findings of this research strongly support the urgent need to integrate theory-based BIM education, either as part of postgraduate programs or through professional training offered by certified institutions and continuous education centers. Furthermore, the study emphasizes the importance of qualified instructors who can act not only as knowledge providers but also as facilitators of critical thinking and project-based learning.

In summary, the research demonstrates that a comprehensive, conceptual BIM education is not only necessary but vital for advancing BIM integration in the Turkish construction industry. The study provides a foundational reference for future curriculum development and highlights the importance of early and strategic investment in theoretical BIM literacy as a key driver for industry-wide digital transformation.

Reframing circulation as a learning space: Non-Formal learning in the architecture schools of TU Delft and Cornell

Nurdan Sezgin Toruk *[1,2], Kunter Manisa[1]

[2] *İstanbul Ticaret University, Department of Architecture,34840, İstanbul, Türkiye*

Abstract. This paper investigates the pedagogical potential of circulation spaces in architecture schools, proposing their reinterpretation as non-formal learning environments. Drawing on the tripartite classification of learning—formal, non-formal, and informal—it highlights how spatially and socially permeable environments can support self-directed, collaborative, and situated learning beyond the formal studio. The study emphasizes that circulation areas—such as corridors, atriums, and transitional spaces—can become integral to architectural education when designed or appropriated with pedagogical intent.Using a qualitative comparative case study methodology, the research analyzes two architectural education environments: the Faculty of Architecture at TU Delft and Cornell University's College of Architecture, Art, and Planning (AAP). These cases are examined through five key spatial criteria: visual openness, programmatic integration, social interaction potential, flexibility of use, and the balance between design intent and emergent behavior.Findings reveal that in both cases, circulation spaces transcend their conventional role as functional connectors. At TU Delft, the post-fire transformation of the Red Building led to the emergence of a "street" concept supporting collective production and exhibition. At Cornell, Milstein Hall's elevated and transparent studio slab integrates informal presentation platforms and spatial overlaps that foster peer-to-peer learning.The study argues that reframing circulation areas as pedagogically active zones enables a more inclusive, dynamic, and responsive learning ecosystem. It contributes a conceptual framework for integrating non-formal learning into architectural design education and offers strategic insights for future spatial planning in academic environments.

Keywords: learning environments; learning space; architecture education; non-formal learning; transitional space.

1. Introduction

In recent years, universities have been increasingly transforming into multidimensional learning environments that go beyond the traditional classroom. While formal educational activities remain central to curricula, a growing body of research highlights the role of non-formal and informal learning processes in fostering creativity, peer interaction and interdisciplinary engagement. Within this broader educational ecosystem, circulation spaces, including corridors, atriums, transit halls and connecting passageways, represent an often overlooked, yet spatially and socially significant category of spatial infrastructure.

Defined by their transitional function, circulation spaces are typically conceived to ensure the movement of people and the connection of programs. However, recent discussions in architectural pedagogy and learning space theory suggest that these in-between spaces may also foster meaningful forms of non-formal learning. They offer opportunities for spontaneous dialogue, informal collaboration, cross-disciplinary encounters, and unplanned moments of reflection—all essential to the formation of architectural thinking and community.

Despite their potential, circulation areas in educational buildings are rarely designed with pedagogical intent. As a result, their spatial configurations often fail to support the kinds of informal and semi-structured learning that contemporary educational models increasingly value. This paper seeks to address this gap by examining the educational role of circulation spaces in architecture schools, particularly in relation to non-formal learning environments—defined as learning contexts that are structured but not part of the formal curriculum, and that occur outside of traditional classroom settings.

The aim of this study is twofold: first, to synthesize the existing literature on circulation spaces and non-formal learning in architectural education; second, to present a comparative spatial reading of two prominent architecture schools—the Faculty of Architecture at Delft University of Technology (TU Delft) and Milstein Hall at Cornell

golden light publishing

University. Through this analysis, the paper discusses how circulation areas may be intentionally designed or reinterpreted as pedagogical tools that contribute to the learning ecosystem of architecture schools.

2. Theoretical Framework & Literature Review

2.1. Learning Spaces in Higher Education

Recent shifts in pedagogical paradigms emphasize the spatial dimension of learning, drawing attention to environments beyond the formal classroom. The tripartite classification of learning—formal, non-formal, and informal—has become instrumental in analyzing the diversity of educational settings. According to the OECD, formal learning is institutionally organized, curriculum-bound, and typically leads to certification(OECD, 2004). Non-formal learning occurs outside this framework but is still intentional and structured, while informal learning is unplanned, often arising through social interaction or environmental immersion. Colley et al., further assert that these categories exist along a continuum rather than as discrete types, and that overlapping characteristics often emerge in practice (Colley et al., 2003).

In the context of higher education, non-formal learning spaces have gained recognition for supporting student autonomy, interdisciplinary interaction, and peer-based knowledge construction (Ellis & Goodyear, 2016). Such environments allow for reflection, dialogue, and experimentation—key dimensions of deep learning (Brown et al., 2020). Architecture schools, with their emphasis on iterative design processes, critique culture, and studio-based pedagogy, particularly benefit from spaces that accommodate spontaneous and collaborative learning.

The shift toward "seamless learning environments"(Kuh, 1996), where learning transcends spatial and temporal boundaries, challenges educators and designers to reconsider the pedagogical role of transitional and informal spaces within university settings.

2.2 Circulation and In-Between Spaces in Architecture

From an architectural perspective, circulation spaces—including corridors, stairwells, atriums, and landings—have traditionally been seen as functional connectors rather than pedagogical domains. However, architectural theory has long interrogated the liminality and symbolic potency of such "in-between" or "threshold" spaces. Wigley and Tschumi frame these zones as spatial conditions that defy binary classifications of inside/outside, public/private, or static/dynamic. These interstitial spaces often embody openness, ambiguity, and social permeability—qualities that align with contemporary pedagogical values such as adaptability, participation, and serendipity. (Wigley, 1991) (Tschumi, 1996)

In the context of learning environments, these spaces support learning outside the confines of formal education and provide opportunities for informal encounters, interdisciplinary dialogue and reflective pause (Harrison & Hutton, 2014). Yet, despite their potential, they often remain under-conceptualized within institutional design strategies.

2.3 Rethinking In-Between Spaces as Non-Formal Learning Environments

While non-formal learning spaces and in-between spaces originate from distinct disciplinary vocabularies—educational theory and architectural theory, respectively—they exhibit substantial thematic convergence. Both prioritize flexibility, openness, and social interaction, and both are situated outside the formal curriculum or programmatic structure. The principal difference lies in intentionality: non-formal learning spaces are increasingly designed to support learning, while in-between spaces often emerge as by-products of circulation or zoning requirements.

Recent literature suggests that these spatial categories need not remain separate. Harrison & Hutton, argue that educational institutions should "design for serendipity" by enabling informal interaction and co-presence through spatial affordances (Harrison & Hutton, 2014),. Temple, similarly posits that transitional spaces can act as pedagogical instruments if designed to foster engagement and belonging (Temple, 2008).

This paper builds on these perspectives by proposing that circulation areas—often conceptualized as threshold or in-between zones—can be reframed as non-formal learning environments when designed or interpreted with pedagogical intent. By comparing two architectural school buildings—TU Delft and Cornell—this study aims to uncover how such reframing may occur spatially and what design principles underpin these transformations.

Figures and tables must be placed centered on the page, closest to where they are first mentioned. Do not put the figures and tables between the two paragraphs. They must be put top or bottom of the page separated from the text.

3. Methodology & Case Selection

This study adopts a qualitative comparative case study methodology to investigate how circulation spaces in architecture schools function as non-formal learning spaces. Based on a spatial-pedagogical framework, the research aims to analyze not only the physical characteristics of these spaces, but also their designed affordances, social behavior and educational outcomes in the context of architectural education.

Case selection was based on pedagogical relevance, architectural distinction, and spatial comparability. Analytical criteria included spatial openness, social interaction potential, programmatic integration, design intent vs. emergent use, and pedagogical typology (formal, non-formal, informal).

While the lack of ethnographic fieldwork is a limitation, spatial-pedagogical interpretation allows for rich conceptual insights, forming the foundation for future field-based researchs.

4. Findings & Comparative Analysis

Circulation spaces in architecture schools are increasingly recognized not merely as connective infrastructure, but as potential sites of pedagogical activation. The spatial strategies employed by TU Delft and Cornell AAP illustrate two distinct yet complementary approaches to integrating non-formal learning into the architectural fabric of their institutions.

At TU Delft, the post-crisis renovation of the Red Building gave rise to a central "street" that reconfigures circulation as an active spatial spine. This corridor not only facilitates movement but also orchestrates social encounters, collaborative production, and exhibition. The integration of workshop zones, lounge areas, and informal seating along the street allows learning to emerge in a layered and unprogrammed manner.

In contrast, Cornell's Milstein Hall, designed by OMA, demonstrates a highly intentional insertion of learning-supportive functions into circulation. The cantilevered studio slab, with embedded informal presentation platforms and visual permeability, reflects a design agenda that seeks to expose and spatialize the act of learning itself. Circulation is not peripheral, but central to the performance of pedagogy.

Together, these cases highlight how circulation spaces—through varying degrees of planning and appropriation—can be transformed into non-formal learning environments. While TU Delft reflects an emergent, adaptive strategy, Cornell exemplifies deliberate pedagogical programming. The following sections examine each case in detail, unpacking their spatial logics, institutional histories, and architectural affordances.

4.1 Case Study: Faculty of Architecture, Delft University of Technology

The Faculty of Architecture at Delft University of Technology (TU Delft) holds a distinguished position within the global landscape of architectural education. Recognized for its excellence in design-based pedagogy, the faculty has historically occupied prominent architectural spaces that both reflect and reinforce its academic identity. Since 2009, the faculty has been located in a striking red-brick building on campus which was reappropriated following a catastrophic fire in 2008. The original faculty building was the result of an internal design competition in 1956, won by Van den Broek and Jaap Bakema, who were also the architects of the university's emblematic auditorium. Completed in 1970, the building exemplified the integration of modernist functionalism with educational programming. Constructed primarily in concrete, the structure reflected a clear hierarchy: the lower levels housed shared functions such as the library, administration, canteen, and workshops, while the upper floors were vertically segmented by academic year, with each studio level tailored to the pedagogical needs of specific phases of architectural training. At the spatial core of the building was a central hall, where the low-rise communal base intersected with the vertical studio tower. This hall functioned as a dynamic and flexible meeting ground, promoting visual and spatial continuity. Open to its surroundings and designed to accommodate multiple activities, it served as a key non-formal learning space within the institutional structure.

In May 2008, a fire devastated the original faculty building, prompting an urgent need for relocation. The university decided to renovate a former Faculty of Chemistry building—previously sold to a private developer—and transform it into a new home for the architecture school. This decision mobilized a consortium of architectural firms, including Braaksma & Roos, Fokkema Architects, MVRDV, and others, who collaborated over five years to create a temporarily permanent environment supportive of studio-based education.

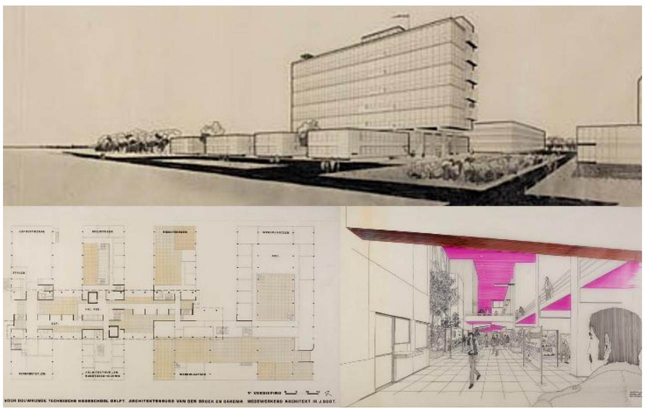

Fig. 1. Drawings of the first Delft TU Faculty of Architecture Building, 1956(NAI, 2008)

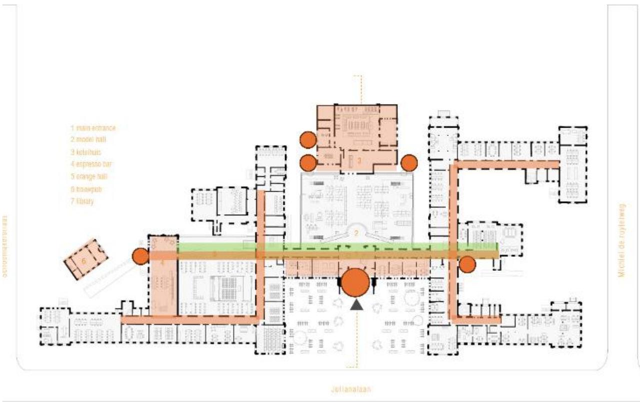

Fig. 2. Relationship analysis of intermediate spaces (Braaksma-Roos, n.d.), Edited by: N. Sezgin

Braaksma & Roos led the architectural coordination, Fokkema oversaw interior design and programming, while Octatube engineered new glazed extensions. The collaborative process emphasized speed, adaptability, and spatial continuity, all of which were essential to restoring the pedagogical rhythm of the school.

A defining element of the adaptive reuse was the incorporation of a "street" concept, inspired by urban morphology. Functioning as the primary circulation spine, this long internal corridor unified various public and semi-public functions, including the print lab, library, café bar, and restaurant, alongside open studios and instructional spaces. The spatial logic echoed that of a city's main thoroughfare, organizing attraction points and enabling spontaneous encounters between students and faculty.

In this configuration, the corridor transcended its role as a mere circulation route and became a social and pedagogical core of the faculty. It connected two enclosed courtyards that acted as internal plazas, further reinforcing the building's role as a site of interaction, appropriation, and informal learning.

4.2 Case Study: Cornell University College of Architecture, Art, and Planning (AAP)

Cornell University AAP is located in the Arts Quad on campus in Ithaca, and consists of Sibley Hall, Rand Hall, and Milstein Hall. These buildings reflect the evolving academic vision of the institution, from 19th century.

Sibley Hall, constructed in three phases between 1870 and 1902, anchors the AAP within the university's central academic zone (*Sibley Hall | Cornell University Veterans Memorials*, n.d.). Adjacent to it, Rand Hall, designed by Gibb & Waltz and completed in 1911, initially served the College of Mechanical Engineering. Over time, it was repurposed as a space for architectural workshops, fabrication labs, and, most recently, the Mui Ho Fine Arts Library, reopened in 2019 following a major renovation. This transformation included the creation of a four-story vertical book stack and a reconfiguration of the ground level into a materials fabrication center housing digital production labs, wood and metal shops, and maker spaces.

In 2001, Cornell launched an invited architectural competition for a new building for the Department of Architecture that would not only meet programmatic expenses but also facilitate a vision of an integrated and integrated architectural education.The shortlisted entries were Steven Holl Architects, Peter Zumthor, Morphosis, and OMA. Though Steven Holl initially won the competition, the project was not realized. (Steven Holl Architects, n.d.)

Fig. 3. Cornell University AAP (Astbury, 2015), Edited by: N. Sezgin

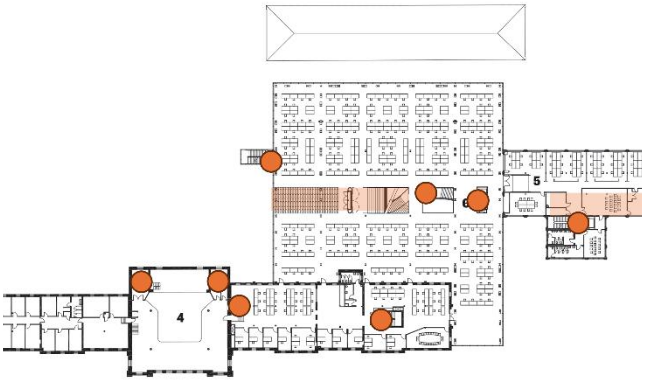

Fig. 4. L.P. Kwee Studios at Milstein Hall (Astbury, 2015), Edited by: N. Sezgin

Completed in 2011, Milstein Hall exemplifies OMA's critical approach to site, history, and program. Rather than demolishing existing structures, OMA inserted Milstein as a mediating volume, weaving together Sibley and Rand Halls without erasing their identities. This act of connection and juxtaposition enabled both architectural contrast and academic continuity.

The building adds approximately 4,400 square meters to the college, with a prominent cantilevered upper level that bridges Sibley and Rand Halls. The second floor houses an expansive studio plate—characterized by a flat, open, and flexible layout—featuring floor-to-ceiling glass façades, 41 skylights, and multiple informal presentation zones centrally embedded within the plan. These areas, equipped with folding partitions and LCD screens, function as non-formal learning environments where peer critique, exhibition, and spontaneous review sessions occur without rigid scheduling.

The studio floor floats above a transparent ground level, supported by slender columns and activated as a circulation and gathering space. This level includes student lounges, gallery zones, and transition areas that operate as thresholds between formal instruction and informal engagement. The architectural articulation of movement—ramping connections, visual transparency, and continuous floor plates—enhances permeability and promotes chance encounters between users from different academic years and disciplines.

Moreover, Milstein's insertion above the University Avenue pedestrian pathway physically and symbolically elevates the architectural program, bridging not only buildings but also ideas and communities. The deliberate visibility of students working inside the glass volume reinforces a culture of openness and learning-as-performance, where the built environment itself becomes an educational medium.

Milstein Hall exemplifies how circulation space can function as pedagogical infrastructure. Rather than relegating movement to the periphery, the project frames circulation as the organizing logic of educational life—a spatial structure that enables collaboration, transition, and reflection. As such, it aligns closely with the theoretical framework discussed earlier, wherein in-between spaces are reimagined as intentional non-formal learning settings. Milstein Hall, in this light, is not merely a connective tissue between historic volumes but a deliberate act of spatial pedagogy—an architectural gesture that embodies the epistemological openness of design education.

4.3 Comparative Spatial Dimensions

The comparative analysis of TU Delft and Cornell AAP reveals distinct spatial strategies that inform how circulation areas are conceptualized and activated as non-formal learning environments. Table 1 outlines six key dimensions. Each reflects varying degrees of design intentionality, user appropriation, and pedagogical alignment.

Table 1. A structured comparison reveals the following key dimensions across both institutions:

Spatial Dimension	TU Delft	Cornell AAP
Circulation as Spine	Central "street" serves as a linear yet permeable connector, linking workshops, cafés, studios.	Cantilevered studio slab bridges buildings; circulation overlaps with programmatic flows.
Visual Transparency	Partial transparency allows glimpses into adjacent spaces, fostering passive observation.	Studio features floor-to-ceiling glazing and skylights, enabling full visual permeability.
Programmatic Integration	Embedded cafés, gallery surfaces, and workshops enhance the corridor's multifunctionality.	Informal review platforms and exhibition areas are directly structured within the studio layout.

Table 1 continued. A structured comparison reveals the following key dimensions across both institutions:

Spatial Dimension	TU Delft	Cornell AAP
Pedagogical Intent	A mix of planned and emergent use; some zones explicitly pedagogical, others appropriated.	High degree of intentionality; non-formal learning is embedded from the outset.
Encounter & Exchange	"Street" encourages unplanned meetings at nodes of overlap; atriums serve as social hubs.	Intersections, visual links, and transitional zones enable peer dialogue and public engagement.
Urban & Campus Interface	Deep integration with the intellectual and spatial identity of Delft's civic fabric.	Milstein bridges historic buildings and the broader campus, symbolizing openness and connection.

4.4 Categorization by Learning Type

The typology of formal, non-formal, and informal learning offers a conceptual lens to evaluate how architectural space supports different modes of education. The examples observed at TU Delft and Cornell AAP reflect a layered spatial ecosystem, where multiple learning modes co-exist, overlap, and transition dynamically.

Table 2. Typology of Use: Formal – Non-formal – Informal

Learning Type	TU Delft Example	Cornell AAP Example
Formal	Studio levels within structured pedagogy; classrooms for theoretical teaching..	Open plan studios and classrooms for theoretical teaching within structured pedagogy.
Non-formal	"Orange Room", model workshop, and integrated display panels along circulation spine.	Informal presentation platforms and basement exhibition spaces embedded in studio fabric.
Informal	Cafés and casual seating spaces; threshold-based interactions.	Comfortable seating spaces and transitional nodes between the new structure and the existing ones.

This triadic framework illustrates a continuum of spatial pedagogies—from rigidly programmed instruction to spontaneous co-learning. Notably, the same space may oscillate between categories depending on use: a gallery wall may support both scheduled critiques and impromptu peer feedback.

By embedding non-formal and informal opportunities into circulation, both schools create learning-rich environments where education is not confined to assigned times and places, but rather enacted across space through presence, interaction, and appropriation.

5. Findings & Comparative Analysis

The spatial case studies of TU Delft and Cornell AAP demonstrate how circulation areas—often conceived as secondary or transitional zones—can be actively engaged as non-formal learning environments when pedagogically reframed or spatially appropriated. While both institutions exhibit design strategies that support learning beyond the classroom, they do so through differing formal expressions, levels of intentionality, and degrees of integration with academic culture.

5.1 Spatial Logic and Pedagogical Intent

At TU Delft, the transformation of the post-fire Red Building into a porous and socially active structure led to the emergence of a central "street," which acts not only as a circulation spine but also as a host of overlapping activities. Some functions—such as the model workshop and Orange Room—were deliberately placed along this spine to support informal review, making, and collaborative work. These zones align with non-formal learning typologies, in which learning is semi-programmed and occurs adjacent to, but outside, the formal curriculum (Colley et al., 2003).

Conversely, at Cornell, Milstein Hall's architectural intent explicitly prioritizes flexible, open-ended learning. The open-plan studio, integrated informal presentation platforms, and exhibition areas reflect an embedded pedagogical strategy to make design learning visible, collective, and situated in space. Circulation here is not simply a means of movement but an architectural act of pedagogical framing (Ellis & Goodyear, 2016).

5.2 Circulation as Pedagogical Infrastructure

In both cases, circulation spaces are not neutral voids but activated volumes. As previously shown in Table 2, these spatial typologies illustrate the spectrum between formal instruction and emergent learning. At TU Delft, the linear corridor facilitates programmed and unprogrammed uses: students move, pause, meet, work, and reflect. The integration of display zones and collaborative working spaces supports a culture of production and feedback.

In Milstein Hall, circulation is vertically layered and programmatically rich. Students encounter each other across multiple axes—visual, spatial, and functional. This complexity encourages inter-year visibility, interdisciplinary exposure, and spatial serendipity. The design strategy aligns with Kuh's call for "seamless learning environments", where spatial transitions support educational continuity (Kuh, 1996). These findings align with Ellis and Goodyear's concept of "relational learning ecologies," where space, interaction, and pedagogy are co-constitutive. In both schools, the boundary between movement and learning is deliberately blurred, allowing circulation to serve as a dynamic infrastructure for informal critique, observation, and reflection.(Ellis & Goodyear, 2016)

5.3 Social Interaction and Encounter Design

Both institutions reveal an architectural emphasis on encounter. TU Delft's "street" functions as a social condenser, integrating academic, administrative, and leisure spaces. Its intersections, visual axes, and spatial adjacencies are designed to support spontaneous exchange.

Milstein Hall leverages its elevated structure and transparency to maximize visibility and proximity. Peer interaction is embedded in the floorplate. The building's design fosters a performative culture of learning, where critique, dialogue, and observation happen in motion—through the space, not around it.

A key distinction lies in the balance between design intent and emergent use. Cornell's configuration stems from a high level of premeditated spatial programming, whereas TU Delft's reuse strategy enabled user-driven adaptation over time. This divergence illustrates two pedagogical paradigms: one that anticipates learning behavior through spatial planning, and one that invites it through open-ended affordances.

Understanding this spectrum is critical to evaluating how spatial agency and pedagogical strategy intersect in design education. Both approaches demonstrate that learning does not solely depend on content delivery, but also on how space enables participation, co-presence, and appropriation.

5.4 Toward Circulation as Pedagogical Infrastructure

Rather than serving as passive backdrops, circulation areas in both cases operate as pedagogically charged terrains. They accommodate formal movement while simultaneously nurturing informal interaction and cognitive extension. Whether shaped through design (Cornell) or shaped by use (TU Delft), these environments demonstrate the potential of circulation to function as infrastructure for deep, distributed learning.

This reconceptualization challenges educators and designers to move beyond the dichotomy of programmed vs. unprogrammed space, and toward a hybrid model that integrates physical flow with epistemic openness.

Circulation in architecture schools is never neutral. It is designed, perceived, negotiated, and inhabited. When intentionally shaped or creatively appropriated, these transitional zones can become pedagogical agents—supporting the informal rhythms, peer-based culture, and spatial freedom that characterize contemporary design education.

6. Discussion

The findings of this study reveal that circulation spaces—traditionally perceived as neutral infrastructural elements—hold substantial potential to function as non-formal learning environments, particularly within schools of architecture where spatial engagement is both the object and medium of education. The comparative cases of TU Delft and Cornell AAP demonstrate that the design, adaptation, and occupation of circulation zones can profoundly influence learning behaviors, peer interaction, and the pedagogical culture of institutions.

6.1 From Threshold to Learning Space: Expanding the Definition

In architectural discourse, in-between and threshold spaces have often been discussed in symbolic or theoretical terms—zones of ambiguity, transition, or resistance (Tschumi, 1996; Wigley, 1991)(Wigley, 1991; Tschumi, 1996). This study extends that discourse by examining how such spaces may evolve into intentional or emergent sites of learning. When circulation areas are spatially open, socially permeable, and programmatically flexible, they become fertile ground for peer exchange, critique, and experimentation—hallmarks of architectural pedagogy.

As Ellis & Goodyear argue, learning environments must be understood not as passive containers but as relational ecologies, where space, people, and pedagogy intersect. The cases analyzed here confirm this view: circulation is not only a backdrop to education but a co-producing agent, mediating between formal and informal, planned and improvised learning encounters. (Ellis & Goodyear, 2016)

6.2 Non-Formal Learning as Spatial Practice

While formal education is structured around defined curricula and time-bound activities, non-formal learning emerges in the interstices—between classes, across studio discussions, in informal reviews, and during spontaneous meetings. The physical support of such learning relies on spatial conditions that afford choice, visibility, adaptability, and comfort.

At TU Delft, the "street" concept illustrates how a retrofitted space, originally not designed for educational purposes, can be appropriated by users to foster a collaborative and iterative culture. At Cornell, OMA's design of Milstein Hall embeds non-formal affordances into the architecture from the outset—platforms, open floors, and visual connections that support spontaneous teaching moments and co-presence.

This comparison highlights an essential duality: non-formal learning can be enabled both through intentional design and emergent occupation. What matters is not only whether a space is designed for learning, but whether it is perceived, inhabited, and transformed as such by its users.

6.3 Pedagogical Implications for Architecture Education

Architecture education is inherently spatial, social, and performative. Its processes depend not only on knowledge transmission but on observation, iteration, and situated dialogue. The spatial environments that support this learning must reflect these dynamics.

Both case studies suggest that circulation zones can operate as pedagogical infrastructure—spaces where informal presentation, critique, and reflection become part of the spatial experience. The presence of non-formal spatial conditions allows students to take ownership of their environment, enabling deeper learning through agency and interaction (Wenger, 1998).

Moreover, when circulation spaces are visually transparent and spatially interconnected, they facilitate a culture of visibility and collective awareness. Students witness others at work, are exposed to different approaches, and internalize architectural thinking not only through instruction but through spatial immersion.

6.4 Rethinking Design Responsibility

The role of the designer—and the institution—in shaping learning conditions must be reconsidered. Circulation spaces are not architectural afterthoughts, but strategic territories that reflect institutional values: openness, trust, collaboration, or control. When conceived as pedagogical infrastructure, these spaces invite designers to think beyond utility and toward spatial pedagogy.

Whether through new construction or adaptive reuse, the challenge is to design circulation not just as movement, but as learning in motion. This requires a shift in mindset—from planning for minimum code compliance to cultivating maximum educational richness.

Ultimately, reimagining circulation as a learning space aligns with wider shifts toward collaborative, inclusive, and responsive education. In architecture—where space is both medium and message—the way students move, pause, and interact is not incidental, but integral to how they learn.

7. Conclusion & Recommendations

This study has explored how circulation spaces in architecture schools can transcend their conventional function as transitional zones and evolve into non-formal learning environments that support collaboration, visibility, and pedagogical fluidity. By comparing two institutionally and architecturally distinct cases—TU Delft Faculty of Architecture and Cornell University's College of Architecture, Art, and Planning (AAP)—the research has shown that learning in architecture occurs not only in formal studio settings, but also within interstitial spaces such as corridors, atriums, foyers, and programmatic thresholds.

At TU Delft, a post-crisis adaptive reuse strategy led to the formation of a layered spatial configuration where spontaneous encounters and informal uses emerged organically along a central "street." At Cornell, the deliberate spatial logic of OMA's Milstein Hall generated a platform in which widespread learning was embedded into the very structure of the circulation system.

These findings reinforce the notion that non-formal learning can be spatially enabled and that architectural design plays a direct role in shaping educational culture. Circulation areas, when designed with openness, flexibility, and social permeability, can promote student agency, foster community, and support the informal transmission of knowledge.

From these observations, several spatial and pedagogical implications can be drawn:

- Circulation should be reframed as spatial opportunity. These areas ought to be treated not as residual voids, but as integral components of the learning ecosystem.
- Design should emphasize visibility and interaction. Spatial strategies such as visual transparency, generous transitions, and embedded programmatic nodes (e.g., seating, pin-up spaces, and exhibition zones) may foster unstructured learning encounters.
- User appropriation should be accommodated. Spaces should allow reinterpretation and adaptation by students and faculty. Flexibility of use encourages ownership and innovation.
- Non-formal learning affordances should be intentionally integrated. Informal review areas, social thresholds, and exhibition zones can be embedded within circulation paths to support layered learning.

- Design intent should be balanced with emergent behavior. Spaces should allow for occupation, personalization, and layered appropriation over time.

Reconceptualizing circulation as a learning space aligns with broader pedagogical shifts toward collaborative, student-centered, and context-responsive education. In architecture, where space is both medium and message, how students move, pause, and interact is not incidental but integral to how they learn.

By linking non-formal education theory with architectural design practice, this paper contributes a conceptual perspective to the discourse on learning environments. Furthermore, it positions circulation as a designable and analyzable typology of learning, offering a valuable foundation for future research in spatial pedagogy within design education.

Regional economics and relocation: A case study of Gümüşhane

Kübra Yaşar*[1], Zeynep Kuban[2],

[1] Erzurum Technical University, Department of Architecture, 25100 Erzurum, Turkey
[2] Istanbul Technical University, Department of Architecture, 34367 Istanbul, Turkey

Abstract. Gümüşhane was founded in the 15th century as a mining town, and was named Gümüşhane later due to its rich silver deposits. The town, where the majority of the people were engaged in mining, preserved this position until the end of 18th century. In the late 18th century, mining activities decreased drastically due to technological insufficiency, and the most of the miners migrated. As Gümüşhane is a very mountainous region and the lack of cultivable land for agriculture made the economy of the town dependent on trade. However, the Trabzon-Erzurum Road didn't pass trought downtown but Harşit Valley which was half hour away. This situation created a local economic crisis for Gümüşhane and inhabitants of the town wanted immediate actions by the authorities to prevent poverty. They send countless petitions to the government which emphasized the road's contribution to the local economy and demanded a change in the route. Their request was rejected; according to the authorities, the slope reaching the town would increase the cost and also would make transportation difficult. After their request was rejected by the government, the inhabitants of Gümüşhane took their own action and started to move to the Harşit Valley towards the road. Even though the government tried to prevent this, the number of people living in Bahçeler, the former summer residence, continued to increase. Finally, only after 1923 the new government decided to move the town center to Harşit Valley and rebuilt a new modern city.

---

1. Introduction

Throughout the history, spatial structure of a settlement always walk side by side with trade routes, natural and geographical sources, and technological developments or in another word economics. Economic power, and relations shapes the growth of a town and contributes to it. In the late Ottoman Era, the government started to reconstruction of the Trabzon-Erzurum Road hoping it would contributed to economics on imperial and regional level. However the government's agenda didn't always meet with the locals. While the Ottoman government was focusing in the broader picture, locals were hoping to maintain their livelihoods.

This study aims to show how infrastructure, regional economics, and governmental decisions effect a spatial and demographic structure of a town. In doing so, it offers a microhistorical perspective on locals and their struggles in Gümüşhane in the late 19th century. Through archival documents, and petitions, the study focuses on Gümüşhane's urban transformation during and after the construction of the Trabzon-Erzurum Road.

2. A mining town: the short history of Gümüşhane

Gümüşhane was founded as a mining town under the name of Canca. Altought we don't know the exact date of foundation, the first apperiance of Canca name in a written document dated 1487. According to the this document Canca was a small settlement with rich silver mines in the administration of the district of Torul (BOA, MAD 828). In this period, during the reign of Mehmed II (1451-1481), some non-muslim people, especially the Greeks settled in Canca where they worked as miner and exempt from taxes. These policies also maintained in the 16th century and population of Canca increased overtime (Pamuk, 2016, p. 169).

During the reign of Süleyman I (1520-1566), the name of the settlement was changed into "Eski Canca" and a new settlement named *Karye-i Nefs-i Canca-yı Maden* emerged (BOA, MAD 828). This "Yeni Canca", also established as a mining town, is the old settlement area of the city of Gümüşhane, now known as Süleymaniye Mahallesi (Fig. 1). The name of the town also mentoned as "Nefs-i Kasaba-yı Gümüşhane Nam-ı Diğer Canca". Hence, it can be concluded that the name "Gümüşhane" began to be used as of this date. In 1583, there were 50 Muslim, 478 Greek and 116 Armenian households and 16 Muslim individuals in the region (Bostan, 2002, p. 234).

*Corresponding author, E-mail: yasarkub@itu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_416

It would not be wrong to say that some of this inhabitants lived in Eski Canca and some in Yeni Canca (Gümüşhane).

By the 17th century, it is observed that Eski Canca was abandoned and the settlement completely shifted to Gümüşhane. In 1643, here were 134 Muslim and 569 non-Muslim households in Gümüşhane. Also, 41 soldiers were stationed in the castle of Eski Canca. The mining activities in Eski Canca, on the other hand, have not stopped. According to administrative records, 99 miners were working in Old Canca and 545 miners in Gümüşhane (BOA, MAD 644). Based on this, we can say that Gümüşhane, which was founded as a mining town, maintained this characteristic also in the 17th century. It can be understand that the settlement maintained this mining identity in the 18th century as well, and that the income from the silver and copper shipped to Istanbul helped Gümüşhane to flourish and thus mining became the main source of income for the town (Dolu, 2010).

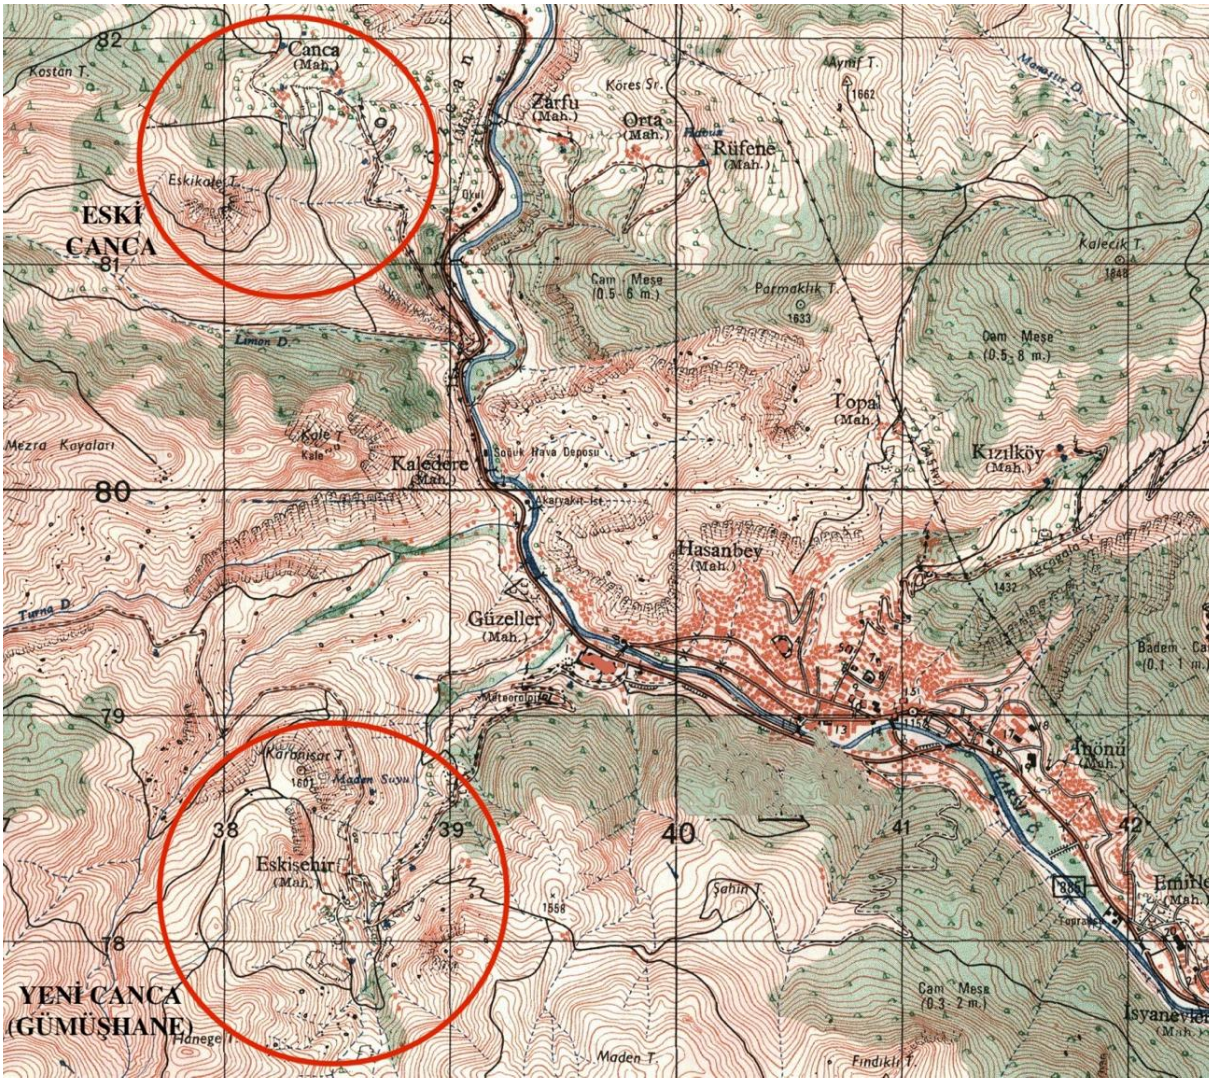

Fig. 1. The settlements of Eski Canca and Yeni Canca (Gümüşhane)

However, by the late 18th century, it is understood that the mining activities in Gümüşhane had paused (TPY, 1870). The mining activities, which were conducted with outdated technological methods, have come to a dead end as a result of this technological inadequacies. The mines have been filled with water and access to the deeper veins has become impossible. Under such circumstances, Gümüşhane, having lost its main source of income, experienced an economic decline and the idea that mining could be replaced by trade seemed a possible solution to cope with these economic circumstances.

3. The reconstruction of the Trabzon-Erzurum Road and the environment led to the relocation

In the beginning of the 19th century, almost 300 years later Ottoman Empire opened Blacksea to the international trade. Thus, Trabzon, one of the port cities of Blacksea, gained a relatively significant importance. This importance led to two significant developments fot the city: new trading possibilities and a visibility in international realm. In a short time Iranian and European merchants began to include Trabzon in their route and the European countries such as England, France, Austria established consulates in the city (Tozlu, 1997).

Following these developments in the Blacksea and with the rising trade potential of Trabzon Port the construction of the Trabzon-Erzurum Road was inevitable. This route started from the port of Trabzon and went to Erzurum through Gümüşhane and Bayburt, and from there to Tabriz via Beyazıd. Therefore, the cities along the route were expected to engage in the commercial activities that would be conducted on this road and profit from them. With these expectations the road works started as an essential government enterprise in 1846 and completed in 1872. However, in 1871, when the road works just started in Gümüşhane region, the trade route did not pass through the town center of Gümüşhane but through Harşit Valley (*Bahçeler*), which is half an hour away (Fig 2). Therefore, the town of Gümüşhane, which was hoping to benefit from the trade, was far away from the road.

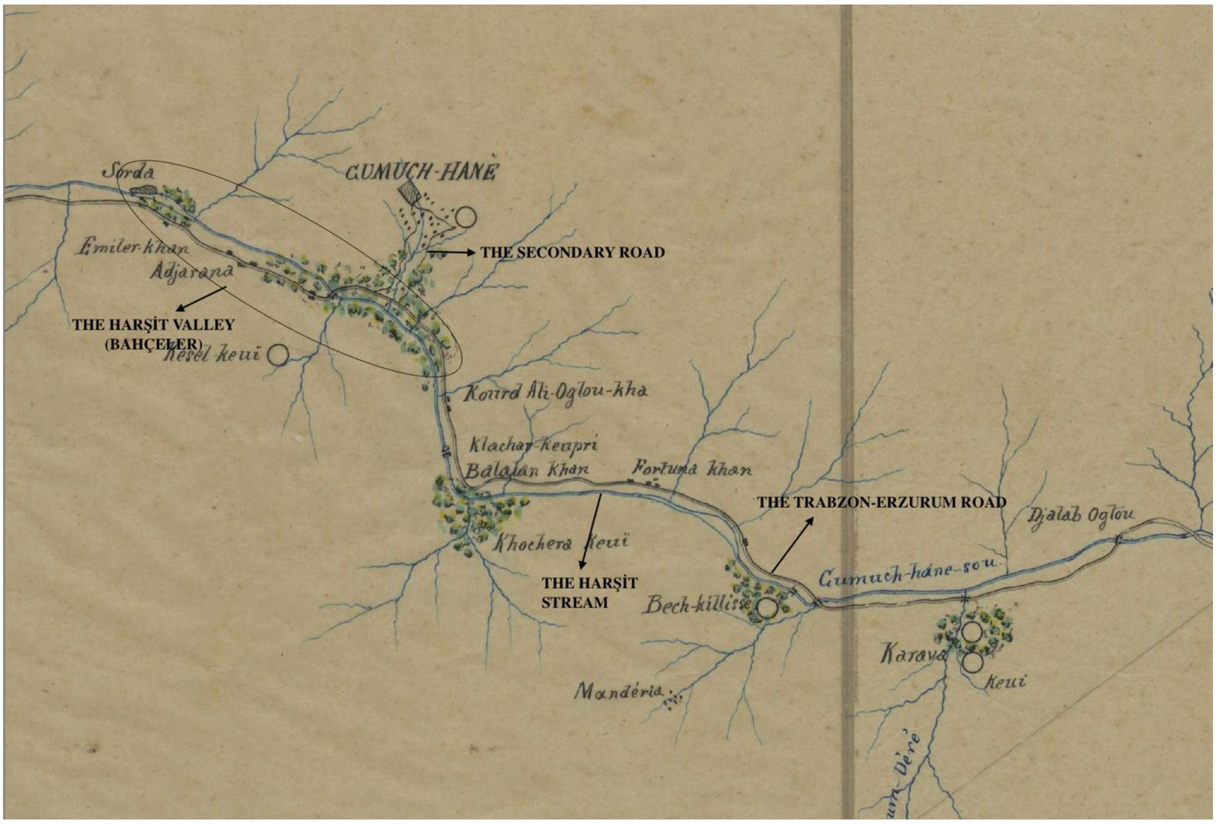

Fig. 2. The Trabzon-Erzurum Road and Gümüşhane town center

The inhabitants of Gümüşhane repeatedly petitioned the Ottoman central government to change the route of the Trabzon-Erzurum road to pass through their town. This was largely because their economy relied heavily on trade, especially after the decline of the silver mines, the main source of income for the town. The first petition sent in 1871, requesting for a route change, which emphasized the contributions to the local economy, was rejected due to the location of town. The justification of the authorities was based on logistical issues such as terrain, construction costs, and the practicality of transporting goods and people (BOA, ŞD 1826/24). The inhabitants sent a second petition in 1873, this time demanding the repair of the secondary road which reach to the town center. We don't have any information how this petition responded, however it is understood from the petitions of the following years that the road was repaired but again was in constant need of repair (BOA, ŞD 1827/49; İ.MMS 78/3421).

Last but not least, in 1892 the inhabitants of Gümüşhane petitioned once more. In this petition, written by a group of 134 people, including leaders of the three religious communities (Muslim, Greek, Armenian), merchants, artisans, craftsmen, tradesmen and locals, the reasons for the route change were clearly presented and asked for a reconsideration. According to the inhabitants, the route change would end the constant repair work that had to be conducted on the secondary road, which would not only reduce costs but also contribute to the local economy. Moreover, the lack of cultivable land in Gümüşhane, a mountainous region, made the economy dependent on trade, and the fact that the mines could no longer be operated increased the importance of trade. In 1883, some attempts were made to operate the silver mines, but failed. All these conflicts piled upon each other and the income of the town declined by 75%. Last bu not least, the miners were migrating to different parts of the empire and the population of the town was decreasing. The inhabitants stated that Gümüşhane was experiencing difficult economic times, that the economic and demographic difficulties would not be reversed unless effective solutions, such as a change in the route, were taken, and that they were disappointed that they had not been able to benefit from the trade road for twenty years, which they had spent a great deal of effort on (BOA, BEO 11/803).

However, all these requests were rejected by the government, which argued that a change of route was not necessary and the extension of the road to the towncenter was also disadvantageous. Without elaborating on the disadvantages, the government noted that even if the route was changed, it would not benefit the town as much as expected because merchants preferred the road through *Bahçeler* rather than climb up to the towncenter (BOA, DH.MKT, 1346/111). In the end, the government never allowed the Trabzon-Erzurum Road to pass through the town center and inhabitants began to look for other solutions to deal with the economic crisis the city was facing.

4. Adapting the new situation: Could relocation possible?

The fact that the trade route was far from the towncenter and the unfavorable conditions of the secondary road forced the inhabitants of the town to search for solutions. The transportation became more challenging, especially during the winter, causing merchants to continue on their way without making a stop in the towncenter, which rendered the inns in there non-functional. As a result, the residents of the town began to leave towncenter and move to *Bahçeler*. We don't know exactly when this relocation process started, but according to the 1877 provincial yearbooks, there were 253 households in the five neighborhoods in *Bahçeler*, which corresponded to 25% of the total population (TPY, 1877). Consequently, the *Bahçeler*, which had previously been used as a recreational area (*mesire*), began to transform into a residential area.

The Ottoman government stated that this attempt was risky for the development of the town and ordered prevention, without elaborating on the details of said risk (BOA, DH.MKT 1130/74). However, this relocation process continued anyway. Moreover, inhabitants of *Bahçeler,* began to ask if the town center could be relocated in Harşit Valley as well. In their opinion, the markets to be established along this road could help revive the town's economy and regain its lost income. It was emphasized that the current town center of Gümüşhane was not sufficient to be a center, and the region was unsuitable for trade and agriculture, regardless of what was done for this location, it would be useless. For this reason, residents suggested that the current center of the Gümüşhane should be moved to the *Bahçeler* region and transformed into a sub-district. They demanded that the police station and telegraph office, schools, the government house and after a while the municipality office should transferred *Bahçeler* as well (BOA, BEO 2242/168091). According to the inhabitants, the relocation of the town to the *Bahçeler* was crucial in many aspects both for the development of the area and preventing depopulation (BOA, DH.MKT 942/49). However, the government rejected all of these requests stating that moving the town to the Harşit Valley, would not benefit the town in the slightest (BOA, DH.MKT 1130/22).

In the early 20th century, the inhabitation in *Bahçeler* continued to rise. In 1907, there were 500 households in Bahçeler and 600 in the town center. Both parts of the town lived in the same time, Gümüşhane (today Süleymaniye) and *Bahçeler* continued to live side by side as parts of a town. The residents of Bahçeler, continued to go town center for work, school or other daily affairs and turn back home in the evening. At the end, the town maintained its current location and the government never allowed a relocation. However, the economic and demographic problems the town was facing remained unsolved.

5. Gümüşhane in the Early Rebublican Era

After WWI, Ottoman Empire collapsed and a new Turkish Republic was founded. This new government aimed to rebuilt the country; whole new economic, education, healt system, and of course new urban plans. Under this new government rule, a new government house for Gümüşhane built in 1922, in *Bahçeler* and we can easily say that this was the first step of the foundation of a new town center. Because, with this step the administrative center of Gümüşhane moved to *Bahçeler* for the first time, and also with this step the decline of Gümüşhane (town center) was started while *Bahçeler* continued to rise. In the first 15 year after the foundation of the republic, a community center (*halkevi*), a modern mosque, an elementary school, a hospital, a middle school, a municipality building, a slaughterhouse, a modern hotel, many fountains for water supply, and 650 houses built in the town (Okay, 1938, pp. 25-28). Also new shops, stores and other commercial building established next to the Trabzon-Erzurum Road (Göktaş, 2020, p. 450).

An important turning point of the development of Gümüşhane province was the foundation of the General Inspectorate III (*III. Umum Müfettişliği*) in 1935 in order to ensure regional development in some provinces of the Eastern Black Sea and Eastern Anatolia. One of the most crucial tasks that General Inspector Tahsin Uzer wanted to accomplish in the area of his inspectorate was the reconstruction of the urban areas. Uzer, therefore, made an intensive effort to transform the inspectorate region, which included Gümüşhane, from its long years of occupation and wars that had turned it into a ruins. In this context, a master plan for the Gümüşhane province was commissioned, and with this new plan *Bahçeler* was designed to be the center of the town and the old town center was transformed into a neighborhood attached to it (Göktaş, 2020, pp. 450-451).

6. Conclusion

This detailed story paints a vivid picture of struggles of Gümüşhane regarding the local economics. The petitions by residents of Gümüşhane reflect the community's desire for economic prosperity, the importance of trade, and a sense of fairness and accessibility. The community's repeated demands for the road to pass through their town center underscore the centrality of infrastructure to economic development, while their frustration at the bypassing of a major trade route highlights how geography and government decisions directly affect local livelihoods. On the other hand, this case shows that how economic problems transforms the urban pattern. The town center of Gümüşhane was forced to relocate by the economic conditions. For a long time, the town existed in two different regions while one part forced to be far away from trading possibilies, the other part to be far away from admimistrative center where the schools and other governmental buildings placed. Finally, in the early republican era its decided to relocate the town in *Bahçeler* and abandoned the historical town center completely. In the end, a historical city turned into a ruined/forgotten neighbourhood and a new town born almost from stracth.

Abstract. The increasing use of Building Information Modeling (BIM) in the Architecture, Engineering, and Construction (AEC) industry, combined with rapid technological progress, has fostered the development of various digital innovations within BIM practices. As the industry undergoes digital transformation, information flows have shifted from human-dependent processes to systems driven by advanced digital tools and platforms. This shift has triggered significant changes in professional roles, collaborative dynamics, operational methods, and stakeholder identities across construction projects. Within this transformation, digital innovation refers to integrating emerging digital technologies, channels, and methodologies that enhance organizational efficiency, service delivery, and building design processes in AEC firms. Technologies central to this innovation include the Internet of Things (IoT), 3D printing, drone applications, sensor integration, augmented and virtual reality (AR/VR), digital twin systems, and cloud-based BIM solutions. This study examines current research on BIM-related innovations, aiming to identify leading technological advancements and trends. The findings contribute to the growing knowledge on BIM innovation and offer insights for researchers and professionals within the AEC industry.

Keywords: Innovation; Building Information Modelling (BIM); Architecture, Engineering and Construction (AEC) industry

1. Introduction

A construction project involves real-world operations unfolding within specific temporal and spatial contexts. Since the progression of time is irreversible and construction environments vary geographically and socially, the participants engaged in these projects are inherently diverse. Consequently, each project is shaped by distinct objectives and constraints. This diversity in individuals, settings, and timelines renders exact replicating construction activities impractical. Every construction endeavor is unique, making innovation a vital element for success (Liu et al., 2020). Factors such as stakeholder complexity, industry fragmentation, and consistently low profit margins and productivity levels underscore the sector's suitability for digital transformation (Morgan, 2019). In an era of digital advancement, there is increasing pressure on the construction sector to deliver higher-quality structures and services more efficiently, within tighter budgets and timeframes. As a result, innovation and performance optimization have become central priorities in the architecture, engineering, and construction (AEC).

Innovation has become a central concept across scientific and technological fields in recent years. It is broadly defined as introducing novel products, services, production techniques, marketing strategies, or organizational structures (Trott, 2005). The innovation process involves multiple stages, including exploration, identification, experimentation, development, and the eventual adaptation or replication of new ideas (Dosi, 1988). At its core, innovation signifies implementing more effective methods for accomplishing specific tasks. It may take various forms, from incremental improvements to transformative or disruptive changes in thinking, processes, products, or organizational frameworks. Fundamentally, it represents generating and applying new knowledge related to ideas, products, or operational approaches. Successful innovations often carry commercial value and contribute to competitive advantage. While innovation is frequently linked to technological advancements, it spans non-technological domains such as organizational and financial systems. It may be realized by introducing new offerings to the market (product innovation) or optimizing internal operations (process innovation). Despite this diversity, all innovation activities aim to boost economic performance and enhance competitiveness.

The literature presents various definitions regarding innovation, some of which are summarized in Table 1. According to Jones and Saad (2003), innovation is composed of two primary components: the internal structure

[*] Corresponding author, E-mail: nurdan.kasul@deu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_423

of the firm and its capacity to engage with innovation, and the external environment, shaped by technical, economic, social, and institutional dynamics. For a change to qualify as an innovation, it must introduce a new or significantly improved product, process, marketing strategy, or organizational method relative to the firm's existing practices. This can include original developments and adaptations of existing innovations from other organizations (Oslo Manual, 2005).

Innovation also possesses several defining characteristics. One such feature is its irreversibility—once a new technology is adopted, it stimulates further development through user interaction. In contrast, older technologies stagnate due to a lack of active engagement (Jorde and Teece, 1989). Another key aspect is the cumulative nature of innovation. Innovations are often grounded in previous scientific or technological advancements and, in turn, lay the groundwork for subsequent developments. Thus, each innovation contributes to shaping the trajectory of future progress (Teece, 2000).

Table 1. Definitions of innovation in scientific literature

Definition	Source
Introducing entirely new components or novel combinations of existing elements into industrial systems.	Schumpeter, 1934
Encompassing all activities from fundamental research to invention aimed at developing and commercializing new products or production techniques.	Kamien and Schwartz, 1982
Involving the creation of a new product, service, or operational method.	Abernathy and Clark, 1985 Papadonikolaki et al., 2017
A comprehensive process including the exploration, development, adaptation, and market application of novel ideas in processes, products, or organizational systems.	Jorde and Teece, 1992
The effective use of a substantially new or enhanced process, product, or system within an organization.	Slaughter, 1998.
Introducing a novel or substantially enhanced product (either a good or a service), process for production or delivery, marketing method, or organizational practice designed to improve performance or create added value.	Oslo Manual, 2005
The effective realization of novel concepts that result in a measurable economic or market advantage.	Ramilo and Embi, 2014

Innovation is critical in advancing the construction industry (Liu et al., 2020; Li, 2008). The innovation process within this sector often begins in response to client requirements and expectations. Different innovative practices can be observed across various stages, including design, construction, project management, communication, manufacturing, and procurement. In the field of architecture, engineering, and construction (AEC), Oslo Manual (2005) categorized innovation into four distinct types:

- Technological innovation: the application of new knowledge or techniques to deliver products or services more cost-effectively or with enhanced quality;
- Organizational innovation: improvements rooted in changes to social structures, interactions, or cultural dynamics, rather than technological advancements;
- Product innovation: technological developments that may reduce hardware dependency while improving resource efficiency and leading to better-quality outputs;
- Process innovation: modifications to workflows or procedures that yield significant efficiency gains, even in the absence of major technological change.

Construction technologies typically emerge through the integration of diverse technical expertise contributed by various stakeholders, making the innovation process in construction inherently collaborative. Collaboration is a defining characteristic and a fundamental prerequisite for successful innovation in the sector. Nevertheless, this collaborative nature can also introduce significant challenges. According to Xue et al. (2014), one of the primary barriers to achieving the performance improvements needed in construction innovation is the lack of enduring and sustainable cooperation within innovation networks.

Skibniewski and Zavadskas (2013) examined the progression of innovation in the construction industry. They highlighted that the development of the internet and information and communication technologies has opened new and promising avenues for innovation in this field. As the construction industry undergoes digital transformation, Building Information Modeling (BIM) has become a central approach driving technological change across the sector (Papadonikolaki et al., 2019).

Initially conceptualized by Eastman in the 1970s, BIM has evolved into a comprehensive process that spans the entire life cycle of a project, from design through to operation. Despite the variety of definitions available in the literature, a common understanding is that BIM serves as a digital platform that integrates both the physical and functional attributes of a building. For instance, the National BIM Standard – United States (2010) describes

BIM as a digital representation of a facility's characteristics. Similarly, the Associated General Contractors of America (2005) defines it as using software tools to digitally simulate construction and management processes.

The resulting BIM models are typically rich in data, parametric, and composed of intelligent, object-oriented components. According to Laiserin (2002), BIM can be seen as a three-dimensional, object-oriented, computer-aided design framework tailored to the needs of architects, engineers, and contractors. Expanding on this, Hardin (2009) emphasized that BIM represents more than just 3D modeling—it also reflects fundamental innovations in workflow and project delivery methods. Succar et al. (2012) characterized BIM as an integrated framework of policies, procedures, and technologies designed to manage project data digitally throughout a building's lifecycle. Azhar et al. (2012), meanwhile, dissected the concept itself: "building" encompasses all types of projects, "information" refers to spatial, physical, and financial data, and "modeling" denotes the digital simulation of a project's physical components.

Collaboration and innovation are recurring themes in Building Information Modeling (BIM) research, as highlighted by He et al. (2017). While BIM is frequently classified as a technological innovation, it is increasingly recognized as a strategic enabler that fuels broader innovation within the construction sector (Holmström et al., 2015). As construction projects grow in complexity, the demand for innovative approaches to address dynamic and intricate engineering challenges becomes more urgent. BIM serves not only as an innovation but also as a tool for process integration, facilitating other innovations by establishing the necessary communication and social frameworks for transformation. BIM is evolving into a foundational digital infrastructure that supports innovation across the lifecycle of construction projects (Holmström et al., 2015; Morgan, 2019). Its implementation can drive both technological and organizational innovations, and it can potentially enable radical change within the industry (Morgan, 2019).

The widespread adoption of BIM in the architecture, engineering, and construction (AEC) industry, combined with rapid technological advancement, has given rise to various digital innovations. These include integrating technologies such as the Internet of Things (IoT), 3D printing, drones, sensors, augmented and virtual reality, digital twins, and cloud-based BIM (Cloud-BIM), all of which are transforming the way construction projects are designed, managed, and executed.This paper reviews research discussing innovations in BIM. The study aims to identify prominent BIM innovations in the AEC sector. The study contributes to a better understanding of innovation for future research in BIM literature and provides insights to BIM practitioners in the AEC sector.

2. Materials and methods

According to the literature, there are three main approaches to conducting review studies: traditional (or narrative) reviews, systematic reviews, and meta-analyses (Moule & Goodman, 2009; Gerrish & Lacey, 2010). A systematic review is characterized by a structured and comprehensive analysis of all relevant published studies within a specific research domain. This approach involves applying explicit inclusion and exclusion criteria, assessing the quality of the identified studies, and synthesizing their findings to address a particular research question or problem (Higgins & Green, 2011). Systematic reviews may incorporate quantitative, qualitative, or a combination of both types of evidence, referred to as a mixed methods systematic review (Hemingway & Brereton, 2009). These reviews are particularly valuable due to their methodological rigor and ability to generate high levels of evidence.

This study conducted a systematic review to analyze research on innovation within the construction sector's context of Building Information Modeling (BIM). The Scopus database was used as the primary data source. The search was performed using the keywords "BIM", "innovation", and "construction". An initial pool of 1,183 publications was identified.

To refine the dataset, filters were applied to limit the subject area to Engineering and the document type to Article, resulting in 323 relevant records. Further screening was conducted based on specific exclusion criteria:

- 25 articles were excluded because they were not written in English.
- 16 articles published in 2025 were removed, as the year was still in progress at the time of analysis, potentially leading to misleading trends in temporal data visualization.
- 1 article dated before 2010 was excluded due to being outside the scope of the study.
- 228 BIM-related articles were excluded because they did not explicitly focus on innovation.

After applying these criteria, 53 articles published between 2010 and 2024 that specifically addressed innovation in the context of BIM were included in the final review. Fig. 1 illustrates the workflow of the systematic literature review, and the findings are presented in the subsequent section.

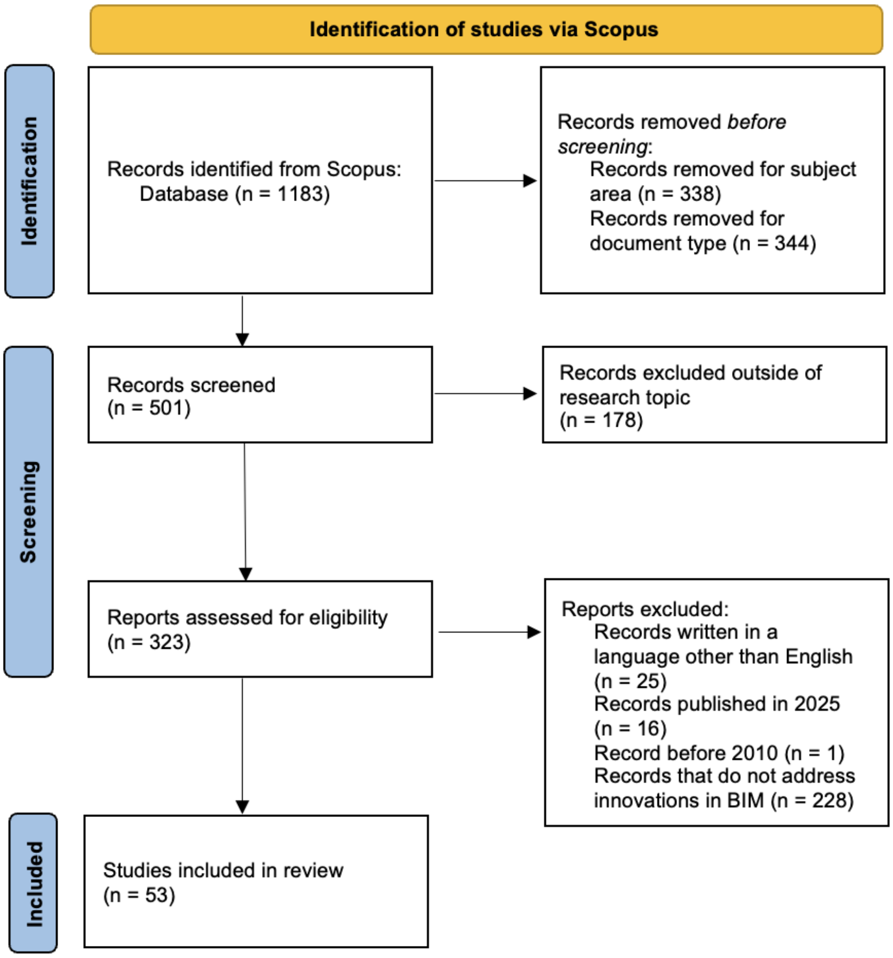

Fig. 1. Framework of the study

3. Results and discussion

In the Scopus database, the distribution of studies addressing innovations in BIM in the Engineering subject area by year is presented in Fig. 2. The first studies on the subject in the literature were published in 2010. Studies addressing innovations in BIM continue to increase each year compared to the previous year. As a result of the systematic literature review, the journals in which 281 articles were published between 2010 and 2024 are presented in Fig. 3. Accordingly, Architectural Engineering and Design Management, Construction Innovation, Engineering Construction and Architectural Management, Automation in Construction, and Buildings were the journals in which the articles within the scope of the subject were published most frequently. When the countries where the research was conducted were considered, most studies were conducted in the United Kingdom, while the fewest studies were conducted in Germany (Fig. 4). When the subject areas of the 281 studies published between 2010 and 2024 were examined, most studies were conducted in the subject area of Engineering, with 51.5%. This was followed by Business, Management, and Accounting with 15.8% and Computer Science with 9.7% (Fig. 5).

As a result of the systematic literature review, 228 out of 281 studies were excluded because they did not focus on a specific innovation in BIM, their subject area was outside the construction industry, or they addressed BIM software as an innovation. The remaining 53 articles were examined in detail within the scope of this research, and the journals in which these studies were published are presented in Table 2. When the journals in which the articles are published are examined, the highest number of publications is in the Buildings journal, with eight articles. This is followed by the Automation in Construction journal with four articles (Table 2).

The innovations discussed in the articles examined within the study's scope were categorized into seven main groups: ND BIM, automation, sustainability, collaboration, management, new model/approach/framework, and technology (Fig. 6).

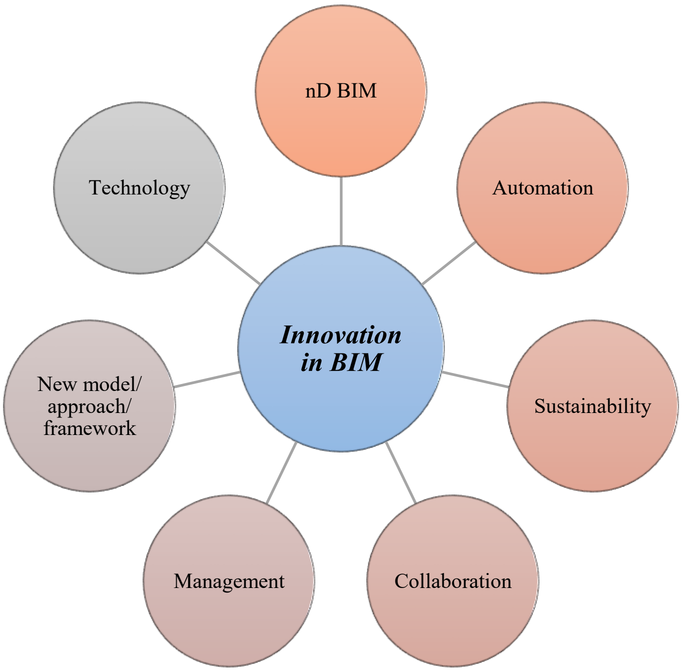

Fig. 6. Categories of innovations in BIM literature

nD BIM: The nD of the BIM development process covers five dimensions. These can be listed as 1D (Planning and Research), 2D (Drawing including plan, section, elevation and project documentation), 3D (Visual representation of the physical structure), 4D (Time planning showing the project schedule), 5D (Cost estimate including material and labor expenses), 6D (Sustainability and life cycle analysis), 7D (Facility management and post-construction data) and 8D (Safety). Umar et al. (2015) stated that project activities can be visually presented with 4D modeling. They examined the impact of 4D applications on Integrated Project Delivery (IPD) in the AEC sector and suggested a strategy for optimizing the tools used in project delivery. Love et al. (2017) discussed the main reasons for cost increases in railway projects and the methods suggested to prevent these increases. They presented that the 5D dimension of BIM can reduce cost uncertainties and increase the probability of completing projects within budget.

Automation: It refers to using automated processes and tools in the BIM platform in construction and architecture to improve various aspects of the project life cycle. Abrishani et al. (2015) discuss the combination of BIM and generative design for an innovative and integrated process management in the early design stages. This research proposes a generative BIM (G-BIM) workspace to overcome the limitations of traditional design processes and develop more effective, flexible, and creative solutions in the early design stages of AEC projects. This environment aims to enable designers to generate alternative solutions through parameters and manage the design process more dynamically. Brosque, Skeie, and Fischer (2021) examine the effectiveness of robotic technology in concrete drilling operations in the construction industry. The study is critical because it presents a detailed analysis of a concrete drilling robot used in the field for the first time. A framework is proposed to compare robotic and traditional construction methods. The study emphasizes the potential of robotic technology in the construction industry and the importance of BIM integration. Baraibar et al. (2022) described the innovative methods used in constructing the Arnotegi Tunnel on the Bilbao Southern Ring Road and their impact on safety, efficiency, and environmental sustainability. To minimize environmental impacts during tunnel construction, parameters such as air quality, noise, and vibration were monitored using various environmental sensors. The machines' positions in the tunnel were precisely determined through 3D digital models and sensors, thus making work processes more efficient.

Collaboration: The BIM collaboration process involves defining different construction phases for a single project. In other words, it consists of understanding the data and information sharing process between different construction phases. Alazmeh et al. (2018) aimed to transform traditional workflows into a BIM-based, collaborative model within a Knowledge Exchange Partnership framework with the University of Salford. The article highlights that BIM has the potential to transform traditional processes in the construction industry and that adopting a collaborative approach can increase the efficiency of projects. Technology development has also pushed the understanding of collaboration in construction projects to change. Gu et al. (2023) examine the social impact of the award-winning U City project in Adelaide, Australia. This research aims to understand the effectiveness of digital collaboration in complex housing projects and stakeholders' perceptions of this process. The research suggests five strategies to increase the effectiveness of digital collaboration in complex housing projects.

Sustainability: Sustainable design can be defined as the purposeful design of buildings and places that minimize harmful environmental impacts, significantly reduce carbon emissions, and positively enhance health, well-being, nature and biodiversity, and social value throughout their life cycle. BIM supports Environmental, Social, and Governance goals by tracking environmental impacts, promoting sustainable resource management, and ensuring transparency and compliance in construction and operations. Zhang et al. (2023) examined the effects of Building Information Modeling (BIM) applications on the sustainability performance of construction projects. The researchers stated that BIM applications increase sustainability performance by encouraging green innovations. Green innovations improve areas such as energy efficiency, waste management, and the use of environmentally friendly materials. The study emphasizes that this process strengthens the impact of BIM on sustainability. Araszkiewicz (2016) discusses the "Green BIM" management method, which combines the concepts of sustainable construction and building information modeling (BIM). The researcher defines the Green BIM concept as an approach that aims to perform energy efficiency, material optimization, and environmental impact assessments in a digital environment by integrating BIM technologies with environmental sustainability goals. The findings of the study;

- Strong institutional support and leadership are required to implement Green BIM effectively.
- Training programs on Green BIM should be organized for engineers and designers, and digital skills should be increased.
- Government policies should encourage sustainable construction practices and ensure the widespread use of Green BIM.

Management: It can be explained as overseeing and coordinating all aspects of a construction project using BIM technology. It enables the efficient management of large amounts of data and information generated during a construction project's planning, design, construction, and operation phases. Ng et al. (2023) examine how digital manufacturing (DFAB), Building Information Modeling (BIM), and Early Commitment Participation (ECI) applications are integrated in construction projects and the effects of this integration on design processes. The study analyzes the effects of these three applications on process integration, information integration, and organizational integration by comparing four different projects.

New model/approach/framework: It defines new models, approaches, or frameworks that have emerged through scientific studies addressing the use of BIM in the construction industry. Khattra et al. (2022) researchers have digitized the design process of structures using the Industry Foundation Classes (IFC) data model, which is the core component of BIM. IFC facilitates data sharing between different software, increasing the accuracy and efficiency of design. The proposed system provides a framework that automatically checks structural elements' design for compliance with a particular country's building codes (e.g., India's IS 13920 seismic code). This reduces human errors in the design process and increases accuracy. This study significantly contributes to automating structural design and ensuring code compliance using a BIM and IFC-based framework. It constitutes a valuable example for increasing digitalization in the construction sector and improving design processes, especially in developing countries.

Technology: Technology in the construction industry is a collection of various tools, applications, software, and machines used in different phases of a construction project. These tools and machines help increase the efficiency of its methods and processes. Peng et al. (2020) examine a digital twin-based building management system implemented in the East Hospital in Shanghai, China. This system is built by continuously integrating static and dynamic data throughout the entire life cycle of the hospital building (design, construction, operation, and maintenance). It includes real-time visual management and AI-assisted diagnostic modules. In addition, Li et al. (2021) propose an innovative digital platform to increase the sustainability of prefabricated housing construction (PHC). This platform aims to make PHC processes more efficient, transparent, and sustainable by integrating advanced information and communication technologies (ICT) such as blockchain, Internet of Things (IoT), Cyber-Physical Systems (CPS), and Building Information Modeling (BIM). Khan et al (2024) evaluate the applicability of 3D printing technology in residential construction in New Zealand regarding environmental sustainability and energy efficiency. The study shows that 3D printing technology can enhance environmental sustainability in New Zealand residential construction. In their study conducted in 2024, Choi et al. (2024) investigated the potential of integrating drone imagery and artificial intelligence (AI) to digitize construction site management. The research aims to create point cloud models (PCM) using drones instead of traditional robots and scanner-based data collection methods, and improve object recognition algorithms by rendering these models photorealistically.

4. Conclusions

This study reviewed the academic literature to identify key innovations in BIM, focusing on the Architecture, Engineering, and Construction (AEC) Industry. The analysis was based on publications indexed in the Scopus database, covering 2010 to 2024.

The findings indicate that early studies from 2015 primarily explored BIM's foundational aspects and potential to transform traditional construction practices. BIM's innovative capabilities are increasingly emphasized in the literature, particularly in supporting digital transformation and improving project performance. With the advancement of technology, BIM-related innovations have increasingly focused on enabling automation within the construction industry. Integrating emerging tools such as sensors, 3D printers, robots, and drones into construction workflows has significantly enhanced operational efficiency. One of BIM's most notable contributions is its ability to facilitate storing and exchanging extensive data among stakeholders during the project process. This has heightened the importance of process management and handling data generated at various project stages. Various BIM-based management frameworks have been proposed to optimize project execution. Furthermore, recent studies have increasingly addressed the challenges and strategies for managing data stored and processed on digital platforms.

As a result, BIM has become increasingly integrated with digital innovations, leading to the development of new models, approaches, and frameworks in the literature. Recent Internet of Things (IoT) and interoperability studies have introduced concepts like digital twin, blockchain, cloud-based BIM, and Intelligent BIM (I-BIM). Finally, while there has been a growing interest in digital twins, blockchain, and I-BIM, further research could examine the practical challenges and opportunities in implementing these technologies in real-world construction projects.

[2] Trabzon University, Department of Computer and Instructional Technologies Education 61335, Trabzon, Türkiye

Abstract. The concept of artificial intelligence, which emerged in the 1950s with Alan Turing's question, "Can machines think?" is a research field that has evolved to enable machines to perform cognitive skills unique to humans. While early applications were limited to algorithms with small capacities and processing small datasets, today's generative AI technologies have transformed into systems capable of designing new and original content. Thanks to these qualities, generative AI has become applicable in various fields of business, from healthcare to tourism and art education. One of these fields is architecture. Technological advancements have significantly impacted architectural design and implementation, making using artificial intelligence in architecture inevitable.
The impact of artificial intelligence on architecture became apparent with the emergence of parametric design in the late 20th century. Parametric design software, one of the earliest applications of AI in architecture, revolutionized the process of managing geometric complexity and expanded its role in architecture over time. In this context, the research aims to examine the innovations and transformations that artificial intelligence has brought to the field of architecture and to evaluate its potential future impacts. By adopting a narrative approach to reviewing the literature, the study synthesizes views from existing literature to provide a multifaceted and innovative perspective. Particular attention is paid to how generative AI can offer solutions for energy efficiency, material optimization, early detection of potential structural errors, and sustainability. Furthermore, the study explores recommendations for interdisciplinary collaborations, particularly between architecture and fields like computer science, civil, mechanical, and electrical-electronics engineering, to produce more creative, efficient, and environmentally friendly projects.

Keywords: Architecture, Artificial Intelligence, AI, Generative AI, Design, Technology, Sustainability, Interdisciplinary Collaboration

1. Introduction

Architecture is an ancient profession whose roots go deep into human history. Over time, the essence of architecture has been interpreted from different perspectives, and various definitions have emerged. The theoretical framework of this art, which has been practiced for centuries, has been shaped after its practical development. The fact that it has been influenced by social and cultural movements in every period has brought about the expression of architecture in rich, detailed, and literary expressions. According to Vitrivius (2017), architecture is a combination of aesthetics, durability, and functionality. Alberti (1485) considers architecture as an art that exists to enhance human dignity and the welfare of society. Le Corbusier (2007) describes the house as the living machine of modern man and architecture as the design and organization of this machine. The philosopher Heidegger (1999) argues that space is a fundamental dimension of human existence and considers architecture as an expression of this existence. Zaha Hadid (2009) states that architecture should have a content that excites, calms and makes people think beyond form and function. As can be understood from these different perspectives, architecture, which is a complex discipline, provides people with environments in which to live, work, and have fun. Thus, human life is in constant contact with architecture. It is possible to define architecture, which does not have a single correct formula and strict boundaries (Ching & Eckler, 2024), in its simplest form as "*a discipline that regulates the relationship between man and space and makes this relationship meaningful*."

Architectural design is a complex discipline that involves solving many problems by bringing together information from different fields of expertise. Although the main goal is to produce aesthetic, applicable, and ideal solutions in the design process, the data density and problems to be handled are relatively high. This situation causes architects to need more efficient and effective methods in their design processes. Today, digital technologies

* Corresponding author, E-mail: seldaal@ktu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_456

alleviate this intensity and improve design and production processes. Using such technologies in architecture has created new communication between the computer and the designer and a turning point in design processes. Especially in recent years, the increasing use of artificial intelligence (AI) in architecture has radically transformed this field (Chaillou, 2020). AI tools are no longer just for automation; they actively participate in the design process and work with architects. In this way, architects benefit from the analysis and suggestions of AI while producing innovative and creative solutions. In this context, AI is positioned as a tool and a creative partner in architecture, reshaping design processes.

The concept of AI began to take shape as a scientific discipline in the 1950s with Alan Turing's question, "Can machines think?" and has developed rapidly since then. AI is a branch of technology that aims to enable computer systems to demonstrate human-like thinking, learning, problem-solving, and decision-making abilities (Pirim, 2006). AI uses disciplines such as mathematics, computer science, linguistics, psychology, and neuroscience to model human intelligence and develop systems that mimic it (Pirim, 2006). This interdisciplinary collaboration has taken AI to a more advanced level, both technically and theoretically, and has made this technology one of today's most effective and remarkable fields. So much so that AI-supported software developed to fulfill specific tasks outperforms them over time thanks to the experience gained from their users (Arney, 2017). AI technology is not only a technical innovation but also can potentially create a significant change in social and economic spheres. Indeed, AI expert Kai-Fu Lee emphasizes the importance of this transformation, stating that this technology can potentially create a greater impact than any other innovation in human history (Lee & Qiufan, 2021). This has made AI one of the fastest-advancing and most remarkable research fields of recent years (Norvig & Russell, 2016). The expanding application areas of AI are also a remarkable discussion topic for the architecture discipline, which focuses on design and creativity.

The innovations brought by AI technology to the discipline of architecture and its potential to transform the profession is a technological advance and a process that redefines the future of the field. This process, which brings various positive and negative effects, needs to be handled with a critical perspective based on scientific knowledge. Thus, AI can be a powerful tool and a creative partner in building the architecture of the future while preserving the fundamental values of architecture. Structured with this perspective, the study examines the effects of AI on architecture and discusses the current and future uses of this technology from a multidimensional perspective. The study aims to synthesize the existing information from different disciplines in the literature. In this context, the research seeks answers to the following questions within the framework of the fundamental problem: "*What are the current and predicted effects of AI technologies on the discipline of architecture?*":

1. For what purposes are today's AI technologies used in architecture?
2. What are the current and potential risks of AI for the discipline of architecture?
3. What are the prominent study trends and gaps in the literature on the subject?
4. What kind of transformations is AI expected to bring about in architecture in theory and practice?

2. Research Methodology

This study was conducted using the traditional literature review method. A traditional literature review is a method that synthesizes the existing knowledge on the subject, allowing the presentation of a detailed analysis of the basic concepts, development processes, and new approaches related to the field (Paul & Criado, 2020). The research process consists of three stages. In the first stage, academic databases were searched to create a theoretical framework, identify trends and gaps in the literature, and synthesize existing scientific knowledge. Using the keywords "artificial intelligence," "AI," "generative artificial intelligence," "Generative AI, "machine learning," "deep learning," and "digital architecture," academic articles, books, conference proceedings, and graduate theses indexed in Scopus, ScienceDirect, ProQuest, and Google Scholar databases were archived. In addition, information and documents from reliable websites on the subject were added to the archive to be used as support when necessary. In the next stage, the archive was examined by two researchers using the skimming technique; the ones that could contribute to answering the problem statements and were scientific and unbiased were selected. The selected sources were read in detail by the researchers; notes were taken and discussed in the context of results, discussion, and conclusions. In order to make the analysis process easier and more systematic, themes created in the context of the sub-problems of the research were used. In the last stage, the information obtained was interpreted and presented from a critical point of view.

The precautions taken to ensure the validity and reliability of the research included searching the literature with keywords using reliable databases, including different types of publications in the process, choosing academically accepted publications and reliable internet sources among them, and presenting the results after the publications were examined and discussed by two researchers. In addition, it is thought that the detailed explanation of the studies conducted in the process increases reliability by providing consistency and transparency.

3. Result and Discussion

3.1. The Use of Today's AI Technologies in Architecture

Architects are expected to solve complex design problems at both global and local scales. This process requires a multidisciplinary and collaborative working environment and designers specializing in multiple fields. This situation transforms the design field into a multidisciplinary structure (Trummer & Lleras, 2012). Bringing together intensive data from different fields and various needs at a common point is an issue that needs to be addressed in interdisciplinary studies. AI helps architects make more effective decisions by analyzing data and optimizing design processes. AI has become necessary to manage the complexity brought about by interdisciplinary cooperation and respond quickly to different demands.

In the literature, some studies address different perspectives and applications on the use of AI in the field of architecture, as well as publications that analyze research in this field in depth. Such publications contribute to understanding the current situation and determining future directions by providing comprehensive and holistic information on the role of AI in architecture. The study by Bölek et al. (2023) is a comprehensive source for understanding AI's current and potential applications in architecture. In this study, the effects of AI on architecture are discussed in a multidimensional manner by bringing together research from different disciplines. It examines how AI is integrated into design processes, how it plays a role in solving complex problems architects face, and how these technologies are shaping innovative approaches in the industry. It also discusses future research directions and how AI can be used more effectively in architecture (Bölek et al., 2023). In another study investigating the applications of AI technology in architectural design and its impact on design efficiency, Li et al. (2025) state that AI has great potential in the architectural design process, covering areas such as creative development, data analysis, and problem-solving. The study also emphasizes other applications of AI throughout the building life cycle, such as predictive analysis, construction supervision, and facility maintenance. Through discussing traditional and AI-assisted architectural design methods, the study summarizes the advantages and challenges of AI technology in architectural design (Li et al., 2025).

The reviewed studies make it clear that the integration of AI applications in the field of architecture is an inevitable reality today. Generative design algorithms, AI-powered virtual reality tools, and machine learning algorithms are increasingly integrated into architecture (Almaz et al., 2024). According to Thomas Lane, AI has the potential to take over 37% of the work performed by architects and engineers (Matoso, 2023). In order to demonstrate this contribution more clearly, Table 1 was created by examining the existing AI-supported software (Autodesk, 2025; Spacemaker, 2025; Tesfit, 2025) frequently used in the field of architecture.

Table 1. Comparative analysis of widely used AI-supported architecture software

Properties		AUTODESK Forma	SPACEMAKER	TESTFIT
2D Drawing		✓	✓	✓
3D Modeling		✓	✓	✓
Integration with CAD/BIM		✓	✓	✓
Interactive Design		✓	✓	✓
	Multiple scenario comparison	✓	✓	✓
	Building mass optimization	✓	✓	✓
	Automatic layout generation	✓	✓	✓
	Volume/density compensation	✓	✓	✓
	Zoning/regulation compliance check	Limited	Limited	✓
AI support	Proposal for space use/function	✓	✓	✓
	Visual landscape / corridor analysis	✓	✓	None
	Air flow /wind direction analysis	✓	✓	None
	Daylight analysis and shadow calculation	✓	✓	None
	Noise modeling	✓	✓	None
	Parking lot / traffic flow proposal	Limited	Limited	✓
	Real-time feedback	✓	✓	✓
	Revit / BIM integration	✓	✓	Limited

The software, examples of which are given in Table 1, has automated many tasks that had to be done manually in older-generation software without AI support. Considering the limitations the user sets, relevant regulations, and real-world data, this software can automatically generate many alternative layout plans on a plot of land whose dimensions are entered. Thus, the user can examine these designs and choose among them. Moreover, as in the case of the TestF monitor, this software, thanks to its algorithms based on data analysis, can decide which of the plans they generate is the most appropriate and offer suggestions to the user. Variables such as road layout, building height, and parking requirements are considered. This feature is handy for an architect who does not have enough time to examine many scenarios based on plans. Considering that in previous generation software such as AutoCAD, the layout plan was drawn manually, the ability to quickly create various layout plans for the same plot, compare these plans, and offer various suggestions to the user brings significant gains in terms of time, cost, and workforce. AI-supported software can easily calculate the sun and shadow effect by considering the plot's geographical location, time zone, surrounding structures, natural obstacles, and the orientation of the building. Thanks to this feature, the designer does not need to relocate the light analysis on the model manually. Suppose many new buildings are to be built on a large plot of land in a densely built neighborhood. In that case, it is possible to realize this in seconds with Spacemaker or Autodesk Forma, while the work to be done for each building to benefit from daylight at the maximum level was quite time-consuming in the recent past.

When the studies on the use of AI in architecture are examined, it is seen that approaches based on this technology are primarily used in interactive facade designs and architectural plan production to protect energy efficiency, such as natural ventilation and lighting (Cantemir & Kandemir, 2024). However, the uses of AI in architecture are not limited to these. When the relevant literature (As et al., 2018; Bölek et al., 2023; Cantemir and Kandemir, Ceylan, 2021; Chaillou, 2020; Çelik, 2023; Demir & Akti, 2024; Li et al., 2025; Yıldız, 2025) is examined, it is possible to categorize the increasing usage purposes of today's AI technologies in the discipline of architecture under three main headings as seen in Fig. 1.

Architectural Design

- Conceptual design (idea generation), developing alternative design proposals
- Create a design from text or image
- 3D rapid visualization
- Design-material analysis
- Comparing different design proposals
- Design expression in different forms (audio, written)
- Augmented reality compatible design
- Developing alternative spatial organization
- Parametric design
- Design based on environmental data
- Specific recommendations for urban design
- Detection of errors in technical expression
- Visualization according to different architectural styles
- Increasing the visual richness of 2D and 3D
- drawings
- Data analysis, classification
- Architectural education
- Protection of historical and cultural heritage

Construction

- Modular building element production
- Customized structural element production
- Workforce planning
- Time management
- Construction site productivity monitoring
- Robotics to reduce manpower
- Material and cost analysis
- Material and resource management
- Construction process simulation
- Early detection of errors and risks
- Quality control during implementation
- Occupational safety with image processing supported systems
- Real-time risk analysis
- Design feedback audit based on field data
- Accurate plan application of buildings with sensor-supported systems
- Interactive worker training simulations
- Automatic compliance with local regulations and standards

Building Optimization

- Energy consumption analysis
- Thermal Comfort Analysis
- HVAC optimization
- Building information modeling (BIM)
- Carbon footprint calculation and reduction recommendations
- Maximizing sustainability values
- Effective management of renewable resources
- Structural performance analysis (prediction of structural behavior)
- Monitoring environmental data
- Building health monitoring, estimation of maintenance requirements
- Automated testing of emergency systemsDetermining user satisfaction and adapting the system accordinglyAnalysis of user behavior

Fig. 1. The use of AI in the discipline of architecture

AI is a powerful tool that supports creativity in the architectural design process, facilitates data-driven decision-making, and offers a wide range of contributions from design processes to sustainability practices, from cultural heritage conservation to urban planning. The most prominent of these contributions is the support of idea generation and concept generation in the early stages of design and the exploration of form and structure alternatives in a variety and complexity not previously possible through parametric modeling and generative design methods (As et al., 2018; Hegazy & Saleh, 2023). AI algorithms, mathematical models, and deep learning techniques allow architects to develop innovative design solutions. This accelerates the process and increases the quality of both learning and professional design (Çelik, 2023; Zhou & Park, 2021). In addition, AI is increasingly forming the basis of new methodologies in architectural education and collaborative design processes. In design studios and academic programs, AI-supported platforms can provide students with interdisciplinary thinking skills and develop analytical and process-oriented approaches to the design process (Cudzik & Radziszewski, 2018; Çelik, 2023). Combining AI and 3D printing technology makes it possible to create innovative shapes and forms using fewer materials and resources. In this way, architects can develop creative, non-standard designs.On the other hand, AI helps architects create more design alternatives with fewer materials by providing data diversity (As et al., 2018). This helps to increase both the visual and functional quality of architectural projects. In addition, AI plays a critical role in the development of future-oriented visionary applications in the discipline of architecture. Thanks to its applications that increase both the creativity and efficiency of design, new digital paradigms are being created in addition to traditional methods, making it possible to restructure architectural processes with more holistic, flexible, and data-driven approaches (Harapan et al., 2021). In this respect, AI stands out as a comprehensive tool that enables the physical form-creation process of architecture and the holistic evaluation of urban, environmental, and cultural dynamics (Hegazy & Saleh, 2023; Yiğitcanlar et al., 2020).

Design implementation is the final stage of the architectural planning process. At this stage, the architect regularly visits the construction site to monitor progress, approve shop drawings and material samples, and try to resolve any problems that may arise during construction. The aim is to ensure the final project fulfills the design intent and meets the client's needs. AI also makes significant contributions to the construction site implementation phase of architectural design in terms of accelerating construction processes, reducing costs, and increasing occupational safety. The applications of AI in the construction industry are quite diverse. By using data mining and analytics on construction sites, significant optimizations can be made to complete projects on time. Analyzing data from previous projects helps determine costs and timelines, and AI can predict the requirements of future projects. This way, workflow is facilitated, all project stakeholders are continuously informed, and significant time savings are achieved (Amer, 2023; Matter & Gado, 2024). In addition, AI-supported robotic machines actively assemble and construct ready-made prefabricated building elements, making it easier for workers to produce more qualified work (Amer, 2023; Mathur, 2015). In addition, AI also makes significant contributions to detecting construction errors, production problems, and occupational safety issues on construction sites. Robots and autonomous equipment save time, cost, and labor by performing regular monitoring, data collection, and repetitive tasks in the field. In order to prevent occupational accidents in the construction industry, AI-supported safety systems can be used to identify potential hazards and take preventive measures. In this way, the efficiency of construction processes is increased, and safety standards are raised (Amer, 2023; Matter & Gado, 2024).

AI, which accelerates design and implementation processes, also contributes to architectural practice in building optimization. Wireless sensor networks (WSN), which are used in environmental monitoring and innovative building applications and are becoming increasingly smaller, energy efficient, and economical, collect large amounts of data, and building automation systems (BAS) transform these data into meaningful information (Hu et al., 2024). AI applications are also utilized in energy efficiency studies in buildings. Doukas et al. (2007) developed a rule-based intelligent decision support model for energy management and the comfort level of a building. This model is integrated into the building rnergy management system (BEMS) and has two main sets of rules, one targeting comfort conditions and the other targeting energy efficiency. Tested in an office building in Athens, this AI-powered system resulted in energy savings of approximately 10%. To support energy efficiency in the early stages of architectural design, AI analyzes climate data to optimize natural light, wind, and airflow, recommends building forms that reduce energy consumption, identifies strategic openings for natural ventilation and window placements that maximize sunlight, thus contributing to environmental sustainability while improving building performance (Ceylan, 2021). AI also helps to measure energy use in buildings in areas such as energy saving, heating, cooling, lighting, sensor systems, data mining, emission reduction, and waste management. Thus, it can contribute to achieving the principles of green architecture (Maksoud & Ahmed, 2024). In addition, AI can make the methods used to solve complex engineering problems in structural analysis faster and more precise. AI integrated with techniques such as Finite Element Method (FEM) can be used to evaluate the effects of variable loads such as earthquakes and wind in dynamic analysis. Combined with software such as SAP2000, ETABS, ANSYS, and Abaqus, AI offers more accurate predictions and optimizations for the safety and durability of structures. For example, in earthquake resistance analysis of multi-story buildings or stress analysis of steel bridges, AI can help engineers save time and achieve more reliable results (Hu et al.,2024; Liu, 2020). Another important issue is that AI is critical in post-earthquake evacuation processes with prediction and optimization tools. Systems that model human movements ensure the effective use of fire exits, accelerate evacuation, and prevent panic situations by providing real-time guidance with sensor data (Yılmaz, 2023).

AI makes significant contributions to sustainability, occupational safety, and energy efficiency in architectural design and implementation processes. Increasing creativity in design stages helps projects to be completed on time with data analytics in construction processes. It also strengthens safety practices on construction sites, identifying potential hazards. As a result, AI is supporting adopting more sustainable approaches by increasing efficiency and safety in architecture.

3.2. Current and Potential Risks of AI for the Discipline of Architecture

AI's positive and negative effects are an important topic of discussion for all disciplines. This is also true for the field of architecture. The integration of AI into the discipline of architecture creates both innovative opportunities in design processes and significant professional, pedagogical, and ethical challenges. Research reveals significant limitations of AI on creative processes. Since AI is based on the process of learning from input data, errors in the data directly affect the results (Wang, Cai, & Tian, 2018). Incompleteness, inaccuracies, or errors in data sets can cause AI systems to produce erroneous results. Such errors can cause serious problems in architectural projects, as these results directly affect the safety, functionality, and aesthetic qualities of buildings (Borglund, 2022). Thus, while AI supports humans in quickly understanding the world and predicting possibilities on this basis, it lacks the ability for true creativity and innovative thinking in the context of architecture (Matter & Gado, 2024). This is because the discipline of architecture is different from a simple question with a specific correct answer or option. This is because the architectural process involves many factors, such as the user, political dynamics, social sciences, engineering constraints, environmental standards, and artistic elements, which play an important role in shaping design choices (Gallo & Wirz, 2020). These factors give a soul to buildings, representing a quality that cannot be created by AI alone and are directly related to designers' vision. In this context, the role of AI in the design process is manifested in its capacity to simulate various design alternatives and process large data sets to maintain and validate the necessary parameters such as material use, energy consumption, exposure to natural light, and noise exposure (Borglund, 2022). However, AI cannot create the essence of buildings independently, as it works within the framework of specific rules and algorithms. Although it can produce similar designs based on existing data, it cannot offer original and innovative solutions. This situation shows that architects should work by preserving their creativity and vision while using AI as a tool (Gallo & Wirz, 2020; Haenlein & Kaplan, 2019).

While using AI-supported design tools partially replaces human input in the design process, it may cause the architect's original creativity and critical thinking processes to take a back seat and regress. The results of the research by Fan et al. (2025) reveal that AI technologies such as ChatGPT can trigger meta-cognitive laziness, which can negatively affect architecture students' self-regulation abilities and in-depth engagement in learning. This negativity is related to students' focus on superficial knowledge and weakening critical thinking skills. Furthermore, there is a risk that the analytical and experimental approaches required in creative problem-solving processes will be replaced by AI tools' fast but shallow solutions. As a result, there is a risk of limiting students' capacity to make independent decisions and develop innovative ideas in the design process, which may negatively affect their professional competence and contribution to the field of architecture in the long term. When these risk situations are considered holistically, the new generation of architects must develop different professional skills (Haenlein & Kaplan, 2019). Integrating AI into the educational curriculum allows educators to foster more interdisciplinary and creative design approaches, equipping future architects with the skills required by a digitally driven society (Almaz et al., 2024). The potential use of text-to-visual converters and other generative design tools supports creative idea generation and design exploration. However, traditional educational methods may be insufficient to effectively embrace these advanced technologies, necessitating a fundamental restructuring of architectural education that emphasizes technological competencies and ethical sensibilities (Almaz et al., 2024; Montenegro, 2024). This educational paradigm shift is critical to ensure that the next generation of architects not only benefits from the efficiencies enabled by AI but also retains the human-centered design skills vital to solving modern architecture's complex and interdisciplinary problems (Leach, 2021).

As in many disciplines, the legal and ethical dimensions of the use of AI in architecture need to be addressed. It is a potential risk that AI products and production may lead to intellectual property problems such as copyright. The issues of who owns the design proposals produced by AI and how to interpret the concepts of originality and creative labor are controversial in architecture. These issues are an important risk factor in terms of determining responsibility and property rights for the outputs produced in architectural design (Wang, Cai & Tian, 2018). Data accessibility and accuracy of AI models are among the critical issues for applications in architecture. Designing robust and unbiased algorithms that can handle large and heterogeneous data sources requires a continuous development and strong collaboration between designers and technologists (Bölek et al., 2023; Płoszaj-Mazurek & Ryńska, 2024). On the other hand, the potential biases inherent in AI systems also raise important ethical concerns. If these biases are not carefully managed, decisions made in design processes risk unintentionally reinforcing existing social inequalities (Bölek et al., 2023; Τέλλιος et al., 2023).

In summary, while AI has significant potential to improve architectural design practices by enhancing creativity, efficiency, and sustainability, its integration into this field faces several challenges. Overcoming barriers such as data limitations, ethical concerns, regulatory hurdles, and the need for curricular reform is critical for the harmonious integration of AI into both professional practice and educational institutions.

3.3. Prominent Study Trends and Gaps in the Related Literature

The integration of AI into the field of architecture is a strong area of research that has received considerable attention in recent years. One of the most prominent trends in the literature on AI is the increasing emphasis on its integration with Building Information Modeling (BIM) and sustainability principles. Studies reveal that AI has the potential to optimize design processes to increase energy efficiency and regulate the construction process more effectively in line with green architecture goals (Hegazy & Saleh, 2023; Maksoud & Ahmed, 2024). Integrating AI's predictive modeling capabilities with BIM enables architects to perform complex analyses that consider the environmental performance of a building throughout its life cycle (Maksoud & Ahmed, 2024). The integrated use of these technologies contributes to the development of innovative design solutions that comply with environmental regulations and align with sustainable building practices (Bölek et al., 2023). Therefore, the strategic integration of AI into architecture offers significant opportunities for developing environmentally responsible design approaches in today's climate-sensitive world.

Despite the growing body of literature examining the role of AI in the discipline of architecture, there are significant gaps in understanding the collective impact of these tools on the future of the architecture industry. Much of the existing research often focuses on individual AI tools or specific functionalities, lacking a holistic view of the impact of these technologies on the broader architectural process, including design, project management, and sustainability efforts (Cortiços et al., 2023). Another critical area where existing research falls short is the comparative analysis of AI tools. While studies have highlighted the capabilities of specific tools, such as AI-enabled generative design platforms and AI-enhanced BIM systems, there is a distinct lack of comprehensive analyses that evaluate these tools in terms of their functionality, market scope, and overall effectiveness across different architectural workloads (Zhang et al., 2024). This lack of in-depth and comparative studies prevents architects and industry professionals from making informed decisions about the AI tools that best suit their needs. The absence of such analyses also means that limited guidance is offered on integrating these tools into existing workflows and maximizing efficiency and creativity (Cortiços et al., 2024).

Existing research often ignores the broader professional, economic, and regulatory factors shaping the adoption of AI in architecture. While the technological capabilities of AI tools have been extensively documented, there is limited understanding of the effects of market dynamics, regional differences in technological infrastructure, and variable regulatory environments on the rate and effectiveness of their adoption (Almaz et al., 2024). For example, in regions with advanced technological infrastructure, such as the United States, the European Union, and China, AI technologies are observed to be adopted more rapidly in the field of architecture. In contrast, economic constraints and the lack of supportive regulatory frameworks significantly hinder the diffusion of these technologies in other regions. An in-depth examination of such factors is critical for developing a global perspective on the role of AI in the future of architecture (Alabdulatif, 2024).

Another important gap in the literature is the limited academic discussion on ethical issues in integrating AI into design processes. Critical issues such as biases in algorithmic decision-making processes and the potential devaluation of human creativity have not been adequately addressed (Zakariya et al., 2023). With architects becoming increasingly dependent on AI-generated outputs, an in-depth consideration of how these technologies may inadvertently reinforce existing biases or limit design exploration is warranted. This highlights the importance of multidisciplinary approaches that bring together experts from disciplines such as AI ethics, architecture, and sociology to analyze the impact of AI technologies on design creativity and integrity (Atwa & Saleh, 2023).

The state of educational practices is another important area that is often overlooked. There are frequent findings that current architecture curricula are insufficient to equip students with the competencies to use AI effectively (Jin et al., 2024; Zakariya et al., 2023). In this context, a consensus is emerging on integrating AI technologies and generative design principles into educational frameworks. Blending traditional pedagogies with innovative AI tools can allow students to use technology more informed and empathetic while developing their design capacities (Atwa & Saleh, 2023; Rane, 2024). This transformation will shape future architects' ability to solve complex architectural problems using AI creatively and effectively.

The role of AI in automating processes ranging from conceptual design to project management is increasingly being explored (Rane et al., 2023). Generative design techniques enable architects to generate and evaluate multiple design variations quickly, providing efficiency and innovation in architectural workflows (Bölek et al., 2023). However, many architecture firms hesitate to adopt AI due to the perceived complexity and risks. This transformation requires a change in design processes and an organizational cultural shift that fosters openness to technological innovation. In this context, comprehensive strategies are needed to manage AI integration effectively.

In the literature, there is a lack of empirical studies that quantify the practical effects of AI in architectural practice. While theoretical reviews are common, case studies documenting implementation results and lessons learned in real projects are limited (Baduge et al., 2022; Özman & Selçuk, 2022). Developing an evidence-based understanding of the effectiveness of AI can offer important insights into best practices and potential challenges. Studies addressing successful AI applications can fill this gap, leading to a broader acceptance of AI in architecture (Jin et al., 2024).

In conclusion, while the use of AI in architecture offers significant opportunities for the digitalization and optimization of design, it also reveals significant research gaps based on methodological incompatibilities, data integration gaps, and ethical debates. Therefore, it is of utmost importance that future studies take an interdisciplinary approach that balances both the technical integration and the human-centered and ethical approach to architectural design processes.

3.4. The Future of AI and Transformations for Architecture

Generative design algorithms, AI-supported virtual reality tools, and machine learning algorithms are increasingly integrated into architecture (Almaz et al., 2024). Methods such as AI, swarm intelligence, neural networks, and evolutionary algorithms offer different approaches to design processes. Research shows that AI combined with vision and robotics-based data input-output methods can facilitate architects' daily practices (Wit et al., 2018; Xu, Dixit & Wang, 2024). With the proliferation of applications supported by intelligent algorithms that offer new spatial solutions and run with specialized software, more intuitive and mainstream design tools are expected to be developed. This indicates that AI will transform the architectural profession in many ways shortly. This transformation will cover various processes from design, production, and post-production to user analysis. The study by Cudzic and Radziszewski (2018) draws attention to this situation and states that AI has great potential to transform the discipline of architecture and offer new possibilities.

It is known that AI can not only transform an architectural idea into a design but also make financial calculations, make construction processes more efficient, and provide personalized space optimization by analyzing sustainability and user experiences. This can transform the architectural profession into a ‘coordinator,’ ‘content manager’, or ‘curator’ rather than a ‘designer.’ Although no android architect gets in his car to survey a plot, draws by hand, and works completely autonomously in creativity, some humanoids can assist architects. Some humanoid and quadruped robots developed by the Boston Dynamics company have started to do transportation and simple installation work on construction sites (Boston Dynamics, 2023). It is also known that assistant robots that assist artisans in building walls and robots that perform coating and whitewashing are being developed (Business.govt.nz, 2024; Carros Show, 2025). In architecture, some developments indicate that there may be exciting innovations shortly regarding creativity and the ability to produce original works, which are thought to be the weakest in the professional sense of AI. Ai-Da, introduced as a humanoid with the skills of a performance artist, designer, and poet, is one of these. Described as the world's first ultra-realistic humanoid robot, Ai-Da can create original drawings and paint thanks to the cameras in its eyes, AI algorithms, and robotic arm (Founders Forum, 2024).

The scientific community accepts that AI will transform the profession of architecture, and it is an important research topic being studied. Some universities have centers where related disciplines work in cooperation to ensure the effective use of AI in architecture and to conduct scientific research (University of Michigan, 2023; UT News, 2024). It is not difficult to predict that, in such research centers, projects on training AI to be fully autonomous architects will be implemented shortly.

5. Conclusion

AI, which is used as an auxiliary tool that facilitates work and increases creativity, efficiency, and sustainability in architecture, has started to take on the role of conceptual designer in a short time. Today, AI in architecture offers innovative advantages at many points, from conceptual design to implementation and building optimization to energy efficiency. In particular, generative design algorithms, machine learning, virtual reality, and robotic applications have enabled architects to develop more design alternatives and manage construction processes faster, safer, and more sustainable. The increasing role of robots and automation on construction sites is optimizing workflows, reducing errors, and improving safety. Furthermore, sensor networks and data analytics contribute to analyzing parameters such as energy consumption, environmental impact, and user satisfaction. However, it is argued that AI is still limited in producing originality and innovation in architectural design processes and cannot fully replace human vision and creativity. Quality problems in data sets and the dependence of algorithms on existing data can lead to limited design alternatives and the proliferation of prejudices.

Furthermore, the proliferation of AI-supported tools may weaken architects' critical and independent thinking and risk a superficial approach to information. Existing studies on AI generally focus on individual tools, with significant gaps in holistic analyses, comparative assessments, professional and economic factors, and ethical issues. Issues such as algorithmic biases and devaluation of human creativity are not sufficiently discussed in the literature, nor is the integration of AI in education.

AI technology is developing very rapidly, and applications using this technology are constantly acquiring new skills. This indicates that AI will soon become an integral part of architectural practice and will fundamentally affect architects' job descriptions and working methods. AI-powered tools are assumed to offer architects unprecedented capabilities to analyze complex data sets, quickly evaluate different design scenarios, conduct energy performance simulations, and even create detailed drawings. These developments will speed up design processes, reduce costs, and increase the potential to design more sustainable, functional, and aesthetically rich buildings. However, the current limitations of AI and the need for sensitivity, particularly about regulatory compliance, structural safety, and local cultural context, suggest that the role of the architect as supervisor and decision-maker will remain important. While elements that will remain the cornerstones of architecture, such as creativity, originality, and ethical values, can be imitated by AI, their actual production and contextualization will remain in human intelligence and experience. It is important to embrace AI as a powerful collaborative partner that strengthens architectural design and construction processes, increases efficiency, and opens up new possibilities without seeing it as a threat or a competitor. Architects need to adapt to this new technology, learn to use AI tools effectively and blend the analysis and recommendations provided by these tools with their own creative vision and professional knowledge. The future practice of architecture will be based on a collaboration combining human and AI capabilities, utilizing both parties' strengths to create smarter, more responsive, and more human-centered environments. This collaboration model has the potential to usher in a new era in the evolution of the architectural profession.

Bridging barriers: Overcoming resistance to digital and computational design in architecture

Fatma İnce*[1], Hakan Anay[1]

[1] *Eskisehir Osmangazi University, Department of Architecture, 26040 Eskisehir, Türkiye*

Abstract. Despite the transformative potential of computational design and digital tools—such as AI-driven generative design, parametric modeling, and virtual reality—their adoption in architecture remains limited, hindering the discipline's ability to fully exploit technological advancements. This study systematically investigates the barriers to adoption through an extensive literature review, identifying five key areas of resistance: insufficient education and training, high implementation costs, inadequate technical infrastructure, organizational inertia in the construction sector, and ethical concerns related to data security and reliability. The findings emphasize that educational gaps, particularly within architectural curricula and professional training, create a foundational bottleneck by limiting architects' exposure to and understanding of emerging computational tools. Without adequate training, designers struggle to integrate digital technologies effectively into practice, limiting their creative and technical potential. Additionally, the high costs of acquiring and maintaining digital tools, combined with a lack of supportive technical infrastructure, further exacerbate adoption challenges, particularly for small and mid-sized firms.

Moreover, the construction sector's resistance to change—rooted in conservative workflows and risk-averse management structures—hampers collaborative efforts needed to integrate innovative digital solutions across design and construction phases. Ethical concerns regarding data security, privacy, and the reliability of AI-generated outputs also contribute to hesitation among stakeholders, creating a need for more robust frameworks that address these challenges. To overcome these obstacles, the study proposes a multi-pronged approach: integrating computational design into core architectural curricula, promoting interdisciplinary collaborations between academia, industry, and technology firms, and implementing sector-specific policies designed to enhance digital literacy and reduce economic and infrastructural barriers.

By offering actionable recommendations, such as establishing industry-academic partnerships, incentivizing digital upskilling, and creating financial support mechanisms for adopting digital tools, this research aims to bridge the gap between theoretical innovations and their practical applications in real-world projects. Ultimately, the study argues that a comprehensive approach to digital integration can foster greater innovation, sustainability, and creative exploration in architectural practice, transforming both the design process and the built environment. By addressing the current limitations, this research lays the foundation for a more adaptive, digitally-driven future in architecture, where technological tools become essential contributors to design excellence and project efficiency.

Keywords: Computational design; Digital design; Artificial intelligence; Barrier; Architecture

1. Introduction

Emerging technologies are transforming architectural practices in unexpected ways, a change that many could have not predicted just a decade ago. In terms of concepts and design, traditional systems are being replaced by computational and digital arhitectures. Digitally guided design proces are enabling new architectural possibilities. The creative and generative potential of digital technologies is beginnig to offer innovative approaches in architectural design, similar to advancements of other diciplinces (Koloreviç, 2004). It is also anticipated that, advances that lead to major changes in other diciplinces will be reflected architecture dicipline (Caetano & Leitão, 2019). However architects tend to be late in adopting technological change (Carpo, 2017). This process, which progresses more slowly in the field of architecture compared to digitalization in other diciplines constitues the main problem. The adoption of digital design is seen as inevitable to close the gap between the virtual context and physical production that emerges with the development of technology (Dritsas, 2012). While some argue that this change has the potential to develop much more than architectural styles, there are also critics (Carpo, 2024). In a study conducted in 2014 in the field of digialization in architecture, identified several challenges as to slow digital

* Corresponding author, E-mail: hanay@ogu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_514

adaptation and criticism. These barriers in digital design are seen as thresholds to be overcome in front of the mentioned and expected transformation. However, the lack of adoption or inhibition of these technologies weakens the relationship between the discipline of architecture and technology (Ramilo & Embi, 2014). It is believed that the relationship between digital design and technologies will contribute to the bacis dynamics of architecture and provide an environment for more effective and faster design solutions. In this context, design approaches that are thought to have the potential to transform not only today's architecture but also future architectural practice, are seen as the pioneers of a great transformation. Therefore, it is important to examine why this change has not been realized for the digital transformation to be experienced healthily. This research aims to determine the resistances encountered in the process of digitalization in architecture, especially with the new technologies developed in the last five years. Identifying the resistances and the approaches to overcome them will provide an understanding of the current state and future potential of digital design. In this context, the research focuses on the following questions:

1. What are the history and nowadays approaches of digital design in architecture ?
2. What are the innovative approaches and tools used in process of digital design ?
3. What kind of resistance is encountered in the adoption of these processes?
4. What are the solutions that can b developed to overcome these barriers ?

This study aims to reveal current limitations encountered in the process of digital integration in architectural practice and offer soluttions to overcome these limitations. In the introduction section, the aim and scope of the research are explained by evaulating the historical development and curret situation of digital design. The process of research, the methods used and the litarature review are detailed in the material and methods section. In results and discussion section, the classification of digital tools and the analysis of the resistance to adaptation of these tools are represented. The suggestions for overcoming these resistance and the findings are evaluated with holistic approach in the conclusion section.

1.1. Perspectives of Digital Design

Digital design has the potential to transform the practice of architecture, rooted in computational design—an approach that uses algorithms to generate, analyze, and optimize architectural solutions. The foundations of computational design date back to the 1960s (Terzidis, 2003; Dritsas, 2012). The Shape Grammers was developed by George Stiny and Jim Gips are shown as important examples in this period (Knight, 2024). Computational design approaches enable the production of complex forms more effectively and can be classified into parametric, algorithmic, and generative design (Caetano, Leitao, & Santos, 2020).

Over time, these approaches have supported by advancement of digital tools. In this context, digital design refers to a process where digital technologies play an active role from sketching to modelling and from visualization to performance analysis (Dritsas, 2012). The introduction of CAD (Computer Aided Design) technologies into architectural practice in the early 1980s marked a significiant transition from traditional drawing methods to digital production. These tools not only accelerated production process but also expanded creative potential (Kolarevic, 2004; Chaillou, 2022). However, since CAD usually can not go beyond digitising the drawing, BIM (Building Information Modelling) systems were developed in 2000s to overcome these limitation. BIM has created a crucial milestone in digitalization by integrating processes such as conflict detectin, cost analysis and sustainability assesment into a comprehensive platform (Bernstein, 2022). Parametric design which formulates a design's form based on a spesific parametres, gained popularity after Patrik Schumacher outlined its fundamental principles in his manifesto (Kolareviç, 2003; Chaillou, 2022). Currently, the most advanced aspect of digital design is artificial intelligence aided generative design. Generative design add ons to CAD, BIM and parametric design software make the design process more data-driven and optimized. Artificial intelligence has evolved beyond a mere drawing tool to become a collaborative partner in the design process, directly contributing to decision-making and providing suggestions (Leach, 2022).

Despite these technological advancements, digital design has not been widely and effectively adopted in architectural practice. The reasons for this slow technological adaptation, particularly in comparison to other disciplines, are debated—whether they stem from rational needs or biases remains unclear. In a world where technological innovation is accelerating daily, various factors such as cultural, social, technical, and economic reservations against technology contributed to this situation (Carpo, 2024).

Consequently, in order to fully utilise the potential of computational and digital design, it is necessary to identify the factors that hinder the adoption of these technologies and develop constructive approaches on how to overcome these resistances. Digital technologies add value to architectural practice not only in terms of efficiency but also creativity, sustainability and holistic design approach. Overcoming the obstacles to integrating digital technologies is critical for fostering awareness that computational design can provide transformative value to the field of architecture, rather than merely serving as an instrumental tool.

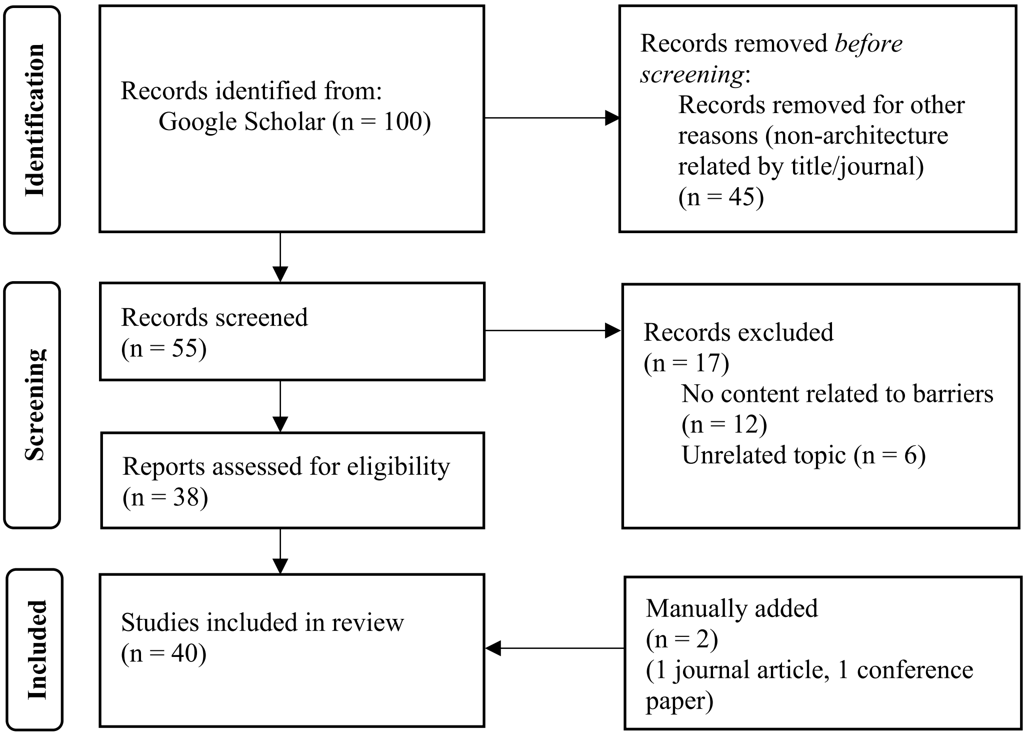

Fig. 1. Revised PRISMA 2020 flow diagram. Adapted from Page et al., 2021.

2. Materials and Methods

The study aiming to evaluate computational design and digitalization process and to identify resitances in the adaptation process, has conducted a literature review focusing on the barriers to digitalization in the field of architecture. The research was conducted through Google Scholar using the following keywords (Table 1.)

Table 1.

Function	Keywords
Google Scholar	architecture AND digitalization AND digital design OR artificial intelligence OR computational design AND barrier OR obstacle

The search covered publications from 2019 to 2024, with results sorted by relevance. The first 10 pages, which included approximately 100 articles, were manually analyzed. From these initial 100 records, 45 articles were eliminated for being irrelevant to the field of architecture based on their titles and journals. Additionally, 17 articles were excluded after abstract screening due to a lack of thematic alignment with the research focus.

After this screening process, 38 articles remained for full-text evaluation. Furthermore, 2 manually selected publications—one journal article and one conference paper—that met the study criteria were included. Thus, a total of 40 publications formed the basis of this literature review. The selection process adhered to the PRISMA 2020 flow diagram guidelines for systematic reviews involving only databases and registries (Fig. 1.). Following the analysis of the available resources, frequently used digital design tools were identified using Voyant Tools. Descriptions of these tools and their applications in the context of computational and digital design were provided. The digital tools were categorized into six headings: geometry and form generation, performance and optimization, data and information management, representation and visualization, generative design, and physical production. Once the digital design tools were determined, the data obtained from relevant literature were further analyzed using Voyant Tools. The most common barriers were grouped into five categories: education, construction, economy, technical issues, and ethics.

3. Results and Discussion

3.1. Digital Tools

The analyzed articles incorporate various digital design tools, physical production methods, and innovative approaches into architectural design. These tools are organized into six categories: geometry and form generation, performance and optimization, data and information management, representation and visualization, generative

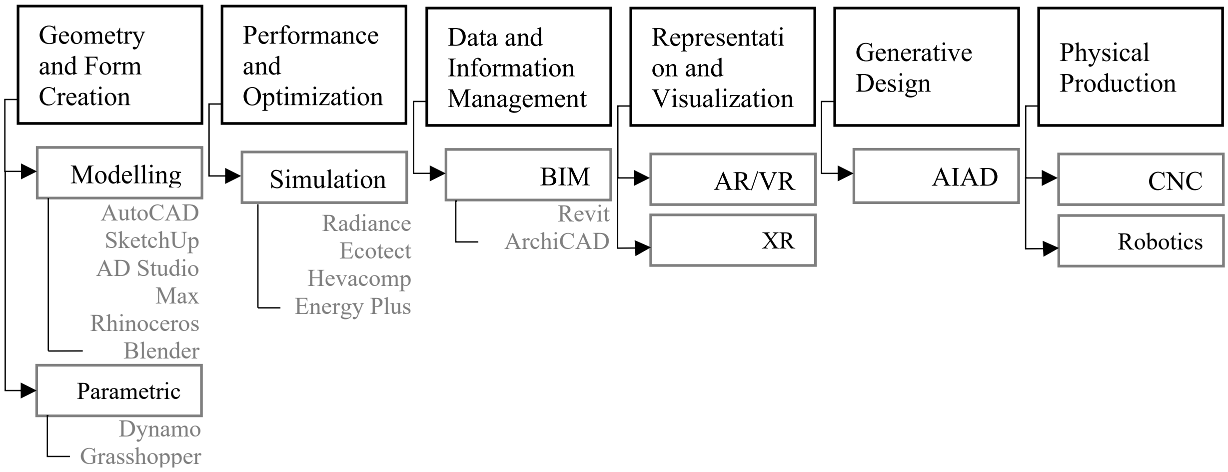

Fig. 2. Classification of digital tools (Source: by authors)

design, and physical production. Under the heading of geometry and form generation, modelling and parametric design tools, simulation tools under performance and optimisation, BIM tools under data and information management, augmented reality, virtual reality and extended reality technologies under representation and visualisation, artificial intelligence assisted design under generative design and CNC manufacturing, robotic manufacturing and digital fabrication technologies under physical manufacturing are mentioned (Fig. 2.)

3.1.1. Geometry and Form Creation

They are tools for creating bacic form and geometries in 2D or 3D in design process. It is examined under two headings as modelling and parametric tools. While modeling tools enable designers to create geometric forms in two- or three-dimensional spaces, parametric design tools enhance this process by utilizing parameters and algorithms to generate multiple design alternatives. These tools, employed at various stages from concept design to detailed technical drawings, assist designers in producing aesthetic and optimized designs, significantly contributing to increased creative potential (Koloreviç, 2003).

The use of digital tools in architecture began with the advent of CAD in the 1960s, allowing designers to explore new forms and structures. This shift introduced concepts such as flexibility, adaptability, and accessibility into the field of design (Giresun Erdoğan & Kutsal, 2024). With advancing technology, the integration of computers into architecture became widespread in the 1980s. During this period, known as "Computer-Aided Design," designers transitioned from traditional manual methods, like rulers and squares, to using a keyboard and mouse (Yıldırım, 2023). Popular non-parametric modeling and 2D drawing tools include AutoCAD, SketchUp, 3D Studio Max, Rhinoceros, and Blender (Algassim et al., 2023; Dauda et al., 2024; Ramilo & Embi, 2014).

Parametric design tools, which incorporate coding methods during the design phase, allow for more flexible and creative designs compared to BIM software (Yıldırım, 2023). The growing adoption of parametric design is gradually evolving into a design philosophy (Soleimani, 2019). One of the most significant advantages of using parametric design tools in architecture is their ability to create building models focused on performance. Examples of parametric design tools include Dynamo and Grasshopper (Delikanlı & Çağdaş, 2021; Ramilo & Embi, 2014). Moreover, by integrating parametric design tools with artificial intelligence algorithms, designers can create more flexible and intelligent designs aimed at various objectives (Yıldırım, 2023).

3.1.2. Performance and Optimization

The performance and optimization tools are used to optimizate design process and to do performance oriented designs. The simulation tools are included in this heading. Simulation tools, used in building performance modelling, are the an another area of digital design. It provides to comprehensive new approach to the design of built environment qualitative and quantitative methods as well as numerical design technologies (Koloreviç, 2003). The sotwares like Radiance, Ecotect, Hevacomp and Energy Plus are used the area of simulation in the design process. With these tools, factors such as energy efficiency, indoor humidity and air flows can be analysed and can be created based on them (Ramilo & Embi, 2014).

3.1.3. Data and Information Management

Under the heading of data and information management, BIM toola are examined. These systems, ensure that data sharing and integration at many stages from design to construction and operation process, provied a more collabrotive evironment in architecture, construction and engineering sectors. In this way, the design process becomes more transparent and efficient (Sacks, Eastman, Lee, & Teicholz, 2018).

BIM technology, in which both 2D drawings are created and the 3D model of the building can be created practically according to these drawings, is widely used in the architecture sector. With the developing technologies, BIM tools also have new integrations based on the use of parameter (Dauda et al., 2024; Elagiry et al., 2019; Olowa et al., 2023; Perez et al., 2022). The tools like Revit and ArchiCAD provide that the users form different diciplines work on the same platform during design and construction process. In this way, the error rate in projects is reduced while cost and time management are well controlled (Ershadi & Lijauco, 2024; Perera et al., 2023; Van Tam et al., 2024; Waheed & Abbas, 2023; Wu et al., 2021).

3.1.4. Representation and Visualization

AR (Augmented Reality), VR (Virtual Reality) and XR (Expanded Reality) are examined as representation and visualization tools that provide enhanced experiences. AR and VR technologies transcend the boundaries of physical reality, enabling the creation of dynamic, adaptive and interactive spaces (Giresun Erdoğan & Kutsal, 2024; Guray & Kismet, 2021). AR and VR in architecture are innovative technologies which especially enhance the BIM process. AR enriches physical space with virtual elements while VR creates immersive environments that represent real-world spaces. These technologies are valuable throughout various stages of the architectural design like visualization of project, communication, education and decision-making. In addition, the ability of AR and VR integrate with BIM makes these technologies more efficient (Gardner, n.d.; Jin, 2024; Noghabaei et al., 2020). AR combines the physical world digital data, enabling more accurate visualization during construction process. The project team can communicate efficiently in this manner. VR technologies provide that the design process more interactive. In this way, designers and engineers can experience the project in a virtual space, allowing them to make decisions quickly and accurately (Mousavi et al., 2024; Soleimani, 2019)

Architectures can design spaces without physical limitations and costs in the digital design realm. The Metaverse offers an environment that promotes flexibility and creativity, shaping both design process and experiences of users. For these reasons, digital tools like the Metaverse are essential for the future of architecture (Erdoğan & Kutsal, 2024).

3.1.5. Generative Design

The roots of artificial intelligence (AI) stretch back many years, but the concept was first introduced by John McCarthy in 1956. Today, artificial intelligence, still in the early stages of development, is viewed as a crucial component of the future (Leach, 2021). The use of AI in architecture and construction increases with developing technologies. The stages such as the design process, material selection, data analysis, time management and risk assessment become more effective with AI. These technologies transform architectural practice and its intellectual structure, are important for the future of the sector (Yıldırım, 2023). The widespeard use of AI is also seen in the construction sector. Researchs has shown that the use of AI can improve safety and productivity in the construction process (Liang et al., 2024). The text-to-image models such as Stable Diffusion, DALL-E 2 and Midjourney are frequently utilized by architects and researchers during the creative design process. AI can be used in different stages of design like conceptual image design, architectural 3D form design, floor plan design, facade design, structural system design and section design. Despite these advantages, they are still some reservations regarding the application of generative AI in architectural design (Li, Zhang, Du, Zhanga, & Xie, 2024).

3.1.6. Fhysical Production

Digital fabrication technologies encompass tools such as 3D printers, robotic fabrication systems, laser scanners and CNC machines. These tools have significiantly transformed design and production process in architecture, enabling designers to create more innovative, efficient and customized structures (Koloreviç, 2003). With these technologies, prototypes and actual structures can be produces using a wide variety of materials, including plastic, metal and ceramic. These tools facilitate the conversion of geometries generated through parametric design approaches into tangible products, enhancing the interaction between the digital and physical realms (Knippers et al., 2021; Sorguç & Yemişçioğlu, 2020). They also allow for the exploration of new materials and structural elements, offering high precision and efficiency in the production process. In addition, these technologies provide advantages such as real-time data collection and visualization during project management and construction. As a result, structures can be digitally modeled on site, allowing for the early detection of inconsistencies and errors between design and construction (Celoza, 2024; Soleimani, 2019).

3.2. Barriers of Digitalization

In the literature review conducted to understand the barriers to the adoption of these technologies in digital design, five areas particular stand out. are attracted in the literature review. Although some of these areas are not directly

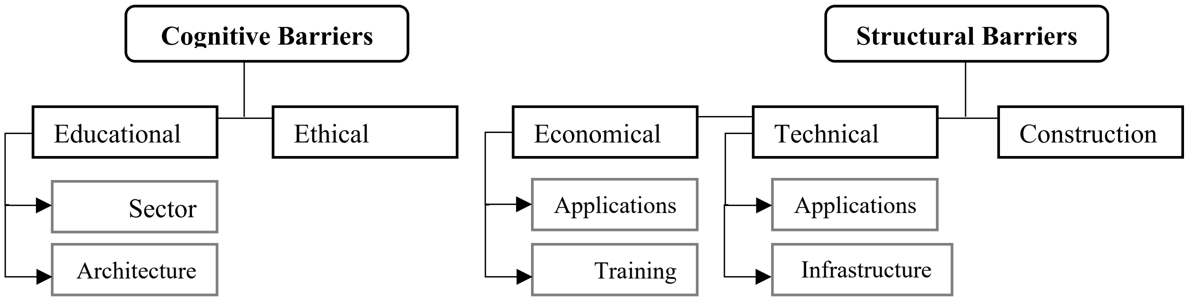

Fig. 2. Classification of barriers (Source: by authors)

related to architecture, they cause barriers to the adoption of digital technologies. The cognitive barriers arising from human-centered and cultural factors, such as lack of knowledge and ethical reservations are divided into education and ethics. The structural barriers arising from the systems, sectors or infrastructure, are categorized under three headings; economic, technical barriers and construction sector (Fig.2.).

3.2.1. Educational Barriers

Education is seen as an important barrier to become widespread these technologies. The general lack of knowledge about computational design and digital design, is mentioned in the conducted articles. This problem of education is analyzed under two headings, education in architecture and sector.

Various studies in the architectural sector highlight a significant issue: many firms lack knowledge in adopting digital design technologies. The primary challenges arise from insufficient skills and a general unawareness of these technologies. Firms that resist change, fail to invest in training, and maintain outdated practices create substantial obstacles to the integration of these advanced technologies (Abhari & Abhari, 2020; Adeusi et al., 2024; Desouki et al., 2023). A study has revealed a significant shortage of skilled and experienced professionals capable of implementing BIM design. This shortage can be attributed to several factors within the industry, such as uncertainty in market demand, general policies, and legal frameworks. Algassim (2024) attributes this inadequacy in the sector to the reactionary attitudes of major industry players. Additionally, Perez et al. (2022) emphasize the necessity of digital transformation while pointing out the lack of incentives for training within architecture and construction firms. Although computational design skills are becoming increasingly essential, they alone will not suffice for a successful transformation. Therefore, we need architects who are fully proficient in these technologies (Celoza, 2024; Perez et al., 2022). Computational design determines what is done as well as how it is done. Therefore, it is necessary to have these skills to adapt to this change. Providing these skills, which are seen as a major deficiency, is possible only if managers provide both the necessary training and a suitable working environment (Bajpai & Misra, 2021; Brozovsky et al., 2024).

According to findings on architectural education, some universities include computational or digital design in their curricula, but it is often treated merely as a tool (Sorguç & Yemişçioğlu, 2020). Gaps in education and existing prejudices hinder the acquisition of these new skills, posing significant challenges that need to be addressed in architectural education (Adeusi et al., 2024; Brozovsky et al., 2024; Cao et al., n.d.). This resistance contributes to a considerable delay in adopting new generative AI models, particularly in the area of computational design. Utilizing AI algorithms in architecture requires extensive specialized knowledge, and architects often struggle to keep pace with rapid technological advancements. As a result, many continue to rely on traditional design processes (Grajeda-Rosado et al., 2024; Li et al., 2025). Additionally, there are reservations about using digital spaces, such as the Metaverse, in architectural education. Concerns about the potential for digital experiences to distract individuals from real-world issues, integration challenges for designers, technological limitations, and the risk of diminishing creativity all impede the adoption of these platforms (Giresun Erdoğan & Kutsal, 2024). However, with the evolution of architectural education, fostering computational thinking skills will help bridge the gap between rational sciences and information technologies. This connection can lead to the exploration of the untapped potential of computational design (Delikanlı & Çağdaş, 2021)

3.2.2. Ethical Barriers

Ethics has been found to play an important role in the adoption of digital transformation. Ethical reservations of architects, students or construction sector employees were identified as another obstacle behind not using these technologies.

In the research conducted, several ethical and reliability issues have emerged, particularly in the field of artificial intelligence. Prejudice against AI tools due to their reliability risks hampers their adoption. This complex problem necessitates the development of an ethical framework for the implementation of AI in project or construction management (Onatayo et al., 2024). These technologies gather data during the design phase for management purposes, such as monitoring, work control, and documentation. Some of the data collected may include information irrelevant to the project's objectives, leading to potential data privacy violations. Concerns about data privacy limit the use of digital design tools and complicate their adoption by stakeholders in the industry (Liang et al., 2024). Watanabe (2014) examined common issues like data privacy, over-reliance on algorithms, and a disregard for technology's limitations, concluding that both students and professionals have decreased trust in digital technologies due to insufficient discussion about data privacy and the implications of computing. The lack of ethical considerations has turned technology into a means to an end. Data transfer processes often create environments vulnerable to data leaks, unexpected changes, or damage, which can lead to private data breaches and make systems untraceable (Liang et al., 2024; Montenegro, 2024; Rane et al., 2023). Addressing these concerns will strengthen the ethical foundations of digitalization and facilitate the wider adoption of digital technologies in the sector.

3.2.3. Economical Barriers

Barriers to the adoption of these approaches include economic and financial problems. Economic constraints are divided into two sub-headings: implementation cost and training cost. In the studies reviewed, it is pointed out that the software and the programs used are inaccessible due to their cost. In addition, it has been determined that even if they have these software, managers who want to increase the level of training resist change due to the cost of training.

Algassim (2024) notes in his study that the high cost of acquiring the most innovative digital technologies presents a significant barrier for organizations. This high price, along with the inaccessibility of these technologies for small and medium-sized firms, poses a challenge that must be addressed for change to occur. The hardware and software required for digital design are perceived as more expensive and complex compared to traditional design methods (Giresun Erdoğan & Kutsal, 2024). Additionally, adopting digital means of production often entails various investment requirements, causing companies to hesitate in allocating resources to digital environments (Ajirotutu et al., 2024; Ramilo & Embi, 2014; Waheed & Abbas, 2023). The adoption of virtual reality (VR) and augmented reality (AR) technologies in architecture is also limited by economic barriers. The costs associated with implementation not only impede technology adoption but also result in the under-utilization of their potential benefits. Addressing these economic obstacles could encourage greater acceptance of these technologies (Mohammadi & Martins, 2023).

Economic barriers extend beyond implementation to the experiential aspects that these applications demand. Employee-related costs, including training and support, further complicate the adoption of these technologies in the industry (Bajpai & Misra, 2021; Mohammadi & Martins, 2023). The projected training expenses for architects lacking the necessary skills have deterred some professionals from pursuing these technologies (Perez et al., 2022). A study concerning the use of generative design in architecture highlights that integrating computational design tools into project management systems requires significant investments in training. For instance, projects incur additional costs for training and maintaining a generative AI model, which slows down the adoption process. These extra costs pose a substantial barrier for stakeholders, particularly for smaller companies (Onatayo et al., 2024).

3.2.4. Technical

The lack of technical infrastructure, which is one of the obstacles to digitalization, is also mentioned in the studies. In the non-adoption of technology, the fact that the software is not accessible and does not have the appropriate infrastructure for it to work are cited as reasons for the lack of acceptance of digitalization.

Certain software and programs are essential for computational design and the implementation of new technologies. Their availability and accessibility are viewed as critical factors for widespread adoption. The articles reviewed present differing opinions regarding the adequacy of these software solutions. For instance, the technical difficulties associated with these applications, along with their lack of user-friendly interfaces, contribute to their unpopularity (Chatzikonstantinou, 2021; Cheung & Dall'Asta, 2024; Perera et al., 2023). Additionally, security concerns regarding these applications are also considered significant issues (Van Tam et al., 2024; Xu et al., 2021).

There are various viewpoints on the deficiencies in the infrastructure necessary for effectively using these technologies. Sorguç (2020) argues that the increasing ease of use of software plays a vital role in this transformation. In contrast, Perez (2022) highlights that a lack of technical support is equally crucial, suggesting that providing training alone may not be enough. A successful digital design experience is contingent upon meeting the hardware and software requirements necessary for access. Technical infrastructure challenges during the design process can hinder efficiency and slow down progress (Giresun Erdoğan & Kutsal, 2024). However, some studies criticize these obstacles. They point to the challenges imposed by the pandemic and the revelation of existing, underutilized infrastructures as examples of potential remedies (Carpo, 2024).

3.2.5. Construction

One significant factor hindering the adoption of modern design processes is the construction industry itself. The studies reviewed revealed that varying attitudes within the sector contribute to its resistance to these changes. There are differing views on why the construction industry is lagging in this regard.

For instance, Carpo (2023) criticized the construction sector as a reactionary and conservative "dinosaur" in its approach to innovation. He describes today's construction industry as a monument to wastefulness, characterized by inefficient and unsustainable building practices. Studies indicate that the construction industry has the lowest level of digitalization and adaptation to change compared to other sectors. This resistance is largely due to concerns about rising costs. Although there have been efforts to encourage the integration of technology in construction, these initiatives have primarily focused on BIM and its incremental improvements. As seen in other fields, true transformation requires embracing advancements in technology. The sector's stagnation is viewed as a major barrier to this transformation. Algassim (2024) cites the rapid construction of a hospital in Wuhan, China, which was completed in just ten days using digital technologies, as a striking example of the construction industry's reluctance to step out of its comfort zone. This project, which typically takes an average of ten years to complete, highlights the potential for efficiency when forced to adapt. Innovations in the industry should not only focus on enhancing existing processes but also on exploring the broader potential of these technologies (Knippers et al., 2021). Additionally, another study within the construction sector points out a lack of contextual input that aligns with the industry's complexity in areas such as structural, mechanical, electrical, plumbing, and project management. Defining and measuring the sector's goals in a manner that an AI model can understand and optimize presents challenges rooted in cultural and social factors. These obstacles further distance the construction industry from adopting advanced technologies (Onatayo et al., 2024).

4. Conclusions

Digital design's adoption of tools and processes emerging with developing technologies is an important step of digitalization in the field of architecture. This change has also affected the processes of thinking, working, designing and producing in architecture. However, there are some obstacles that cause these changes to be adopted later in the field of architecture than in many other disciplines. Due to these obstacles, problems are encountered in the use of digital design technologies. As a result of the literature review, different views were identified and ranked against the resistances affecting the adoption of the mentioned technologies in architecture (Fig.3.). According to this ranking, the most common resistance in the field of digitalization is education. The obstacles encountered in the field of education are mostly due to the lack of education in the sector. These problems are listed as follows:

- Lack of awareness and understanding of digitalization in the sector
- Lack of specialized people and practical training in the sector
- Skills gaps between professionals
- Prejudice against learning and professional development in the sector
- Inadequate collaboration between architects and IT professionals
- Lack of incentives for continuing education

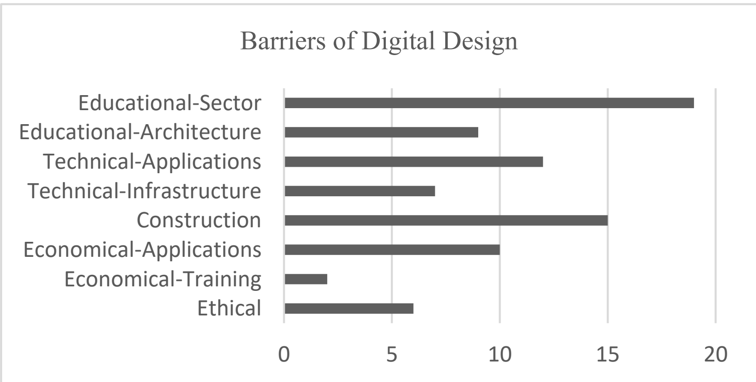

Fig. 3. Barriers of digitalization in architecture (Source: by authors)

The difficulties in architectural education, which is another title where problems in the field of education are seen, are listed below:

- Unrenewed architecture curriculum
- Failure to integrate BIM and digital tools into education
- Limited exposure to emerging technologies in schools
- Lack of formal training on AI/digital tools

- Lack of training programs at university level
- Lack of awareness and skills among students

In the second place, these barriers are most common in technical areas. The technical barriers experienced in digital design tools are listed below:

- Software that is difficult or complex to use
- The “black box” nature of AI tools
- Interdisciplinary incompatibility (architecture and computer science)
- Difficult technical processes requiring expert intervention

Infrastructural problems, another heading of the technical field after digital applications, are listed as follows:

- Lack of infrastructure, standardization and regulation
- Data interoperability issues
- System compatibility issues
- Inadequate data security measures

In the construction sector, which ranks third, the resistances affecting digitalization in architecture are listed as follows:

- General resistance to change and low adoption in the construction industry
- Conservative practices and habits
- Organizational resistance and leadership gaps
- Lack of awareness in construction companies

One of the reasons for the economic barriers in the fourth row, resistance in implementation costs, is listed below:

- High cost of software and hardware
- Expensive license fees and infrastructure
- Budget constraints for digital transformation

The problems encountered in employee training, another heading of economic barriers, are listed below:

- High cost of professional training programs
- The financial burden of continuing education
- Costly transition for teams and organizations

The fifth and final heading, ethical resistances, is listed as follows:

- Data privacy and security concerns
- Algorithmic bias and its ethical implications
- Job security concerns related to automation
- Lack of ethical framework and guidance in the use of AI

Overcoming these resistances faced by the digitalization process, which has the potential to transform the field of architecture, will accelerate the digital transformation process by enabling easier adoption of technologies. Different solutions to overcome these resistances have been proposed in the literature (Table. 2.).

Table 2. Recommended solutions for barriers of digitalization

Barrier	Explanation	Recommended Solutions
Educational	Insufficient knowledge of digital tools among students and professionals	Integration of AI, data science and computational design into the curriculum, certificate programs, mentoring systems, online courses
Ethical	Data privacy, algorithmic biases and human-machine interactions	Increasing ethical education, adopting a people-oriented
Economical	High costs	Long-term benefit and return on investment analysis
Technical	Lack of infrastructure and technical skills required for the integration of new technologies	Creating the necessary technical infrastructure, ensuring that architects are familiar with the applications
Construction	Adherence to conventional methods	To more clearly demonstrate the economic benefits of digital tools in the construction sector and create strategic plans

One of the most common sources of resistance to digital transformation is the lack of knowledge regarding digital technologies, both in the industry and in architectural education. In this context, Onayato (2024) advocates for the inclusion of courses on artificial intelligence, machine learning, and data science in university curricula as a solid foundation for digital transformation. Interdisciplinary programs and specialized courses can help students adapt to digital tools at an earlier age. This approach will encourage architects to adopt more collaborative and technology-sensitive methods in the future (Onayato, Onososen, Oyediran & Oyediran, 2024). A study utilizing digital design tools found that 91.7% of students indicated they would use computational design in their careers, while 45.4% believed this course should be mandatory. These findings underscore the necessity of introducing students to these technologies and providing them with hands-on experience in design studios, as well as in theory and structure courses (Soleimani, 2019). Consequently, architectural education should not only focus on technical skills but also promote a design thinking approach that critically assesses the potentials and limitations of digital tools (Sorguç & Yemişçioğlu, 2020).

It's also essential to consider the ethical dimensions of technology. Watanabe et al. (2014) highlight that a lack of ethical considerations can undermine trust in technology, turning it into an end rather than a means. Thus, a greater emphasis on ethical issues by educational institutions and professional fields can guide healthy human-computer collaboration. Carpo (2024) stresses that technologies should be regarded not as "the future" but as "today's reality," and architects must take responsibility for shaping the future by embracing these technologies. In this regard, universities should not be the only institutions involved; certificate programs, workshops, and online training opportunities in the sector also play a critical role in helping architects adapt to the digitalization process. These resources—which cover areas such as programming, data management, and artificial intelligence—are instrumental in bridging knowledge gaps. Furthermore, mentorship programs fostering knowledge sharing among experienced professionals in the industry are also valuable. By taking these hands-on approaches, AI-based solutions can be more effectively integrated into architectural practice (Onayato et al., 2024). It is vital for the sustainability of the transformation process that the industry comprehends digital transformation, identifies existing gaps, and develops appropriate strategies (Higgins, 2023).

In the construction industry, various factors contribute to resistance, including cost concerns, reluctance to abandon established habits, and issues related to ease of use. However, Mohammadi (2024) asserts that VR technology is likely to become a reasonable investment for construction companies within five years. During this transition, companies must conduct economic evaluations that align with their projects. A study by Noghabaei et al. (2024) suggests that the majority of young architects predict that BIM and AR/VR technologies will be widely adopted in projects within the next 5-10 years. This expectation illustrates the rapid acceptance of digital technologies within the sector.

The research highlights several key factors that hinder the digital transformation process in the construction sector. These include deficiencies in education, high costs, a lack of technical infrastructure, traditional practices in the industry, and ethical concerns. One significant finding is the need to restructure architectural education to incorporate digital skills, as the current lack of knowledge in this area poses a major barrier to the effective and innovative use of digital tools. To facilitate the adoption of these technologies, it is crucial to establish cross-sector collaborations and develop policies that address both economic and technical challenges.

The research not only identifies sources of resistance but also suggests practical solutions to accelerate digital transformation. Key proposals include increasing digital literacy in education, developing sector-specific digital strategies, and creating frameworks that promote the ethical use of technological tools in architectural practice. In conclusion, the comprehensive integration of digital technologies into architecture can lead to a more innovative, sustainable, and human-centered future for the construction industry. This shift will redefine not only design processes but also the theoretical and practical boundaries of architecture.

From notes to structures: Translating musical composition into the architectural realm

Ebru Erdogan*[1]

[1] *Selcuk University, Department of Architecture, Konya, Türkiye*

Abstract. Throughout history, architecture has been regarded as both a design discipline and an artistic endeavor. By its very nature, this artistic dimension has compelled architecture to maintain close ties with sculpture, music, dance, theater, and literature. Over the centuries, the relationship between architecture and music has been analyzed from various perspectives by philosophers, literary figures, architects, musicologists, and design theorists. Notably, in ancient Greece, mathematical theorists sought to establish arithmetic relationships between musical and architectural works, and similar connections have continued to exert an influence into the modern era. Philosophers and literary scholars, in contrast, primarily addressed the relationship between music and architecture in symbolic and metaphorical ways, without fully exploring their shared structural and design languages. Despite the distinct ways in which architecture and music are perceived, it is evident that their creators—architects in the case of architecture and composers in the case of music—exhibit parallels in their modes of thought, design processes, design principles, and structural characteristics. When both disciplines are viewed as products of design, indirect connections can be observed in their creation, presentation, and reception. Moreover, the outputs of both disciplines qualify as compositions, each organized according to a specific design framework. This study aims to explore various facets such as the relationship between music and architecture, the translation of music–architecture interaction into the design realm, and the influence of music on creativity in the architectural context.

Keywords: Architecture; Music; Basic design; Education; Creativeness.

1. Introduction

"*The sense of physical space in architecture manifests as an emotional space phenomenon in music, creating a hybrid relationship between the two disciplines*" (Denari, 1994).

Although music and architecture appeal to different senses, they share a strong relationship through common design principles such as rhythm, proportion, harmony, and composition. Architecture shapes space to establish a visual order, while music structures time to create an auditory order. However, both disciplines guide human perception, evoke emotions, and offer aesthetic experiences. Throughout history, architectural spaces have been specifically designed for musical performances; structures such as cathedrals, concert halls, and theatres have shaped the musical experience through their acoustic and spatial arrangements. Likewise, philosophers and artists have referred to architecture as "frozen music," emphasizing the similarities between the order and rhythm of buildings and musical compositions. In this context, music and architecture interact both sensorially and structurally, shaping human artistic and spatial perception. In De Architectura, an essential work on architectural theory from antiquity to the present, Vitruvius states in the chapter On the Education of the Architect;

"The architect must not only be knowledgeable in the theory of canon and mathematics but also have an understanding of music to correctly tune ballistae, catapults, and scorpiones to the appropriate pitch... An architect cannot be a musician like Aristoxenus, yet should not be entirely ignorant of music either" (Vitruvius, 1999).

The conceptual relationships between architecture and music have been influenced by the mathematical ideas of Pythagoras and Plato, and from the Renaissance onward, they have been examined both theoretically and practically (Fig. 1). Antoniades (1990) argues that the arrangement of columns and spaces in Greek temples follows the principles of musical harmony, emphasizing that this correlation is not coincidental. Similarly, Georgiades highlights that the harmony between visual and acoustic perception fosters an aesthetic appreciation. During the same period, Alberti incorporated harmonious musical proportions into his architectural works, an approach that has continued to be embraced by architects and composers in the modern era.

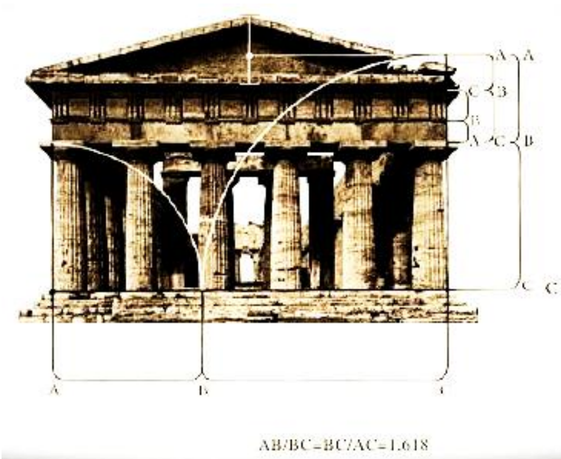

Fig. 1. The Temple of Neptune, Italy, and the Golden Ratio.

Throughout history, the Golden Ratio and the Fibonacci series have served as essential tools in establishing the connection between beauty and mathematical order in art and architecture (Fig. 2). Bartók was among the first composers to systematically integrate these proportions into his music. Similarly, just as Vitruvius argued that the human body should be structured according to arithmetic and geometric measurements, Le Corbusier considered the human scale as a fundamental element of architectural design (İzgi, 1999).

The Philips Pavilion, as one of the pioneering structures where architecture and music converge, embodies the concept of "frozen music." Unlike previous examples, it integrated advanced mathematics and specially composed music to incorporate the third dimension into architectural design, strongly reflecting the relationship between sound and space. Designed for the 1958 Brussels World's Fair on behalf of Philips, this structure was realized through the collaboration of Le Corbusier, the renowned Greek composer and architect Iannis Xenakis, and Edgar Varèse (Fig. 3). While Le Corbusier conceptualized the project, Xenakis developed its innovative structural design, and Varèse provided its acoustic identity through his spatial composition Poème Électronique. Reflecting Le Corbusier's modernist approach, the pavilion combined rational forms and free curves, generating complex surfaces that challenged the architectural terminology of its time. Xenakis, through mathematical calculations, developed these forms, making the Philips Pavilion a unique example of the fusion between architecture and music (Xenakis, 1958). His proposal to Le Corbusier was to conceive an architectural design inspired by his own musical composition Metastasis, emphasizing an interdisciplinary creation process (Leopold, 2003). Xenakis worked on translating the glissando[2] transitions in his composition into architectural form, employing visualization techniques that relied on abstraction and mathematical calculations.

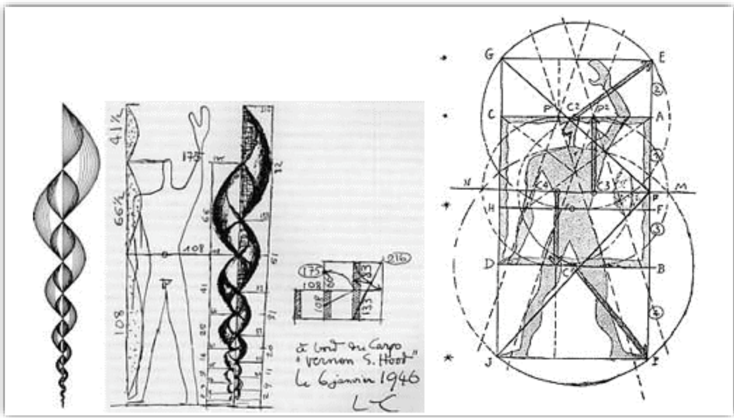

Fig. 2. Le Corbusier and Le Modulor (Url-1)

[2] The term "glissando" in music refers to a gradual transition along a scale, moving either from high to low or from low to high in pitch.

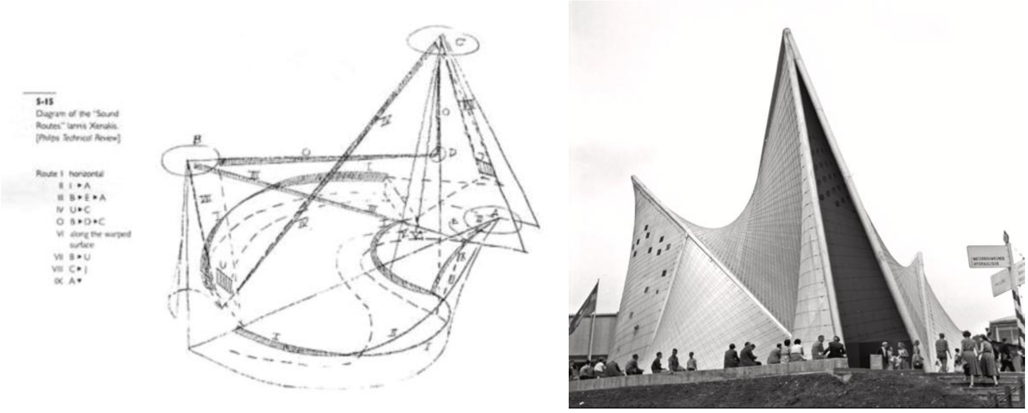

Fig. 3. The music broadcasting diagram designed for the Philips Pavilion (Treib, 1996).

Just as in the Philips Pavilion, Xenakis demonstrated the harmonious integration of architecture, music, and mathematics in both his individual projects and significant collaborations with Le Corbusier, such as La Tourette Monastery (Fig. 4). In La Tourette, the interplay between solid elements (such as walls) and voids (such as windows and doors), along with contrasting light and dark surfaces created through material variations, generates a rhythmic flow. Xenakis's innovative musical notation system not only influenced 20th-century architecture but also reinforced the high rhythmic order in Le Corbusier's projects through his knowledge of geometric proportions (Matossian, 1986).

Designed by Steven Holl, Stretto House was constructed using concrete blocks and distinctive metal curves. Holl is an architect who draws inspiration from music in his designs, and the name of this house is derived from the musical term "Stretto." Stretto in fugue music refers to the overlapping of the main theme as it transitions closely between different voices. Holl applies this principle to architecture by creating an interconnected, overlapping, and fluid design. The integration of the floor with the upper level, the merging of the roof with the walls, and the use of slanted walls to direct natural light inside exemplify this design approach (Fig. 5).

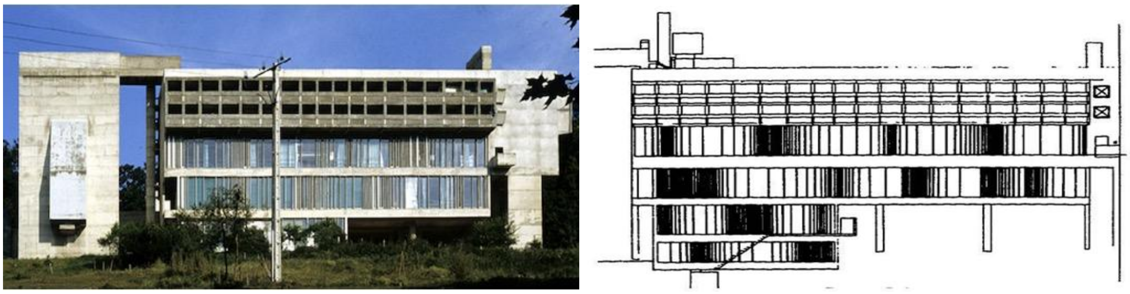

Fig. 4. The undulating 'musical' representation of the glass designed by Xenakis using Le Corbusier's Modulor system (Matossian, 1986).

Fig. 5. Holl's Stretto House (Url-2)

Holl's inspiration for the Stretto House was Béla Bartók's Music for Strings, Percussion, and Celeste. This musical structure was directly integrated into the house's design. For instance, the four masonry walls were based on the second cello's recurring main theme at the end of the composition. Additionally, Holl selected building materials according to the tonal characteristics of the instruments: the light and delicate sounds of the string instruments were represented by glass-enclosed metal roofs, while the heavy and deep tones of percussion were embodied in masonry walls (Fig. 6, Fig. 7). Through this approach, Holl successfully translated the balance of sounds in music into architecture, creating a unique and innovative design.

2. The relationship between music and architecture

Throughout history, architecture and music have been examined from various perspectives and interconnected in multiple ways. The interaction between these two disciplines can be analysed in terms of their functional, philosophical, perceptual, and creative dimensions.

2.1. The functional relationship between music and architecture

The necessity of performing musical activities in dedicated spaces establishes a functional and interactive link between music and architecture. Various architectural structures have been designed specifically for musical performances across different historical periods. Hypostyle halls in Egyptian temples, odea in ancient Rome, Greek arenas, medieval cathedrals for church music, and 18th-century aristocratic salons were all specialized spaces designed for different musical performances. During the 18th and 19th centuries, composers were significantly influenced by the acoustic properties of the venues where they repeatedly performed. For instance, Bach's compositions were shaped by the reverberation characteristics of Thomaskirche Church, where he served as the principal musician. Similarly, the acoustic properties of St. Mark's Basilica in Venice contributed to the emergence of polychoral concert styles, inspiring Giovanni Gabrieli to compose works specifically tailored to this space (Fig. 8).

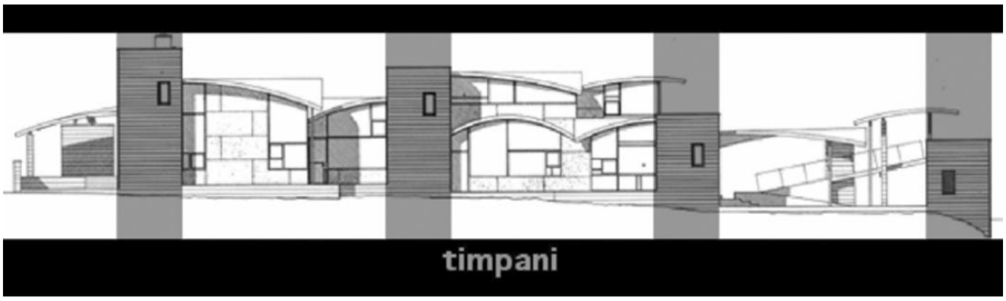

Fig. 6. Extracts from the multimedia analysis of Holl's Stretto House. Heavy elements – orthogonal brick walls – kettledrums (Capanna, 2009).

Fig. 7. Extracts from the multimedia analysis of Holl's Stretto House. Light elements – metallic roofs – violins (Capanna, 2009).

 

Fig. 8. Saint Thomas Church and Saint Mark's Basilica

2.2. The philosophical relationship between music and architecture

Numerous philosophers and architects have drawn metaphorical parallels between music and architecture through various analogies and interpretations. The philosopher F. W. Schelling's definition of architecture has been a source of inspiration for many thinkers. Schelling described architecture as "solidified music", while Schopenhauer referred to it as "frozen music" (Sack, 1997). Similarly, Goethe characterized architecture as "silent music", and Victor Hugo, in his novel, described Notre Dame Cathedral in Paris as "a grand symphony in stone" (Antoniades, 1990) (Fig. 9).

Schopenhauer likened a solid wall in a building to a monotonous sound, while comparing columns arranged at regular intervals to a scale played in an even rhythm. Similarly, Beltcher associated the heavy and imposing walls of a prison with the largo sections of musical compositions and the dynamic facades of Gothic architecture with vivace sections. Such metaphorical connections between architecture and music have persisted through modern and postmodern periods. For example, Daniel Libeskind, who is also a professional accordion virtuoso, seeks order within poetic complexity in his works (Fig. 10). In this context, he frequently establishes non-representational symbolic relationships with music. One of the most notable examples is the Jewish Museum, where he constructs a symbolic bridge between music and architecture. The museum embodies a sense of absence and invisibility, referencing the Holocaust. The concept of void and non-existence is metaphorically linked to Arnold Schönberg's opera Moses und Aron, particularly in its final section, "Der Erinnerungsraum" (Memory Void), where Moses remains silent for an extended period, creating an echo of emptiness (Libeskind, 1992).

 

Fig. 9. Milan Cathedral and Notre Dame Cathedral

Fig. 10. Jewish Museum Berlin (Url-3).

By considering Arnold Schönberg's innovative approach to music as a form of enlightenment, Daniel Libeskind integrated this perspective into his architectural approach, distancing space from traditional typological concepts and conceiving it as a void rather than a structure. This approach illustrates that Libeskind conceptualizes the building as an instrument, highlighting its function by generating resonance through the void. In this way, he transforms the creative process, shifting the museum beyond a conventional exhibition space into a memorial that embodies the spirit of its era (Libeskind, 2008). In his design for the Jewish Museum, Libeskind did not merely use music as a metaphor to shape architectural forms, nor did he directly translate fundamental musical elements such as intervals, rhythm, or meter into architecture. Instead, he explored the relationship between music and architecture by capturing moments of musical incompleteness. Libeskind engaged with the unfinished final section of Schönberg's composition, attempting to complete its absence through architectural expression and thus reinterpreting the boundaries of music within an architectural context (Franck, 2004).

Among architects who translate musical inspiration into tangible architecture, Erich Mendelsohn and Daniel Libeskind stand out as figures who employ music as an architectural paradigm, yet in vastly different ways. While Mendelsohn translated the emotions evoked by music into architecture, Libeskind established a connection with music through a highly intellectual and rational perspective (Franck, 2004). The modernist architect Erich Mendelsohn, known for his expressionist formalism, exemplified this approach in the Einstein Tower, where he employed a musical metaphor to articulate his architectural vision. He likened horizontal architectural elements to melody, while vertical elements represented chords (Fig. 11). In Mendelsohn's view, every architectural structure is akin to a musical composition performed visually.

The fundamental characteristic of music lies in the fluidity of tones and the structuring of its performance technique. The beginning, climax, and conclusion of a musical composition share similarities with Mendelsohn's architectural perspective, which emphasizes a dynamic progression of space. Mendelsohn associated architectural elements with music, emphasizing the principles of harmony and counterpoint. The foundation of this similarity lies in his perception of architecture as an organic whole, where individual elements interweave seamlessly. According to Mendelsohn, harmony can be applied along both horizontal and vertical axes. This approach represents the direct translation of musical harmony and melody into architecture. Rather than considering the concept of time as a third dimension, this reflection—depicted through horizontal and vertical axes in a two-dimensional plane—integrates the notion of melody within a two-dimensional framework.

Fig. 11. Einstein Tower, Germany (Url-4).

2.3. The perceptual relationship between music and architecture

The perception of music through listening and architecture through sight occurs on specific planes that can be simultaneously apprehended. While architecture takes shape in space, music exists within time. A musical composition is an auditory phenomenon, whereas an architectural structure is a visual one. However, in both art forms, aesthetic perception shares common aspects in both the design process and the evaluation of completed works. Before they are performed or constructed, both music and architecture exist merely as potential aesthetic objects. Architecture attains the quality of a real aesthetic object when it becomes tangible in space, while music does so when it becomes auditory. At this point, a distinct parallel emerges between the ways in which these two art forms are perceived.

According to Murray, the perception of music through listening and architecture through sight can be experienced on three fundamental levels:

Sensory Perception – Music is often enjoyed unconsciously, as most people engage with it casually in daily life. Similarly, architecture provides a sensory experience, particularly in Baroque and eclectic architectural styles, where form is shaped predominantly by aesthetic concerns.

Semantic Perception – This level establishes a deeper connection between music and architecture. Music, as an abstract art form, is highly effective in conveying meaningful forms. An essential aspect of the perception of meaning is repetition. While a constantly repeated melody may bore the listener, music that exhibits variation tends to sustain interest. Similarly, architectural structures that repetitively convey the same message tend to lose their appeal over time.

Technical Perception – In music, this involves notes, rhythm, harmony, timbre, and structural composition, while in architecture, it relates to material selection, construction techniques, and functional planning. In both fields, technical elements serve as the foundation for ensuring both aesthetic appeal and functional integrity (Pasin, 2007).

2.4. The creative relationship between music and architecture

The architectural creation process fundamentally consists of analysis, concept development, and synthesis stages. Considering these stages, the striking similarities emerge between the architect and the composer. Some artists experience their inspiration spontaneously and instinctively. Composers like Mozart perceive their musical compositions in a holistic form mentally before transcribing them onto paper, envisioning music as a painting or sculpture. On the other hand, some artists meticulously develop and structure a musical or architectural idea within a specific thematic framework. While Beethoven shaped his music through meticulous refinement and prolonged effort, Mies van der Rohe adopted a similar approach, translating his ideas into architecture through logic, aesthetics, and imagination, using modern materials such as steel and glass. From a traditionalist perspective, Johann Sebastian Bach's music aligns with the architectural expressions of his time, reflecting the era's sophisticated formal structures. Similarly, Ictinus, who composed music inspired by ancient Greek works such as the Parthenon, was also influenced by the artistic sensibilities of his time. However, the art world has always been shaped by pioneers who break away from tradition and embrace innovative approaches. In the 17th century, Berlioz, and in the 20th century, Debussy and Schönberg introduced radical transformations in music, while in architecture, Brunelleschi and Le Corbusier similarly challenged traditional paradigms, developing distinct and original design approaches. In this context, the relationship between music and architecture shares numerous commonalities in terms of the creative process.

3. Conclusions

The examples examined in this study demonstrate that music and architecture share similar design principles and that both disciplines integrate aesthetic, mathematical, and perceptual components. As interconnected fields, music and architecture contribute to the enhancement of artistic perception and the enrichment of spatial experiences. Considering architecture not merely as a visual art but as a multi-sensory, temporal and spatial discipline perceived through all senses will contribute to the development of innovative approaches in design processes. In this context, integrating music into architectural education and utilizing it as an analytical tool in design can be regarded as an effective method for stimulating creative thinking.

According to Robert Morgan, "although music possesses a temporal dimension of perception that is entirely independent of space, space remains an integral part of the musical experience" (Mitchell, 1980). Numerous studies have highlighted the impact of music on architectural design and how music, as a historical and artistic phenomenon, has influenced the evolution of architecture over time. This study has explored the ways in which musical principles resonate within architectural design processes and examines how music functions as a generative force in spatial composition. By analysing historical influences, theoretical frameworks, and practical applications, it has underscored the interdisciplinary relationship between music and architecture. Specifically, this study investigated the impact of musical structures, rhythms, and harmonies on spatial organization and architectural expression, demonstrating how these elements inform and shape the design process.

The influence of music on architecture, through various modes of interpretation and perception, plays a significant role in shaping and developing an individual's architectural style. The ability to analyse a musical composition conceptually, theoretically, structurally, and in terms of its patterns defines a contributory force to architectural composition. Approaching architecture not solely through visual perception but by engaging all sensory perceptions can lead designers to new and innovative design possibilities.

Evaluation of wood material awareness in architectural education

Nilay Aykan[1], Esra Lakot Alemdağ*[1]

[1] Recep Tayyip Erdoğan University, Department of Architecture, 53100 Rize, Türkiye

Abstract. Wood stands out as a sustainable building material due to its carbon sequestration capacity, recyclability, biodegradability, and renewability. With advancing technology, industrial wood products have improved strength compared to natural wood, along with enhanced resistance to moisture and fire. These developments have made it possible to construct multi-storey and wide-span buildings using wood. Considering these advantages, the use of industrial wood contributes significantly to ecological sustainability in construction. Therefore, it is important for future architects, who play a key role in material selection, to be aware of wood materials and construction systems. This study evaluates the knowledge and awareness levels of architecture students from Karadeniz Technical University, Recep Tayyip Erdoğan University, and Atatürk University regarding wooden building design and industrial wood materials. A questionnaire was conducted to assess the extent of related course content in their undergraduate education and the students' familiarity with these topics. Based on the survey results, the level of recognition of wood materials within the existing curriculum was identified.
Professionals in the construction sector have a responsibility to support ecological balance through sustainable material choices. In this context, the study aims to contribute to the development of environmental awareness among architecture students by emphasizing wood materials at the undergraduate level. It is expected that this awareness will encourage environmentally conscious material decisions in their future professional practice.

Keywords: Wooden buildings; Wooden construction systems; Industrial wood materials

1. Introduction

The materials used in the building sector have many negative impacts on the environment from the production process to the end of their life cycle due to resource consumption, energy-intensive production processes, greenhouse gas emissions and waste generation.

Global warming and climate change, among the major global environmental problems, are caused by excessive carbon dioxide emissions (Švajlenka & Pošiváková, 2023), which jeopardizes the sustainability of the ecosystem. One of the three main goals set within the scope of the "Sustainable Development Goals" adopted by the United Nations in 2015 is the fight against climate change. All sectors have various responsibilities in achieving these goals. According to 2023 emission data, 34% of carbon dioxide emissions originate from the construction sector (United Nations Environment Programme (UNEP), 2025). This ratio shows that production in the construction sector generates high levels of emissions and that the sector has a great responsibility in this area. Available data reveals that it is imperative to take effective measures to reduce carbon dioxide emissions (Demir et al., 2024). Investigations using life cycle assessment methods specific to building materials show that wood-based buildings have 81-94% lower global warming potential compared to concrete buildings and 76-91% lower global warming potential compared to steel buildings (Wang et al., 2024).

Wood, one of the forest products, is a renewable resource (Falk, 2010), as well as a carbon absorber (carbon sink) by sequestering and storing carbon (Iordan et al., 2018). Being a lightweight material that is easy to process and transport, it allows maintenance, repair and modifications to be made easily (Cabeza et al., 2021). Wooden structural elements can be connected to each other by means of interlocking systems, joined or glued with screws, nails, bolts and metal elements. In addition, the detachable nature of the joint connections enables the reuse of wooden elements through disassembly (Çalışkan et al., 2019).

Wood, which has been the most common building material throughout history, has experienced a significant decline in its usage rate with the development of reinforced concrete and steel building systems after the industrial revolution (Çelik et al., 2022). Among the reasons for this situation are the limited cross-sectional dimensions of wood and its lower durability compared to other building materials (Çelik et al., 2022). Growth variations and

* Corresponding author, E-mail: esra.lakotalemdag@erdogan.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_638

internal defects can affect the strength of wood (Tonyalı et al., 2025). On the other hand, thanks to technological developments, the properties of existing building materials are being improved and new biodegradable building materials are being developed. In this direction, natural wood is transformed into materials with higher mechanical and physical properties by undergoing various processes in the industrial environment. Thus, it has become possible to produce higher and wider-span buildings using wooden construction. In buildings constructed with industrial wood products, waste generation is minimized thanks to prefabricated elements, and environmental pollution such as noise and dust are reduced with advantages such as ease of assembly and shortened construction site time. In addition, the low thermal conductivity of wood (Abed et al., 2022). increases the energy efficiency of buildings and reduces their environmental impact.

In this framework, material selection plays a critical role in reducing the environmental impact of buildings. In order to preserve the natural balance, it is of great importance to choose sustainable building materials. It is within the scope of their responsibilities to protect the ecological balance for experts working in the building sector to choose sustainable materials. At this point, the adequacy of the course contents of architecture and civil engineering departments, which guide the selection of materials and train experts in the sector, is also important. Within the scope of this study, the courses taken by the students of Karadeniz Technical University, Recep Tayyip Erdoğan University and Atatürk University Department of Architecture on wooden building design and traditional and industrial wooden materials during their undergraduate education and their knowledge-awareness levels on this subject were evaluated by questionnaire method. In line with the data obtained from the questionnaire study, the level of recognition of wood material in the current curriculum was determined. This study is expected to, which aims to create awareness from the perspective of wood materials during undergraduate education, will contribute to the students to make material selection with environmental sensitivity in their professional lives.

2. Wooden materials

Wood is a renewable raw material and an easy-to-process natural building material, provided that it is used in a controlled manner (Hegger et al., 2022; Güzel & Yesügey, 2015). It has high heat storage capacity and low thermal conductivity. Being a flexible and lightweight material makes wood a durable option against lateral forces such as earthquakes (Tandoğan Kibar& Aykan, 2024). It also has the ability to store carbon (Tupenaite et al., 2021) and is biodegradable without creating waste in nature. End-of-life wood materials can be reused, recycled as energy and raw materials, or decomposed without harming the environment (Türkeri, 2021). Although wood is a flammable material, it delays the burning of the interior parts by forming a layer of embers from the outside to the inside during combustion and maintains its carrier for a while (Türer, & İzol, 2024). This feature makes wood advantageous in terms of fire resistance.

The use of wood in traditional architecture is generally concentrated in regions with large forested areas. Geographical conditions, climate, cultural needs and local material resources have been effective in the distribution of wooden structures. It is seen that traditional wooden architecture is widespread in countries such as Norway, Sweden, Finland, Canada, USA, Turkey, China, Japan and Korea (Tandoğan Kibar & Aykan, 2024).

Traditional timber construction systems in Turkey are mainly composed of timber masonry and timber frame systems (Fig. 1). The timber masonry system is constructed with wooden elements arranged horizontally on a stone foundation or masonry floor. Connections are provided by "karaboğaz", "kurtboğaz" and "çalmaboğaz" techniques. In the timber-framed system, a stone wall is built up to the flood level, wooden posts and beams are placed on top of it, and the space between the posts is filled with local materials such as mudbricks, stones and bricks. The structures formed with this construction technique are called "hımış structures" (Tandoğan Kibar& Aykan, 2024).

Fig. 1. Timber masonry and timber frame system (Meyveli Köyü Camii, 2025; Yalçın et al., 2022)

Wood material is hydroscopic; it can expand, swell or contract depending on temperature and humidity changes (Hegger et al., 2022; Akkan Çavdar & Lakot Alemdağ, 2024). Natural wood is susceptible to risks such as fungal growth and insect damage. For this reason, more resistant wood species such as cedar and cypress have been preferred in traditional architecture against these problems (Oymael, 2018; Akkan Çavdar & Lakot Alemdağ, 2024). In addition, the limited size of trees made it difficult to pass through large openings (Alkan, 2024). Because of technological developments, industrial wood products with increased strength and expanded dimensional limits have been developed to overcome the disadvantages of natural wood (Alkan, 2024; Yaygır & Korkmaz, 2022). Industrial wood has made it possible to construct wide-span and high-rise buildings, which has increased the use of industrial wood by providing flexibility in design.

Industrial wood products shorten the construction site time, facilitate assembly works and minimize environmental impacts by reducing energy consumption during the construction process thanks to prefabricated elements (Alkan, 2024). These products are produced by combining wood parts such as timber, chips, boards, fiber and sawdust with adhesives and binding agents, impregnation and pressing (Tandoğan Kibar& Aykan, 2024; Avlar & Ustaoğlu, 2017). The main industrial wood products are as follows: Glued Laminated Timber (GLULAM), Cross Laminated Timber (CLT), Nail Laminated Timber (NLT), Dowel Laminated Timber (DLT), Structural Composite Lumber (SCL), Laminated Veneer Lumber (LVL), Parallel Strand Lumber (PSL), Oriented Strand Lumber (OSL), Laminated Strand Lumber (LSL) and Timber Concrete Composite (TCC) (Tandoğan Kibar& Aykan, 2024; Avlar & Ustaoğlu, 2017).

Along with industrial timber, panel systems, cell systems, mixed timber systems and hybrid construction systems have been developed (Tandoğan Kibar& Aykan, 2024). These systems have enabled high-rise timber building designs around the world. For example, the Mjøstårnet building in Norway, built in 2019, has 18 floors and a height of 85.4 meters. The structural system of the building is a hybrid construction system consisting of wood and reinforced concrete (Fig. 2). Reinforced concrete slabs are used in the last seven floors of the building to control the sway caused by the increasing height. The columns and beams of the building are constructed with GLT, the shaft wall is constructed with CLT panels and the floors are constructed with LVL and reinforced concrete ("Mjøstårnet The Tower of Lake Mjøsa", 2025; "World's tallest wooden building. Mjøsa Tower by Voll Arkitekter", 2025 ; Şanlı, 2020). Fire retardant coatings were applied to the wooden elements; firewalls were created and designed to be resistant to fire for 90 minutes (Arıcı, 2024). Mjøstårnet is a mixed-use building serving residential, office and hotel functions ("Mjøstårnet The Tower of Lake Mjøsa", 2025; "World's tallest wooden building. Mjøsa Tower by Voll Arkitekter", 2025; Şanlı, 2020).

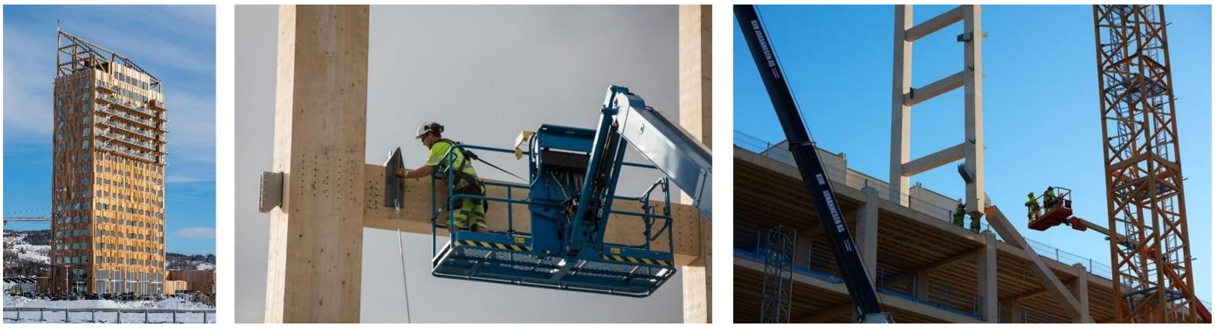

Fig. 2. Mjøsa Tower ("World's Tallest Timber Tower to Be Built in Norway—Thanks to New Rules on What Defines a "Timber Building"", 2025; "World's tallest wooden building. Mjøsa Tower by Voll Arkitekter", 2025)

Ascent Tower, built in 2022, is the tallest wooden structure in the world with its 25-story structure. With 19 floors of timber and 6 floors of reinforced concrete, the building has a hybrid structural system with GLT columns, CLT panels and reinforced concrete cores. For fire safety, measures have been taken to provide 3 hours fire resistance to columns and 2 hours fire resistance to fasteners. The building is equipped with a sprinkler system; a pressurization system was installed in the stairs and corridors to ensure smoke control during fire ("Ascent", 2025) (Fig. 3).

Fig. 3. Ascent Tower ("Ascent", 2022)

In addition to examples of high-rise timber buildings, scientific studies also reveal the critical role of timber in sustainable construction in terms of energy consumption and carbon emissions, as well as its environmental advantages. In a study by Börjesson and Gustavsson, it was revealed that timber framed buildings consume 60-80% less energy in material production than concrete framed buildings (Börjesson & Gustavsson, 2000). In another study, it was stated that if the Stadthous building in London, which was built with CLT in 2009, was constructed in reinforced concrete, 125 tons of carbon emissions could be emitted to the atmosphere ("The Stadthaus", 2025). The findings on energy consumption and carbon emissions in these studies also support the preference of wood as a sustainable building material. In order to meet the need for sustainable construction, there is a need for building sector experts who are effective in the preference of wood building material to be conscious and knowledgeable in this regard.

More effective use of timber in the building sector is possible not only due to its environmental benefits, but also by implementing it within the framework of appropriate engineering standards. In this context, there are various standards and legal regulations regarding timber construction techniques in Türkiye. The standards and regulations for timber building design in Türkiye are as follows: TS 647 "Calculation and Construction Rules for Timber Structures", TS EN 1912 "Construction Timber - Strength Classes - Classification of Tree Species and Visual Classes", TS EN 1995-1-1 "Design of Timber Structures (Eurocode 5)" and "Regulation on the Design, Calculation and Construction Principles of Timber Buildings" which entered into force in 2025.

3. Materials and methods

3.1. Research model

This study is a descriptive field research that aims to evaluate the level of knowledge and awareness of architecture undergraduate students about wood materials, traditional and industrial wood construction systems. The research was conducted within the framework of a mixed research model in which quantitative and qualitative data collection methods were used together. In this direction, a questionnaire form containing structured and semi-structured questions was developed as a data collection tool.

The questionnaire consists of three sections. The first section includes demographic questions that inquire about the participants' gender, age, university of study, grade level and taking courses on wood materials. The second section includes multiple-choice and 5-point Likert-type scale questions that aim to measure the level of knowledge and attitudes about wood construction systems and industrial wood materials. In the third section, there are open-ended questions aimed at revealing students' opinions, comments and conceptual perceptions on the subject in more depth. The answers given to the open-ended questions were evaluated both thematically through content analysis and by visualizing them with the word cloud technique. In this way, students' mental representations and prominent key concepts were analyzed in a qualitative context.

3.2. Sample of the study

The sample of the study consists of 3rd and 4th year undergraduate students studying in the Architecture Departments of Karadeniz Technical University (KTU), Recep Tayyip Erdoğan University (RTEU) and Atatürk University (ATAUNI). The main reason for selecting these class groups is the assumption that students have acquired basic knowledge about timber building systems through courses such as building knowledge, building elements, building technologies and building materials that they have taken in the first years of undergraduate education. Fig. 4 shows the flow diagram of the research methodology.

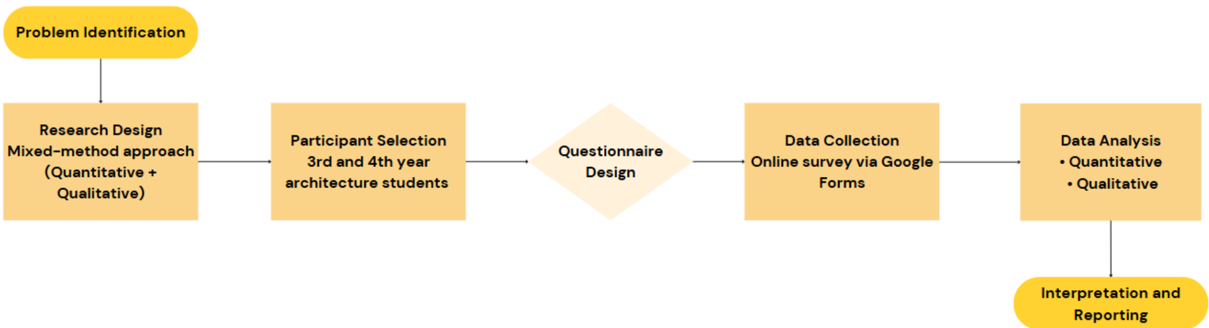

Fig. 4. Research methodology - flowchart steps

Purposive sampling method was adopted in the selection of participants and data were collected online (Google Forms) on a voluntary basis. The survey questions were approved by RTEU Social and Human Sciences Ethics Committee with the decision dated 12.03.2025 and numbered 2025/093. The survey was conducted in the spring semester of 2025 and the total number of participants from the three universities was determined to meet the target sample size. After the number of 3rd and 4th grade students of the three selected universities was obtained from the YÖK Atlas data, a calculation was made by taking into account the 95% confidence level and 5% margin of error in determining the number of samples, and a total of 203 students were surveyed. The research data were analyzed using the SPSS program; descriptive statistics were presented in terms of frequency, percentage and mean values. In addition, the data obtained from open-ended questions were supported and interpreted with qualitative analysis techniques.

4. Findings

In the questionnaires conducted within the scope of the study, the answers given to 5-point Likert-type and multiple-choice questions aiming to measure the level of knowledge and attitudes of students on wood construction systems and industrial wood materials were evaluated and the results are as follows.

66% female and 34% male students contributed to the survey study. 56.1% of the participants were 18-22 years old, 41.9% were 23-27 years old and 2% were 28 years old and above. The sample of the study consisted of students from Karadeniz Technical University with 62.6% (127 people), Recep Tayyip Erdoğan University with 3.4% (7 people) and Atatürk University with 34% (69 people). 52.2% of the participants were third year students and 47.8% were fourth year students. 63.1% of the students stated that they took courses on wood materials and wood construction systems. Among these courses, the most common courses are building materials with 31.3%, building project with 11.44% and building elements with 11.44%.

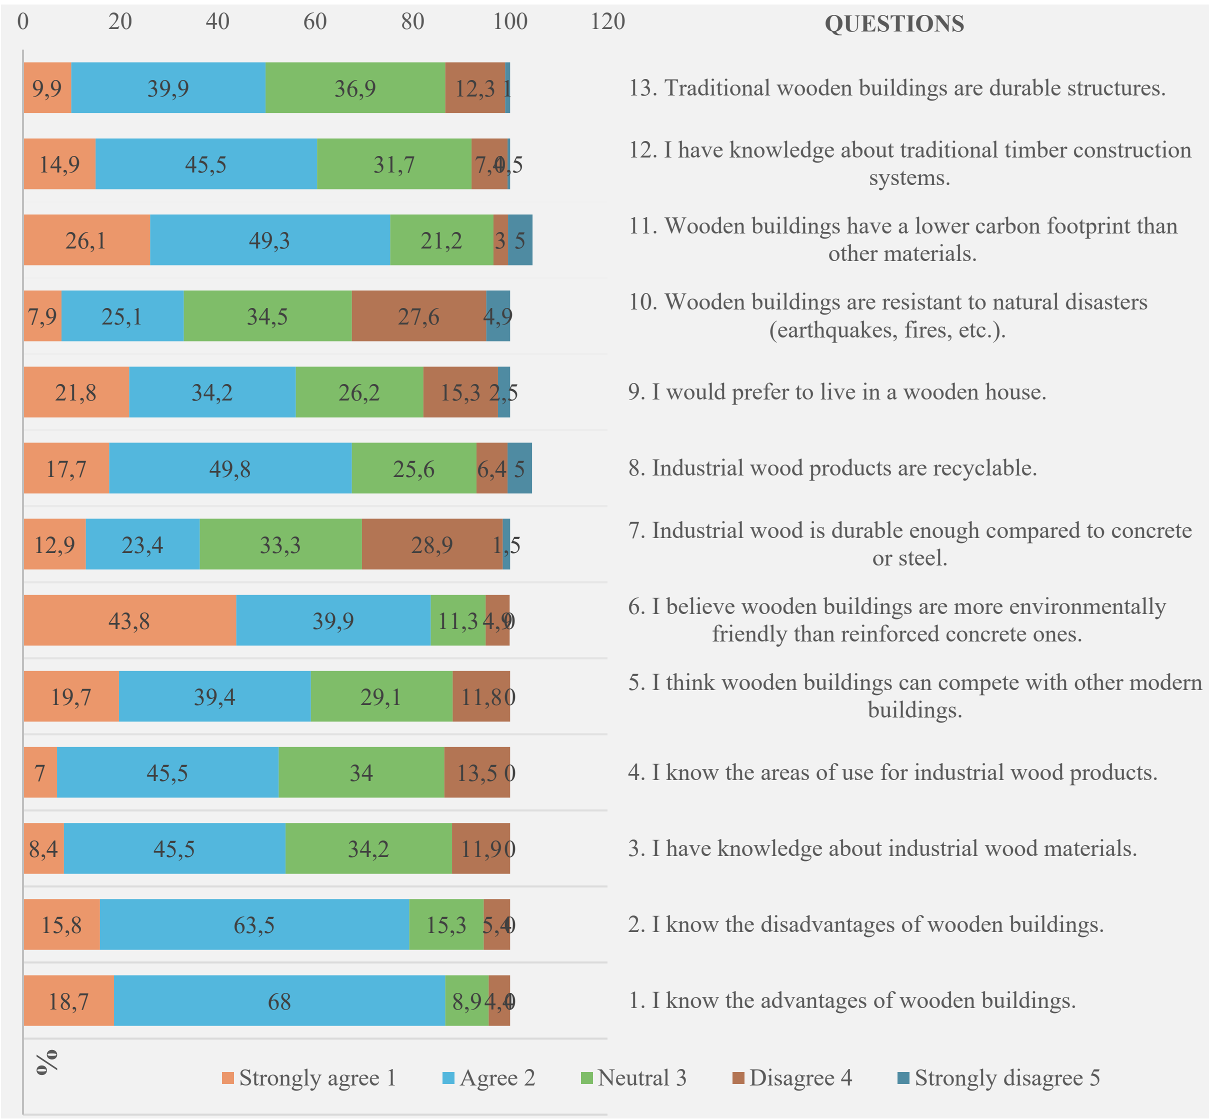

Fig. 5. Distribution of responses to likert-scale questions

When the students' answers to the 5-point Likert questions are analyzed through the graph in Fig. 5, it is seen that the students have a high awareness of the advantages of wooden structures. While 68% of the students stated that they had knowledge about the advantages of wooden structures, 18.7% stated that they were quite knowledgeable. While 8.9% of the participants were undecided about this question, only 4.4% of the participants stated that they had no knowledge. These results show that students generally have a positive and confident attitude towards the benefits of wooden structures. When the level of knowledge about the disadvantages of wooden structures is evaluated, 63.5% of the students stated that they have knowledge about this issue, while 15.8% stated that they have a strong knowledge. This indicates a positive opinion rate of 79.3%. However, a 15.3% rate of indecision indicates that some students are uncertain about the disadvantages.

According to the survey data, a strong consensus was obtained that wooden structures are more environmentally friendly than reinforced concrete structures. While 43.8% of the students completely agreed with this view, 39.9% partially agreed. Only 4.9% of the students expressed a dissenting opinion. Regarding the durability of industrial wood, 12.9% of the participants stated that it was very durable, 23.4% stated that it was durable, while a group of 33.3% students remained undecided. The fact that 28.9% of the group expressed the opposite opinion to this question shows that students have doubts about the durability of industrial wood.

Awareness that industrial wood products can be recycled was found to be generally positive. While 49.8% of the participants stated that they were informed about this issue, 17.7% strongly agreed. However, 25.6% were undecided and 6.4% disagreed, indicating the need for more education on this issue.

The rate of those who preferred to live in a wooden house was 56%, while 26.2% were undecided and 17.8% expressed the opposite opinion. This shows that although there is a general interest in wooden houses, some students are undecided about this issue. In the question that wooden structures are resistant to natural disasters, only 7.9% of the participants stated that they were quite sure about this issue, while 25.1% stated that they partially agreed. The undecided rate of 34.5% and the opposing opinion rate of 27.6% reveal that students lack knowledge on this issue. The view that wooden structures have a lower carbon footprint than other materials is generally supported. While 49.3% agreed with this view, 26.1% strongly agreed.

When the level of knowledge about traditional wooden building systems is analyzed, 14.9% of the participants stated that they were quite knowledgeable, while 45.5% stated that they were knowledgeable. However, an undecided rate of 31.7% and an opposing opinion rate of 7.9% indicate that students need more information on this subject. When the opinions on the durability of traditional wooden structures were analyzed, 39.9% of the participants stated that they were durable, while 9.9% stated that they were very durable. The fact that 36.9% of the students remained undecided on this question and 13.3% of the students expressed the opposite opinion reveals that students need to learn more about this issue. When the answers given in general are evaluated, it is understood that students have a high awareness of the advantages and environmental benefits of wooden structures, but they need more information on technical issues, especially in areas such as durability and resistance to disasters. In this context, it is thought that the content of education on topics such as industrial wood products and traditional building systems should be strengthened.

In the second part of the questionnaire, 10 multiple choice questions were asked to measure students' knowledge and opinions on the use of wood materials, construction systems and industrial wood products. The answers to the questions reveal the level of awareness of the students on the subject. Looking at the opinions of the participants regarding the reasons for the preference of wooden structures, it is seen that the answer "sustainability and environmental friendliness" stands out with a rate of 36.34%. This shows that students prioritize environmental factors in the selection of building materials and are aware of the ecological advantages of wood (Fig. 6).

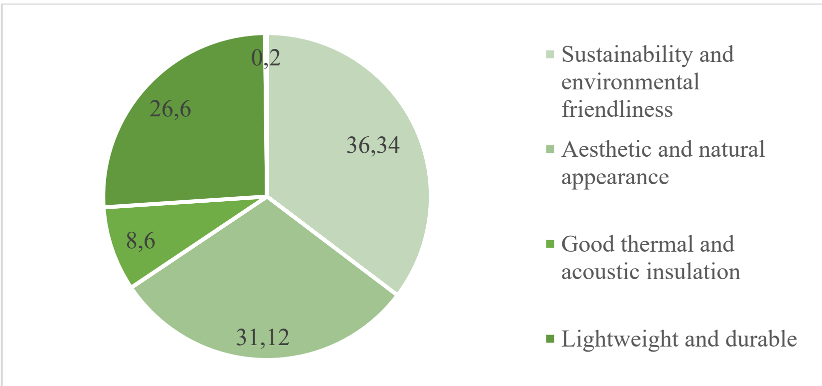

Fig. 6. Reasons for preference of wooden structures

In the responses to the question about the lifespan of wooden structures, 47.3% of the participants foresee a lifespan between 30 and 50 years. This rate shows that students have a realistic and technically based perception of the durability of wood. When the level of knowledge about the proportion of wooden buildings in Turkey is questioned, it is noteworthy that the majority of the participants chose the “no idea” option. This finding indicates that students lack knowledge about the building stock and the rate of use of building materials.

When asked why timber structures are less preferred in Turkiye, cultural habits were cited by 26.5%, perception of fire risk by 25.6% and lack of engineering knowledge and regulations by 17.21%. This distribution shows that in addition to technical inadequacies, social perceptions are also decisive (Fig. 7).

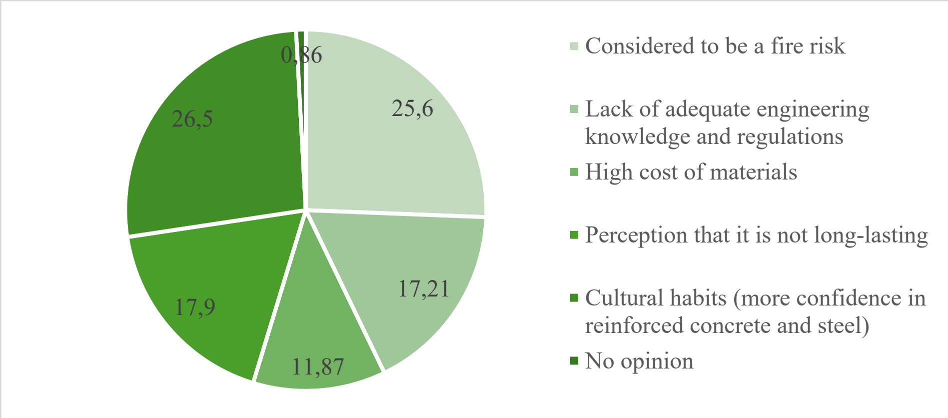

Fig. 7. Reasons for low preference of timber structure in Türkiye

When the answers to the question of which factors play an important role for the proliferation of high-rise wooden buildings in Turkey are evaluated, the options such as the development of fire-resistant materials with 21.7%, raising public awareness with 21.6% and regulations and legislative arrangements with 19.55% come to the fore. These results indicate that both technical and social factors should be addressed together.
In the question measuring the level of knowledge about traditional timber construction systems, 37.26% of the participants stated that they knew the timber frame system, 34.16% the masonry timber construction system and 16.35% the infilled timber frame construction system. These rates show that the building systems emphasized more in the training are better known. In the question asking which system is more advantageous when traditional and modern construction systems are compared, 65,02% of the participants stated that both systems are advantageous in different areas. This approach shows that students are able to make technical evaluations in a holistic manner.

When the answers to the question measuring the level of knowledge about industrial wood materials were evaluated, MDF with 18.64%, laminated wood with 18.54% and plywood with 17.74% were the most known products. This finding shows that students are more familiar with the products they encounter in daily life, while more technical products (CLT, PSL, LVL, etc.) should be covered more in the education process (Fig. 8).

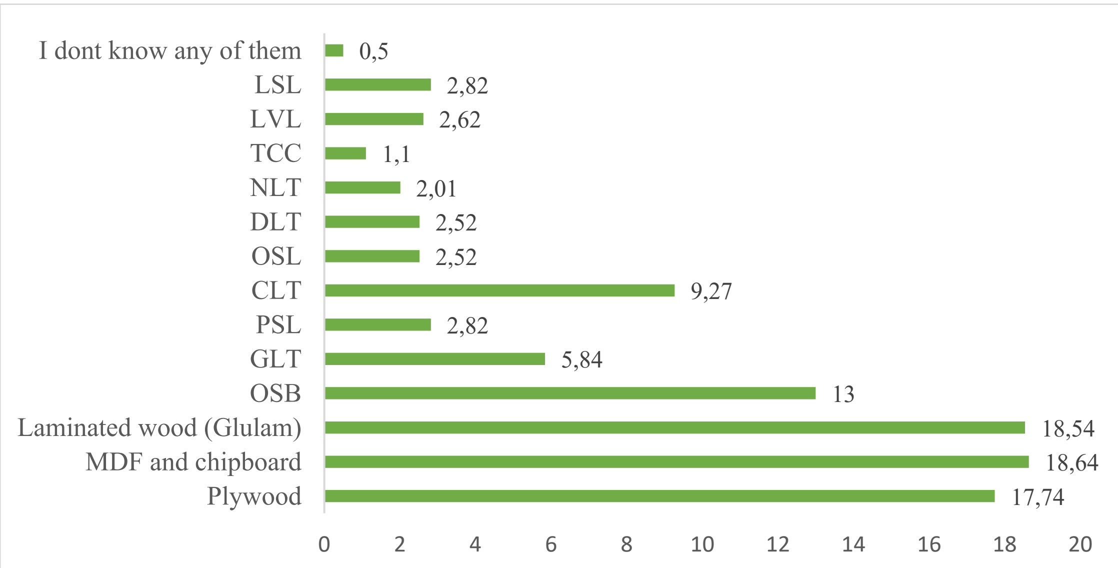

Fig. 8. Recognition of industrial wood materials

The answers given to the question measuring the purpose for which industrial wood material is used in the construction sector were “furniture and interior design” with 13.78%, “facade cladding” with 12.89% and “roof systems” with 12.65%. This result shows that students are more familiar with aesthetic and architectural uses, while technical areas such as structural systems are less known.

Wooden structures have an important place in a wide range from architecture to the construction sector. In the last part of the survey conducted in this context, 3 open-ended questions were asked to determine the first three concepts that came to the minds of the participants about the concept of “Wooden Structures”. In line with the answers given to the questions posed to the participants, various concepts came to the fore. The word cloud images obtained from these concepts are shown in Fig. 9, 10, 11. In the first question, the first three words that the participants associated with the concept of “wooden structures” were; Naturalness (21.8%), Sustainability (12.6%) and Aesthetics (11.9%). These findings emphasize the harmony of wooden structures with nature, their environmentally friendly features and their visual appeal. Wood, as a material known for its naturalness, is preferred because it is in harmony with the constructed structures and keeps its environmental impacts to a minimum.

Fig. 9. Word cloud about wooden structures

In the second question, the first three words that the participants associated with the concept of 'Industrial Wood Material' were MDF (17.13%), OSB (11.9%) and Plywood (10.9%) respectively (Fig. 10). Industrial wood materials are the leading processed wood products used in the modern building sector. Respondents' preference for products such as MDF, OSB and plywood reflects the advantages of these materials such as strength, durability and workability. Such materials are widely used in modern construction as they offer functional solutions. However, words such as “biomaterial” or “wood composite” are less likely to come to mind in relation to industrial wood materials, which may be due to respondents being less familiar with these more technical and emerging concepts. These words require more awareness of new trends and innovative technologies in the sector.

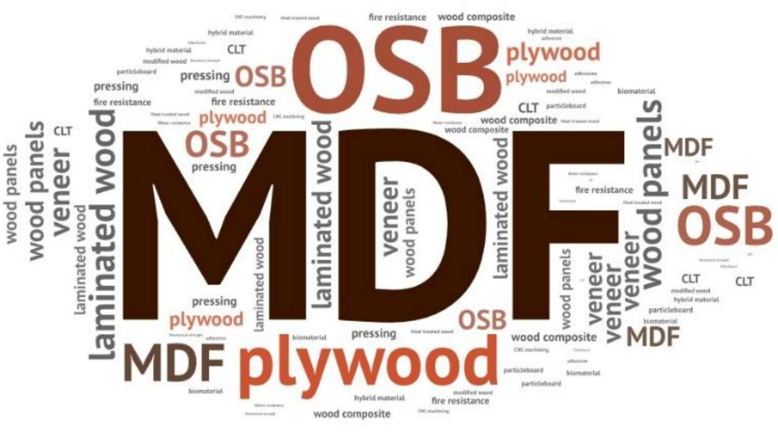

Fig. 10. Word cloud about industrial wood material

Fig.11. Word cloud about traditional wood material

In the third question, the first three words that the participants associated with 'Traditional Wood Materials' were Oak (17.4%), Craftsmanship (12.1%) and Pine (10.2%) (Fig. 11). Traditional wood materials have an important place in historical and cultural contexts. These materials are associated with natural and solid wood species, often shaped by the handcraftsmanship of local craftsmen. Durable wood species such as oak and pine are also among the basic materials for long-lasting and aesthetically valuable buildings. Respondents' high rates of traditional wood species such as oak and pine indicate a strong association with the durability and aesthetic value of these species. The prominence of handcraftsmanship is a reflection of the importance given to fine workmanship and details, which are characteristic of traditional wooden structures.

5. Conclusions

This study aims to evaluate awareness of wood materials in undergraduate architectural education by examining the role of sustainable building materials particularly wood in reducing the environmental impacts of the construction sector. Considering that 34% of carbon dioxide emissions are attributed to this sector, the significance of wood as a renewable material with a low carbon footprint becomes increasingly important. Wood stands out due to its environmental advantages, such as carbon sequestration, ease of processing, recyclability, and energy efficiency. Technological advancements have made it possible to construct high-rise and wide-span structures using industrial wood products.

In this context, the knowledge and awareness levels of third- and fourth-year students from the architecture departments of Karadeniz Technical University, Recep Tayyip Erdoğan University, and Atatürk University were evaluated through a survey. The results, based on responses from 203 students, indicated that while students generally hold positive attitudes toward the environmental benefits of wooden structures, they lack sufficient knowledge about industrial wood products and traditional construction techniques. Students tend to associate the concept of wooden structures with naturalness, sustainability, and aesthetics, and they are more familiar with products such as MDF, OSB, and plywood. However, the education provided regarding the technical advantages of wooden structures, their resistance to natural disasters, and lifespan appears to be inadequate. This is primarily due to the limited coverage of wood-related content in general courses like building science or construction materials.

Therefore, it is recommended that compulsory and elective courses specifically focusing on wood materials and construction systems be introduced or expanded within undergraduate architecture programs. Moreover, incorporating site visits, hands-on examinations of industry examples and materials, and more frequent technical seminars would help enhance students' practical knowledge and support environmentally conscious material selection in their professional practice. This study serves as a pilot research conducted in three universities; thus, broader and comparative research is needed across undergraduate architecture curricula throughout Turkey. Furthermore, since courses on wood materials and construction systems are predominantly offered at the graduate level, this implies that the topic is reserved for specialization. However, as not all graduates pursue postgraduate education, integrating these subjects into undergraduate programs is essential to ensure all future architects gain a fundamental understanding.

The role of material passports in the integration of building materials with circularity strategies

Betül Alankuş*[1], Sinan Çelik[1]

Gebze Technical University, Department of Architecture, 41400 Kocaeli, Türkiye

Abstract. In the construction sector, the inability to track the stock and flow of materials due to rapid population growth and urbanization brings environmental, economic and social impacts. In order to mitigate these impacts, the importance of transitioning from linear economy to circular economy (CE) strategies in the construction sector becomes clear. Material passports (MP) are considered to be a potential tool for this transition. Material passports are a design optimization tool that reduces the use of primary materials by controlling the stock and flow of building materials. It includes data sets created to facilitate the integration of building materials into their next function by recycling and reusing them. In this study, it is aimed to examine the research on material passport in the construction sector and to evaluate its impact on circularity. The impact of material passports on circularity in the design, construction, operation-maintenance and end-of-life phases of buildings is discussed. In this context, research questions were identified and a systematic literature review was conducted in the Scopus database. The publications accessed as a result of the search were analyzed by addressing the research questions. In the findings, the potentials and challenges of material passports in the specified life cycle stages of the building were identified and their impact on the circularity of building materials was evaluated. It is envisaged that this research is important in terms of material passport analysis in the construction sector and will contribute to future studies.

Keywords: Building materials; Material Passports; Material stock and flow; Circularity; Reuse and recycle

1. Introduction

Since the Industrial Revolution, the rapidly growing global economy has brought about environmental crises. Increased consumption of non-renewable resources, a decrease in the amount of primary raw materials, and uncontrolled waste production threaten ecosystems (Cossu et al., 2015). One of the sectors at the center of these environmental crises is the construction sector. Rising urbanization rates, housing demand, and infrastructure needs driven by population changes are accelerating construction activities and creating environmental impacts. According to the United Nations Department of Economic and Social Affairs (UN-DESA), the world population is projected to reach 9.7 billion by 2050; this population increase means increased demand for materials and energy for the construction sector (UN-DESA, 2024; Lieder & Rashid, 2016). In addition to the demand for materials and energy, challenges are being faced in waste management. It is stated that the construction sector is responsible for 50% of total raw material consumption, approximately 40% of total energy consumption, and 38% of waste production in Europe (WGBC, 2022; Hu et al., 2025; Eurostat, 2024). In this context, ensuring the management of construction and demolition waste and reducing raw material consumption have become important. Additionally, the increase in carbon emissions alongside these issues in the sector has become critical. Globally, the construction sector accounts for approximately 37% of carbon emissions (UNEP, 2023). These data highlight the environmental responsibilities of the construction sector and bring with them the need for transformation.

The construction sector operates based on the traditional linear economic model of "take-make-dispose." This model creates a production cycle that increases resource consumption and carbon emissions, leading to uncontrolled waste generation (Frosch & Gallopoulos, 1989). In this context, the need for a new approach that addresses the entire life cycle of buildings has come to the forefront. The concepts of "circularity" and "circular economy" form the basis of this new approach. Awareness of environmental issues increased in the 1970s, and studies on this subject began. The United Nations Conference on the Human Environment (Stockholm Conference) in 1972, the establishment of the World Commission on Environment and Development in 1983, the publication of the Brundtland Report in 1987, the Rio Conference in 1992, the Kyoto Protocol in 1997, the Paris Agreement in 2016, and the European Green Deal in 2019 were realized.

*Corresponding author, E-mail: betulalankus@gtu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_645

It is stated that the concepts of "circularity" and "circular economy" are based on the "cradle to cradle" approach, which was drafted by Walter R. Stahel in the 1970s and developed by Michael Braungart and Bill McDonough (EMF, 2023). Circularity was transformed into a strategy in the European Green Deal of 2019; its importance increased with the "New Circular Economy Action Plan" adopted by the European Commission in 2015 and published in 2020 (European Commission, 2020; Ma et al., 2023). Along with this action plan, the aim is to reduce the negative environmental impacts caused by various sectors, including the construction sector.

The circular economy is a model that enables the value chain to operate at maximum efficiency by keeping resources within the system for as long as possible and returning waste to its source (Papamichael et al., 2023). In the construction sector, the approach of keeping materials within a closed loop is prevalent. The construction sector has been categorized under "Key Product Value Chains" in a report published by the European Commission, emphasizing the need to rethink the built environment (European Commission, 2020). In the construction sector, the adoption of circularity strategies has become a priority not only in the production of new buildings but also in the reuse and recycling of existing building materials.

Although there is no clear definition of the concept of circular economy, the 3R (reduce, reuse, recycle) strategies are commonly used (Purchase et al., 2021). These strategies are at the forefront of reducing environmental problems through the efficient use of natural resources. More detailed research has identified the "10R" strategies (refuse, rethink, reduce, reuse, repair, refurbish, remanufacture, repurpose, recycle, recover) as a general guideline (Potting et al., 2017). It is anticipated that circular strategies will have a significant positive impact in the construction sector. This new model is thought to support environmental, economic, and social sustainability in contrast to the shortcomings of the linear economy model. The reuse and recycling of construction materials and the reduction of raw material consumption create an efficient system. However, there are certain challenges in integrating circularity strategies into the construction sector. Many different actors are involved in the life cycle of buildings, and supply chains are complex (Pomponi & Moncaster, 2017). In this context, controlling building material flows becomes difficult. Circular approaches require that materials used in the built environment be safe and accessible. As a solution to these challenges, digital databases have come to the forefront. Digital systems support the conversion of existing building stock into raw materials, the tracking of material flows, and the evaluation of buildings as material banks (Heisel & Rau-Oberhuber, 2020; Honic et al., 2019a). In this bank system, buildings are not only considered for their lifespan but also as a potential resource for future constructions. One of the most prominent tools used in treating buildings as material banks is "Material Passports (MP)".

Material passports are digital-based systematic datasets that include the technical properties, environmental impacts, and reuse and recycling potential of a building material or element (Honic et al., 2024). These passports give materials and elements an identity, transforming them into recyclable assets. Thanks to material passports, the recycling and reuse status of a building can be analyzed at every stage of its life cycle. These circularity tools enabled by digital transformation are increasingly integrated into BIM (Building Information Modeling)-based systems, facilitating the traceability and management of building components (Atta et al., 2021). With the Material Passport, product characteristics can be transferred to new users. This system, which creates digital twins of building components, facilitates information sharing among stakeholders, bringing all stakeholders from designers to demolition contractors together on a common platform.

MP applications have gained popularity in Europe with the "Buildings As Material Banks (BAMB)" project. This project is an initiative carried out in 2015 by 7 countries and 15 partners within the scope of the Horizon 2020 project funded by the EU to facilitate the transition to a circular built environment (Debacker & Manshoven, 2016; BAMB, 2025). BAMB provides a digital platform for collecting, storing, and using building data. According to the BAMB project's approach, materials are temporarily stored in buildings and can be reused in the long term (Leising & Bocken, 2018). The project utilizes various tools, with the material passport platform being one of them. The material passport platform contains comprehensive data sets on material information, recycling and reuse potential, health and safety data, usage history, environmental impact data, assembly and disassembly, etc. (Heinrich & Lang, 2019). Madaster, a similar application to BAMB, is based in the Netherlands and is used in many countries, including Germany and Switzerland (Madaster, 2022). Madaster archives material data in a digital format and converts it into passports, supporting circular strategies (Costa & Hoolahan, 2024). Users can view the material flows, lifespan, carbon footprint, and reuse and recycling status of building components. The MP system enables data transfer from BIM models (Heisel & Rau-Oberhuber, 2020). In addition to these platforms, software such as ÖKOBAUDAT, SundaHus, and One Click LCA have also been developed. Since 2019, with the increasing importance of circularity, studies have been conducted on the contributions that material passports can make to the circularity of building materials. However, in addition to these contributions, there are also challenges and obstacles in MP applications.

This study highlights the importance of circular strategies and digitalization in addressing environmental issues such as increasing energy consumption, resource depletion, carbon emissions, and waste production in the construction sector. Within this scope, the concept of Material Passports, developed to support the circularity of construction materials, is discussed; the aim is to identify the potential offered by these digital tools and the challenges encountered in their implementation.

In the study, a systematic literature review was conducted using the Scopus database. A general overview was provided by referencing studies related to construction materials, circularity, and the circular economy. For the analysis of publications related to Material Passports, quantitative data analysis was conducted by including relevant keywords. As a result of this phased analysis, it was determined that the proportion of publications related to material passports is low. The data obtained in both phases were visualized using VOSviewer software. After the preliminary screening process, the publications were filtered according to their relevance through full paper analysis. The relevant publications were analyzed in detail to identify the potential and challenges that emerge in the integration of material passports into circularity. This study is significant in that it systematically evaluates the role of material passports in the circularity of construction materials in the literature, and it is anticipated that the findings will contribute to future studies.

2. Methodology

There are many studies and publications in the construction sector focusing on the circularity of construction materials. This study examined how many of these publications included material passports and the challenges and potential for their implementation. After providing detailed literature information on the concepts, a search was conducted in the Scopus database using general terms ("building materials," "circularity," and "circular economy"). It was determined that studies gained momentum following the presentation of the European Green Deal in 2019. Publications from 2019 to 2025 and those in English were referenced in the search. As a result of this filtering, a total of 831 publications were identified. To determine how many of these publications included material passports, the same filtering steps were used, including the concept of "material passports." The search of the database revealed 17 publications. This value indicates that material passports need to be studied more in the construction sector. The results of the two-stage search were visualized in VOSviewer software to produce a network map and clusters. The 17 publications were analyzed by reviewing their abstracts and full papers. One full paper could not be accessed and was excluded; nine publications were observed not to directly focus on potential and challenges. The purpose, scope, methods, and findings of the seven publications selected through the screening process were examined. The findings were categorized from environmental, economic, political, technological, social, and technical perspectives. The research flowchart is presented in Fig. 1. The study, which evaluates the potential and challenges of material passports, a digital tool, using publications, was based on the following research questions:

- RQ1: What is the number of publications examining the circularity of building materials and what are the prominent concepts?
- RQ2: What is the number of publications examining the circularity of building materials and material passports and what are the prominent concepts?
- RQ3: Which of the publications examining material passports address potentials and challenges?
- RQ4: What are the potentials and challenges in integrating material passports to circularity?

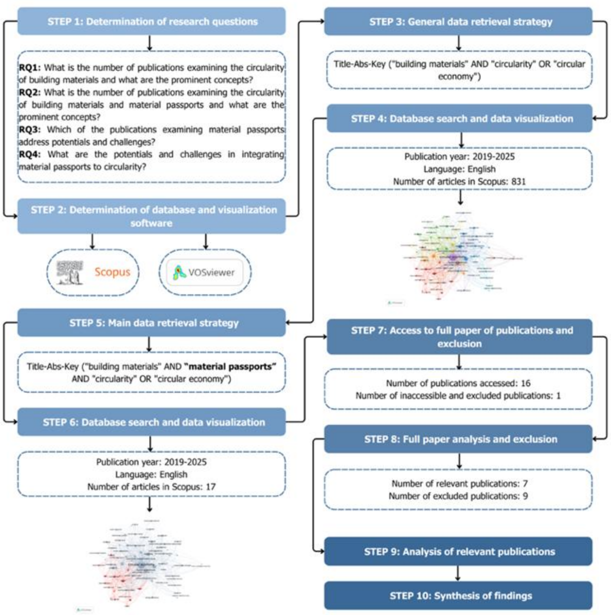

Fig. 1. Flow chart of the study

3. Findings

As a result of the search conducted using the terms “building materials,” “circularity,” and “circular economy,” 831 publications were visualized using VOSviewer software. Co-occurrence and keywords were examined in this analysis. A total of 82 keywords and 8 clusters were identified. The circularity of building materials and the circular economy are studied in many different fields and in connection with each other. The keywords that stand out in the cluster analysis are shown in Fig. 2. Node sizes indicate how frequently the concepts are studied. Cluster 1 (indicated in red in the figure) contains the concept “material passport” and related keywords. In this cluster, the concepts of reuse, recycle, waste, demolition, deconstruction, disassembly, BIM, LCA (Life Cycle Assessment), and End-of-Life (EoL) stand out. It is known that the use of material passports in the construction sector is directly related to these concepts.

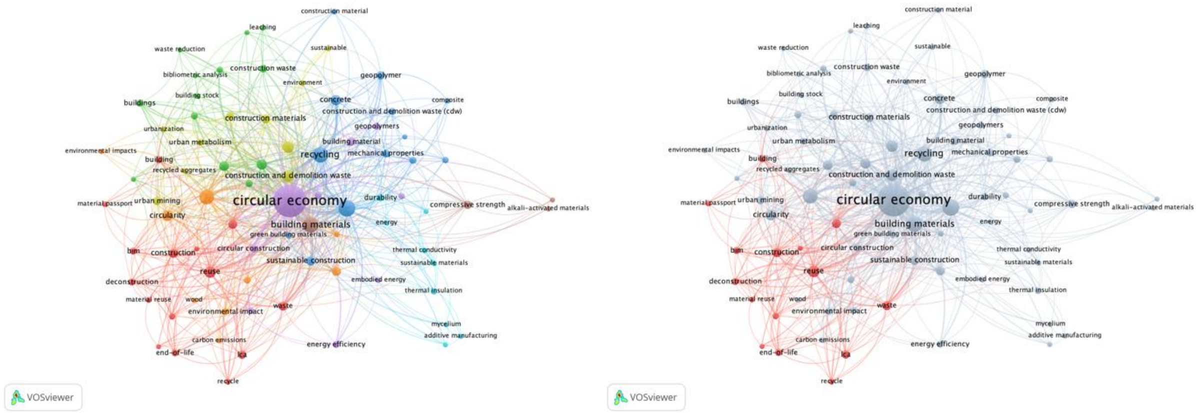

Fig. 2. Cluster and network analysis with VOSviewer software

As a result of the search customized with the concept of material passport, 17 publications were accessed from the 831 publications obtained. These publications focus on 7 publications as a result of abstract and full paper analysis. These publications include the difficulties and potentials in the application of material passports. The authors, titles, years, author keywords, and document types of the identified publications are listed in Table 1. The publications were analyzed in detail, focusing on their objectives, scope, methods, and findings.

Honic et al. (2019b), propose a BIM-based semi-automatic MP methodology to assess the recycling potential of building materials according to circular economy strategies. Based on the research project titled “BIMaterial-Process Design for a BIM-based Material Passport” and tested on an office building, it was determined that 48% of the materials are recyclable. Additionally, challenges related to data gaps and stakeholder coordination were identified. These challenges include inconsistent naming in databases, unit differences, and stakeholders lacking sufficient knowledge on the subject. In this context, a multi-dimensional data and stakeholder management framework aimed at enhancing collaboration between Architecture, Engineering, and Construction (AEC) organizations, industry, and regulatory bodies has been developed. In conclusion, the study demonstrates that BIM-based semi-automatic MP can be created, that MP implementation in the construction sector relies on collaboration among stakeholders, and that passports are an effective digital tool for achieving circularity goals.

Munaro et al. (2019), propose a building material passport (BMP) model specific to timber frame building systems in Brazil and assess its applicability within a circular economy framework. The study defines the eight main components of the BMP (general data, security, sustainability, use and operation, disassembly guide, reuse, history, other information) and tests the model using technical documents from a company in Brazil. The results showed that data for the main components of sustainability, disassembly guide, and reuse were missing. This situation hinders the implementation of circular strategies and makes it difficult to evaluate the system based on the material bank concept. These challenges have been identified from political, commercial, and social perspectives. The study emphasizes the importance of encouraging the adaptation of BMP to wooden frames in Brazil and implementing the necessary regulations.

Kovacic et al. (2020), evaluate the potential of digital technologies to achieve circular economy goals in the AEC sector in a research project-based study. In this context, the study proposes an integrated digital model called DEEP (Digital Platform for Circular Economy). A case study was conducted at a planning company using the research projects "BIMaterial (Process-Design for a BIM-based Material Passport)" and "SCI_BIM (Scanning and data capturing for the Integrated Resources and Energy Assessment using Building Information Modeling)." The findings indicate that BIM has the potential to serve as a data management tool that contributes to CE. However, data inconsistencies, lack of standards, and insufficient coordination among stakeholders were identified as challenges. The proposed DEEP platform aims to facilitate data sharing among stakeholders and improve material efficiency by tracking material flows throughout the lifecycle. The study highlights the significant role of digitalization in the renovation of the construction sector.

Munaro and Tavares (2021), through their systematic literature review, aimed to raise awareness by examining the contribution of material passports to circular economy strategies in the construction sector. By reviewing 15 academic publications, the political, commercial, and social barriers to the widespread adoption of material passports, as well as the opportunities they offer, have been identified. The study developed an MP model consisting of nine sections that can be used throughout a building's life cycle. However, numerous challenges hindering the widespread adoption of MP applications in the sector were also addressed. These include the lack of data standardization, complex supply chains, insufficient material information, the absence of quality assurance for recycled materials, the need for continuous updating of MP, inadequate digital infrastructure, and the reluctance of suppliers to share data, among others. The study emphasizes that the MP can be used as a multi-stakeholder and innovative tool to contribute to circularity by implementing the necessary systematic regulations in its application.

Göswein et al. (2022), evaluate the Circular Material Passport (CMP) system, a digital data tool developed to support the transition to circular economy principles in the construction sector, and propose a new model. In this evaluation, relevant sections within the EU Level(s) framework applicable to office and residential buildings were examined. The proposed model evaluates data from three perspectives: "general data," "product context use, and location," and "circularity potential." The study analyzes existing barriers to CMP and examines proposed measures. These barriers include lack of awareness and standardization, data uncertainty, misinterpretation of data, interoperability issues between different scales of passports, oversimplification of material quantities, misleading estimates of building and material lifetime, neglect of structural and insulation materials, and data input fatigue of the user. In conclusion, the research demonstrates that CMPs are a strategic tool that contributes to circularity in the construction sector and provides a methodology to support implementation processes.

Abuhalimeh et al. (2023), systematically analyzed the contribution of material passports to the circular economy. In this study, which examined 37 academic studies conducted between 2015 and 2022, a bibliometric analysis was firstly conducted to determine the direction of the research. In the next phase, the contributions of MP to CE at the end-of-life (EoL) stage were examined. Finally in study, the benefits of implementing MP's were classified in terms of environmental, economic, and social aspects, while the challenges were classified in terms of technical, market, regulatory, political, commercial, and social aspects. When examining the benefits of MP, the following stand out: in environmental terms, the conservation of natural resources, reduction of CO_2 emissions, and reduction of waste; in economic terms, reduction of government spending and development of the second-hand material market; and in social terms, increase in employment and positive effects on human health. The challenges include data deficiencies and inadequate digital infrastructure in the technical field; lack of legal standards in the regulatory field; lack of economic incentives in the market; and conflicting environmental and energy policies at the political level. Based on the analyses, the study argues that there are gaps in the implementation of material passports and that existing barriers could be overcome through further applied research.

Andisheh (2024), focuses on the Steel Circularity Passport (SCP) system developed to facilitate the reuse of structural steel within the circular economy. Through a systematic literature review, Material Passport applications were examined on a global scale, with a particular focus on regulatory, technical, and economic barriers encountered in structural steel in the New Zealand context. The study also explored potential measures that could be taken to facilitate the implementation of the proposed SCP system. The study emphasizes that the SCP is an important element in transitioning New Zealand's steel sector toward a more circular economy.

Based on the studies reviewed, the potential and challenges of integrating material passports into the circularity of construction materials have been identified. These findings have been categorized under environmental, economic, political, technological, social, and technical headings (Table 2).

Table 2. The potential of MP and challenges in implementation

Category	Potentials	Challenges
Environmental	• Increasing material recycling rates • Evaluating materials through reuse • Reducing raw material consumption by using secondary materials • Ensuring waste management during construction demolition and dismantling stages • Reducing energy consumption during life cycle stages • Reducing carbon footprint	• Lack of LCA data • Insufficient data on the existing building stock • Control of material toxicity
Economic	• Reducing material costs • Creating secondary material markets • Reducing construction and demolition costs • Extending the material value chain	• Cost uncertainty due to lack of standards • Underdeveloped market • Storage costs and space constraints • Perceived high cost of establishing a material passport infrastructure
Political	• Infrastructure opportunities compatible with circular economy policies • Ability to integrate with the European Green Deal and certification schemes	• Inconsistencies in measures included in environmental and energy policies • Lack of standards for the use and sale of secondary materials • Lack of a quality assurance system for recycled and reused materials • Inadequacy of government incentives
Technological	• Digitalization with BIM and LCA • Integration with smart buildings and digital twins • Automatic data processing capabilities	• Lack of knowledge about BIM and LCA • Lack of data format standardization • Databases are still developing • High volume of data and digital storage • Difficulty of real-time data updates
Social	• Enhancing trust through transparent data sharing • Increasing user awareness • Creation of new business areas and opportunities • Supporting participatory design processes	• Lack of awareness and incentives • Insufficient stakeholder participation • Lack of applicable and flexible work areas • Low demand for secondary materials • Lack of information and stakeholders' concerns about using second-hand materials
Technical	• Design guidance for demolition and reuse • Infrastructure development for material traceability and analysis	• Complexity of the material supply chain • Lack of knowledge about building materials and components • Lack of data accuracy and consistency • Long-term durability of buildings

4. Conclusions

The construction sector plays a significant role in the emergence of environmental issues such as raw material consumption, energy use, increased carbon emissions, and waste production. In addressing these issues, circular economy strategies, particularly "reduce, reuse, and recycle," are gaining prominence. It is believed that the compatibility of construction materials with circular strategies throughout the building's life cycle is crucial for minimizing environmental impacts. Material passports, developed to support the circularity of construction materials, serve as an important digital optimization tool for this purpose. This tool, which gives building materials an identity, supports circular economy strategies with systematic and accessible information. MP plays an important role in keeping building materials in a closed loop by enabling the tracking of material stock and flow. Although these digital tools hold significant potential, their effective use also brings about various challenges.

This study aims to determine the potential and application difficulties of material passports. A workflow was followed according to the research questions identified. Systematic literature reviews were conducted using the Scopus database. It was determined that there are few studies on building materials, circularity, circular economy, and material passports. The potential and challenges identified in the accessed publications were analyzed in detail. The findings were evaluated according to environmental, economic, political, technological, social, and technical categories. There is a cause-and-effect relationship between the potential and challenges both within the category and across categories. For example, the environmental potentials include "increase material recycling rates," "reduction of material costs," and "infrastructure compatible with circular economy policies." Similarly, the economic challenges include "lack of standards for the use and sale of secondary materials" and "cost uncertainty due to lack of standards." The importance of using material passports in the construction sector can be examined those potentials and challenges to address information gaps and increase usage. Countries may have different positions, policies, and practices in this area; therefore, priorities may vary.

In conclusion, material passports hold significant potential for supporting the circularity of construction materials. However, for MP applications to be realized, environmental, economic, social, political, technical, and technological barriers need to be overcome. It is believed that this process can be achieved through steps such as strengthening regulatory frameworks, fostering collaboration among stakeholders, raising awareness, addressing knowledge gaps, providing government incentives, developing innovative technologies, and promoting market maturity. This study is expected to contribute to future research on the alignment of material passports with the circularity of construction materials.

Spatial and physical studio configurations: a conceptual model for student satisfaction and efficacy

Husam Ali Husam Al-Rubaye*[1], Melody Safarkhani[1]

[1] *Istanbul Okan University, Department of Architecture, 34959 Istanbul, Türkiye*

Abstract. Studios serve as essential physical learning environments within higher education institutions, fostering experiential and reflective learning practices. They play a critical role in cultivating skills, creativity, collaboration, and professional identity. Although virtual environments offer flexibility and accessibility, physical studios remain fundamental to architectural education due to their pedagogical significance and their embodied, spatial, and interactive dimensions. Focusing on the studio as a physical environment, this study develops a conceptual model that distinguishes spatial and physical characteristics and investigates how the relevant features shape cognitive, emotional, and behavioral responses, which are collectively referred to as human-place interaction dimensions, ultimately influencing student satisfaction and academic performance. Drawing from a narrative literature review of theoretical and empirical studies sourced from academic databases, the proposed model identifies spatial characteristics, such as layout and floor plan, scale and proportions, spatial flexibility and adaptability, circulation and flow, and visual connectivity, alongside physical characteristics, including materials and construction, furniture and workstations, technology and equipment, visual comfort-lighting, thermal comfort, and acoustic comfort. Moreover, the study synthesizes the key features of these characteristics. The conceptual model underscores how targeted, user-oriented studio environments can significantly influence cognitive processes, emotional well-being, and constructive behaviors, ultimately enhancing student engagement, comfort, productivity, and psychological well-being. This research provides a blueprint for architects, and planners aiming to create inclusive, innovative, and pedagogically effective studio environments that foster academic success and creative development.

Keywords: Learning Environment; Architectural Design Studios; Spatial and Physical Characteristics; Student Satisfaction and Efficacy; Conceptual Model

1. Introduction

Learning environment within educational settings is a specific context where individuals engage in teaching and learning activities through various information resources and tools designed to support the accumulation of knowledge and serve educational purposes (Seel, 2012). Fraser (1998) conceptualizes learning environments as perceptual, relational, and context-specific constructs, with a strong emphasis on their psychosocial dimensions as important characteristic. Learning environments should not be seen simply as physical enclosures for activities, but as complex entities that transcend their architectural structure (González-Zamar et al., 2020). A learning environment is not simply a physical setting. It is a dynamic, fluid, and socially-constructed environment, shaped by interactions among people, practices, discourses, and material conditions (Mulcahy et al., 2015). A learning environment refers to the full range of factors that shape how students experience and engage with learning, including contextual elements such as psychological, social, cultural, political, and educational conditions, as well as pedagogical aspects such as curriculum, teaching, and assessment methods (Hounsell & Hounsell, 2007; Cleveland 2009; Abualrub et al., 2013). Radcliffe (2008) defines a learning environment through a conceptual model comprising three components: “Pedagogy, Space, and Technology”. The author emphasizes that all three pillars must be considered when planning, designing, and evaluating such environments.

Learning environments are categorized as either physical, virtual and hybrid, depending on whether learning occurs in a tangible setting or through technology-mediated platforms. Virtual learning environments include distance learning, e-learning, and online learning, though these terms differ. Distance learning involves separation of instructor and learner in time or place and includes various delivery modes. E-learning uses electronic tools and offers interactive, flexible instruction. Online learning is internet-based, involving fully web-delivered content such as courses, webinars, and video lectures (Moore et al., 2011). On the other hand, a physical learning

* Corresponding author, E-mail: husaal-rubaye@stu.okan.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_653

environment refers to a tangible setting that includes spatial, material, and technological conditions that support learning objectives (Salomon, 1998), involving face-to-face interaction in settings such as classrooms, seminar and lecture halls, laboratories, and studios. In recent years, the integration of physical and virtual formats has given rise to hybrid learning environments, which combine face-to-face and online pedagogical strategies. The type of learning environment often depends on factors such as the learning objectives, target audience, content type, and the availability and accessibility of resources.

Virtual learning environments offer flexible, personalized, and accessible educational experiences, often enabling collaboration across distances (Al-Fraihat et al., 2019). These beneficial features that make them widely used and preferred learning environment by both institutions and students (Valtonen et al., 2021). However, they also require strong digital literacy skills and may lack the spatial and social dynamics inherent in physical learning settings. Consequently, growing attention has been directed toward the role of physical learning environments in enhancing student engagement and learning outcomes (Vercellotti, 2018).

In higher education institutions, physical learning environments encompass a variety of spaces such as classrooms, seminar rooms, lecture halls, laboratories, and studios. Classrooms are typically enclosed spaces used for interactive or lecture-based teaching, with seating and technology arrangements that support group learning. Seminar rooms are learning spaces intended to promote communication, debate, and interaction, where students are encouraged to engage critically with course content and one another, often under the guidance of a facilitator rather than a lecturer . Lecture halls or lecture theaters (Jamieson et al., 2000) are larger venues designed for formal, instructor-centered presentations, often accommodating large audiences. Laboratories offer hands-on learning environments for disciplines such as science and engineering, where specialized tools and equipment are essential. Studios, on the other hand, are adaptable spaces tailored to design-oriented disciplines.

In architectural education, the design studio serves as the primary physical learning environment, particularly within higher education institutions. Since applied courses form the core of the curriculum, studios are essential for fostering the experiential and reflective processes central to architectural learning (Salama, 2015; Emam & Taha, 2021; Wong, 2023). This pedagogical model closely aligns with Kolb's (1984) experiential learning theory, which builds on Lewin's (1946) foundational work. Widely applied in architectural education, Kolb's model describes learning as an iterative cycle consisting of four stages: "Concrete Experience, Reflective Observation, Abstract Conceptualization, and Active Experimentation". These stages capture the dynamic qualities that define studio-based learning. Complementing Kolb's framework, Schön (1984) emphasizes the importance of "learning by doing" through activities such as drawing, building, and writing core elements of the studio experience. The author characterizes the studio as a "reflective practicum" where students engage in "reflection-in-action," developing knowledge and insight through the process of design itself. This reflective, practice-based learning mirrors real-world professional practice and supports the development of both creative and disciplinary skills. Dutton (1987, p. 16) further describes architectural studios as "active sites where students are engaged intellectually and socially, shifting between analytic, synthetic, and evaluative models of thinking" across a variety of activities such as drawing, conversing, and model-making. Beyond their educational function, studios often become deeply personal spaces for students. As Oh et al. (2013) note, the studio evolves into a second home a space where students not only work intensively but also socialize, study, and even rest.

The pedagogical value of studio-based learning in architectural education depends on studio spaces that function effectively and support educational goals. To achieve this, a collaborative, needs-driven approach to studio design is essential. It begins by identifying the intended learning outcomes and then shaping the environment to support those objectives (Jamieson et al., 2000; Kokko & Hirsto, 2020). Bamford (2008) highlights the importance of creating learning spaces in higher education that foster both knowledge acquisition and the development of discipline-specific skills, ultimately preparing students for their professional futures. Similarly, learning environments in higher education institutions are increasingly viewed not just as places for transferring knowledge, but as catalysts for critical thinking, creativity, and the formation of professional identity (Mulcahy et al., 2015). Several studies focus on the impacts of physical learning environments in shaping students' satisfaction and academic performance in higher education. Findings consistently emphasize that well-designed spaces that are user-oriented and aligned with intended learning outcomes significantly enhance comfort, focus, and motivation. These qualities contribute to more meaningful engagement with learning activities, promote deeper understanding, and ultimately support academic success (Hill & Epps, 2010; Jin & Peng, 2022; Costa & Steffgen, 2020). Soleimanipirmorad and Vural (2018) highlight that the quality of the physical environment in educational buildings plays a critical role in shaping students' well-being and academic performance. They suggest that when basic environmental factors such as air quality, lighting, acoustics, and spatial organization are inadequate, they can trigger symptoms of "Sick Building Syndrome", leading to physical discomfort, reduced focus, and diminished productivity. Rather than viewing educational spaces purely as architectural forms, the study frames them as functional environments that must support health, comfort, and cognitive efficiency for effective learning to occur. Akimova and Chikeneva (2019) support this idea by emphasizing that an educational environment should minimize risks to students' physical, mental, and social well-being. They highlight the need for environments that support health, safety, and positive development.

A physical learning environment comprises both physical and spatial characteristics, each playing a distinct role in shaping the user experience. The distinction between the two is essential for understanding how places are perceived, experienced, and function. Physical characteristics refer to the tangible, material elements of a space including materials and construction, furniture and workstations, technology and equipment, visual comfort (Lighting), thermal comfort, acoustic comfort which directly affect comfort, usability, and sensory experience. In contrast, spatial characteristics relate to the configuration and organization of the space including layout and floor plan, scale and proportions, spatial flexibility and adaptability, circulation and flow, visual connectivity. These features influence how individuals navigate, interact within, and interpret the environment, ultimately impacting both behavior and learning outcomes.

Building on these discussions, this study aims to differentiate between the physical and spatial characteristics of studios as physical learning environments. It develops a conceptual model that identifies and explains the key features of architectural design studios that influence student satisfaction and academic performance. Specifically, the study addresses the question: What are these characteristics, and how do they enhance student outcomes? By synthesizing theoretical perspectives and empirical findings through a comprehensive literature review, the study proposes a structured framework for evaluating studio environments. This model not only demonstrates how specific design features contribute to learning effectiveness but also offers practical guidance for educators, architects, and institutional planners in creating more inclusive, engaging, and pedagogically supportive studio spaces in architectural education.

2. Method

This study adopts a narrative literature review approach to explore the physical and spatial characteristics of learning environments and their impact on student satisfaction and academic efficacy, with a particular focus on studio-based education in architecture. Relevant literature was collected through targeted searches in reputable academic databases known for high-quality coverage, including Scopus and Web of Science (Burnham, 2006; Guz & Rushchitsky, 2009; Mongeon & Paul-Hus, 2015), along with Google Scholar to ensure a broader inclusion of sources. The initial search employed combinations of keywords such as pedagogical, architectural education, learning environment, physical learning space/environment, and studio, alongside student outcome-related terms including satisfaction, academic performance, efficacy, engagement, and productivity. To deepen the investigation, a second round of searches targeted more specific documents addressing particular aspects of studio configuration, especially those related to spatial characteristics such as layout and floor plan, scale and proportions, spatial flexibility and adaptability, circulation and flow, and visual connectivity and physical characteristics, including materials and construction, furniture and workstations, technology and equipment, lighting, thermal comfort, and acoustic comfort. This dual-phase search strategy ensured both breadth and depth in identifying relevant literature for conceptual model development. The selected studies were analyzed to synthesize both theoretical and empirical insights that inform the development of a conceptual model for the architectural design studio. Table 1 presents keywords used in literature review search.

Table 1. Litreture review keywords query.

Main Category	Subcategory	Keywords
Pedagogical Context	Higher education institution	Architectural Education
Learning Environment	Physical	Studio
User	Student Outcomes	Satisfaction, Academic Performance, Efficacy, Engagement, Productivity
Studio Configuration	Spatial Characteristics	Layout and Floor Plan, Scale and Proportions, Spatial Flexibility and Adaptability, Circulation and Flow, Visual Connectivity
	Physical Characteristics	Materials and Construction, Furniture and Workstations, Technology and Equipment, Visual comfort (Lighting), Thermal Comfort, Acoustic Comfort

3. Theoretical framework

Place is constructed through human-place interaction, which is commonly understood through three interrelated dimensions: behavioral, cognitive, and emotional (Low & Altman, 1992). The behavioral dimension refers to the physical actions and activities individuals perform within a place. The cognitive dimension involves how individuals perceive the place through meanings, beliefs, and knowledge and personal associations with a place.

It encompasses personal interpretations, memories, and mental mapping. The emotional dimension captures the affective responses and attachments individuals develop toward their environment, including feelings of comfort, belonging, and emotional bonds that connect people to specific places. These three dimensions provide a valuable lens for examining the relationship between place and user, particularly in understanding how students engage with studio environments as meaningful places within the context of architectural education (Peng et al., 2022). The spatial characteristics of studio environments play a critical role in shaping students' interactions, interpretations, and emotional responses to their learning space, as spatial qualities are known to influence human behavior (Baldassare, 1978). Layout and floor plan influence behavioral engagement by guiding how students move and act within the studio, while also influencing cognitive dimension through understanding of spatial perception and orientation. Scale and proportions primarily affect the cognitive domain by informing how space is mentally processed and contribute to the emotional dimension by influencing feelings of comfort, enclosure, and psychological well-being. Spatial flexibility and adaptability enable a range of activities, thus supporting behavioral needs, and foster cognitive engagement by encouraging autonomy and creative exploration. Similarly, circulation and flow affect behavioral ease of movement through the space and enhance cognitive clarity regarding spatial organization. Lastly, visual connectivity contributes to cognitive understanding of the spatial structure and promotes emotional well-being by fostering a sense of openness and connection within the environment. The physical characteristics of architectural studios significantly influence students' behavioral, cognitive, and emotional engagement with the learning environment. Materials and construction contribute to the cognitive dimension through their aesthetic and symbolic qualities, while also shaping emotional responses by evoking familiarity and sensory appeal. Furniture and workstations support behavioral interaction by affecting usability, posture, and movement within the space, and also influence both cognitive and emotional dimensions by enhancing comfort and overall satisfaction. Technology and equipment enable students to perform learning tasks, reflecting the behavioral dimension, and promote cognitive engagement through interaction with tools that support design processes. Visual comfort (Lighting) impacts the cognitive dimension by affecting visibility, attention, and task focus, while also shaping the emotional atmosphere of the space through its influence on mood and ambiance. Thermal comfort is primarily associated with the emotional dimension, contributing to physical well-being and overall satisfaction with the studio environment. It also engages the cognitive dimension by influencing concentration and mental alertness, particularly in learning settings that require sustained focus. Similarly, acoustic comfort plays a key role in the emotional experience, affecting stress levels and the sense of tranquility within the space, while also supporting the cognitive dimension by minimizing distractions and facilitating auditory processing and verbal communication. Table 2 illustrates the alignment between studio configuration components and the behavioral, cognitive, and emotional dimensions of human-place interaction.

Table 2. Alignment of studio configuration components with human-place interaction dimensions.

4. Spatial characteristics

4.1. Layout and floor plan

The layout and floor plan of an architectural studio's spatial organization are more than matters of convenience; they fundamentally frame students' cognitive and behavioral experiences; subsequently academic performance of students (Omale et al., 2024). Jin and Peng (2022) demonstrated that layout arrangements significantly influence collaboration and perceived comfort, emphasizing that eliminating a fixed front in active-learning environments compared to passive, traditional row-based learning settings enhances these outcomes. Similarly, Abdelbaky et al. (2022) highlighted that centralized and U-shaped layouts were most effective for fostering group interaction, whereas radial and clustered configurations supported individual exploration, underscoring the importance of aligning spatial arrangements with learning activities.

Expanding on the relationship between studio layout and learning effectiveness, Arshard et al. (2023) revealed that narrow aisles and overcrowded layouts suppressed movement, ventilation, and student engagement, while open-plan studios with generous walkways encouraged adaptability and higher participation. Circulation patterns and visual openness were found to significantly impact how comfortably students transitioned between individual critique and collective discussion. Reinforcing these insights, Thoring et al. (2020) argued that open-plan and visually connected settings promote spontaneous encounters that enhance creativity, while flexible zones allow students to reconfigure spaces according to the evolving phases of the design process.

4.2. Scale and proportions

In studio environments, scale and proportion mediate the fit between human bodies, furniture, and enclosure, directly shaping comfort and cognitive ease. Achieving this means supplying each student with sufficient personal area, matching furniture dimensions to anthropometric data, and preserving harmonious spatial ratios throughout the space. Jin and Peng (2022) showed that enlarging personal space from ~0.8 m^2 in passive classrooms to ~2.2 m^2 in active-learning settings markedly increased comfort and spatial satisfaction. Peng et al. (2022) added that generous floor area aids movement but excessive distance can hinder group audibility, underscoring the need for an optimal not maximal scale. Likewise, Arshard et al. (2023) found that cramped desks, low clearances, and mismatched furniture heights caused discomfort and restricted circulation, while Abdelbaky et al. (2022) observed that limited floor space curtailed activity choices. Thoring et al. (2020) further linked a sense of “spaciousness” to freer and creative thinking. Accordingly, providing approximately 2 m^2 per student, aligning furniture and walkways with anthropometric data, and maintaining balanced proportions enhance physical comfort, reduce cognitive noise, and enhance creative engagement; undersized or poorly proportioned spaces undermines these benefits.

4.3. Spatial flexibility and adaptability

Spatial flexibility enables the studio environment to evolve alongside changing pedagogical needs and project phases. Across multiple studies, three key insights emerge: reconfigurable layouts enhance learning, flexible furniture systems promote collaboration and creativity, and adaptability must be paired with active teaching methods to yield real benefits. Jin and Peng (2022) found that movable furniture and modular layouts were the strongest drivers of student satisfaction, allowing learners to tailor the space to their tasks. Similarly, Salama (2015) criticized static, traditional studio models and emphasize emphasized the need for adaptable environments to meet the demands of contemporary education. Abdelbaky et al. (2022) and Arshard et al. (2023) further demonstrated that flexible layouts supported higher engagement and iterative work, while fixed arrangements limited movement and dialogue. Thoring et al. (2020) linked flexible zones to greater psychological freedom, a catalyst for creativity. these findings position spatial flexibility and adaptability as essential for fostering dynamic learning within the architectural studio.

4.4. Circulation and flow

In studio environments, effective circulation determines how easily individuals move through the space, supporting comfort, collaboration, and creativity. Studies highlight three key points: wide, clear walkways promote interaction; narrow or linear ones create congestion and limit participation; and intuitive, easily navigable layouts lower mental effort and sustain focus. Field measurements by Arshard et al. (2023) and observations by Jin and Peng (2022) found that wide walkways facilitated smooth movement and peer interaction, while narrow aisles led to congestion, discomfort, and disrupted activities. Specifically, Arshard et al. (2023) reported that walkways measuring $\geq$ 2.4 meters enabled seamless peer exchange, whereas aisles $\leq$ 1.4 meters caused crowding and task disruption. Similarly, Thoring et al. (2020) and Higuera-Trujillo et al. (2021) emphasized that clear spatial organization and appropriate distances between work zones encourage spontaneous encounters, reduce cognitive load, and enhance positive emotional responses. Taken together, the evidence positions circulation as a critical element in studio design: wide, obstacle-free routes enable dynamic learning and interaction, while cramped, poorly planned paths limit movement, disrupt focus, and hinder collaboration.

4.5. Visual connectivity

In studio environments, visual connectivity plays a crucial role in linking separate zones into a shared, perceptually open space where ideas, feedback, and motivation circulate freely. Studies highlight three main insights: unobstructed sight-lines enhance instructional clarity; open visual links foster peer learning and community; and well-calibrated transparency stimulates creativity without overwhelming individual focus. Jin and Peng (2022) and Peng et al. (2022) demonstrated that movable whiteboards, mobile boards, and distributed screens positioned throughout active-learning spaces improved multi-angle visibility, ensuring all students could access teaching content and participate fully during group activities. Observations by Arshard et al. (2023) showed that open-plan studios, with strategically placed furniture and workstations, allowed students to observe each other's work, encouraging spontaneous critique and informal mentorship a principle also advocated by Salama (2015), who emphasized the importance of transparent, integrated workspaces where students "learn by seeing."Thoring et al. (2020) further reinforced the value of calibrated openness, showing that transparent materials such as glass partitions and layered interior vistas maintained visual connection across zones, stimulating cognitive engagement while preserving focus. Collectively, these findings highlight that the strategic positioning of furniture, boards, and transparent materials is essential for creating a visually connected, collaborative, and creatively charged studio environment.

5. Physical characteristics

5.1. Materials and construction

The materials and construction features of a studio significantly influence its aesthetic quality, safety, and physical comfort. Among these, aesthetic quality plays a critical role in shaping students' experiences. Frazier (1973) emphasizes that thoughtful spatial design enhances students' engagement, sense of comfort, and feeling of belonging, positioning aesthetic experience as a fundamental component of learning environment rather than a decorative addition. The aesthetic quality of a space is largely determined by the choice of materials, colors, and finishes, which together create visual harmony and foster creativity and focus (Cleveland & Fisher, 2014). Natural materials such as wood or stone can evoke a sense of warmth and connection to the environment, creating a more welcoming learning atmosphere. In contrast, modern finishes contribute to a clean, professional aesthetic that supports concentration and productivity. Additionally, the use of vibrant colors, engaging textures, and dynamic patterns can further stimulate learning motivation by making the environment visually stimulating and inviting (Taylor, 2008).

Beyond aesthetics, material and construction features must also address physical comfort including visual, acoustic, thermal, and tactile aspects to create an effective learning environment. While visual comfort (in relation to lighting), acoustic comfort, and thermal comfort are discussed in their respective sections, this part focuses specifically on tactile comfort. The role of materials in shaping tactile comfort is critical, as it directly influences students' physical interaction with the learning space. Surfaces such as desktops, flooring, and furniture finishes significantly affect how comfortable and inviting a space feels. Smooth, soft-touch materials enhance tactile comfort, whereas rough, hard, or cold surfaces can cause physical discomfort and distraction. Regulating surface temperatures through appropriate material choices further contributes to maintaining a pleasant tactile experience. Equally important is ensuring safety through durable material and construction features. Savolainen (2023) emphasizes the significance of a safe physical learning environment, highlighting the role of risk management practices, fire safety compliance, and the prevention of physical hazards through durable and well-maintained facilities. Essential elements include slip-resistant flooring, sturdy furniture, secured fixtures, and non-toxic, fire-resistant materials, all of which are critical to minimizing risks and fostering a secure and supportive learning environment.

5.2. Furniture and workstations

Ensuring the ergonomic and anthropometric suitability of furniture is essential for supporting comfort, focus, and engagement in studio environments (Arshard et al., 2023). Appropriate furniture, particularly generously sized and well-designed drawing tables, is highly valued by architecture students for facilitating daily tasks, creative work, and productive engagement; notably, workspace size was found to significantly impact architecture students' design processes (Nik Bahari Shah et al., 2019). Additionally, movable, adjustable, and ergonomic furniture enhances both physical comfort and psychological well-being, providing spatial autonomy and improving students' overall satisfaction with their learning environment (Jin & Peng, 2022). Providing flexible furniture is essential for supporting diverse group activities and enhancing the adaptability of learning environments. Modular tables enable rapid reconfiguration, facilitating multiple uses and transformable layouts to meet changing pedagogical needs. In addition, mobile chairs with wheels, flexible backs, adjustable seat heights, and adequate foam padding promote both physical comfort and ease of collaboration (Cornell, 2002). Together, these design features contribute to greater student engagement, comfort, and the effectiveness of active learning practices.

5.3. Technology and equipment

Technology and equipment are essential in architecture education studio environments. As Hill and Epps (2010) note, physical learning spaces integrate computer technology, audiovisual systems, projection tools, and communication equipment to support diverse learning styles and enhance instructional delivery. Recent studies highlight that learning environments are evolving to incorporate emerging technologies that enrich the educational experience. Traditional setups, once focused on drafting tables and modeling equipment, have evolved with the integration of advanced tools such as computer-aided design software (CAD), 3D printers, laser cutters, VR platforms, and AI. Wang et al. (2023) emphasize that these technologies transform spaces into immersive, interactive, and personalized learning environments. Kuleva (2024) states that VR-based interventions improve engagement, motivation, and learning efficiency. Lee and Lee (2021) argue that AI personalizes instruction, supports real-time evaluation, and fosters adaptive learning environments. To support these innovations, modern learning studios need to feature multi-display systems, interactive software, and mobile devices, creating flexible spaces that enhance collaboration and engagement (Peng et al., 2022).

5.4. Visual comfort (Lighting)

Lighting is a critical component of the studio environment, affecting visual comfort, cognitive performance, and academic achievement (Samani & Samani, 2012). Both natural and artificial lighting contribute to the overall quality of the space, with key technical factors such as illuminance levels, uniformity, glare control, color temperature, and the color rendering index (CRI) significantly affecting its effectiveness. The EN 12464-1:2021 standard provides guidelines to optimize both comfort and performance. It recommends 500 lux for general tasks and 1000 lux for more detailed work, with a uniformity ratio of 3:1 to prevent visual discomfort. To minimize glare, the UGR should be below 19, while a color temperature of 4000K–5000K is ideal for focus, and 3000K is suited for relaxation areas. A CRI of above 80 ensures accurate color representation, essential for tasks like design and reading. The standard also emphasizes integrating natural daylight to improve comfort and reduce energy consumption, while specific tasks benefit from higher illuminance and cooler lighting.

Research by Zhao et al. (2025) highlights that optimal indoor conditions featuring a high color temperature (4400-4900 K) and medium to high illuminance (500-800 lx) enhance visual comfort, thereby supporting cognitive function. In contrast, Mott et al. (2012) found that focused lighting with high illuminance levels (1000 lux) and a cool color temperature (6500 K) significantly improved reading fluency, suggesting that while balanced lighting supports overall comfort, intense lighting can optimize performance in specific tasks. Ricciardi and Buratti (2018) further emphasized the importance of lighting design, noting that higher illuminance levels can enhance visual comfort, reduce fatigue, and improve concentration, but cautioning that excessive brightness could lead to glare and discomfort. Natural light also plays a crucial role in enhancing students' satisfaction and well-being (Dahlan et al., 2015). Studies have shown that access to daylight improves concentration, cooperation, and reduces symptoms like headaches and fatigue, with architecture students particularly preferring spaces with abundant natural light (Emara et al., 2024). These findings underscore the need to carefully tailor lighting environments to meet educational goals, balancing comfort and performance to enhance student success.

5.5. Thermal comfort

Thermal comfort in studio environments is influenced by several interrelated factors, both physical and personal. Key physical parameters include air temperature, mean radiant temperature, relative humidity, and air velocity, all of which shape students' thermal sensations. Personal factors, such as clothing insulation and metabolic rate, also play an important role in how individuals perceive the indoor climate. Objective indicators, like the Predicted Mean Vote (PMV) and Predicted Percentage of Dissatisfied (PPD), are commonly used to assess thermal conditions, while subjective assessments, such as thermal acceptability and preference, provide valuable insights into students' comfort perceptions (Corgnati et al., 2007). According to EN ISO 7730:2005, the recommended air temperature range for educational settings is between 20°C and 26°C, with a mean radiant temperature between 18°C and 26°C. Air velocity should be maintained between 0.1 m/s and 0.2 m/s, and relative humidity should ideally fall between 30% and 60%. To achieve and sustain these optimal indoor conditions, the installation and proper operation of appropriate HVAC (Heating, Ventilation, and Air Conditioning) systems are essential. HVAC systems regulate thermal parameters, ensuring a stable and comfortable environment alongside a metabolic rate of 1.2 met (light work) and clothing insulation of 0.5 to 1.0 clo. Lack of thermal comfort leads to distraction, fatigue, and reduced cognitive ability, whereas optimal thermal conditions support concentration, learning efficiency, and overall well-being in educational settings. Wargocki and Wyon (2013) emphasize that improved thermal and air quality conditions can be cost-effective and beneficial for students, suggesting that enhancing ventilation rates improves student performance by reducing CO_2 levels and boosting air quality. Similarly, Krawczyk and Dębska (2022) found that maintaining classroom temperatures between 22°C and 24°C results in higher student comfort and more efficient work, highlighting the strong link between thermal comfort and academic performance. These studies underscore the importance of thermal comfort, and by extension effective HVAC system implementation, as critical factors influencing both well-being and academic success in educational settings.

5.6. Acoustic comfort

Acoustic comfort is a crucial factor that influences both student satisfaction and academic performance in studio environments. In studio settings, where both individual concentration and collaborative discussions are required, effective management of acoustic comfort is essential for supporting focused work, clear communication, and reducing cognitive fatigue. The activities within a studio environment include individual study, desk critiques, group study, and group critiques, as well as jury critiques all of which require distinct acoustic considerations to maintain comfort and productivity (Ozcevik & Yuksel, 2004). Poor acoustic conditions, such as high noise levels and long reverberation times, can significantly hinder students' learning, concentration, and well-being, while also affecting instructors' vocal health (Zhang et al., 2024). Achieving acoustic comfort in higher education learning environments depends on several factors, including maintaining background noise levels of ≤ 35 dBA, controlling reverberation time based on room volume, and ensuring high speech clarity with a Speech Transmission Index (STI) of ≥ 0.75 (ISO 3382-2:2008). The integration of balanced acoustic materials and properly designed voice amplification systems further contributes to creating learning spaces that support concentration, communication, and student well-being (Duran, Ausiello, & Battaner-Moro, 2019). Additionally, the acoustic properties of materials and the room's geometry, including size, shape, and surface finishes, play a critical role in ensuring a balanced and comfortable auditory environment (Tabatabaei Manesh et al., 2024).

6. Discussion

The spatial and physical characteristics of architectural studio environments are pivotal in shaping students' cognitive, emotional, and behavioral development. A carefully designed studio environment can significantly enhance learning outcomes, student satisfaction, engagement, productivity, and psychological well-being. The key spatial and physical features synthesized through the literature review are presented in Tables 3 and 4, emphasizing the importance of adopting a holistic, user-oriented approach to studio space design.

Table 3. Key Features for the spatial characteristics of studio environments in architecture education.

Spatial Characteristics	Key Features
Layout and floor plan	Clear, open layouts Centralized/U-shaped layouts Radial/clustered layouts
Scale and proportions	Providing approximately 2 m² space per student Furniture dimensions aligned with anthropometric data Balanced spatial proportions Avoid inadequate proximity as well as excessive separation
Spatial flexibility and adaptability	Reconfigurable layouts Flexible zones Adaptable and movable furniture
Circulation and flow	Wide, unobstructed walkways (≥ 2.4 meters) Avoid narrow aisles Intuitive, clear circulation Open paths
Visual connectivity	Unobstructed sight-lines Open visual links Transparent materials (glass partitions, open interior views) Strategic furniture and board placement

Table 4. Key Features for the physical characteristics of studio environments in architecture education.

Physical characteristics	Key Features
Materials and construction	Aesthetic quality (materials, colors, finishes) Tactile comfort (surface temperature, smoothness) Use of natural materials (wood, stone) Safe materials (non-toxic, fire-resistant) Slip-resistant flooring Sturdy furniture and secured fixtures
Furniture and workstations	Ergonomic furniture Adjustable and movable chairs and desks Modular and flexible layouts for group/individual activities Proper sized workstations (drawing tables) Mobile chairs with wheels, adjustable heights, flexible backs Adequate foam padding for comfort

Table 4 continued

Technology and equipment	Integration of computer technology and CAD software Use of 3D printers and laser cutters VR platforms for immersive learning AI tools for personalized instruction Mobile devices and multi-display systems Audiovisual and projection systems
Visual comfort (Lighting)	Balanced use of natural and artificial lighting Illuminance levels: 500 lux (general), 1000 lux (detailed tasks) Uniformity ratio 3:1 Glare control (UGR<19) Color temperature: 4000–5000K (focus), 3000K (relaxation) Color Rendering Index (CRI >80) Integration of daylight to enhance well-being
Thermal comfort	Installation of appropriate HVAC system Air temperature between 20–26°C Mean radiant temperature between 18–26°C Relative humidity between 30–60% Air velocity between 0.1–0.2 m/s
Acoustic comfort	Background noise levels ≤ 35 dBA Short reverberation times adjusted to room volume High speech clarity (STI ≥ 0.75) Balanced use of acoustic materials Proper voice amplification systems Optimized room geometry and surface finishes for acoustics

7. Conclusion

Although virtual learning environments have become increasingly prevalent, physical learning environments such as studios remain fundamental to architectural education, where experiential, spatial, and practice-based learning establish the core of its pedagogical approach. Building on this understanding, this study provides a conceptual model that identifies the spatial and physical characteristics of architectural design studios essential for enhancing student satisfaction and academic efficacy. Grounded in a synthesis of theoretical frameworks and empirical findings, the model emphasizes the critical influence of spatial and physical studio configurations on students' cognitive, emotional, and behavioral responses. In particular, the study underscores the importance of aesthetic quality, ergonomic flexibility, technological integration, environmental comfort, and safety in shaping productive and supportive studio environments. It highlights spatial factors such as clear, open layouts; centralized or clustered configurations; adequate personal space aligned with anthropometric data; reconfigurable zones and movable furniture; wide, unobstructed circulation paths; and visual connectivity achieved through transparent materials and strategic spatial arrangement all of which contribute to enhanced user experience, collaboration, and academic engagement. Accordingly, this study offers a structured framework for studio planning and design, equipping educators, architects, and institutional policymakers with a blueprint to create inclusive, adaptive, and high-performing studio spaces that promote academic success, creativity, autonomy, and innovation in architectural education. Future research should evaluate students' perceptions and satisfaction with studio environments through a comprehensive assessment that includes all physical and spatial characteristics, test the proposed model in diverse contexts, and explore how emerging technologies and sustainable strategies can further enhance learning outcomes.

Abstract. Social housing is shaped by the changing needs and desires of its residents. This article examines the adaptability of social housing in response to changes initiated by residents and studies the Malagueira Neighborhood in Évora, Portugal, designed by Álvaro Siza, and Shushtar New Town in Iran, designed by Kameran Diba. Siza envisioned Malagueira as a flexible and evolving urban fabric, creating a structural yet open framework that allowed residents to personalize their spaces over time without compromising architectural coherence. Similarly, Diba's design for Shushtar New Town combined traditional Iranian urban patterns with modern housing needs, emphasizing a human-scaled environment that could adapt to residents' changing lifestyles. Based on documentary analysis, field observations, and academic sources, the study explores how residents interact with their environment and how it changes over time. The results show a complex relationship between the architect's initial intention and the changing needs of residents, reflecting broader social, economic, and cultural developments. Through a comparative analysis of the two case studies, the research identifies shared strategies and differences in how flexibility, resident participation, and architectural integrity are addressed. While both designs encouraged adaptation and sustained urban vitality, challenges such as infrastructure limitations, maintenance, and regulatory frameworks persist. Ultimately, this research contributes to discussions on sustainable and human-centered housing and provides insights into how flexibility can be integrated into future social housing developments without compromising architectural integrity.

Keywords: Social housing; Architectural flexibility; Resident transformations; Malaguera neighborhood; Shushtar New Town

1. Introduction

As urban populations grow and diversify, the challenge of designing housing that can meet the evolving needs of residents has become increasingly important. Flexibility and adaptability in architectural design are now recognized as critical strategies for fostering sustainable, human-centered communities. According to Davis (1995), "Social housing projects hold considerable historical and architectural significance within the realm of modern architecture. They arose in response to the urgent need for affordable and suitable housing". Social housing is not simply shelter or protection from the outside environment. Rather, it should deliver a sense of dignity and pride to its inhabitants through its architectural style, materials, and design (Amirjani, 2020). The term itself implies that a responsible and humane society has an obligation to assist those who cannot afford the free market price of housing (Davis, 1995).

As many studies have indicated, affordable housing and decent housing is a primary need, and also a human right, which has an effect on the education, health and employment productivity of the inhabitants, as well as on the general well-being of the society. Among the notable examples of such adaptable social housing are the Malagueira Neighborhood in Évora, Portugal, designed by Álvaro Siza, and the Shushtar New Town in Iran, designed by Kamran Diba.. Both projects, although rooted in different cultural and historical contexts, share a common commitment to creating living environments that respect traditional patterns while allowing for future growth and personalization.In general ‹Siza and Diba executed their housing projects during a specific historical period (1977), employing similar strategies, ideas, and design concepts (Amirjani, 2017).

The two aforementioned projects were destined to be unique 20th-century designs due to the architects' intense focus on their traditional, cultural, social, and historical elements. In Malaguera, Siza's strategy placed a strong emphasis on structural openness, which promoted residents' gradual modifications and preserved the

https://doi.org/10.31462/icearc2025_a_arc_670

neighborhood's architectural coherence. In parallel, the new city of Shushtar Diba reinterpreted vernacular Iranian urbanism to create an environment that was human-scale and responsive to the daily lives of its residents.

The purpose of this study is to find out how social housing can adapt to residents' evolving needs over time without compromising social cohesiveness or architectural integrity.

By conducting a comparative analysis of Malaguera and the new city of Shushtar, this study seeks to identify key strategies and challenges related to resilience, resident participation, and sustainability. Ultimately, the findings contribute to broader discussions on the design of resilient and adaptive urban environments appropriate to contemporary and future social developments.

2. The emergence of the Malagueira Neighborhood and Shushtar New Town

Following the so-called "White Revolution" in Portugal in April 1974, which marked the end of 48 years of dictatorship, the newly appointed Minister of Housing and Urban Development set out to address the country's housing shortage. The Malagueira Housing Project was a component of Évora's broader social housing program. While building 1,200 affordable housing units suitable for middle-class and lower-class populations on a 27-hectare plot of land, the goal was to preserve Évora's cultural features. Within four months, Siza developed the initial strategic design, and the project board approved the final architectural plans in November 1977. Out of the 1,200 planned residential units, 1,100 had been built by July 1997, with the entire project completed by 1998 (Zapatel, 2001).

In a different geographical context, far from the West, where modernization started, Iran saw the rise of social housing and corporate towns as a direct result of rural-urban migration to industrial areas and larger urban centers.

This population shift was predominantly driven by the White Revolution, a modernization program executed in Iran between 1963 and 1979 (Mohammadpanah, 2022).

Shushtar New Town is located near the historic city of Shushtar in Khuzestan Province , southwestern Iran. The project was designed to house the workers of the Karun Agro-Industry Company, one of the largest sugarcane production industries in the region(Shirazi, 2016). The town wanted to support the growth of the local sugarcane industry by giving its workers access to modern living facilities.

The project was to be completed in five phases by 1985. Construction of the first phase, which was intended to house 4200 residents, started in 1976 and was almost completed, with 600 units built, between 1977 and 1980 (Sedighi, 2016).

In fact, both projects are clustered low-rise carpet housing with Medium-Density settlements(Amirjani, 2020). The Shushtar New Town project is situated on a gently undulating site near Shushtar, offering river views (Diba, 1981). In contrast, Malagueira is located in Évora, a historic city in Portugal that is characterized by its gentle slopes and rich Roman heritage. Both locations experience extremely hot summers and mildly dry winters(Amirjani, 2017) (Fig. 1 and Fig. 2).

Fig. 2. Shushtar New Town, Shushtar, Iran, 1976

3. Flexibility in architecture

Any space system with the ability to change internally can respond to a greater number of needs of its users at different times and thus have a more desirable function than single-function space systems. A subfield of the field of space flexibility is the achievement of changeability in space systems. In recent years, a number of researchers have examined the problem of flexibility in architectural spaces, which has drawn increasing attention from the architectural community. One key reason for this attention is the need to accommodate and ensure the fulfillment of various user needs at different times. It is anticipated that this feature can be used for a variety of purposes due to the effectiveness of flexible design. Since the home is where people spend the most time out of all the different uses, it is crucial that it be able to accommodate the various (and occasionally conflicting) needs of its occupants (Wielland & Wallburg, 2012: 890).

In addition, the way residents use their homes tends to change more rapidly than in other building types, which requires the living space to adapt to a diversity of activities. Based on this perspective, flexibility in housing emerges as one of the key concepts in this field. By comparing different residential models, it is possible to analyze how this concept has evolved over different periods in the development of Iranian domestic architecture. ibid

In fact, flexibility in the early stages of design refers to the initial thinking in the design process and how to arrange the space in a way that can accept changes. It includes a chain of physical changes that provide the building with the ability to adapt to changing conditions (Habraken, 2008: 291).

Meanwhile, Gruter believes that complete flexibility is not possible and that there are limits to this, because the entire system and its original structure must be preserved(Grutter, 1987). According to the above definitions, flexibility can be understood as the ability to make changes that involve both the field of activity and the architectural form, in order to meet user needs. In other words, whenever user needs arise regardless of time or place flexibility enables the spatial and activity systems to adapt accordingly. Moreover, a change in the activity system may require the user to modify a specific architectural element in a specific location to better accommodate those needs.

This concept of flexibility is clearly evident in notable residential projects such as Malaguera by Álvaro Siza and Shushtar New town by Kamran Diba, each of which demonstrates a distinct but contextually rooted approach to adaptive residential design. Both architects incorporated the flexibility of unit extension into their design approach, allowing for future expansions of the dwellings. In Malagueira, Siza implemented building regulations that allowed for the evolution of unit plans and the merging of adjacent houses. Similarly, Diba incorporated a design concept in Shushtar New Town that facilitated the growth and extension of houses through simple modifications to the walls between units(Rodrigues, 2015).

According to Diba, this design approach prevents stagnation in the urban fabric while enhancing the eco-dynamic, social sustainability, and diversity of families residing in the area(Eloy, 2018).

In Malaguera, Siza uses a modular and expandable system in which residential units are built according to simple, repeatable typologies. This allows residents to modify or expand their living spaces over time according to changing needs. The uniformity of the infrastructure – particularly the system of elevated concrete channels used for utilities – ensures that the houses can evolve without disrupting the overall urban plan. The architectural form, while visually coherent, is intentionally open to user-driven change and embraces the core principles of flexibility(mota, 2014). Conversely, Shushtar New Town, on the other hand, represents an indigenous and culturally sensitive interpretation of flexibility. Diba encourages a variety of social and practical uses by incorporating traditional Iranian architectural features like courtyards, winding passageways, and flexible semi-public areas. There is flexibility in the residential designs. They adapt to changes in lifestyle, family structure, and even small-scale commercial use in the future. The project's spatial arrangement encourages social interaction while letting each unit change to reflect the needs of its occupants(Amirjani, 2020) (Fig 3 and Fig 4).

4. Architecture with the people, by the people, for the people Malagueira designed by Alvaro Siza

In fact, the conflict between ownership and the right of residents to personalise the design has been another universal challenge in creating sustainable social housing. However, some architects and government agencies have come up with innovative solutions for responding to this conflict. Alvaro Siza uses a unique approach to design in which users actively participate in the shaping of designs and ideas. This practice, called participatory methodology, is seen throughout Siza's housing design and aims to reflect the wishes of the people and to revive the relationship between the designer and the users. In the Malaguera project, Siza began his work with conversations with future users, authorities, and representatives of the local housing cooperative, and from these conversations, concepts and initial designs were formed (Mota, 2011).

After completing the designs, Siza proceeded to build several full-scale models of spaces such as the rooms, kitchens, and living rooms using lightweight blocks to explore client feedback on their ideas and spatial experience. Siza frequently highlights the value of user interaction, viewing it as one of the key tenets that ought to be given top priority throughout the entire design process. However, expressing all the requirements and demands could be frustrating and time-consuming for a designer. According to Siza, responses from authorities and users can sometimes be tyrannical and authoritarian; they try to impose their point of view while rejecting all architectural complexity. According to Siza, a designer could just accept this drawn-out process in order to avoid conversations, but a genuine engagement process requires that one accept tensions because the outcomes of these interactions are crucial (Zapatel, 2001).

It can be argued that these direct interviews not only improve the dialogue between "object" and "subject" by reflecting the demands of users, but they also help architects become more aware of how well their design concepts and ideas are received by the residents. Álvaro Siza originally planned a 3.5-meter wall separating public and private areas in the Malagueira housing project (Siza, 1979), However, he added a window facing the street and lowered the wall after residents complained that the house was too obstructed, striking a balance between social interaction and privacy (Leger, 2004). These changes helped to reflect the cultural and social preferences of the early residents and the contrast between closed and open design. Early occupants designed more varied and intimate areas with shorter walls, whereas government-built units with taller, more homogeneous walls showed less evidence of personal identity. (Sennett, 2018).

Table 1. Resident-led spatial transformation, Malagueira, Portugal

Reasons	Spatial Transformation	Visual Documents
Modification of boundary walls Mean	Originally designed with 3.5-meter-high walls between public and private spaces, the wall height was later reduced and a window was added facing the street in response to resident complaints about excessive enclosure	 
Contrast in wall heights between unit types	Early resident-built units featured shorter. more personalized walls, while government-constructed units retained taller, uniform walls, resulting in less expression of individual identity	 
Informal conversion of streets into parking	Streets were intentionally designed without sidewalks or parking to promote social interaction, inspired by traditional Alentejo villages. However, residents' refusal to purchase garages led to the use of these spaces as informal parking, undermining the project's original communal Vision	 

Due to residents' reluctance to buy garages, the Malagueira neighborhood's winding streets, which were intended to promote social interaction by avoiding sidewalks and parking spaces and drawing inspiration from Alentejo village life, gradually became unofficial parking areas (Gomes, 2016). Siza's idea of a vibrant, social street life was weakened by this change. High walls stayed the same in the areas created by the government organization FFH, creating a more constrained and closed streetscape. Public opinion was sharply divided after the first units were built in Malagueira; some locals referred to it as “the Arab neighborhood,” criticizing the monotony and comparing the houses to animal pens (Robalo, 1983). Siza accepted the critique and underlined that using aesthetics alone to combat monotony would lead to artificiality (Siza, 2009). Although there was disagreement over the exterior homogeneity, subsequent reports commended the homes' interior comfort and quality (Rocha, 1985).

In actuality, the Malagueira Neighborhood project evolved into a platform for political conflict that transcended its unique advantages and disadvantages. The Malagueira plan was perhaps the most significant example of a participatory design decision-making process created in Portugal following the post-revolutionary experience with citizens' participation during the SAAL process, despite the challenging circumstances in which the project's development was managed. However, Siza believes that involvement involves more than just a conciliatory strategy. It’s also about exploring the creative potential of conflicts. Architectural historian Kenneth Frampton made the following argument in reference to Siza's experience with citizen participation in the design process: "In hindsight, this intense and challenging experience has led him to caution against the simplistic populism of 'giving the people what they want.'" (Frampton, 1986).

Definitely, the conflicts between the architect and the other stakeholders in the process became part and parcel of the design process and played an important role in the processes of subjectivation. Siza claimed, “Participation procedures are above all critical processes for the transformation of thought, not only of the inhabitants’ idea of themselves but also of the concepts of the architect” (Siza and Vanlaethem, 1983).

In many cases, the residents changed the circulation structure of the house and connected the patio directly to the roof terrace on the first floor, a possibility that Siza had not considered in the initial versions of the project. By doing so, the residents enlarged their sky-facing spaces and also expanded the functional possibilities of the house. Now, the roof terraces could be used for drying clothes or just to give first-floor bedrooms direct access from the patio. The patio became a privileged territory for the production of subjectivity (Gomes, 2016).

5. Shushtar New Town Kamran Diba

The Design Method of Kamran Diba in Shushtar New Town It is possible to conclude from examining Kamran Diba's architectural sketches and interviews about Shushtar New Town that the architect used what can be referred to as a "sentimental approach" when designing the project. This approach was based on feelings, memories, tenderness, and utopian nostalgia for a vanished past and a world that is disappearing.

This, along with Diba's intentions of "reviving the traditions" and "resisting the universal mass production culture," played a key role in the creation of the Shushtar New Town project.

As Diba has stated time and time again, "When designing social housing in any culture, users have a particular lifestyle with certain needs," and the architect's primary duty is to address these common needs while having a thorough awareness of people's lives (Khanizad, 2014). Diba's understanding of the distinctive way of life of the locals was evident in his early plans for the Shushtar New Town. Diba's own sentiments and emotions are also conveyed, along with his longing to bring back his adolescent and childhood memories of living in the contemporary uptown Tehran neighborhoods and his longing for the dwindling traditional Iranian way of life (Daneshvar, 2016).

Shushtar New Town is a creative recreation of the traditional housing pattern that simultaneously meets the needs of contemporary life. This complex's design incorporates innovative elements of traditional urban planning and lifestyle, such as a compact texture, rooftops that can be used for nighttime sleeping, thick walls, dead-end alleys, narrow streets, and small windows that create a cozy and comfortable atmosphere (Diba 1980). "We planned two- and three-room housing units that could become four-, five-, or six-room houses as the family's standard of living improved." (Diba 1980). This flexible configuration, what Diba calls "soft furniture" (Javaherian and Diba, 2005), enables residents to move between different spaces to avoid the sun or to enjoy it in different seasons. The rooms measure 5×5 m, 4×4 m, and 3×4 m, with the smallest being the smallest. On this flexibility, Diba writes: "Our goal was akin to writing a script for human interaction, anticipating all possible action and yet leaving room for spontaneous improvisation within the given architectural spaces." (Diba 1980). A distinctive feature of Diba's reinterpretation and unique approach to new creation is the way he subtly deconstructs and reframes traditional architectural and urban principles to achieve new designs and configurations. This process of de-familiarization creates a context of tension in which the familiar and the unfamiliar are brought together in a dialectical interaction(Amirjani, 2017).

5.1. Spatial transformations and structural damages caused by resident-led ınterventions in Shushtar New Town

Shushtar New Town's design and construction started in 1974. Due to Diba's departure from Iran and the changes brought about by the revolution, the complex's construction was initially sluggish and eventually came to a complete halt in 1979. Following the start of the Iran-Iraq War, most of the original residents left the buildings, and war victims along with immigrants from various cities, villages, and surrounding areas moved into this town and settled there. The arrival of war refugees to the unfinished New Shushtar; the social structure of the city could not be well organized and could not be a good host for its residents along with its physical structure As a result, the town reached the stage of occupancy before it was truly ready and under unauthorized conditions. The town's inhabitants, each contributing their own customs and cultures, stayed for eight years, allowing for the project to undergo changes. This was because everyone brought the culture and customs of their respective cities to the complex. However, their overcrowding caused the complex to sustain additional damage (Amirjani, 2017).

From the start, Shushtar New Town's design demonstrated a tension between users' real lifestyles and Diba's perception. Shortly after occupancy in 1979, two major privacy-driven transformations occurred: windcatcher holes were filled, and openings facing pedestrian walkways were blocked. In courtyard and apartment typologies, ground-level windows compromised privacy, leading residents to wall them off. During the Iran-Iraq war, overpopulation caused shared use of units and extensive interior modifications, such as building new walls, transforming balconies, and altering entrances (Bakhtiari & Mosavi, 2017). Diba's design excluded cars from narrow alleys to enhance comfort, safety, and environmental quality, with parking placed at the street ends (Diba, 1980). However, insecurity and vehicle theft led residents to modify homes to accommodate cars, often demolishing courtyard walls. These changes, including roofing courtyards and blocking windows, disrupted the original spatial logic and image of the town (Daneshvar, 2005).

5.2. Physical pathography

Physical injuries in the complex include:

- Humidity
- Flowing sewage in the area
- Accumulation of loose waste in the complex
- Inappropriate additions
- Deterioration of some walls and flooring in the passageways over time
- Failure to repair and address existing damage
- Lack of plumbing (gas, water, electricity, and sewage) in some parts of the complex

- Closure of air vents and alteration of the balcony parapet height

Table 2. Resident-led spatial transformation, Shushtar New Town, Iran

Reasons	Spatial Transformation	Visual Documents
Privacy	• Filling the windcatcher holes located in the walls of the courtyard • Blocking openings facing pedestrian crossings • Creating a roof for the courtyard and blocking the windows to prevent visual access of other units	 
Security	• Converting a private yard into a parking lot • Replacing the entry doors with gate-like doors for cars • Extending the wall up to the second floor and roofing the void from the to • Transforming the rooms according to their own condition and needs	 
War	• Builting walls inside the rooms, creating new spaces for sleeping, or as kitchens • Converting a large number of balconies into small rooms	

5.2.1. Windows

The following are the reasons why residents have altered their windows:

The primary rationale behind window modifications is the necessity to create more space. In other words, many changes in window openings have resulted from residents' interior home modifications made to accommodate spatial needs.

- Unsuitability of the window for its intended use: This is a reference to the prevalent use of air conditioners and other cooling devices in this region. The window openings' dimensions, shapes, and proportions do not satisfy the users' needs for comfortable living spaces.
- Creating privacy: A few residents have expressed dissatisfaction over being able to see inside their homes. To address this, they have altered the windows to enhance and ensure their privacy.
- Enhancing the sense of security (security against theft).
- Increasing the Feeling of Protection (protection of people and objects from falling).
- Amount of Natural Light: Customers have complained that the units do not get enough natural light. However, this factor has been the least important reason for users to make changes to the windows. Among the reasons for this are the heat and climatic conditions.

Additionally, the most important methods of making changes, in order of priority, include changing the use of the space behind the window, altering the location of the opening, changing the size of the opening, and modifying the shape of the opening.

6. Conclusion

This study highlights the subtle yet important conflict between the original architectural vision and the realities of daily life as shaped by the locals in the Malagueira Neighborhood and Shushtar New Town. In both situations, people's gradual adaptation of their living spaces was greatly influenced by the lack of a clear post-occupancy management plan and continuous supervision. The majority of people in Shushtar New Town made modifications mainly to accommodate their basic needs, which included wanting more privacy and space. However, cultural context was not given much thought when many of these changes occurred. Research has indicated that the initial spatial arrangement did not offer sufficient comfort or a feeling of safety, resulting in discontent, particularly with regard to privacy. The fact that the project ultimately housed a population that was primarily made up of immigrants, which was not foreseen in the early planning stages, further complicates matters. Events like the Iran-Iraq War, alongside administrative mismanagement, only deepened the challenges. Because designers and potential residents did not communicate well, the architecture frequently did not represent the daily lives of the occupants. These findings imply that more successful outcomes might have been achieved by incorporating users earlier in the process and raising awareness of their social and cultural customs.

By contrast, Malagueira presents a more optimistic picture. Álvaro Siza's approach provided a flexible but coherent urban system where people could gradually personalize their houses. This flexibility helped maintain architectural unity while making space for individual needs to emerge. Residents felt more in control of their surroundings and had more agency because of the design process's participatory nature, even though the neighborhood also had problems, such as shared streets being turned into unofficial parking lots.

These two instances unequivocally demonstrate that social housing is a story that continues after construction is completed. When people are left to adapt mass-produced housing on their own without supervision, the lack of planning or regulations frequently results in chaos and a decline in the quality of the design. Sustainable housing demands more than just good design, particularly when it comes to large-scale projects. It requires careful maintenance that lasts long after residents move in. Ultimately, designing housing that not only lasts but also changes gracefully with its occupants requires a deeper understanding of culture, early user involvement, and an architecture that permits change.

Abstract. As cultural heritage sites globally face challenges in preservation and visitor engagement, this research explores the integration of AI-driven smart systems to enrich the visitor experience, with a focus on the ancient cities of the Troas region. The study addresses the challenges of preserving and presenting complex historical narratives, particularly in archaeological sites where traditional static informational tools (e.g., brochures, display boards) often fail to provide meaningful and interactive experiences.The proposed solution combines deep learning (DL) and augmented reality (AR) technologies to develop an intelligent information system that enriches the visitor experience while promoting the sustainability of cultural heritage. The system integrates two key AI fields: computer vision (CV) for object detection (OD) and natural language processing (NLP) for personalized content delivery. By identifying key architectural elements and artifacts on-site, the system provides context-aware, interactive narratives tailored to each visitor's interests and knowledge level. This dual-modality approach enhances both intellectual and sensory accessibility, fostering deeper engagement through multi-sensory storytelling and dynamic interaction. Conceptually, the study is grounded in John Dewey's theory of experience, which emphasizes the active and continuous interaction between individuals and their environment. The system aims to transform passive observation into active participation by stimulating curiosity and enabling personalized exploration. This approach not only increases cultural awareness but also improves knowledge retention, making the experience more meaningful for visitors. Preliminary results from fieldwork in the Troas region, including Alexandria Troas, Apollon Smintheion, Assos, and Parion, indicate that interactive, AI-powered environments hold significant potential for creating immersive and contextually enriched heritage experiences. The findings are expected to contribute to both architectural and technological fields, offering a scalable model for similar cultural heritage preservation efforts globally. By aligning digital innovation with the ethical imperatives of heritage conservation, this study highlights how advanced technologies can foster new opportunities for sustainable and meaningful visitor engagement across cultural heritage sites globally.

Keywords: Artificial Intelligence; Cultural Heritage Sites; Visitor Experience; Deep Learning.

1. Introduction

The preservation and presentation of cultural heritage sites, which contain valuable information such as daily life, economic situation and aesthetic perception, presents a context that needs to be addressed in a special way. In particular, archaeological sites, whose different historical layers have disappeared or have been articulated during the historical process, have difficulty in interacting with visitors. Although additional resources such as information boards and brochures are used to increase the quality of the experience, they are not sufficient to convey the historical and cultural value of the cultural asset (Anay et al., 2022). These structures and artifacts, which were built at a time in history, are open to connecting with people as soon as they are uncovered. On the other hand, for the visitor who does not have expert knowledge, the main problem is to understand and interpret the multi-layered and at the same time incomplete data presented by the site. Therefore, improving the visitor experience in these areas is of great importance in creating cultural heritage awareness and ensuring its sustainability and transferring it to future generations.

With the aforementioned problem framework, the study proposes a proof-of-concept model for an AI-driven intelligent information system for enhancing visitor experience in cultural heritage sites. It aims to develop a system that aims to provide an intelligent and interactive information system and an "augmented" environment

* Corresponding author, E-mail: merve.unal@ostimteknik.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_714

fed by this system by combining the potentials of Large Language Model (LLM) under Natural Language Processing (NLP) and Object Detection (OD) under Computer Vision (CV). With this intelligent information system, it aims to enrich the cultural heritage site experience and make it meaningful. In this context, the Ancient Troas region is considered for the proposed intelligent information system, and the ancient cities of Alexandria Troas, Apollon Smintheion, Assos and Parion in the region and the Classical Architecture assets they contain constitute the application framework of the study.

The “experience” mentioned here is a term that has the ability to create a common synthesis by bringing together many concepts and meanings. At this point, theoretically, the study is based on John Dewey's theory of experience. John Dewey(1986) defines experience as a relationship between nature and organism. This relationship is an interactive communication process between the object and the subject (human). Both sides form a whole with their own unique qualities as known or knower according to each other. This interaction between the organism and nature occurs at every moment of life, so experience is continuous and means “experienced situations/things”. The individual is not only a passive observer in this interaction, but also an actor who is affected by his/her environment, reacts to it, makes sense of the elements of experience with his/her senses and mind, and is transformed in this process. The individual who can develop himself/herself by extracting information and meaning from some external inputs sometimes gains habits. Dewey defines this process as experience (Dewey, 2008). Dewey's definition provides an important framework for examining the problems encountered in the presentation of archaeological sites to visitors and visitor expectations. With a Dewey’s perspective, the presentation of archaeological sites can gain meaning through a much more interactive and richer approach that integrates with the visitor and encourages them to explore its different layers. On the basis of this approach, the study reconstructs the visitor experience as an interactive, contextualized and layered experience of place and story, rather than a mere transmission of information.

2. Methodology

The study proposes a proof-of-concept model for an AI-driven intelligent information system for enhancing visitor experience in cultural heritage sites and adopts a two-stage research design. In the first stage, a literature review was conducted to establish the theoretical and conceptual foundation of the model. As such, the theoretical background of the study is examined under three main headings: Dewey's theory of experience, experience in archaeological sites, which are important cultural heritage sites, and AI applications in cultural heritage sites. The theoretical background of the study was created by reviewing articles, conference proceedings and books on these topics.

In the second phase, an intelligent, interactive and context-aware information system model built on this foundation is presented. This system aims to identify architectural elements through OD, which is one of the fields of AI, to provide personalized content tailored to the visitor's own interests through NLP, and to make these processes possible in a multi-sensory experience environment through AR.

For the data set of the study, data collection was carried out in an unstudied area (Ancient Cities of Troas Region, Classical Architecture) with on-site video shootings, and a unique data set that did not exist before is being created.

2.1. System Design

The system design of the proposed intelligent information system is given in the Fig. 1. At this stage, after the integration of OD module and NLP, it is aimed to transform the system into a holistic structure by developing the information database with interface design and integrating this database through the Information Retrieval System to be designed.

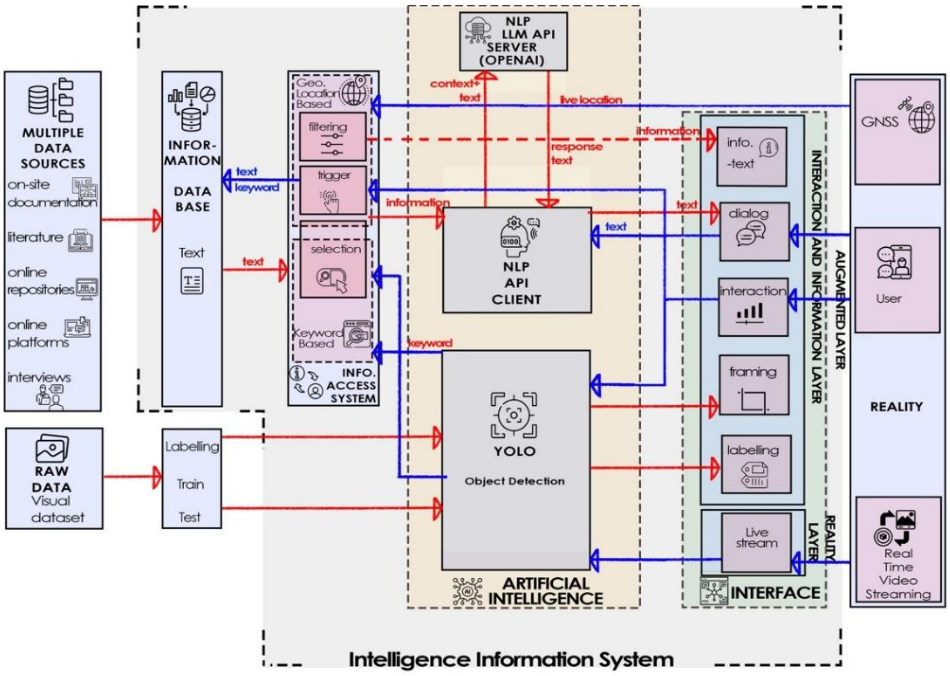

Fig. 1. System Design.

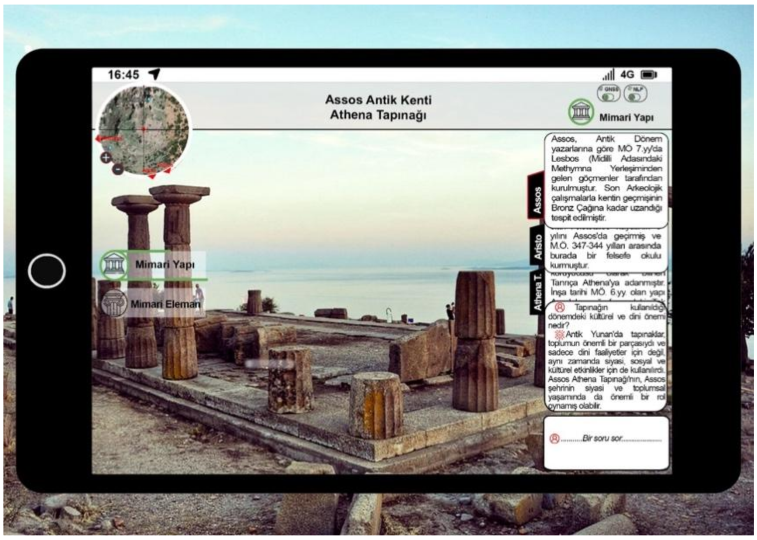

Fig. 2. Concept/Scenario 1 (Architecture).

The system receives the current position from the GNSS. Accesses the Geolocation based triggering module in the Information Access System. If the location is within an area in the database, it filters the relevant database and highlights it. Basic information about the area fills the first information tab. An aerial photo of the area is placed on the mini-map. A location-based search/selection is performed in the selected database. Important points (architectural elements, stories, events, people, etc.) around the location are identified. Distant elements in the immediate vicinity of the location (but not in its sphere of influence) are marked on the mini-map with direction markers. For example, Theater, Agora and Necropolis are marked on the map. Information about the elements within the sphere of influence is retrieved from the database and fills the other tabs. For example, in the image, the ancient city of Assos, Aristotle, who is known to have spent 3 years here and laid the foundations of western philosophy at that time, and the Temple of Athena, which the user was standing in front of at that time, are the items that fill the tabs. The user can get basic information by selecting the tab of their choice. This information also feeds the NLP module. The system first transmits the data obtained in the process outlined above through the client to the NLP server as the "context" of the dialog (contextual preprocessing). If the user enters a dialog, a dialog evolves based on the currently selected tab. The dialog is contextual, but open-ended.

Fig. 3.Concept/Scenario 2 (Architectural Element).

The system receives the current position from the GNSS. It accesses the Geolocation based search module in the Information Retrieval System. If the location is within an area in the database or in the domain of an important structure, this information is processed in the title and mini-map. For example, in the image, the information about the Sanctuary of Apollo Smintheus (area) and Sminthéion (architectural element) is entered in the title, while the mini-map contains information about the bathhouse, street and water tank. When the system is operated at the architectural element scale, no filtering and triggering is done for elements related to the area, architecture, story, event, etc. from the database. The Architectural Element module is location independent, universal, and works in areas that are not in the database.

OD module is active. The system examines the streaming image and performs classification and labeling. The labels are not completely processed into the image, but the labels are transmitted to the keyword-based search module of the Information Retrieval system and the tabs are filled with the returned information. In the example image, 5 elements are identified as Frieze, Architrave, Ionic Cap, Fluted Column Body and Pedestal. Since the user clicks on the Frieze tab, the Frieze element in the image is labeled and the relevant information tab is active. This information also feeds the NLP module. The system first transmits the data obtained in the process outlined above through the client to the NLP server as the "context" of the dialog (contextual preprocessing). If the user enters a dialog, a dialog evolves based on the currently selected tab. The dialog is contextual, but open-ended.

3. Theoretical Framework

The study addresses the issue of "historical (architectural) conservation and the experientialization and sustainability of cultural heritage", which is a specific problem situation in the field of architecture, through John Dewey's theory of experience, and aims to investigate the potential of DL research under AI towards this issue. As such, the theoretical background of the study is examined under three main headings: Dewey's theory of experience, experience in archaeological sites, and AI applications in cultural heritage sites. An important group of references in connection with the focus of the research are the motivations for the use of DL applications in the intersection of architecture and cultural heritage and the studies that include different examples in these fields.

3.1. Visitor Experience in Archaeological Sites

Archaeological sites are underground, aboveground and underwater areas that contain social, cultural and economic traces that have reached the present day since the existence of humanity. These sites have the quality of historical documents where clues about the life of the societies living in the past can be traced (ICOMOS, 1990). This definition makes archaeological sites more than just being environments that contain "things" from the past; they are also important in making sense of the past, enriching social identities and transferring the accumulation of knowledge that has continued in the historical process to future generations (Özdoğan, 2008). However, from the time they were built to the present day, these spaces are difficult to read and require expertise due to the historical layers they have lost or added (Anay et al., 2023). Hall and McArthur (1996) emphasized that visitor experience is a priority for cultural heritage sites and their management, and stated that visitors should be given enough importance for effective cultural heritage management. In order to achieve this, they argued that the visitor experience should be improved and thus visitors should be encouraged to behave more responsibly towards these sites.

Briefly defined, visitor experience is defined as a subjective or personal reaction to activities, environments or situations outside of one's usual environment (Packer & Ballantyne, 2002). Here, the experience starts with the individual's motivation to visit the site and ends with the benefits gained during and after the visit (Tezgel & Akova, 2017). The visitor experience in cultural heritage sites such as museums and archaeological sites can be defined as a kind of "dialogue" between the site and the individual (McCarthy & Ciolfi, 2008). Visitors' experiences in cultural heritage sites are related to complex factors such as individual characteristics, interests and physical conditions of the site (Falk & Dierking, 1992). In addition, individuals' reasons for visiting such sites may be based on a conscious choice or by chance. This creates diversity in the motivations and expectations of visitors (Kempiak, Hollywood, Bolan, & McMahon, 2017). For a consciously planned visitor, the primary purpose may be to gain information, whereas for an accidental visitor, factors such as the desire to discover new places, having fun and having a pleasant time may be at the forefront. Masberg and Silverman (1996) and Packer and Ballantyne (2002) state that the main motivation for visitors to experience cultural heritage sites is to gain information. While Moscardo (1996) evaluated the reasons why visitors come to these sites under three main headings: entertainment, information and social interaction; Poria et al. (2004) based the experience of cultural heritage sites on five main reasons: information, creating cultural heritage awareness and the desire to pass it on to future generations, connecting with cultural heritage and having fun.

When cultural heritage sites are considered on the basis of visitors with quite different motivations and expectations from each other, the first step can be seen as the identification of themes that can attract attention in order to meet these expectations and ensure cultural heritage transmission. For example, narratives about a past event, story, a person's life, beliefs, aspirations, longings and fears are such interesting for visitors. The sense of curiosity about past life/human experiences is an interesting subject for today's people. Therefore, themes that can arouse curiosity in visitors and enable them to make past-present comparisons provide an opportunity to present archaeological sites in a memorable and interesting way (Moshenska, 2017). In addition to the content of the experience that will arouse curiosity, the senses of the visitor also play an important role. Visual, auditory and sometimes even olfactory senses become important for the visitor who experiences an archaeological site to make sense of the structure and its function. In fact, the narratives and sounds experienced regarding the usage scenario of the building/building remains are powerful sources of teaching and reminding. In this way, the visitor has the opportunity to interact with the building and its surroundings, and tries to listen and feel the space (Silberman, 2015). At this point, applications that visitors can use with their mobile devices provide advantages in the presentation of archaeological sites. In particular, applications that can be personalized and where the visitor can obtain information in line with their curiosity and interest stand out. This kind of presentation method can be incorporated into the experience without the hassle and complexity of learning how to use the device. In addition, the ability of the visitor to choose their own stopping and waiting points has a positive effect on the sustainability of the experience (Grima, 2017). It is thought that the way of inviting individuals to be present and connect with the site, which Li and Jia (2010) mentioned as one of the main objectives of cultural heritage sites, can be achieved by using digital tools effectively and creatively to make sense of the historical environment.

3.2. John Dewey's Theory of "Experience"

John Dewey (1986) defines experience as a relationship between nature and organism. This relationship is an interactive communication process between the object and the subject (human/knowing). Both sides form a whole with their own unique qualities as known or knower according to each other. This interaction between organism and nature occurs at every moment of life, so experience is continuous and refers to "experienced situations/things". But often experience is ambiguous. Events happen in the course of everyday life but may not become experience. There is a distraction when our observations, thoughts and feelings conflict with each other. We start something but sometimes stop before completing it. On the contrary, when the experienced situation continues in its normal course and is completed, it becomes an experience. When a problem is solved, a game is played, or whatever the experienced situation is, an action is complete when it ends satisfactorily. This doesn't have to be an ending; what the experience needs is completion. Such a situation is complete in itself and fulfills the necessary qualifications (Dewey, 1986). Dewey states that such a situation can be defined as experience.

We can have many experiences in our daily lives that have different levels of significance. All of these experiences have their own beginning and end, their own internal characteristics and dynamics. A meal eaten in a nice restaurant that is etched in our memory and a catastrophe experienced can also be described as experiences. In such experiences, from the beginning to the end, the parts have a flow within themselves. Each part leads to the next and this continuity causes the parts to become clearer. Thus, all these successive parts form a permanent whole of experience. Within this whole, there are sometimes some pauses. However, these prevent the continuous acceleration of the parts, summarize and define the events experienced. Just as in a conversation, speakers use variable emotions and expressions according to the flow of the conversation in their own unique characters (Dewey, 1986). According to Dewey, experience, which is such a continuous and dynamic process, is fed by the interaction between the individual's inner world and inputs from the external environment. This continuity of experience contributes to the emergence of certain habits in the individual, helps him/her to improve himself/herself in relation to the subject experienced, and to develop his/her creative thinking ability. However, if an experience arouses curiosity in the individual or increases the desire to take action, it can offer new goals to the individual. So every experience is also a source of motivation. The habit development feature of experience also shows that it is an educational process. Dewey says that the continuity of experience should be considered together with interaction. As long as the individual continues his/her life and learns, the process of experience continues. If this relationship is broken, the ability of experiences to qualify and develop each other is disrupted (Dewey, 2008). For Dewey, it is sensations that enable perception of environmental conditions and concretization of experience. A guitarist can improve himself by experiencing sensations over and over again, or a tailor can become a master through the repetition of sensations. As in these examples, the comprehension of the principles that enable one to master a subject is through the reference provided by sensations. Through these sensations, humans strengthen their interaction with the object (Dewey, 2008). For this reason, Dewey defined sensations as one of the integral elements of experience.

When considered within the framework of Dewey's definition of experience, the presentation of archaeological sites will gain meaning with an approach that is much more interactive, rich, integrating with the visitor and encouraging them to discover layers of meaning. In order to make sense of the multi-layered but incomplete and ambiguous data-presenting structure of archaeological sites, it points to the existence of a multi-sensory, interactive tool that will awaken the consciousness of the visitor and push them to feel the site. However, it is understood that visitors experience cultural heritage sites with different motivations and therefore their expectations vary. However, no matter how diverse the visitor profile of these sites, the basic expectations of acquiring information, having fun and connecting with the site stand out. For visitors who actively participate in the experience while gaining information, the experience of the place becomes more meaningful and the knowledge gained becomes permanent. In this way, visitors can not only observe the area but also establish a connection with the architectural structures and elements. Visitors who participate in the experience and feel that they are a part of the area by controlling it can gain cultural heritage awareness. All these elements increase the general satisfaction level of visitors and create a sense of curiosity towards cultural heritage, history and culture. Each visit is decisive for the next heritage site experience and is an encouraging experience for the visitor who meets their expectations. This plays a vital role in preserving cultural heritage and ensuring its transmission to future generations.

3.3. AI in Cultural Heritage Areas

One of the AI-driven studies carried out in cultural heritage sites is the architectural style identification and classification study carried out by Shalunts et al. (2011). The researchers carry out building style classification using DL over the window element with the idea that the architectural styles discussed in the study (Romanesque-Gothic-Baroque) have a typical window style. Accordingly, in the study, DL was able to categorize the structures as Romanesque, Gothic or Baroque using visual data. The researchers reveal that a database categorized based on architectural style in this way will produce effective and fast results in studies such as 3D reconstruction, urban modeling, virtual tourism and cultural heritage protection. Again, Shalunts et al. (2015) conducted a study for the identification of the tower structural element and the classification of the buildings. The results reveal that with high verification rates, architectural styles can be distinguished from the distinctive features of the structures.

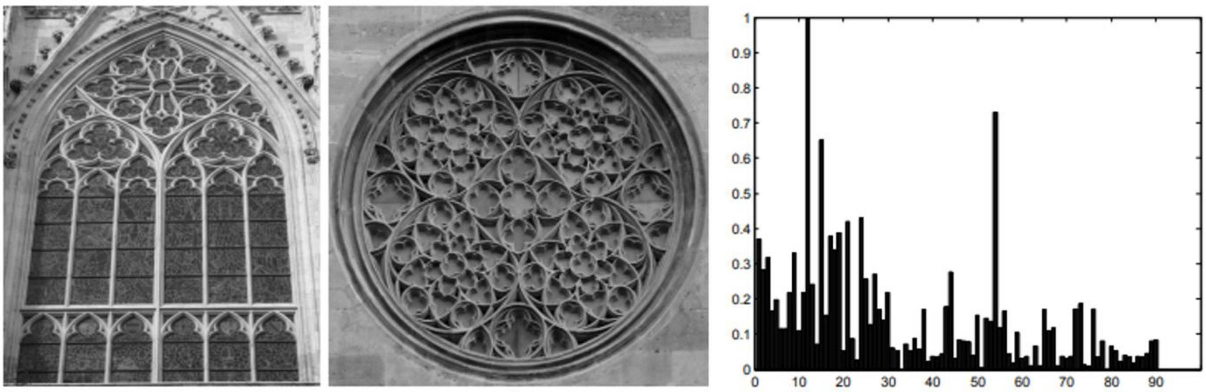

Fig. 4. Classification of architectural style according to window element, Gothic style example (Shalunts, Haxhimusa, & Sablatnig, 2011).

Llamas et al. (2017) used image processing techniques to classify and evaluate architectural elements of cultural heritage structures. They developed a classification algorithm that can detect 10 different types of architectural elements: Apse, Vault, Dome (interior and exterior), Column, Gargoyle, Stained Glass, Altar, Flying Buttress, and Bell Tower. With this study, the researchers presented a tool that can be used in the analysis, evaluation and conservation processes of cultural heritage structures, and they created a publicly available digital dataset consisting of 10,235 visual data, called the Architectural Heritage Elements Dataset (AHE_Dataset). This dataset was later used in the study of Ćosović and Janković (2020) for the digitalization of cultural heritage. The researchers worked with two different datasets using the same methodology. The first one is the Architectural Heritage Elements Dataset mentioned above, while the other one includes 5 categories of this dataset, namely bell tower, stained glass, vault, column, external dome (Ćosović & Janković, 2020).

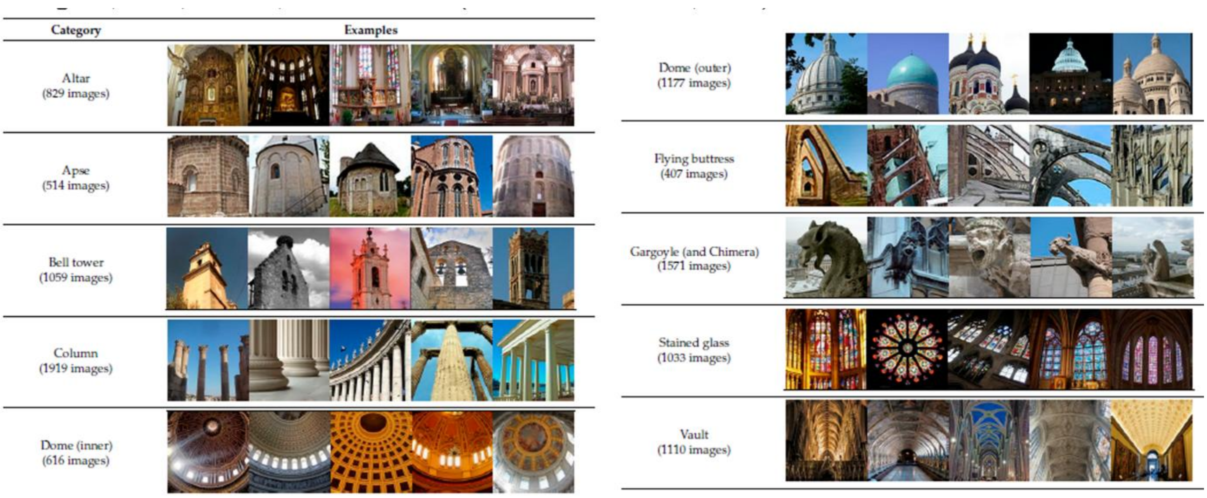

Fig. 5. Architectural Heritage Elements Dataset (AHE_Dataset) created within the scope of the study (Llamas, Lerones, Medina, Zalama, & Gómez-García-Bermejo, 2017).

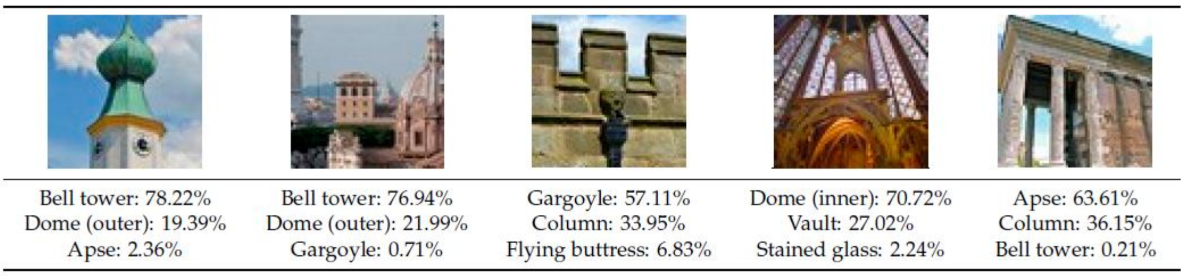

Fig. 6. Examples of predictions of the algorithm for given cultural heritage items (Llamas, Lerones, Medina, Zalama, & Gómez-García-Bermejo, 2017).

MonuMAI is an application that uses image processing algorithms to obtain architectural information from monumental building images. The application performs architectural building element detection, style classification and holistic monumental building definition. When MonuMAI users upload an image of any building facade to the system with this application, they can access various data about the structure. In this way, it has been demonstrated that cultural heritage awareness can be improved with an automatic system that can obtain monumental architectural information with a single visual data (Lamas, et al., 2021). Unlike other studies, MonuMAI is an application that the public can access and use in daily life to obtain architectural information.

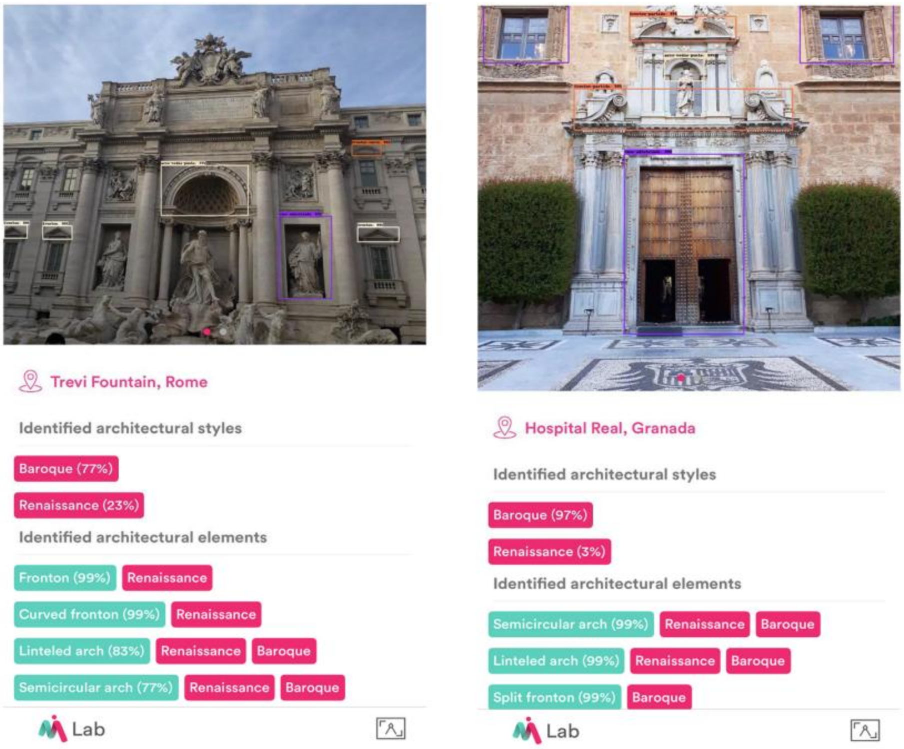

Fig. 7. MonuMAI application examples (Lamas, et al., 2021).

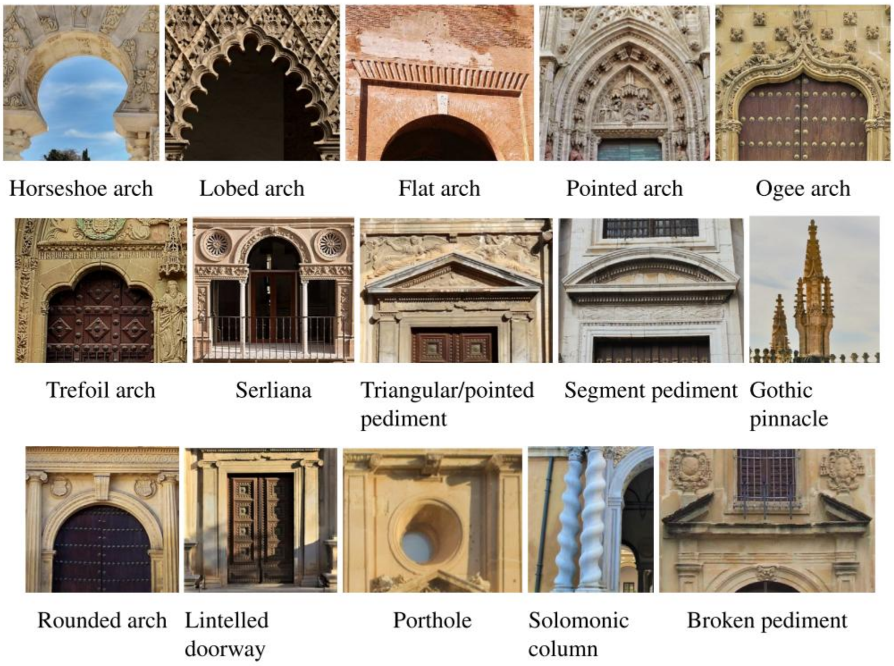

Fig. 8. The MonuMAI app includes fifteen architectural elements used to define Gothic, Renaissance and Baroque styles (Lamas, et al., 2021).

An example of AI language models used in documenting and ensuring sustainability of cultural heritage was carried out for the Gynasium structure of the Ancient City of Side. In the study, the Gymnasium structure was first documented using aerial photographs and laser scanning systems, and 3D models were created. Then, ChatGPT used to evaluate the results obtained. In this direction, articles and related examples about to the gymnasium structures, the ancient city of Side, and ChatGPT was requested to prepare a report referring to the examples but independent of them. At the end of the process, ChatGPT presented technical information consisting entirely of its own independent evaluations and all of which were correct. In the study, it was stated that ChatGPT and similar AI models have serious potential in documenting cultural heritage, transferring it to future generations, and ensuring its sustainability (Yurtsever, 2023). Another study offers an approach to developing cultural heritage field experience using the GPT-4 model, the most up-to-date version of OpenAI in that time. In the study, a digital guide called "MAGICAL" was created using the GPT-4 model in its infrastructure. The aim of MAGICAL is to establish a dialogue with visitors in museums or cultural heritage sites, to offer a route suggestion based on the feedback received from visitors, and to enrich the visitor experience by creating narratives on the relevant subject. Visitors can communicate with the MAGICAL digital guide by using natural language and speech without writing or reading any text. In this way, visitors can get information without losing visual contact with the exhibited cultural heritage object. One of the advantages of the digital guide is that it provides multilingual support. Visitors can change the language at any time, and the digital guide can answer in the language asked. Another advantage is that MAGICAL can change the speaking style depending on the age of the visitor. With all these advantages, visitors can have a personalized experience and can obtain information (Trichopoulos, Konstantakis, Caridakis, Katifori, & Koukoul, 2023). It is clear that the experience of the museums and cultural heritage sites can be enriched with language models with similar applications.

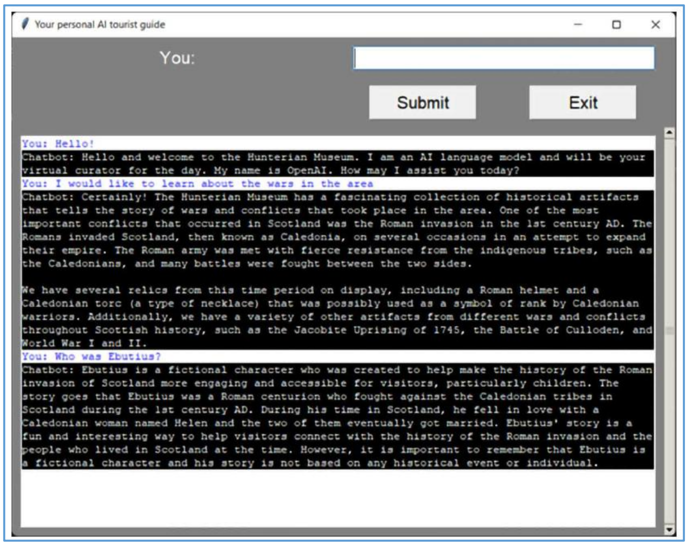

Fig. 9.MAGICAL test implementation using GPT-3.5 (Trichopoulos, Konstantakis, Caridakis, Katifori, & Koukoul, 2023).

Another example is the chatbot study that aims to create context-aware dialogue. In the study using the Multimodal Big Language Model, visual data containing cultural heritage artifacts were considered and the system was specially trained for cultural heritage sites. A training set consisting of 500 thousand visuals and 6.5 million question-answer pairs containing cultural assets such as archaeological findings, paintings, and sculptures was studied. The system uses the information in its infrastructure to answer questions about cultural assets. The questions were categorized as visual, contextual, and mixed, and the system was provided to learn the historical context as well as perceiving visual data. The chatbot approach presented in the study is a tool for understanding cultural assets in cultural heritage sites such as museums and archaeological sites, as it can work integrated with visual data and interact with the user to answer relevant questions (Rachabatuni, Principi, & Bertini, 2024).

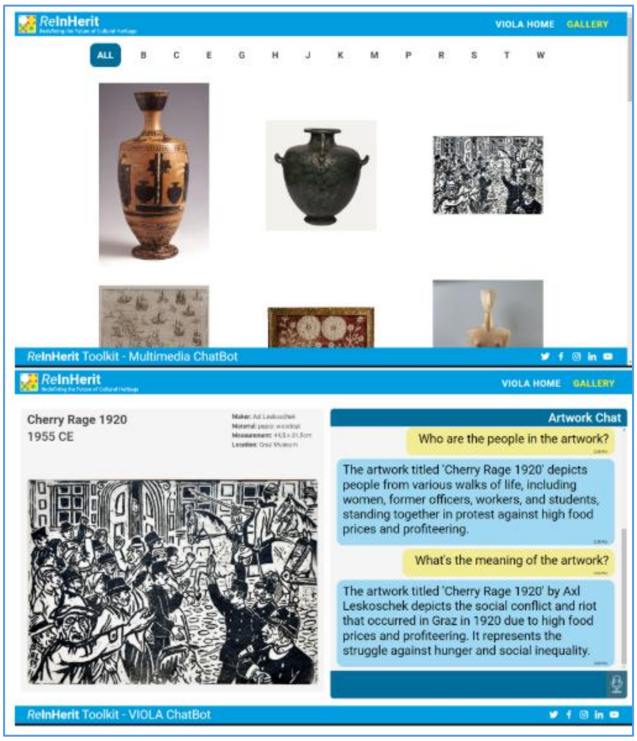

Fig. 10. Chatbot usage example (Rachabatuni, Principi, & Bertini, 2024).

4. Expected Contributions and Conclusion

The system proposed within the scope of the study provides a proof of concept model for enriching the visitor experience in cultural heritage areas with a focus on archaeological sites. The model, shaped within the framework of Dewey's theory of experience, aims to provide interactive, customizable and multi-sensory content for cultural heritage. In this context, this model can be considered as a step taken for alternative applications to traditional methods that can be developed for application in cultural heritage sites. It is clear that the study will restructure the "place" within a framework nourished by experience design, focusing on tangible and intangible values, and will contribute to the field experience as an original and intelligent system that will allow visitors to experience it emotionally in an immersive manner in the context of understanding, meaning and interpretation focusing on narratives and sub-narratives in different contents. At the same time, this study will create awareness for both application development and scientific research, and will form the basis for future studies. The study also presents a multidisciplinary and interdisciplinary research, and considers together the components such as methods, approaches, processes and the body of information they provide, fed by different disciplinary frameworks. In this context, the intelligent information system proposed for the presentation of cultural heritage in the disciplines of architecture, computer science and archaeology presents a new model and method with its originality. The study also brings a new and quite comprehensive data set for the Classical Architecture elements it focuses on to the literature. It is expected that all these findings and the data set created will form the basis for studies to be developed in different disciplines and different focuses. The system presented has the potential to transform the way we interpret and understand cultural heritage experience. It is expected that the personalized, interactive and on-site sensory experience it offers will allow visitors to spend more time in the area, enjoy the experience and trigger their next experiences. This situation is believed to play an important role in raising awareness of cultural heritage and ensuring its sustainability.

An artificial intelligence aided design process from text to 3D printing

İ. Emre Karadelioğlu*[1], Selin Oktan[1]

[1] *Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye*

Abstract. The rapid development of artificial intelligence in production systems is providing a significant transformation in architecture and design disciplines. The integration of artificial intelligence technologies, text-to-image generation, 3D modeling and digital fabrication processes opens up new possibilities in architectural design and production processes. The aim of this study is to reveal the transformation created by artificial intelligence in architectural design and digital fabrication processes and to discuss this transformation through an implementation process from design to production.The study aims to discuss the design process update on the impact of artificial intelligence on architectural design processes. This design process is planned in seven stages: programming, data collection, analysis, synthesis, evaluation, development and communication. These stages were compiled as a result of literature research. The equivalents of the stages of the design process determined within the scope of the study will be discussed in the design process aided by artificial intelligence. The effect of artificial intelligence on this process, which starts with the generation of the first ideas and goes up to production with digital fabrication, will be aided by an applied example. The process progresses from text to visual, from visual to 3D and from 3D printing to the final product. Thus, the positive and negative aspects of the integration of artificial intelligence into the architectural design process, the role of artificial intelligence as a designer and the potentials it creates in the design process will be discussed.

Keywords: Artificial intelligence; Digital fabrication; Design process; 3D printing; Text to fabrication

1. Introduction

Nowadays, artificial intelligence (AI) technologies are rapidly developing and progressing by constantly updating themselves. These developments in the field of AI affect not only the field of software but also fields such as art, design and architecture. Especially in recent years, the fact that AI technologies have become accessible to almost every individual with an internet connection expands the usage area of these technologies and enables new experiments. At the same time, the widespread use of generative AI tools such as ChatGPT, DALL-E, Midjourney, and Stable Diffusion has facilitated the development and public release of many similar tools, particularly those focused on text-to-image generation. On the other hand, the discipline of architecture has historically been influenced by technological advancements, with each new development bringing significant changes to design and construction processes. In this context, the advancement of AI technologies has opened up a wide range of applications in the field of design, from the emergence of new design methods to the optimization of production processes, and even to the simulation of human behaviors. (Leach, 2022). In particular, the recently widespread generative AI tools, with their capabilities in text-to-image and text-to-3D generation, have also been utilized in architectural studies. However, it has been observed that these applications often remain at the stage of image or 3D model generation. (Petráková & Šimkovič, 2023; Radhakrishnan, 2023; Doumpioti & Huang, 2023).

This study aims to rethink the traditional design process, introduced by Bruce Archer (1964) and Erdem Aksoy (1975) through AI-aided design processes. In this way, it seeks to establish a systematic approach to AI-aided design. The AI-aided design process conducted by text-to-image and text-to-3D generation processes. The final 3D product is produced with 3D printing tools. In other words, the study experinces to start from text input, create images and 3D models through generative AI tools, and ultimately produce a physical product within the scope of additive manufacturing, while also analyzing the process (Fig. 1).

To ensure a more systematic approach, it has been decided to base the planned process on a traditional architectural design process. The process, which begins with a textual command, progresses systematically by linking the mentioned design steps at each stage, ultimately concluding with the creation of a physical final product (Archer, 1964; Aksoy, 1975).

2. The Method of The Study

In the design process developed within the scope of this study, the stages of the design models proposed by B. Archer (1964) and Erdem Aksoy (1975) are used as the base of the study. In both design processes, the stages of data collection (information gathering), analysis, synthesis, and development are commonly present. While B. Archer (1964) includes a "development" stage following the "synthesis" phase, E. Aksoy (1975) inserts an additional "evaluation" stage between these two phases. Moreover, Archer defines the first stage as "programming," whereas Aksoy identifies it as "problem identification." At the final stage, Archer adds an extra step: "communication." The new design process, which results from the integration of these two models, is illustrated below.

- Programming
- Data Collection
- Analysis
- Synthesis
- Evaluation
- Development
- Communication

These traditional design process steps are carried out within the AI-aided design process through the stages of text (prompt), image, 3D, and fabrication (Fig. 2).

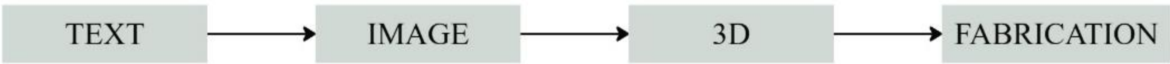

Fig. 1. Text-to-Fabrication Workflow

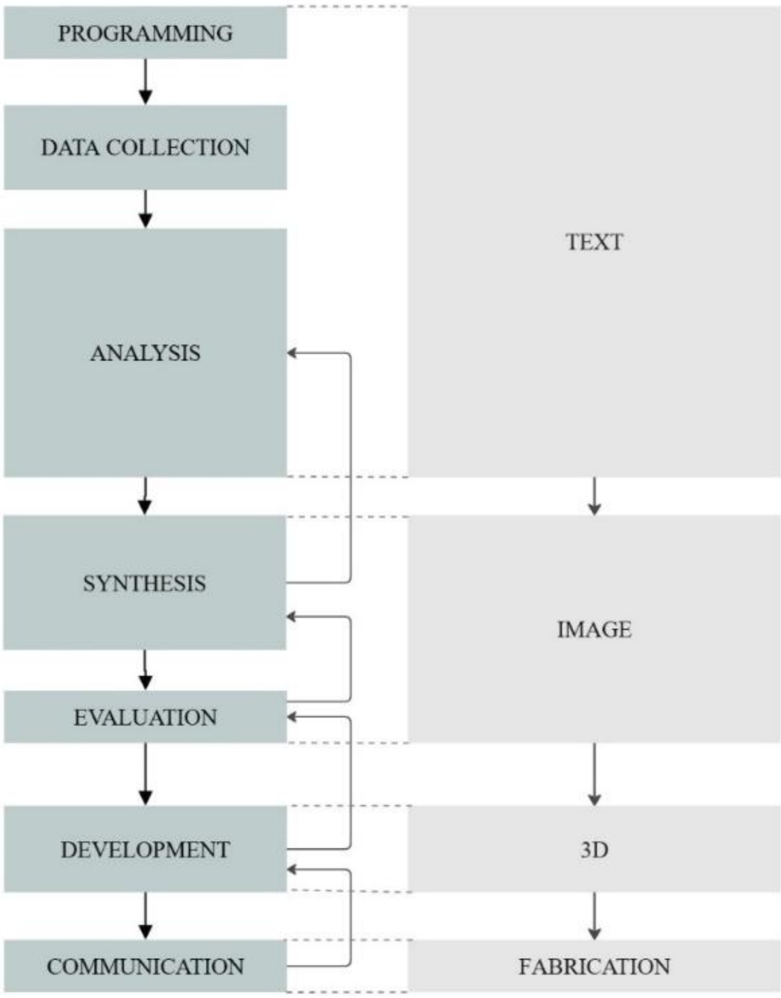

Fig. 2. The production process based on the traditional design process.

The design process begins with determining the output path and concept of the production. In this context, textual commands are defined. To transform these commands into visuals, an AI tool operating in a web platform called "Dream Studio" is used. At this stage, alternative visuals are produced and selected based on their suitability to the concept. The chosen visual is then transformed into 3D in STL through a web platform “3dp.rocks”. In the final step, the resulting 3D model is used to produce the final product with the help of a desktop 3D printer.

3. AI – Aided Design Process and 3D Printing

The details of the process developed in accordance with the design method referenced in this study are explained below:

3.1. Programming

Programming, the first stage of the design process, is defined as the identification of key issues and the creation of an action plan. In this stage, the output path and concept of the product to be designed are determined. This stage also serves as an initial step through its effective data collection within a specific framework. During the programming stage, conversational AI tools such as ChatGPT can also be utilized while developing ideas. In this context, the use of AI in stages other than visual production can be beneficial in terms of the diversity of the output. In this study, the concept has been defined as "the styles of famous architects or artists." The aim is to create a surface design based on the styles of architects and artists with the help of AI.

3.2. Data Collection

After the concept has been defined, the process moves on to data collection. This stage is defined as the process of gathering, classifying, recording, and transforming data into usable information (Bayazıt, 1968; Archer, 1984). Within the framework of the defined concept, textual and visual data are obtained from various sources. The quantity of data in this stage is important for the diversity of the production, as it allows for variation in the command generation process. Since a feedback-driven process is applied in this study, experiences from later stages can also enrich this phase. In this stage, data has been collected regarding famous architects and artists with more characteristic styles, such as Zaha Hadid, Daniel Libeskind, Vincent Van Gogh, and Picasso, within the framework of the defined concept. Once the collected data reaches a sufficient level, the process moves on to the next stage.

3.3. Analysis

The analysis stage can be defined as the process of simplifying data through observation and experimentation or transforming design requirements into meaningful and functional characteristics (Jones, 1992; Aksoy, 1975). This stage is where suitable words or word groups are determined to create commands that will be used in the visual production of the data obtained during the data collection process. The main goal of this stage is to create a word pool for the diversity and updating of the commands that will be used to generate visuals from text using AI. Visual contents can also be gathered at this stage; however, in this study, only textual commands were used. In this context, words such as "surface, style, design, architecture, monochrome, abstract, texture, inspire, Zaha Hadid, Daniel Libeskind, architectural surface," etc., were generated. Once the generated words reach a sufficient level, this stage is completed.

3.4. Synthesis

The synthesis stage is defined as the process of combining different variables to produce new solutions and integrating these partial solutions into a whole. It is also the stage where creativity is most involved, and design ideas are developed (Aksoy, 1975; Archer, 1984). In this study, this stage is considered as the phase where the words determined in the analysis stage are combined to create commands that will be used in the AI tool, and visual productions are made using these commands. In this sense, while the conversion of the obtained data and words into commands is related to human creativity, the ability to generate various visuals from the determined commands is related to the creativity of AI.

In this context, the creativity of AI can be associated with the data it was trained on during its development. Therefore, different AI tools can produce different visual outputs for the same commands. In this study, only one AI tool was used. Since a feedback-driven process is implemented, the outputs in this stage are evaluated, allowing the commands created in the analysis stage to be updated and improved. The visual diversity in this stage is important for visual selection, both in terms of suitability for the purpose and manufacturability.

In this study, DreamStudio, an AI tool operating on a web platform, was used for visual production. DreamStudio allows users to create visuals by defining scenes, characters, or concepts with text descriptions. Using the words identified in the analysis stage, visuals were produced in different styles. While producing the visuals, words such as "monochrome" or "surface design" were used for both ease of transfer to 3D and production convenience. This approach aimed to generate visuals with contrasting colors (especially black and white), as distant as possible from the perception of three-dimensionality (Fig. 3).

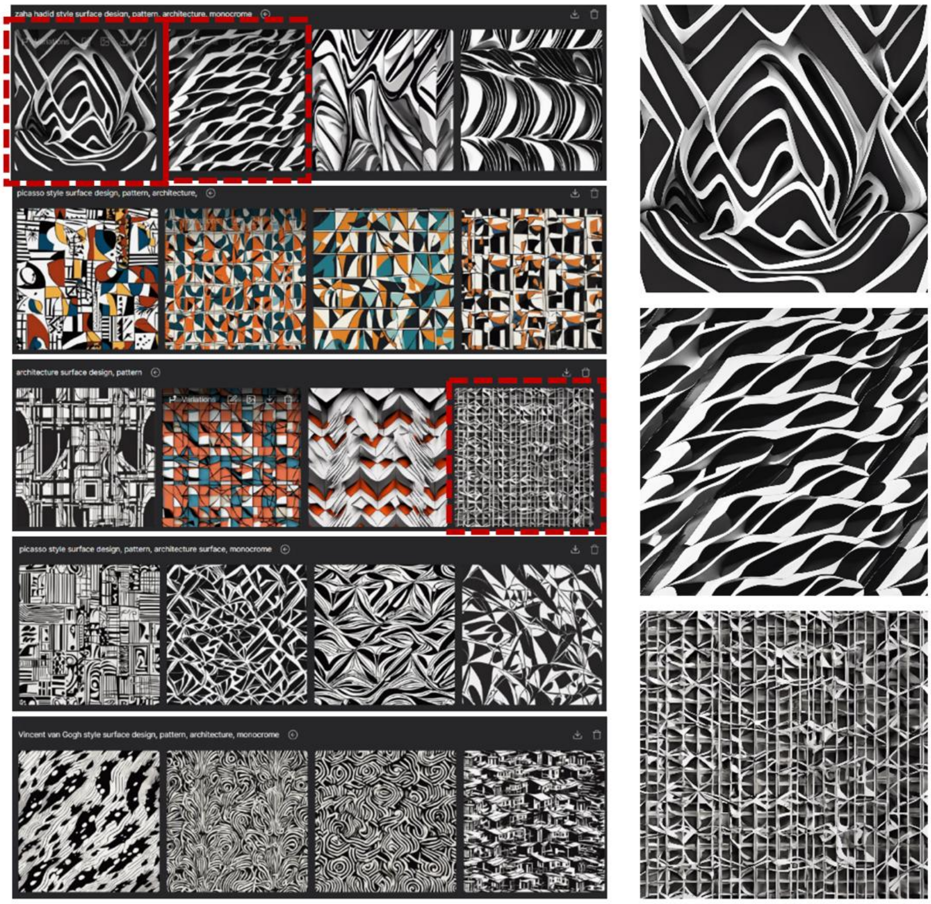

Fig. 3. The visuals obtained from the DreamStudio AI tool with the generated commands

3.5. Evaluation
In this stage, the visuals are evaluated in terms of their suitability to the concept, transferability to 3D, and manufacturability, and a selection is made for the next step. During the transfer to 3D, it is important for the visual to be simple, free of excessive details, and to have contrasting colors in order to ensure a smoother production process (Fig.3). Specifically, choosing visuals with less light and shadow effects, and a more two-dimensional perception, helps the 3D model form more clearly. On the other hand, some of the AI-generated productions may differ from the concept or the input command. Within the framework of all these criteria, three visuals that reflects the concept and is more manufacturable was selected, and the process continued.

3.6. Development
This is the stage where the visual selected during the evaluation phase is transferred into three dimensions and further developed. This stage was carried out using two different methods. In the first method, one of the selected visuals was directly converted into three dimensions as raised patterns on flat and cylindrical surfaces with the help of the web-based tool “3dp.rocks”. The software performs this process by creating a depth map based on the tones of the colors in the visual, thus generating depth. Each color value in the image is mapped to a numerical height value, and points are generated at these heights. This point cloud is then transformed into surfaces through triangulation, resulting in a "mesh model." With the help of such software, visuals can also be applied onto different geometric forms, such as cylinders, spheres, or curved surfaces. As a result of this method, STL-format 3D models of the designs were produced on one flat and one cylindrical surface (Fig. 4). In the second method, the other two obtained visuals were used. This method aimed to create structural forms with a perforated structure. For this purpose, the surface visuals obtained in the previous stage were first uploaded to the ChatGPT tool, and 3D visuals of these images applied to cylindrical and hemispherical forms were requested (Fig.5). The obtained visuals were then converted from image to 3D using the web-based tool “meshy.ai.” As a result, one STL-format 3D model in cylindrical form and one in hemispherical form were generated for each of the two visuals (Fig. 6).

3.7. Communication

The final step of the process, communication, can be described as the stage where the design—along with its purpose, functioning, and details—is conveyed to the producer, user, or evaluator in a clear and effective manner (Aksoy, 1975; Archer, 1984). In this context, it represents the stage where the final product is achieved. Productions carried out with continuously advancing AI technologies often conclude in the creation of visuals or 3D models. Therefore, it is crucial to materialize the final product using digital fabrication methods. In this stage, the simulation of the 3D model, achieved in STL format during the development phase, was examined using a slicing software designed for 3D printers (Fig. 7). Among the final products, the model created using the first method was selected, manufactured with a desktop 3D printer using PLA material, and the resulting outcomes were obtained. (Fig. 8).

Fig. 8. Final products

3. Results and discussion

In this study, the "text-image-3D-printing" process was developed into a more systematic model, based on a traditional architectural design process. The steps in the process, extending from text to fabrication, were related to the stages of "programming, data collection, analysis, synthesis, evaluation, development, and communication". In this context, the design process began with the goal of creating a surface design based on the characteristic styles of famous architects and artists. Within this framework, data was collected and key words were generated. Using the created keywords, various commands were produced, and these commands were visualized using an AI tool that generates images from text. The resulting visuals were evaluated for their suitability in manufacturing with a 3D printer, and one that was considered appropriate was selected. Since the visuals are transferred to 3D using a depth perception method based on color tones, in this stage, visuals that are free from excessive complexity, generally containing no more than two tones, and lacking a 3D perception were taken into account. Additionally, for visual productions that did not meet these criteria during the process, improvements were made in terms of command-output visual relationships through command adjustments. The selected visuals were transferred to 3D on flat and cylindrical surfaces using a software tool operating in a web environment. The created 3D models were produced with PLA material using a desktop 3D printer, and the final product was obtained.

This study also dicusses an AI-aided design process that extends from text input (prompt) to additive manufacturing within the context of the rapidly evolving potential of AI technologies in architecture. In a period where AI-generated visuals and 3D productions have become widespread, advancing this process one step further by concluding it with a physical final product is considered valuable. Within the scope of this study, the production criteria for designs that originate from text prompts and are transformed into 3D models through visual generation are evaluated using a 3D printer. Through the feedback-oriented process established in this context, solutions are proposed to address encountered and potential problems, thereby enhancing the overall production process.

As a result, the rapidly advancing AI technologies' abilities to produce visuals and three-dimensional objects hold significant potential for the field of architecture. In this regard, the study discusses to provide solutions to the challenges of how design can be brought to life by taking productions a step further from the third dimension. These rapidly evolving technologies are continually enhancing creativity and the ability to diversify production. In this study, a surface design with more defined boundaries has been addressed; however, with the development of AI tools capable of producing both visual and three-dimensional outputs, it is anticipated that different production potentials will emerge, particularly in the fields of architecture and design. At the same time, with this design process, the potential for producing a variety of outputs using subtractive, formative, or joining-based digital fabrication methods with different materials is considered highly valuable. In this regard, the insights gained are anticipated to provide a methodological foundation for future research.

Place-specific structures: The effect of hidden designs on the spirit of space

Özlem Nur Samancı*[1], Hare Kılıçaslan[2]

[1] Karadeniz Technical University, Graduate School of Natural and Applied Sciences, 61080 Trabzon, Türkiye
[2] Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye

Abstract. In an era where the meaning of architecture in relation to place has diminished, globalization and rapid urbanization have given rise to monotonous and identity-lacking structures. Designs that fail to grasp the importance of the spirit of place create spaces that are disconnected from their surroundings, turning them into closed boxes -essentially inward- focused spaces. Architecture confined to a specific design type not only weakens its own identity but also diminishes the essence of the place it occupies, leading to cities that lose their character. Structures that fail to establish a connection with their location are seen as designs that lack harmony with their surroundings and the topography they inhabit. These buildings hinder the sense of belonging to a place, compromising the quality of life for their users. However, in architectural design, "place" holds a crucial position. Place, regarded as a primary element in architecture, is the foundational component around which design is shaped. While the concept of place is an empty space that exists in relation to itself and its surroundings, the inclusion of architecture transforms it into a meaningful spatial whole by creating harmonious relationships. In this context, creating region-specific designs serves as a bridge that strengthens the relationship between users and place. Designs imbued with originality make the environment more visible and legible, thereby enabling the preservation of the spirit of the place or topography. Structures that integrate the characteristic features of the area into their designs aim to make architecture a part of the topography, creating structures that are integrated with nature. Designs that are embedded within the topography adopt the environmental, physical, and social characteristics of the place, contributing to environmental sustainability. These designs also reflect the lifestyles of the community onto architecture, fostering a sense of belonging to the place. A design approach that respects the collective memory of the community simultaneously preserves cultural heritage. In this context, this study examines place-specific design approaches and evaluates architectural designs integrated with the topography. The selected designs are chosen from the ArchDaily web database. The compiled structures are discussed in terms of design criteria such as aesthetic and functional features, sustainability, and place-specificity. It is anticipated that the discussions carried out on individual structures will shed light on future architectural design approaches, contributing to the creation of unique urban spaces.

Keywords: Topography; Originality; Context; Spirit of place structures

1. Introduction

First and foremost, architecture starts with 'place' and exists together with it. While the place establishes the architecture, the architecture should also be able to transform the place. Architectural design becomes meaningful as long as it harmonises with the place. The place, which plays a decisive role in architecture and makes the building a meaningful whole, gains meaning again with the previous formation in every relationship established with it and establishes a relationship with it (Kuyrukçu & Alkan, 2019). 'Place', which can only be formed when a meaningful relationship is established with the environment, gains meaning by integrating with the lives it harbours and the elements around it. Thanks to the meaningful relationships it creates, the place goes beyond mere space and opens up to 'relations' and 'actions' that are realised through users (Berber, 2011). In this respect, it is necessary to expand the interpretations of space to understand a place and to understand that urban spaces depend on daily lives, experiences and collective memory. It is important that architectural designs in the place respond to people's sensations, make them feel a sense of belonging to that place and respond to their needs (Özcan & Güngör, 2019). Norberg-Schulz defines architecture as the abstraction of the spirit of the place; 'Architecture is for designing meaningful places'. Schulz attributes the human tendency to design places to three phenomena: 'revealing the meanings hidden in nature, revealing the meaning of nature, and boasting that they have created by

* Corresponding author, E-mail: ozlemnursamanci@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_766

designing what does not exist’. He says the main reason underlying these is ‘man's desire to create a small universe of his own’ (Kaymaz Koca, 2005). Since ancient times, man has endeavoured to change and mould the earth to fit his own image of it.

The relationship between place and topography is very important in creating meaningful spaces on earth where human beings try to create a universe of their own. Topographic structure is an important phenomenon that designers should consider. The topography of the place consists of a dynamic and fluid structure that is naturally and culturally open to human influence. This structure is articulated on urban layers such as ‘form, texture, urban planning and architectural history’. In cities; every event such as physical, social, cultural and economic elements leaves a trace on the geographical structure. With each trace left, the phenomenon discussed in terms of topography ceases to be only land and creates new geometries, surface forms and layers with new additions (Köse, 2010). Artificial traces, which are decisive on the physical topographic surface, depend on the life cycle established on it, such as how much diversity the human impact on the ground, how much it blends with time and how active daily life is (Küblü, 2015). However, architectural structures that have human touch and exist on the topography leave artificial traces on the earth.

According to this context, it is possible to say that ‘structures’ and ‘place’ should be considered whole. Within this unity, the topographic layers of the city and the structures can be expressed as complex, intertwined and in conflict with each other, tense unions that continue with the transition from natural to built. This tension between the layers brings along the dynamism of the city. This dynamism can be defined as a different dynamism far from the state of equilibrium, undergoing unique metamorphoses, and subject to intense flows. Thus, the buildings that continue to exist on the land, over time, integrate with the surface on which they are located, interact with their physical environment, and define the ‘urban topography’ by taking a constantly changing form (Küblü, 2015; Fig. 1).

In the formation of urban topography, the formation of the topography is important. Different topographical forms bring along different space formations and create the unique structure of the city (Saçık, 2018). In this context, the creation of architecture with design approaches that are compatible with the place, can be hidden in the natural texture where it is located and are environmentally sensitive, will ensure the protection of the original stance in cities (Fig. 2).

Structures integrated with the topography create useful spaces by providing a strong indoor and outdoor connection. The approach creates sustainable living spaces integrated with nature, while at the same time enriching the user experience by strengthening the interaction with the landscape (Fig. 3).

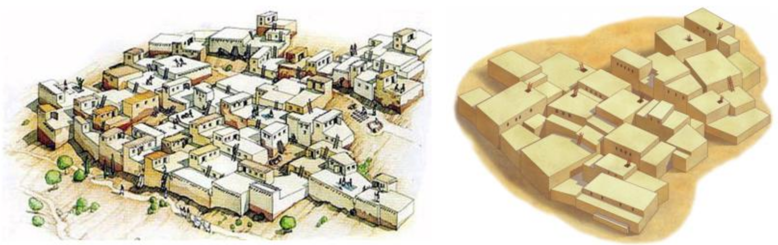

Fig. 1. Integration of Çatalhöyük houses with the city (URL 1; URL 2)

Fig. 2. The topographical layout of Villa D'este, hidden in the natural landscape (Desnoyers, 2015; URL 3)

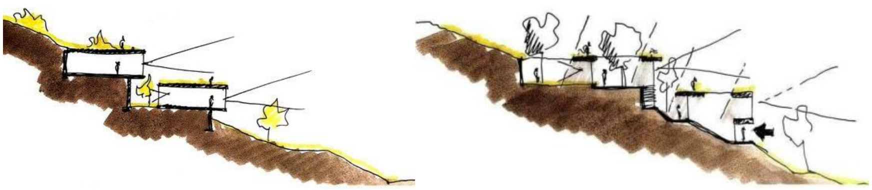

Fig. 3. Landscape interaction of topography-specific structures (URL 4; URL 5)

The buildings are in harmony with the local ecosystem as they are designed by considering criteria such as climate, orientation, temperature and the diversity of living organisms/flora specific to the place. The building also provides energy efficiency by utilising natural ventilation and daylight (Fig. 4). When site-specific design approaches are evaluated as a whole, they also increase urban resilience. These buildings not only harmonise with the environment but also consider the cultural and historical context of the locality. The use of local materials and traditional construction techniques in the buildings acts as a bridge between the past and the future.

Wells states, ‘Buildings created with the understanding of gentle architecture will give life back to the place where they are located instead of stealing life from it. These structures, which provide users with safe and psychologically revitalising environments, resemble nature itself.’ (Heffner, 2013; Fig. 5). In this context, site-specific buildings are design approaches that provide environmental sustainability by integrating the forms and characteristics of the nature in which they exist into architecture. These buildings become a part of the natural landscape by protecting and observing the slope and character of the area. At the same time, the design concepts reinforced with green roofs and placed under the ground make the building feel like an extension of the environment. These designs contribute to the deepening of the spirit of the space by giving the users the feeling that they are part of nature. Hidden designs aim not only to build a structure but also to create a dialogue between the natural and artificial environment.

Adapting to the natural slope during the placement of the building minimises the intervention to the land by minimising excavation and filling operations. Thus, natural drainage is preserved and the building is integrated with the topography. In addition, layout strategies that are parallel to the slope or staggered increase the view opportunities and make the best use of natural ventilation and sunlight (Fig. 6). The choice of materials and the design of the building envelope should also be determined to adapt to the microclimate conditions offered by the topography. This not only ensures energy efficiency but also supports the longevity and sustainability of the building.

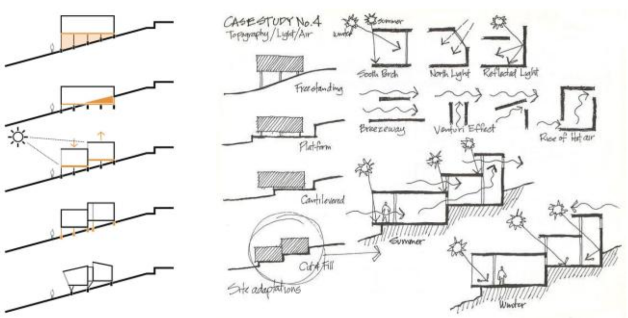

Fig. 4. Natural ventilation and daylight efficiency in site-specific design approaches (URL 6; URL 7)

Fig. 5. Satellite image and sketch of Cherry Hill Office with its gentle architectural approach (URL 8; Wells, 1998)

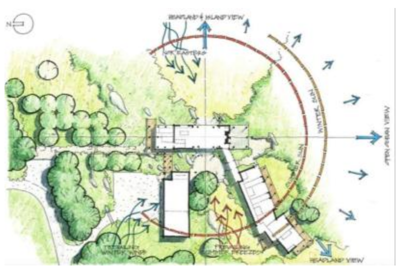

Fig. 6. Natural ventilation/lighting possibilities in slope-appropriate layout (URL 9)

In site-specific designs, the way of positioning the mass is differentiated according to the function of the building and the slope of the topography. This differentiation is within the scope of strategies to increase energy efficiency while ensuring the harmony of the building with the environment. The change of settlement patterns is also realised to increase the comfort of the users. There are six different massing types within the scope of adaptation to the terrain (Fig. 7).

1.1. Terracing and console
The terracing method created on steep terrains allows for natural lighting in stepped building designs, while at the same time providing a view by establishing a relationship with the environment. The levelled masses created in the building also allow for terracing and outdoor designs. The console designs offer a good planning method to complement the slope. This concept helps to protect the slope while creating more space for the spaces. It also creates an aesthetically pleasing visual appearance (Kader & Kupik, 2011, Fig. 8).

1.2. Cut and fill
An important technique for adapting to sloping or uneven terrain, the cut-and-fill method is essentially the process of carving a plinth to build a house designed for use on flat land. The pieces cut from the terrain were reused to create the levels at the lower edge (URL 11, Fig. 9).

1.3. Columns
Column designs eliminate the need for expensive foundations, reducing the negative effects of moisture and allowing natural ventilation. These designs enable planning without touching the natural ground and without damaging the environment. In addition, the mass rising from the columns protects the natural environment and allows wildlife to thrive underneath the structure (URL 11, Fig. 10).

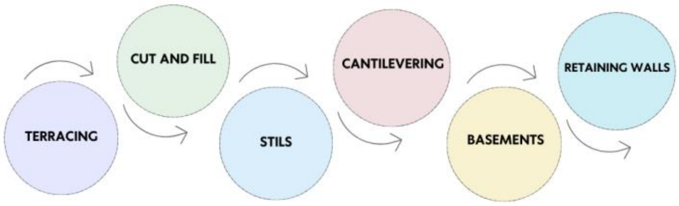

Fig. 7. Types of terracing on slope

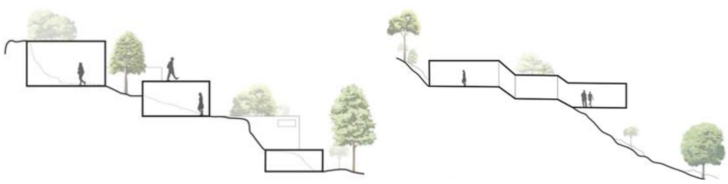

Fig. 8. Terracing and console design (URL 10)

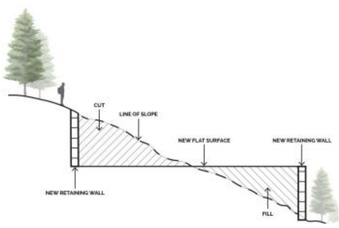

Fig. 9. Cut and fill (URL 10)

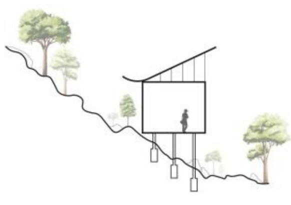

Fig. 10. Columns

1.4. Retaining walls and basements

On sloping terrain, masses that cut into the site are a useful technique for managing the degree of slope and preventing the risk of erosion on the site. These designs also allow the creation of large spaces that open up to views. Another technique, designing the building completely under the ground, serves to protect the natural slope and creates an important factor for the continuity of the ecosystem on the site (URL 10, Fig. 11).

2. Site-specific building design reviews

2.1. Library in the Earth

Library in the Earth, a sustainable living and cultural centre located on an organic farm in Japan, was designed by Hiroshi Nakamura & NAP (Fig. 12). This futuristic design is built on a hillside, disappearing into the natural landscape and integrating into the environment with its cascading greenery. Unlike traditional typologies, the library structure is positioned around a slit-shaped courtyard resembling a water drop. In this hidden underground structure, cantilevered concrete slabs are used to create integrated spaces. The structural design choice allows the interior spaces of the library to blend organically with each other. The earth coverings in the spaces evoke a sense of unity with the surrounding earth structure. The ceiling heights are shaped according to the slope, creating low-ceilinged niches in the space. In the reading room, the heart of the library, an overhead skylight provides a serene view of the sky, while at the same time providing natural ventilation to the space (URL 12). While the project endeavours to blend nature with the building in the best possible way, it also embodies the philosophy of the library as a place of refuge.

2.2. Issa Megaron

The design philosophy of the Issa Megaron building, located in Croatia and planned by PROARH, is related to the solution of the context of the boundary perceived as a 'void' in the area (Fig. 13). The project consists of designing a temporary retreat house for a family. The building is designed with the philosophy of 'Genius Loci', the design concept of the Mediterranean region. In the house, ancient stone plasterboards are reinterpreted and harmonised with the region. The new/old stone walls create a symbiosis with the existing topography by using materials that subtly harmonise with the ground. The building, which is intended to give the effect of an artificial cave / excavated volume, uses sustainable design methods such as natural cooling/ventilation, solar panels, and rainwater utilisation. The materials used are renewable and adapt to the region (URL 14). The building, which disappears in the topography while at the same time harmonising with it, is a warm 'house' design that reflects the unique spirit of the Mediterranean region and matches nature.

Fig. 13. Issa Megaron (URL 15)

Fig. 14. UCCA Dune Art Museum (URL 17)

Fig. 15. Villa Aa (URL 19)

2.3. UCCA Dune Art Museum

Located on a quiet beach in China, the art museum was designed by OPEN Architecture (Fig. 14). The building, which has an extraordinary design with its appearance disappearing in the sand dunes, is inspired by the cave structures, which are the oldest settlements in human history. Hidden between the sea and the sand, this structure creates timeless spaces while prioritising pure and touching space design. Designed to be hidden, the structure respects nature while protecting the dune ecosystem that covers it. Composed of a series of cell-like spaces, the spaces accommodate galleries of different sizes. The complex three-dimensional geometry of the museum shell, which creates the effect of a secret sanctuary, intertwined with the body and soul, draws attention. The skylights of the building, with different orientations and sizes, provide natural lighting to the museum spaces at all times of the year. The sand-covered natural roof of the building greatly reduces heat loads and contributes to energy efficiency (URL 16). UCCA Dune Art Museum, which integrates with the sea and sand, continues its existence in the area where it is located as a structure that respects the ecosystem with its sustainable features.

2.4. Villa Aa

Villa Aa is an extension of a historic farm building in Denmark and is a 'house' by CF Moller Architects (Fig. 15). This invisible structure is shaped according to the nature of the site and opens up to the views of the region. The design aim of the villa is to integrate the office with the house. It is intended to create a flow and connection between work and home, thus preserving practicality and personal well-being. However, the south façade of the building opens up to the garden and the terrace that connects to the outside, allowing views of the site-specific landscapes. The spaces have skylights that provide natural light. The roof of the roof, designed as a green roof, harmonises with the area where it is located and at the same time serves as an upper terrace as a spatial function. The pool on the terrace establishes a visual connection with the existing water by reflecting the skylight. The choice of concrete used in the building is to respect the historical farm structure. The polished concrete used on the floor of the space continues to the outer terrace and is one of the design decisions to break the distinction between the interior and exterior (URL 18). All these design decisions connect Villa Aa to its location and the historical farm it is located in, while protecting and respecting its environment.

Fig. 16. Audemars Piguet Workshop Museum (URL 21)

Fig. 17. Ncaved House (URL 23)

2.5. Audemars Piguet Workshop Museum
The Audemars Piguet Workshop Centre for the Swedish watch brand was designed by BIG (Fig. 16). With a distinctive and innovative design in line with the company's philosophy, the building is planned in a spiral shape and in a concept that integrates with nature, with an ancient understanding of the area where it is located. The iconic, double-helix workshop centre is embedded in the topography, with a glass façade and a spiral shape. The pavilion is an urban landmark that reflects the company's watch designs, at the same time being timeless and sculptural in its landscape. The design concept, created by establishing a link between the building and the watch discipline, pays tribute to both the arts. The glass and metal materials used add movement to the identity of the building, while the curved glass walls are positioned to let the sun in. The spirals, which are the design philosophy of the building, are intertwined and interconnected in a way that guides visitors through the building. The spiral takes visitors through the spaces in a systematic order and finally leads them to the centre, the heart of the building. The heart of the building is the final destination of this journey, symbolising the independent and pioneering spirit of the company and its deep commitment to its origins (URL 20). The building expresses Audemars Piguet in its dynamic and intertwined form with its spiral design, while at the same time, it continues its existence with an understanding of continuity that will harmonise with nature in the landscape in which it is located.

2.6. Ncaved House
Located in a small bay on an island in Greece, Ncavedv House is a holiday home designed by Mold Architects (Fig. 17). The idea of avoiding the strong north winds in the region while at the same time dominating the landscape has created the need for the building to hide in the slope where it is located. Offering a spatial experience intertwined with nature, the building has a design that will announce its existence to its surroundings as well as its respect for the soil. The building design also protects the cultural heritage by reinterpreting the traditional behaviours of the region with the dry stone it uses. The raw material designs, such as stone, bare concrete, wood and steel in the building also intensify the feeling of living in a natural space. The roughness of the materials used together with the processed details create a warm and natural contrast in the spaces. With the front part of the building facing east, the rear windows opening to the inner gardens below the ground level provide natural airflow and natural light to the underground floors (URL 22). With the material and colour decisions used in the design, the building's feeling of an unprocessed, natural rock cavity and several active/passive planning decisions, a concept that is sustainable and connected to/integrated with the area where it is located has been put forward.

2.7. Felderhof House
Felderhof House, which is located in the unique nature of Italy and whose architecture was undertaken by Pavol Mikolajcak Architekten, is a building consisting of two single-type structures built by shifting to adapt to the slope

of the slope (Fig. 18). The existing farm building, which is unique to the valley slope where it is located, is an authentic representative of life in ancient times with its stone-dominated facade and wooden shingle roof. In this context, the building design is based on a balance between contemporary life and historical authenticity.

Fig. 18. Felderhof House (URL 24)

Fig. 19. Homescape House (URL 25)

Since the topography of the building is seen as a suitable land for underground design, a connection opportunity to the existing old building was also created. Almost completely hidden in the valley, the house offers a strong mountain view with its long glass facade extending to the south. The open space design, high ceilings and skylights of the house provide a high contrast to the closed and delicate texture of the existing historic building to which it is connected. The skylights offer views of the larch trees native to the region, while at the same time providing natural lighting and light play to the spaces. The materials used in the building, such as natural stone, exposed concrete, steel and wood, are in harmony with the surrounding landscape. The concrete used in the geometric ceiling bears the trace of the raised hill. The wooden furniture and classical surfaces of the dwelling take care not to disturb the original character of the preserved building (URL 24). The building, which shows how a historical building can be integrated with a modern residence, is in harmony with the region with its materials, building design and landscape dominance.

2.8. Homescape House

Homescape House, designed by MXarchitecture, is located on a high plateau on an island in Greece (Fig. 19). In the region where fruit and olive trees are grown, human interventions have been aimed at strengthening the spirit of the place without disturbing the area. The building, planned in an authentic environment, is a project in which it is desired to reveal the habitat together with nature. The design concept is to create a permeable spatial style in which nature and structure are interrelated. The design concept, where the common areas of the building are open to the landscape, continues with the adaptation of the living spaces to their surroundings. The service spaces are located at the underground level. Artificial and natural verandas provide natural comfort and lighting as well as multi-directional ventilation. Raw wood, red, white and black stones, marble and aluminium are the local materials of the area. While the openings provide sunlight to the spaces, the mass inertia of the mineral floor and stone walls provides a natural heating/cooling function that follows the day-night course (URL 25). Homescape House, with its defined mass and space distributions and the local and natural materials it uses, encompasses and integrates with nature without harming it.

3. Conclusion

Topography, which is one of the elements most affected by urbanisation among natural data, determines the design formations of cities and buildings to a great extent with the change of land structures. In this context, the topography of the area will reflect the natural character of the city. The more different movements the topography land, which has its characteristics, and harbours, the more differences and originality the city/building articulations to be built on it will harbour. This study, which aims to explain the essence and meaning of building plans hidden in topography, also consists of analysing some examples to comprehend the importance of site-specific designs. The projects examined in this context show that building designs that integrate with nature contribute to energy efficiency by minimising damage to the environment, integrating with the surrounding ecosystem, and becoming one with the space in which they exist. In this context, topography-specific design approaches can be seen as approaches where human impact will be the least visible in nature, will leave fewer traces in the original geographical structure, and are more compatible with the dynamic field structure. In the case of building designs, different topographic components inspire unique designs and enable new space formations. These design approaches will also contribute to indoor and outdoor connections that will add innovation and originality to the spatial contexts. In addition, designs that utilise natural data provide natural lighting/ventilation, wind isolation and landscape dominance. According to this context, it is thought that the sensitivity shown to site-specific design approaches and the continuity of these approaches will contribute to the formation of cities that are sustainable, in harmony with nature and people, and that do not damage the area where they are located and are at peace with it.

[3] Karabük University, Department of Architecture, 78050 Karabük, Türkiye

Abstract. The history of railways and train stations in Anatolia began with the construction of the İzmir-Aydın railway and the first train stations, İzmir-Alsancak and Aydın Railheads, between 1856 and 1866, with the privilege given to the British during the reign of Sultan Abdülmecit. Especially after the proclamation of the Turkish Republic in 1923, 'weaving the country with iron nets' was seen as an important national goal. Train stations have been influenced by movements such as the First and Second National Architecture and modernism, which reflect the political and cultural situation, technological and economic development and expectations of the society of the period in which they were built. Since the 2000s, high-speed train lines and stations began to be planned in Turkey and in 2009, the Ankara and Eskişehir High Speed Train Stations have started to be used. Train stations of Turkey have been the subject of academic studies in many fields due to their effects on Turkey's urban, social, economic and political aspects. Today, architectural structures belonging to railways in Turkey consist of 4 main groups: Railheads (important train stations where the railway ends), Train Stations (at the middle of the railway) Suburban Stations and High-Speed Train Stations. This research examines the architectural, aesthetic and material features of train stations in Turkey, their changes and their effects on the urban texture and morphology in the past and today, how they were constructed, used and repaired structurally and materially, how they were re-used for different purposes. Three case studies of historical train stations as İstanbul, Ankara and Konya Train Stations, which are located on the high-speed railway network of Turkey, were analysed in architectural and structural aspects and at urban, regional and national scales, with considering their relations with newly built high-speed train stations.

Keywords: Historic train stations; High-Speed Train Station; Conservation of cultural heritage; Modern Turkish Architecture; Ankara train station; İstanbul train station, Konya train station.

1. Introduction

Railways, which have been instrumental in important developments in the world and in Türkiye, have led to the formation of new structures and urban areas, and have brought with them many effects reflected in urban architecture. In every settlement area where railway buildings and rails pass, effects such as acceleration of transportation and raw material supply, improvement of infrastructure, revival of production and employment, increase in cultural interactions, urbanization and migration have been observed (Başar & Erdoğan, 2009, 29-30).

The station buildings constructed with the construction of railways, although they were mostly located outside the city settlement during the period they were built, created a force of attraction over time and paved the way for physical, social, cultural and economic transformation in their surroundings. Railway buildings reflected the characteristics of both the city they were located in and the period, and at the same time became a symbol of the change they created in the city, the development they provided and the new areas they created. Station buildings may reflect the culture of the region they were built in or the culture of the country that built them, and may also include the interpretation of the old architectural language with today's conditions (Başar & Erdoğan, 2009, 30-32). With the change and development of train technology, new technologies and architectures have also begun to be used in addition to old systems and structures. For these reasons, the architecture of railway structures, their interaction with the city and the relationship of old structures with the new are multifaceted and worth researching.

The fact that train station structures were built by foreign architects in those periods led to the emergence of structures inspired by different geographies. The station buildings built by European states served as an educational

* Corresponding author, E-mail: cansu.turker@isikun.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_855

tool for local architects, leading to the more frequent use of new trends and architectural technologies in the country (Başar & Erdoğan, 2009, 32).

Then, the national architectural movement, which started in Anatolia close to the declaration of the Republic of Türkiye, led to the formation of national architectural structures in cities such as Ankara, Eskişehir, Konya, Adana and Kayseri. Before World War II, the New German Nationalist Movement that emerged in Germany also affected Turkish architecture, and traditional motifs in architecture faded away. During this period, rational uses of reinforced concrete and steel began to prevail on an international scale. This situation is especially seen in Ankara Train Station and its surroundings and in Eskişehir's new train station building. Especially after 1931, local architects were supported to produce architectural works using local materials (Tankut, 1994, 23, as cited in Yakın, 2021, 42). From the 1960s onwards, architectural design concerns and aesthetic efforts began to disappear in train stations built in Türkiye (Yılmazyiğit, 1991, as cited in Başar & Erdoğan, 2009, 32). After these dates, the increase in investments in road transportation caused the railways to become secondary. The railway structures built by the state began to become ordinary buildings with no concern for style.

From past to present, train stations have held an important place in the memory of the city dwellers as public structures that form the identity of the city, the prestige and symbolic structure of the city (Özkaynak & Korkmaz, 2019, 216). The place of train stations in the architectural memory of the society has been used as an ideological, cultural, economic tool and/or symbol (Yakın, 2021, 38-39).

2. Materials and Methods

2.1. Train Stations in Architectural and Urban Scales and Relationships between Old and New Structures

Train station structures, due to both their functions and architectural characteristics, create a focal point for the surrounding area. They create a gravitational effect similar to that of a square or a bazaar that brings people together in the settlement they are located in (Akdemir & Keskin, 1993, as cited in Başar & Erdoğan, 2009, 39). Railways, on the other hand, enabled rapid product transportation and passenger travel in the areas where they were located, accelerated trade and production in the areas where the railways passed, revived cultural interaction with the outside world, and increased population and investments through migration (Ayvaz & Halaç, 2023, 65). In short, an important determining factor of the city identity (Uslu et al, 2025, 430), railway structures act like a magnet in the urban fabric of the city they are located in, becoming

Although there are many station structures on the railway line, the most important ones are the main stations, which serve as an ending and a beginning, are generally located in the city center or close to the center, and become an urban image and landmark for the city. These structures were generally designed by famous architects, and since the political, economic, cultural and social structure of the period was greatly influential in their design, they have become important historical documents. Train stations have served as a gateway to the outside world for city dwellers, and have held an important place in the memories of visitors as the first structure they encountered in the city (Yıldız, 2013, 52).

Railway lines and structures are entering a transformation process, where the effects of the 21st century in transportation are intensified, systems are modernized, and passenger and freight capacity is increasing. In particular, new technology high-speed train systems and the construction of new high-speed train stations are replacing existing railway structures (Sedes & Çıkrıkçı, 2022, 1554). Due to new technologies, historical train stations are in danger of losing their function that has a place in the memory of the society or becoming the focus of other profit-oriented investments.The High Speed Train Lines under construction are located very close to the historical station buildings in many cities such as Ankara, İstanbul, Konya, Eskişehir and Sivas. However, these new structures are far from complementing the existing station buildings, but they are a dominant structure that is integrated into the urban fabric. In fact, these new High Speed Train Stations located in the city center stand out by being significantly different from the existing settlement texture in terms of volume, ratio, proportion, facade and material (Sedes & Çıkrıkçı, 2022, 1554), causing the historical railway axes to become secondary and the station buildings to become dysfunctional. This situation creates physical, social and economic transformative and transformative effects on the urban fabric that has been shaped around the historical station for many years.

2.2. Selected Examples of Train Stations of Three Cities of Turkey: İstanbul, Ankara, Konya

In this article, the main station buildings (railhead stuctures) of historical railways and the main high-speed train lines from three metropolitan cities in Türkiye (İstanbul, Ankara, Konya) were examined comparatively. In the selection of these cities, the criteria has been determined as having both a historical station structure that has become the image of the city and high-speed train lines associated with it. The relationship between these historical and new station structures and how the stations and stations built with new technologies affect the urban texture that developed around the old station were examined.

2.4.1. İstanbul Train Stations

From 1872 onwards, the opportunities provided by the railway caused the trade volume to increase gradually in Haydarpaşa, and the Ottoman Empire gave the railway and port constructions to German companies due to the political circumstances. The first Haydarpaşa Train Station was a wooden 2-storey building, which existed between 1872 and 1939. This structure served a single-track railway between Haydarpaşa and Pendik (passing through Kızıltoprak, Feneryolu, Göztepe, Bostancı, Maltepe and Kartal stations). Haydarpaşa Port, designed and built by the Philipp Hollzmann company, was opened in 1903, which increased passenger traffic, and therefore a comprehensive train station structure that could serve together with the port was needed (Kösebay Erkan, 2013, 103-104). The station to be built would be the starting point of major projects connecting Istanbul to Baghdad and connecting Europe to the Hejaz and the Persian Gulf (Başar & Erdoğan, 2009, 33).

Todays Haydarpaşa Train Station in Kadıköy, İstanbul, has been built in 1908 with the Concession given by the Ottoman Empire to the Germans, designed by Hellmuth Cuno and Otto Ritter. The building has become an urban, architectural, aesthetic and social image of the city and a landmark with its striking appearance on the shores of the Bosphorus since the beginning of the 20th century. Haydarpaşa was designed at the request of Abdülhamit II, reflecting the magnificence of the period and containing a variety of forms. It has an eclectic style that bears the symbols of the Ottoman Empire, Middle Europe Baroque, German Renaissance, with its empire style decorations (Kösebay Erkan, 2013, 108), which are considered the second phase of neoclassicism (Fersan, 1991, Koçer, 1995, Soğancı 2001, as cited in Başar & Erdoğan, 2009, 33). The structure is a masonry system supported by steel beams in places and its foundations resting on wooden piles. The north door of the building served arriving passengers, while the south door served departing passengers. In first floor plan, there are sections such as offices, waiting rooms, conference rooms, glass-fronted offices above the passenger lounge. There is a manager's office in the north tower, and a general manager's office in the south tower. There are also offices in the short arm, and an inspector's room, telephone and telegraph rooms in the long arm. The most important feature of Haydarpaşa today on an environmental scale is that it is a symbolic structure that has been used by the masses for over a century.

Yonca Kösebay Erkan has worked on the interaction of Istanbul's railway heritage with the Marmaray project, which connects the Asia and Europe continents with an undersea railway tunnel (Kösebay Erkan, 2012a, 2012b). After the Marmaray Project began to take shape in 2004, the presentation of Haydarpaşa Train Station to urban competition brought about discussions. The Marmaray Project connect the Anatolian side of Istanbul to the European side with a tunnel passing under the Bosphorus, which has removed Haydarpaşa from being a starting or ending point in urban transportation. This situation led to legal changes that allowed the 1 million square meter area, which includes the Haydarpaşa Train Station and its surrounding area, to be reused for functions such as hotels, etc., instead of serving the original function of the building. Although TCDD officials applied to the Constitutional Court to cancel the decision to declare Haydarpaşa and its surroundings an urban protected area, the decision has not changed. The 1/5000 scale conservation zoning plan prepared for Haydarpaşa and its surroundings in 2009 was rejected as unconstitutional, and the new zoning plan study was approved by the Istanbul Metropolitan Municipality Council in 2011. The Conservation Development Plan prepared for the Haydarpaşa area in 2012 proposes a multifunctional, mixed use in the area and includes the use of the Haydarpaşa Train Station building for accommodation purposes (Kösebay Erkan, 2013, 99-101).Finally, although the Ministry of Transport of the Republic of Turkey announced that the building could not be a hotel, the function to be given was left unclear.

With the decision to connect the Rumelia railways, the most important railway of the Ottoman Empire opening to Europe, to Sirkeci, two small-scale two-storey and two four-storey station buildings, which do not exist today, were built on the seashore in 1872. However, the construction of the main station building (Sirkeci Train Station) began in 1888 upon the order of Abdulhamid II (Ayvaz and Halaç, 2023, 70). As the beginning of the Rumelia Railway Line, the structure serves as a gateway to Europe and foreign trade (Ayvaz & Halaç, 2023, 62). After the construction of Sirkeci Train Station was completed, it was called "The Gate of the East" by the Western states and "The Gate of the West" by the Ottomans (Durmaz Aktaş, 2019, 6, as cited in Ayvaz & Halaç, 2023, 65). Designed by German architect August Jasmund, who wanted to reflect Middle and Far Eastern influences, Sirkeci Train Station was put into service in 1890 as the starting point of the Istanbul-Sirkeci-Pythion railway. The building is Jahmund's only work in this style, and it influenced the styles of stations that would later be built in Central Europe (Büyükdemir 1999, as cited in Başar & Erdoğan, 2009, 34). There are eight railway structures in the Sirkeci Train Station Area. The first structure, built in 1972, is currently used as the Old Chieftainship Building. The structure of the State Railways Directorate of the Republic of Turkey was destroyed by fire, and the Section Chief, Locomotive Maintenance Workshop, Wagon Chief Service and warehouse structures remain idle and are not used due to the Halkalı station put into service (Ayvaz & Halaç, 2023, 73-74).

Although the Sirkeci Train Station area was declared a cultural area in 1995, the project aiming at a transformation focused on culture and arts has not yet been determined in its final lines (Ayvaz & Halaç, 2023, 74). The Istanbul Railway Museum was opened in Sirkeci Station on September 23, 2005. With the commencement of the Marmaray project on October 29, 2013, Sirkeci Station was closed. On March 12, 2019, it was decided that the railway line between Sirkeci and Kazlıçeşme would be used as both a railway and a recreational area, and trains returned to Sirkeci Station on February 26, 2024. between the State Railways of the Republic of Turkey and the General Directorate of Cultural Heritage and Museums in 2024, Today, Sirkeci Station is on the industrial heritage routes determined by ERIH (Geyyas Gören & Manisa, 2021, 882).

With the protocol signed between the General Directorate of TCDD Operations and the General Directorate of Cultural Heritage and Museums in 2024, the Haydarpaşa and Sirkeci Station buildings and areas outside the railway function were transferred to the Ministry of Culture and Tourism for 29 years to be used for "culture and tourism" purposes ("Haydarpaşa ve Sirkeci garları 29 yıllığına devredildi", 2024). The threat of losing the original functions of Istanbul's most important train stations has been met with public reaction.

It is known that there is no symbolic railway structure in the area where the Söğütlüçeşme High Speed Train Station is located. The Söğütlüçeşme Main Station Project is planned to be built in this area ("Söğütlüçeşme Anagar Projesi", n.d.)

2.4.2. Ankara Train Stations

The old Ankara Train Station, which no longer exists, was built when the first locomotive arrived in Ankara in 1892. This structure has the same plan and facade layout as the first train station of Eskişehir, and very similar to the train station of Konya (Başar & Erdoğan, 2009, 35). Later, Ankara Gazi Station, which is designed by Ahmet Burhanettin Tamcı in 1926, the project became a symbol for the capital Ankara as one of the first station buildings of the National Architecture Period (Başar & Erdoğan, 2009, 36). Then, Ankara Train Station Building of today, described as the entrance gate of Ankara and one of the important structures of the Republic Period, has been constructed in 1937 and became a symbolic structure due to its architectural features. It was designed by architect Şekip Akalın, with the views of Professor Blum from Germany about the size and location of the station, and put into service in 1937. The role of the station structure is to reflect the power of the young republic and to create squares and spaces for the modern city dweller to pass through. Since the station is the first gate that those coming to the city pass through, it was aimed to meet the Youth Park with its landscaping and pools, in contrast to the arid and barren climate created by the geography. (Yakın, 2021, 42-43).

The building has a symmetrical volume and has 4 floors starting from the basement. There are circular staircase blocks on both sides of the entrance tower. The ceiling of the waiting hall is made of opaque laminated glass on a metal construction and allows daylight in. While the ground floor entrance hall contains buffets, ticket offices, luggage storage, staff offices, a barber and a lounge of honour, the upper floor of the side areas connected to the waiting room serve as lodgings (Uslu et al, 2025, 431). The reinforced concrete structure is covered with the characteristic pink Ankara Stone.

The important buildings around the Station Building, such as TR State Railways General Directorate Building, Direction Building, Ankara Hotel, 2nd Region Building, Train Maintenance House, Station Casino, lodging and guest houses, form a complex (Uslu et al, 2025, 432). Also, this structures are in a close physical relation with the newly constructed Ankara HST station. In 2019, a portion of the Ankara station buildings and the southeastern half of the Ankara station area were transferred to the use of a private university (Altın, 2025, 370). Located close to the station and built in 1927, Maintenance Units (*Cer Atölyeleri*) has been used as a modern arts center and art gallery with a since 2010, Wwith adaptive reuse found to be architecturally successful (Uysal et al., 2019, 76, Geyyas Gören & Manisa, 2021, 890).

Ankara HST Station was built on October 29, 2016, on the land next to Ankara Train Station, as a commercial complex consisting of the main high-speed train station and social areas such as a shopping mall, cinema, hotel, meeting halls, etc. Ankara HST Station was built as a total of 8 floors, approximately 400 meters long and 220,000 square meters of closed area. Ankara HST Station, unlike the old train stations, was built with the "build-operate-transfer" model. As a result, it has moved away from being a purely service-oriented public structure and has become a partially commercial investment. The structure was designed not only as a transportation venue but also as an urban center, even similar to a shopping mall. (Yakın, 2021, 49-50). It is seen that the station buildings in Ankara have transformed from a single small-scale building to a campus consisting of many buildings, and following the high-speed train technology, they have been designed as a large mass where all functions are gathered. In fact, it has been discussed architecturally that the new station, so close to the old station but so different in terms of scale, almost makes the old station structure invisible.

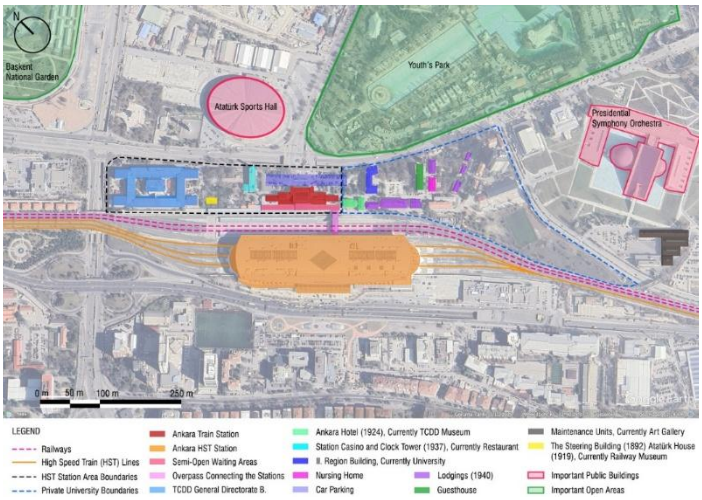

Fig 12. Building Functions Around Ankara Station Complex (Google Earth, 2025, Uslu et al., 2025, 432, Reproduced by authors.)

2.4.3. Konya Train Stations

First Konya Train Station was built in 1896 as the end point of the Eskişehir-Afyonkarahisar-Konya railway, which was built by the Chemins de Fer Ottomans d'Anatolie / Ottoman Anatolian Railways (CFOA) Company between 1894 and 1896 with an eclectic style (özkaynak & Korkmaz, 2019, 220). Konya station buildings were built as a complex along with other complementary structures, on a 160 x 22 m land (Yavuz Pakih & Sarıman Özen, 2022, 885).

For the main station building, stone, brick and wood materials were used in the masonry structure and the walls were plastered. Windows and doors on the facades are emphasized with stone arches. The arc-shaped structure located northwest of the Main Station building is a maintenance workshop structure consisting of 13 sections and houses a circular platform used to turn the locomotives in the direction they will enter. A section of this structure was demolished due to the road changes planned around it (Uysal et al., 2019, 80). After the 2014-2015 restorations, the 14 lodging structures were rented to the municipality and private institutions and started to be used for other purposes (Yavuz Pakih & Sarıman Özen, 2022, 886). Today, it is observed that the Konya Train Station Complex cannot keep up with changing conditions, developing technology and urbanization, and reuse proposals are being developed for the structures (Uysal et al., 2019; Yavuz Pakih & Sarıman Özen, 2022).

As addition to historical train station, a new station building is constructed in 1956 (Özkaynak & Korkmaz, 2019, 216). While the scale of the building can be considered compatible with the old building, its incompatibility in terms of architectural language has been subject to criticism. Konya Train Station has also started to be used as a stop for the High Speed Train. However, due to the expansion works to be carried out on the Meram Yeniyol Bridge, it will not be able to provide service for three months as of March 10, 2025 (Elmas, 2025).

Fig 13. Konya Historical Train Station
(Selman Bayrakçı, Retrieved from http://turkiyeturizmansiklopedisi.com/konya-tren-gari and https://www.dogrulukpayi.com/dogruluk-kontrolu/konya-daki-tarihi-tren-gari-yikilip-yerine-yenisi-mi-yapildi)

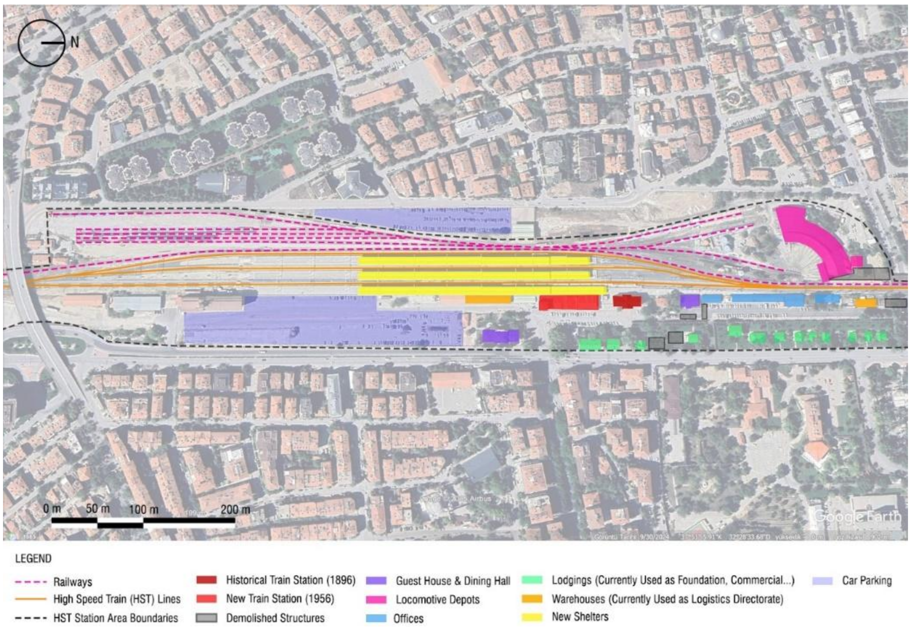

Fig 15. Building Functions Around Historical Konya Train Station
(Google Earth, 2025, Yavuz Pakih & Sarıman Özen, 2022, 885, Reproduced by authors.)

With the arrival of high-speed train technology in Konya in 2011, the Selçuklu Station Building, whose project was prepared in 2013, put into service on October 2, 2020. Currently, there are two high-speed train stations in Konya city. Selçuklu YHT Station is the first stop for high speed trains coming to Konya city, close to commercial areas and the tram stop, constructed in October 2021, which is 4.5 km far away from the city center. The second Konya HST Station, located on the site of the old Konya Train Station, consists of only a superstructure. On the other hand, Selçuklu HST Station onsists of a vertical big rectangular mass on a horizontal road route and platform structures adjacent to it parallel to the road. It is considerably larger and more dominant than the surrounding buildings in terms of scale and silhouette.

3. Results and Discussions

Effect of high-speed train stations on existing urban texture around train stations in selected examples are examined in this section with comparison of aerial photograos from different years.

3.1 İstanbul

When the existing port activities in Sirkeci and Haydarpaşa were supported by the railway, the trade volume of the area reached its highest level and it became an important logistics and commercial center in freight transportation. With Haydarpaşa and Sirkeci Train Station Areas, the city has experienced developments in social and economic areas, and with increasing industrialization, production facilities, shipyards, warehouses, and industrial enterprises have been put into service in the port and coastal areas close to Haydarpaşa and Sirkeci (Ayvaz & Halaç, 2023, 68, 71).

In addition to the construction of the Sirkeci Train Station, the construction of warehouses and docks in the area changed the character of the area and allowed the city to take on a new identity (Kuban, 2010, 99, as cited in Ayvaz & Halaç, 2023, 72). Around Sirkeci Train Station, there are important city places such as Topkapı Palace, Gülhane Park, Sultanahmet Mosque, Hagia Sophia Mosque, Mısır Bazaar, Galata and Golden Horn bridges.

The opening of the Marmaray Tunnel (for railways) in 2013 and Avrasya Tunnel (for automobiles) in 2016, which connect the Asian continent to Europe and passes under the Bosphorus, and the construction of the High Speed Train 2014 have caused Istanbul to undergo many changes on an urban scale. The facilitation of intercontinental and intercity railway transportation for Istanbul has paved the way for new investments. Two city parks, one of which is the largest in the world, were built by filling the sea in Maltepe and Yenikapı in Istanbul in 2014, increasing the surface area of İstanbul by approximately 2 square kilometers. In the Kadıköy-Fikirtepe neighborhood, which is very close to Söğütlüçeşme HST station, a comprehensive urban transformation project and the construction of multi-storey residential buildings have greatly affected the urban fabric. The Fikirtepe urban transformation area is an example of the changing and transformative effect of newly constructed railways on the city.

3.2. Ankara

Ankara was chosen to lead the country entering a new era in the Republican Period, and planned development was implemented as a method of achieving this (Tankurt, 1994, 23, as cited in Yakın, 2021, 42). In 1925, with the efforts to modernize and strengthen production, Atatürk Forest Farm (AFF) was established by Mustafa Kemal Atatürk on a 50,000,000 m² land, in order to realize pioneering developments in production. Ankara Gazi Station is also located within the borders of Atatürk Forest Farm.

Throughout time, the capital Ankara has become a much more traveled place compared to the past, which has led to the inadequacy of Gazi Station and the need for a new train station. The new train station is located between Anıtkabir and Gençlik Park, at the intersection of Talatpaşa Boulevard, Cumhuriyet Avenue and Hipodrom Avenue, which are important transportation axes of Ankara. Then, with the arrival of high-speed train technology in Ankara, the High Speed Train Station, which is closely related to Ankara Train Station, was built, and this led to an increase in investments and construction around the station.

For Ankara, it is seen that the Atatürk Forest Farm, which started to disintegrate in Ankara in 2006, is gradually losing its green land due to new constructions. Reasons such as the failure to protect the Atatürk Forest Farm as a whole and the construction taking place on lands allocated for agriculture have caused the farm to disintegrate. In this case, it can be investigated whether the construction investments that started after the Ankara High Speed Train project have an effect on this disintegration.

3.3. Konya

While the old train structures of Konya are located as a campus in the city center, Selçuklu HST station is located next to the industrial center, 4.5 km away from the city center, as a large mass that includes all functions. The nearest residential area is 300 meters away. The structure is designed to serve as a bridge connecting the two sides of the city by crossing over the railway line. With the selection of the location of the HST station, it was aimed to transform the surrounding small industrial center into a new center with residential, social and commercial structures by joining the urban transformation areas. It was aimed for the HST station to be integrated with transportation axes such as tram, bus, suburban train, light rail system, etc. and to give the city a new identity (Özkaynak & Korkmaz, 2019, 222). In fact, it can be observed from aerial photographs that there are urban transformation areas around the train stations in Konya, and that the urban fabric has been completely renewed in a fairly large area.

4. Conclusions

The crumbling Ottoman Empire made efforts to keep up with global developments, to make cities livable by granting privileges to foreigners, and to build railways and train stations. The advancement of railway technology and the constant change and transformation of station structures in terms of architecture were shaped by factors such as political policies, the socio-cultural situation of the period, and the economic structure of the state. Railways are versatile connecting elements that are not limited to space, in terms of establishing connections between other cities, ensuring the flow of goods and people, and ensuring integration between regions (Sedes & Çıkrıkçı, 2022, 1552). Station buildings, generally positioned close to the city but not restricting city development, are designed as a living campus within themselves (Uysal et al., 2019, 68).

The High Speed Train technology, which was put into service in Japan in 1964, started to be used in Türkiye with the commissioning of the Ankara-Eskişehir HST line on March 13, 2009. HST, which is preferred by passengers more because of the time and comfort it saves, has caused traditional train systems to become secondary and even some train station structures to become idle. In some cases, since it is not possible to transfer old train structures to future generations and maintain their current functions (Ayvaz & Halaç, 2023, 65), adaptable reuse proposals have been made for the structures.

On the other hand, high-speed train stations under construction may be dominant and contemporary structures that are integrated into the urban fabric, far from being complementary to historical station structures. These structures, which differ in volume, proportion and facade, may have negative effects on historical stations (Sedes & Çıkrıkçı, 2022, 1554) and may also cause changing and transforming effects on the urban fabric. HST stations, which change the linear and multi-part campus/complex pattern of the railway structure, gather all the functions in a large mass, create a focus within the city and cause differentiation in the settlement texture. This situation distances them from integrating with the old station structures, on the contrary, makes it difficult to perceive the original stations. In addition, HST stations as macro projects at the urban scale can cause significant changes in the settlement texture, landmarks and focal points, silhouette and socio-economic structure in historical areas. They may also lead to the loss and loss of identity of old train stations (Markoç & Elyazıcıoğlu, 2014, s cited in Sedes & Çıkrıkçı, 2022, 1557).

Railway structures can be evaluated within the scope of architectural, historical, cultural and industrial heritage. However, preserving these structures, which have been damaged and relegated to the background over time, with sustainable strategies and transferring the values they contain to future generations requires close cooperation between institutions such as the Republic of Turkey State Railways, Cultural and Natural Heritage Protection Regional Boards and the Ministry of Culture and Tourism.

The ecological survey of semi-open spaces in hot-dry climates to achieve a cultural and zero-energy housing model

Sahel Ghasemi Baghdadi*[1]

[1] Bonab University, Department of Architecture, Velayat Highway, Bonab, Iran

Abstract. Visual and thermal comfort for the inhabitants of residential spaces significantly depends on the weather conditions of the external environment, which are constantly changing, and these changes are visible due to the climate contrasts according to the culture of each region of the world. The research method is based on qualitative and quantitative, ENVI-met software is used for climate calculations, Python software, and igraph is used for fuzzy data. The dominant architectural forms and structures of these spaces in the studied hot and dry climate region are closely compatible with local resources, land, culture, and climate, and are related to the human need for a culture-oriented housing and the identity of hot and dry regions. Concept of sustainability and its special position is emphasized. The research findings can contribute to the critical rethinking of semi-open spaces and their intrinsic value in renovation projects as well as in contemporary residential architecture.

Keywords: Semi-open spaces; Housing anthropology; Cultural ecology; ENVI-Met; Python

1. Introduction

Occupant's comfort and energy consumption are critical issues within the field of structural plan and building innovation. The request for warm and visual consolation from inhabitants has been expanded impressively. The vitality utilization and CO_2 emanation as well as the capital taken a toll of building's operational vitality have been expanded. The utilize of passive plan techniques within the early stages of the plan may be a need for modelers and engineers to optimize the benefits from on-site renewable vitality assets such as sunshine. Be that as it may, optimizing inhabitant consolation by utilizing sunshine is challenging since there are two unmistakable spaces counting insides (interior) and the environment (exterior), which are association together. Moreover, optimizing visual and warm consolation is troublesome due to clashes between them. In specific, sun diurnal developments giving rise to diverse hourly sunshine circumstances that impact the indoor consolation conditions. Be that as it may, intrigue consider through building plan, light and human well-being seem lead to the discovery of ideal arrangements with respect to all previously mentioned criteria.

Semi-open spaces (i.e., open spaces with roofs) have constituted an essential component of innate private structural plans over the past centuries. These inactive plan components reflect the genuine parameters of the communities and societies of the locale, as they react to the gentle climate conditions, way of life designs, and mindset of the nearby individuals (Sadanand, 2020). Rudofsky, within the book Design Without Designers, a presentation to non- pedigree design, emphasizes the natural and social qualities of conventional semi-open spaces (Rudofsky, 1964). The plan of these spaces was based on a profound understanding of nature, climate, and accessible assets, as well as the characteristics and values of the prevailing way of life of the inhabitants. Agreeing with Foruzanmehr (2015), conventional semi-open spaces may be more reasonable for a wide run of social and individual exercises compared to open spaces (Foruzanmehr, 2015).

Artificial intelligence today is undoubtedly an interactive and disruptive technology, with countless applications and more prospects for every industry and background, from healthcare to agriculture, engineering to finance, sports transport, and more (Cugurullo, 2020). In addition, artificial intelligence is one of the main drivers of the world's smart city movement (Singh et al., 2020).

The research presented here aims to fill this inquire about crevice with an orderly survey and basic and all-encompassing survey of diverse shapes of semi-open and semi-open spaces in hot, and dry climates based on natural execution. Particularly, this investigate tries to relate their spatial, typological and basic characteristics (substantial values) with natural, utilitarian concerns (intangible values). It looks at conventional houses in several

* Corresponding author, E-mail: sahel.ghasemi1394@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_862

climates and topographies. This investigation is based on a comparative evaluation that can give experiences into how distinctive neighborhood conditions, for illustration, climate, geology, assets and way of life profiles, impacting parameters such as recurrence. Considering the danger of slow vanishing of these plan components, we expect that this think about will raise mindfulness for their preservation.

2. Research literature

2.1. Building form as a microclimate modifier

Regulatory function of façade benefits from modifying microclimate in ambient environment by controlling airflow, solar radiation across the facade body resulting in adjusting surfaces temperature of the building nearby the interior spaces. Courtyard building, as an old form of dwelling, pervasively applied in all times, climates and locations such as Iran, China and Middle East. Despite the socio-cultural aspects, courtyard building demonstrated extraordinary response to climate specifically in harsh condition. (Grobman, 2017). In addition, they concluded that a microclimate modifier can affect air movement, daylight, ventilation and living style resulting in improving thermal comfort in enclosed public area and surrounding spaces. Modifying microclimate is studied based on method, software, climate, microclimate modifier type, function, effective parameters and microclimate forces which are explained in the following. (Agency, 2020). Therefore, in the current research, we dealt with the hot and dry climate in three regions of the world, and in the first stage, a general understanding of this climate, and in the second stage, the investigation of traditional and responsive architecture in the hot and dry climate, and finally, the ecological investigation of open and semi-open spaces. Again, in a hot and dry climate, we will work towards zero energy housing (using Python and ENVI-met software).

2.2. Knowing the hot and dry climate

The planning should be compact, and under one roof to avoid a lot of movement, which can cause unnecessary thermal loading and discomfort to occupants. The orientation of the longer side facade should be North-South, as the solar radiations are less harsh than East or West. The sun moves from east to west; therefore, the sun's rays are at a maximum in this direction (Cauwels and Sornette, 2022).

The concept of planning in context with climate is seen in traditional times. Jaipur comes under a hot and dry climate, the Havelis were designed close to each other with narrow lanes, for an effective flow of wind as hot air when passed through narrow lanes cools the flow.

The shading is an essential part of hot and dry climates, unlike warm and humid climatic zones. Characteristics of Hot and Dry Region are as following:

- The temperature in these regions ranges from 27 and 49°C and 22 °C at night
- Humidity is moderate to low, with clear-skied most of the time
- The low humidity means less rainfall and therefore less vegetation in the region
- The wind flow is minimal but when there it's hot and dusty (Altomonte, 2020).

In recent residential projects, we have seen the need to bring the outdoors indoors, whether through green walls, Biophilic designs or interior courtyards, especially in countries with dry and hot climates. When it comes to countries with hot, dry climates, creating these outdoor-inspired interiors is about more than bringing in sunlight and fresh air, it's an architectural expression of a rich culture that spans generations. It goes beyond and inspires nations beyond their borders. In fact, how cultural and social norms affect the creation of traditional courtyard houses in hot and dry regions of the world and how to visualize their unique architectural features can achieve ecological sustainability in the field of building construction.

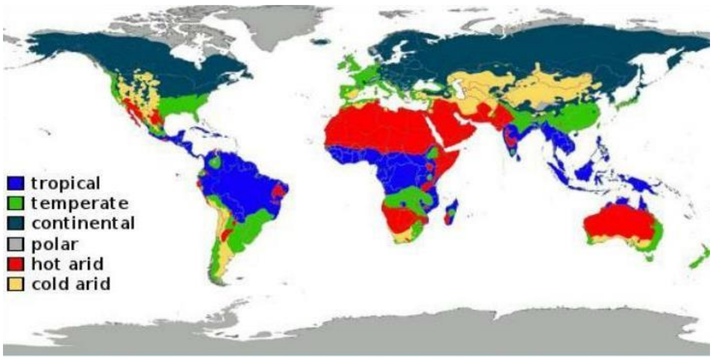

Fig. 1. Different types of weather in different parts of the world

2.3. Energy efficiency: Net zero energy building

In a net zero vitality building (NZEB), the sum of vitality is decreased by the legitimate plan of the envelope, cover and warm recuperation (winter), shade (summer), and normal ventilation. Agreeing with the definition of NZEB, the vitality required to function the building is delivered by renewable vitality sources in or close to the building. (Marszal, 2011). NZEB are characterized as the taking after standards including a) the utilization of renewable vitality sources on location, b) the yearly vitality utilization breaks even with to or less than the vitality generation from on-site sources, c) yearly capital fetched of operation rise to or less than the vitality lattice and d) diminishment of carbon emanations and reliance on fossil powers. In any case, Wang et al. (2009), the integration of detached plan methodologies and dynamic innovation within the shape of the dynamic veneer leads to an adjusted vitality prerequisite and a consistent reaction to diverse conditions. Inactive methodologies allude to cautious sun-based plans with the point of lessening warm pick-up, the requirement for manufactured cooling, warming, and visual glare (Kima, 2019) (Grynning, 2018) (See Fig. 2 and Table 1).

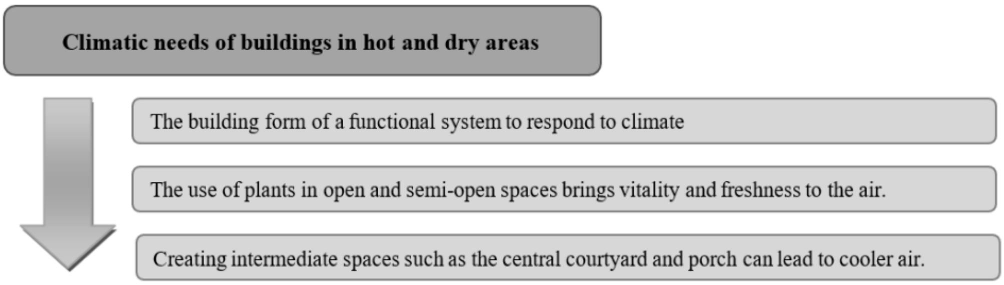

Fig. 2. Climatic needs of buildings in hot and dry areas

Table 1. Review of three case studies around the world based on native houses in hot and dry regions

Area	Features	Plan	Open/semi-open spaces
Yazd - Iran	Central and semi-introverted courtyard Wide and high porches orientation (East-West)		
Diyarbakir-Turkiye	Use of thick walls for minimal heat transfer. The use of plants next to the external walls of the building for thermal insulation and air conditioning		
Sham-Syria	Introversion and central courtyard wide porches use of ponds and water ponds		
USA - Arizona	Using local materials to create sustainability. Using introverted spaces and central courtyard to create coolness and temperature balance		
Mexico	Using plants for shading. Use of balconies and windows with large openings		
Libya	The spaces of verandas from head-to-head inside the central courtyard. Culture and religion show introversion in this climate		
4. Discussion

4.1. Spatial syntax and culture

The syntax of space is a theory and method based on the abstract recognition of space, quantification of spatial components, and analysis of the relationship between comprehensive spatial systems and local construction. Based on this model, comparative research can separate the logic and rhythm of spatial distribution and combine spatial construction with the economic and social system. The aim is to reveal the causes, mechanisms, and development trends of the distribution of economic and social elements (Qin, 2023). In recent years, the syntax of space has been widely used to study the semantic relations of building culture due to its ability to study the relationships between spatial form, spatial structure, and human social behaviours (Zhang, 2021).

Table 2. Syntax of space based on climatic and native findings of housing in hot and dry regions

Area	Culture - religion	Climate	Sustainable Element
Yazd - Iran			Diyarbakir-Turkiye			Sham- Syria			USA - Arizona			Mexico			
Libya			

*: Culture-religion with this color indicates that spaces are separated into inner and outer based on cultural and religious intellectual principles, or the spaces have privacy. ; : The climate is shown with this color and thus the climate design refers to the introversion of the residential spaces around the central courtyard.; :The stable element is shown with this color and shows elements such as the central courtyard and the porch and balcony or the air cooling corridors that are common in all plans.

The syntax of the culture is related to privacy or permission to enter the house and is trusted. Therefore, the idioms of the realm of mahram bring intimacy, kinship and closeness. The meaning of culture in architectural buildings is to build a place in such a way that it has architectural symbols such as a porch and a central courtyard from both physical and semantic aspects (Gholshan, 2020). The style of space in the present research briefly refers to the formation of spaces in residential plans in hot and dry regions and how the culture of these regions has affected the arrangement of internal spaces.

5. Ecological investigation of open and semi-open spaces in hot and dry climates

Using ENVI-met software and the model presented based on outdoor thermal comfort indicators, the results obtained by Excel software will be presented and analysed in the form of graphical charts. The basic information that is needed for modelling is given in this step.

These data, according to the geographical location of the region, generally include the prevailing wind of the region throughout the year, whether at night or during the day, the westerly wind, according to the location of the region in latitude and the angle of sunlight in the lowest annual position and in the highest How many degrees is the annual position. Therefore, with the desired data, we will analyse separately the three cases mentioned in the table above. Modelling and analysis of the variables of orientation, height, sunlight and reflection, which are influential factors in thermal comfort, have been done in ENVI-met software.

6. Analysing the criteria with Python

Performing numerical calculations using conventional Python methods and using the Pandas library can be converted into a quantitative method, and this main library for scientific calculations in Python helps speed up calculations and allows your system to work efficiently.

According to the above investigations and qualitative knowledge, it can be said that in a hot and dry climate, criteria such as temperature, humidity, air flow, if they are controlled by the climatic and ecological design approach, can be the optimal model in this climate for areas with this climate. The world was achieved.
Therefore, we will analyse the criteria based on coding and numbers in Python software to get a suitable answer in terms of measuring the criteria and the correctness of the assumptions.

Table 3. Distinctive features of traditional architecture of hot and dry regions of the world

Features	Description
The buildings are in the form of a central and semi-introverted courtyard	The climatic behavior of the central courtyard is such that with the vegetation and generally the water in it, it produces a microclimate in which the temperature is lower than the outside temperature and the air humidity is higher. In addition, the trees create shade and the breeze that is directed into the yard
The height of the rooms is high and the windows are long	The high height of the room is up to 4 meters, which causes the heat of the air to rise and the temperature to decrease in the lower height of the room, and finally, hot air ventilation through the windows under the ceiling
Wide and high porches	The presence of wide and shady porches and proper ventilation in the porch and the location around the central courtyard or on both sides of the building, which reduces the ambient temperature and comfort of the space
Orientation (east-west) of the building	Orienting the building in accordance with the wind direction, creating opposite openings to produce blinds, creating windy spaces (narrow and long alleys), using wind deflectors
Prevent heat and cold exchange	Using wood as the best type of material due to the slowness of heat transfer and the use of materials with high thermal capacity such as brick and straw that do not return heat to the interior space
Optimum use of building temperature in different seasons	Division of living spaces into two parts, summer and winter

Table 4. Based on the analysis made by ENVI-met software, the following results have been obtained

Area	Description	ENVI-met
Yazd – Iran	By examining the reflections of 40% and 94% for the surfaces around the courtyard, it was concluded that the reflection of 70% in the layers and side walls of the building benefit from the draft of solar energy.	
Diyarbakir-Türkiye	To receive solar energy for long hours and exchange air in the building, it is between 12:30 PM and 2:30 PM. This analysis is specific to the summer season.	
Sham-Syria	After examining the reflections of 62% and 97% for the surfaces around the courtyard, it was concluded that the reflection of 78% in the layers and side walls are less benefited from the solar energy draft	
Results	As a result, according to the above graphs, the effective indicators for receiving solar energy for long hours and air exchange in the building are between 11:00 AM and 03:00 PM.	
```
import pandas as pd
data = {
  'temperature': [3, 2, 0, 1],
  'Air flow': [1, 3, 2, 0]
}
```

Based on the data of fuzzy logic 0 and 1, the analysis was done in Pandas library.

The two main criteria of temperature and air flow are considered as 0 and 1 phase data.

	temperature	air flow
0	3	1
1	2	3
2	0	2
3	1	0

Fuzzy logic is a method of reasoning that is similar to human reasoning and decision-making and includes all intermediate possibilities between yes and no.

	temperature	air flow
0	Use of plants	introversion
1	Central courtyard	East-west direction

The second stage of temperature is measured based on the two variables of the use of plants and the central courtyard.

	temperature	air flow
Q0	Use of plants	introversion
Q1	Central courtyard	East-west direction

The third stage of the air flow is measured with two variables of introversion and building rotation in the east- west direction.

Fig. 3. Python-based criteria analyses and criteria

7. Recommended pattern

The recommended patterns related to the three building types have been stated in Table 5.

Table 5. Patterns use with SPSS

Typing	Period	Property	Pattern house
Type I*	1800	There is a space between the entrance such as a corridor and a corridor between the entrance and the interior spaces of the house. This paradigm implies the preservation of the privacy of the residents and spaces such as the central courtyard based on the need for climatic stability and air cooling.	Type II*	1900	According to culture and religion, the hierarchy of entrances in this type is as follows: front entrance, main entrance, middle and inner space. In terms of localization, the architectural point of view is to determine the main spaces based on interior and exterior and to create porches all around the central courtyard, which causes climate stability	Type I*II	2000-2024	This pattern is a combination of both extracted patterns. In this model, modernity and tradition are infused together and by placing the central space as the central courtyard and the balconies on the east and west sides, they greatly help to cool the air.	
8. Conclusions

Looking at tropical regions, we find that it has always been tried to design houses based on compatibility with the environment and climate, with the least samount of energy wastage and the least amount of use of technological devices in these areas. Also, by studying native residential patterns, we have achieved similar results in the direction of reducing energy consumption, and by combining the structural methods of these three styles of architecture, a common pattern can be achieved under the title of sustainability pattern. Among the methods used in the housing sustainability model, the following can be mentioned. .

- In general, in very hot climates, architects can design structures to absorb cooling breezes and allow warm indoor air to escape through openings in the roof during the cooler hours of the evening or night, and avoid installing windows. Large, south-facing sunshades can also be avoided.
- The type of placement and placement of the building should be such that it is inside the yard and can use more thermal energy.
- In order to use the proper air flow in the design of the building and in the joints, large openings should be considered so that the rooms are connected to each other and benefit from the cool wind flow in the summer and the heat of the sun in the winter.
- The use of high-thick walls in order to store heat energy inside the building, as well as materials that have a high thermal capacity, which should be given more attention in the south side.
- The maximum use of the depth of the ground is due to the two reasons of using the cooler air of the depth of the ground and the category of greater strength of the building.
- Creating conditions to facilitate air flow: for this purpose, giving the northwest-southeast direction to the building not only reduces the solar radiation energy in the hot season, but it can also reduce the air flow that is in the west and east directions to a large extent.

Effects of water level changes of Lake Burdur and Lake Van on built environment

Güler Özyıldıran*[1]

[1] Van Yüzüncü Yıl University, Faculty of Architecture and Design, Department of Architecture, 65080 Van, Türkiye

Abstract. Van city center and Burdur city center are similar with their location on the lake shore. The concerns about climate change draw attention to the water level changes in Lake Van and Lake Burdur. In fact, they are very different in terms of topography and climate. Lake Van, the biggest lake of Turkey, is located in the Eastern Anatolian Region, which has continental climate. Lake Van Basin is surrounded by snowy mountains. Lake Burdur is located in the western part of Mediterranean Region and has the Mediterranean climate. Burdur Basin is at the western end of Taurous Mountans and full of small lakes, and Burdur Lake is the biggest one. However, Lake Burdur has been rapidly drying in recent decates. On the other hand, Van experienced a disaster in 1990s due to the increase in the water level of Lake Van. Some areas of the city center were evacuated. In the recent years, Lake Van also started to lose its water level which might cause other type of danger for the natural and the built environment. This study examines the effects of water level changes of Lake Burdur and Lake Van on built environment. The study is based on the review of the related literature, the written news, old photographs and site analysis.

Keywords: Built environment; Climate change;. Lake Burdur; Lake Van; Water level change

1. Introduction:

Climate change is a significant problem of today and might cause different results in the near feauture. Water levels of lakes are sensitive to variability and changes in climate. The frequency and severity of extreme climate events can increase and enhance floods and droughts in many regions (Ozdemir et al., 2023). Van and Burdur are the two city centers which are located in the lake side. Both lakes have been faced with climate change as flooding or drought in recent decades. Since these lakes are near the city centers, the effects of water level changes on built environment are in question. This study aims to examine the effects of water level changes of Lake Burdur and Lake Van on built environment.

Lake Burdur is located within the borders of Burdur and Isparta provinces in western Mediterranean Region. It is one of the deepest lakes in Turkey (maximum 110 m), with an average depth of around 40 m. According to the water level of 848 m, the total lake area within the borders of Isparta-Burdur is around 184.2 km2. An area of 38,125 ha in and around Lake Burdur was declared as a "Wildlife Conservation Area" in 1993. In 1994, the part of the lake covering approximately 50% (12,600 ha) was included in the “Ramsar Convention” list (Fig. 1) (WWF Türkiye, 2008). The Ramsar Convention is an international convention that aims to ensure the protection and sustainable use of wetlands (especially as Waterfowl Habitats). Burdur city center is located in the southwest side of the lake. The water level of the lake has dropped by 27 meters between the years of 1998 and 2008, and there has been a 27% decrease in its volume. Burdur Lake Management Plan Study was coordinated by the Ministry of Environment and Forestry and completed in 2008 (WWF Türkiye, 2008). The decrease in the water level of Lake Van is still continuing.

Lake Van is located within the borders of Van and Bitlis provinces in Eastern Anatolian Region. It is a volcanic barrier lake formed by the eruption of the Nemrut Volcanic Mountain, blocking the tectonic depression area in the region. It is surrounded by high mountains and plateaus. The Van Lake Basin, which cannot send its waters to the surrounding seas, is the second largest inflowing basin in Turkey after the Konya Basin. Lake Van, which is the largest lake in Turkey in terms of areal width, ranks 15th among the closed lakes in the world. Lake Van, which is considered as soda based on the high salt content of its waters, is also the largest soda lake in the world. The annual water potential is estimated to be approximately 3.5 billion m3 (Tarım ve Orman Bakanlığı, 2025).

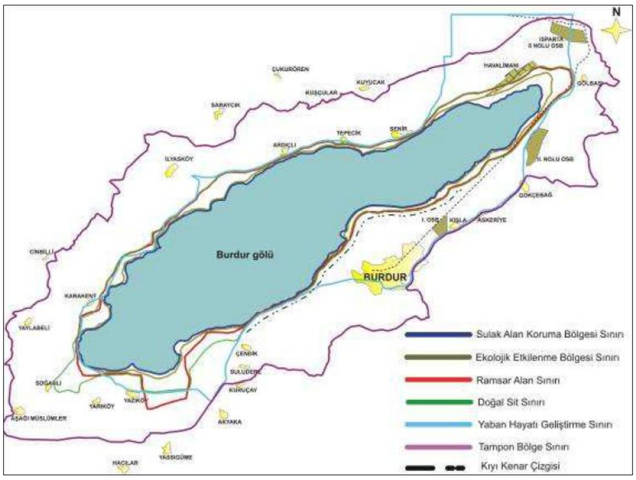

Fig. 1. Map of Lake Burdur and its significant conservation borders. Yellow area is city center, dark blue lines are wetland conservation borders, red lines are Ramsar convention border (WWF Türkiye, 2008).

According to bathymetry studies of Lake Van, the bottom elevation of the lake was determined as 1,195.42 m. Considering the long-term average lake water level (1,648.33 m) observed in the 67-year period between 1944 and 2010. When the low base elevation obtained from the lake bathymetry map, the deepest point of Lake Van is approximately 452.91 m and the average depth is 162.42 m. During the 67-year observation period between 1944 and 2010, the lake area of Lake Van varied between 3558.2 km2 (1962) and 3623.6 km2 (2996). Similarly, the lake volume was the lowest with 563.3 km3 in 1962 and the highest value with 575.0 km3 in 1996 (Tarım ve Orman Bakanlığı, 2020). In the years of 1990s, flow-through lake occurred in Van. On the contrary, Lake Van is facing with drouth in the current time. Although the extent of drought is not as high as in Burdur, the changes in precipitation in recent years are thought-provoking.

2. Materials ans methods

In this study, by considering the above mentioned georgraphical information about these two Lakes, water level changes are attempt to be analysed in terms of their effects on built environment. The research study is based on the review of relevant literature and site observations. The reviewed literature is mostly related to geographical reports and regulations of official institutions. Their effects on built environment are analysed by satellite map compariosons and site observations of the author with an experience for the last 10 years in Van and last 35 years in Burdur.

3. Lake Burdur and the effects of water level changes in Burdur City Center

Lake Burdur in located in the west side of Mediterranean Region in Anatolia. There ara lots of lakes in its surroundings. Hence the region is also called the District of Lakes. Some of these lakes have been faced with drought. Lake Burdur is one of the most affected lakes in this region. Fig. illustrates the changes of Lake Burdur from 1990 to 2020. It has almost lost its 1/3 area for the last 35 years. Since the Burdur city center is located on the lake side, the lost in water level affects city siluette, building qualities, besides the damages in the nature.

When 1990 and 2025 views of Lake Burdur (Fig. 2 & Fig. 3) are compared closely, it is seen that some new settlements added close to the area where the lake recedes. In Fig. 3, 1995 borders of the Lake Burdur is marked with blue lines on the 2025 satellite view. When compared with the 1995 satellite view (Fig. 2), it is clearly seen that “Isparta Süleyman Demirel Organised Industrial Zone” was constructed in 1992 -2000 close to the old borders of the Lake Burdur. Similarly, “Isparta Süleyman Demirel Airport” was constructed in 1997 in the old borders of the Lake Burdur. The old northern border of the lake was included in the provincial borders of Isparta. In the southwest border of the city, the new building of Burdur State Hospital opened near the old borders of the lake in 2023.

Fig. 2. GoogleEarth maps of Lake Burdur and the changes of water level, 1990, 2000, 2010, 2020.

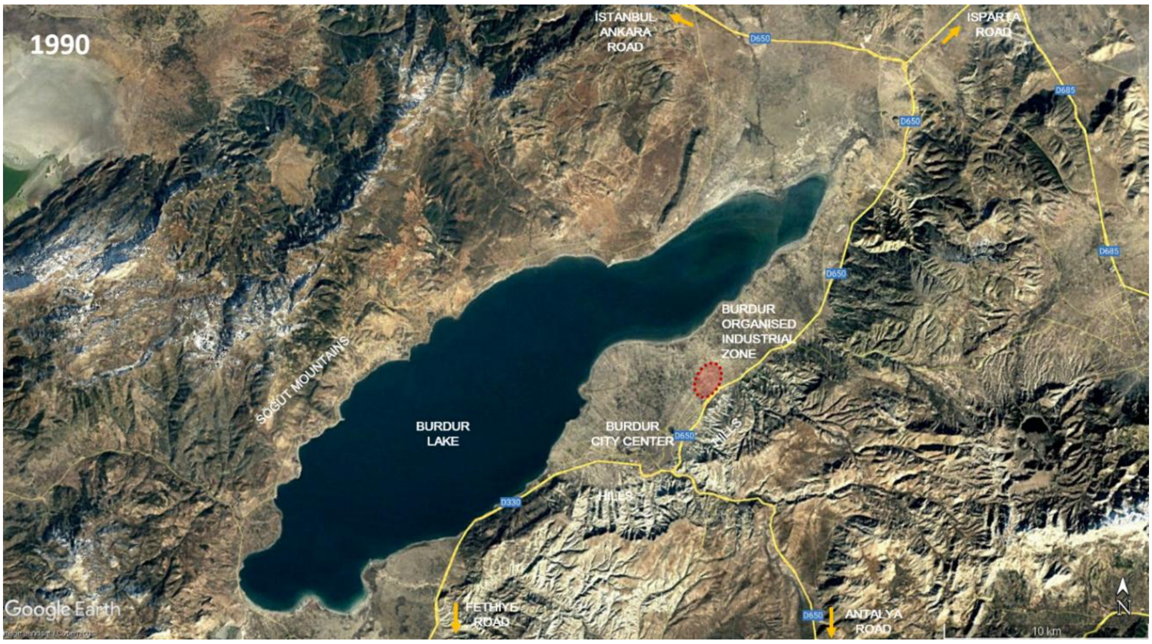

Fig. 2. GoogleEarth map of Lake Burdur, 1990. Marks are added by the author.

Fig. 3. GoogleEarth map of Lake Burdur, 1990. Marks are added by the author.

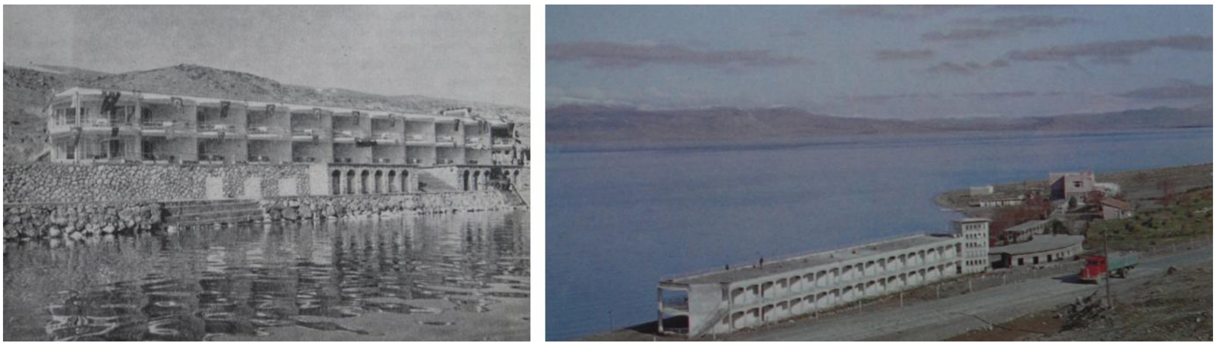

Fig. 4. Çendik Motel; north view and south view, 1967 (Burdur Valiliği, 1967).

Fig. 5. Çendik Motel; Googleearth 2025 view and the pier at its north, 2021 (TRT Haber, 2021).

The southwestern part of Burdur city centre, which is close to the lake side, is reserved for recreation areas, hotels, and summer villas. The negative effects of drought are most clearly and dramatically seen on these settlements. Fig. 4 illustrates the Çendik Motel which was opened by the Burdur Governorship in 1967. It is seen that the motel is located in the intersection of the intercity road and the lake side. The building, raised with a stone basement, rests on the lake border on its northern facade. On the other hand, Fig. 5 illustrates the water level changes in 2021 and 2025. Current lake border is far away from the motel. Although a long pier was constructed to reach the water level in 2019, the pier also became far and high from the current lake border (Fig. 5).

In addition to the water level decrease of lake Burdur, the WWF Türkiye (2008) claimed that the main problems of the Lake Burdur area are organized industry, factories and city sewage, which have insufficient treatment. Additionally, since Burdur is earthquake prone area, seismic risks might be also added to these problems. In the history of Burdur, two major earthquakes occurred in the last century; 1914 and 1971. Burdur is one of the cities through which a fault passes. The fault runs parallel to the mountains in the south of Burdur through the city and intersects with the lake border at the northwest end. The northern areas of the city close to the lake are soft ground which is not very suitable for constructions, so the city did not approach these sides. The area is mostly used as agricultural lands. In the past, the historical city center of Burdur was located on the hill where the *Ulu Cami* (Great Mosque) is located, which is in the center of the city today. Although there is no written information on this subject, it is possible that earthquake resistance and overflow of the lake were taken into account based on past experiences in the past settlement selection. However, today, while the lake waters are receding dramatically, it is seen that the constructions are shifting towards the old lake borders. This situation brings to mind the major damages caused by the constructions in the Amik Basin, which was established after the great losses experienced in Hatay after the earthquakes of February 6, 2023. While discussing the drop of the lake, the damage caused to nature and migratory birds, and the focus on saving the lake, the issue of the risks that may be brought by the shift of constructions towards the lake escapes attention.

4. Lake Van and the effects of water level changes in Van City Center

Lake Van located in the East Anatolian Region. It is surrounded by high snowy mountains, such as Erek, Artos, Nemrut and Süphan. The snows of the mountains feed important waterways. In the years between 1990 and 1995, Van had heavy snows than normal, and water level of Lake Van rose slowly day by day. This caused flows in Van city center, especially İskele Neighbourhood, and other lake side settlements. This water level changes cannot be clearly seen in satellite views of 1995 and 2025 (Fig. 6 & Fig. 7). However, old photographs can illustrate the effects of water level changes on lakeside settlements (Fig. 8).

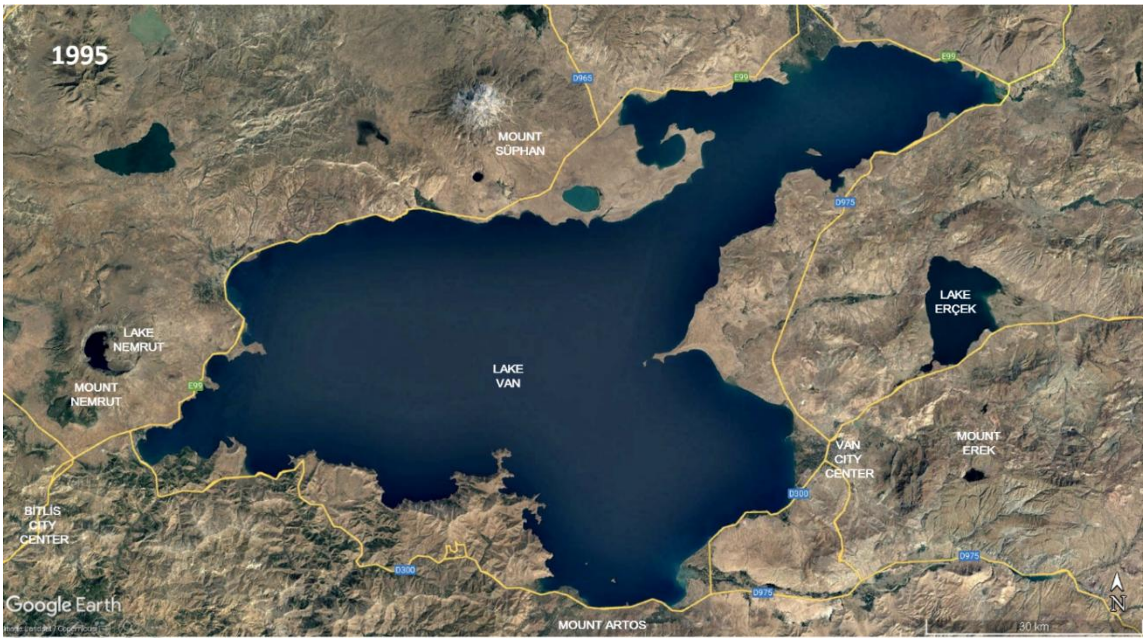

Fig. 6. GoogleEarth map of Lake Van, 1995. Marks are added by the author.

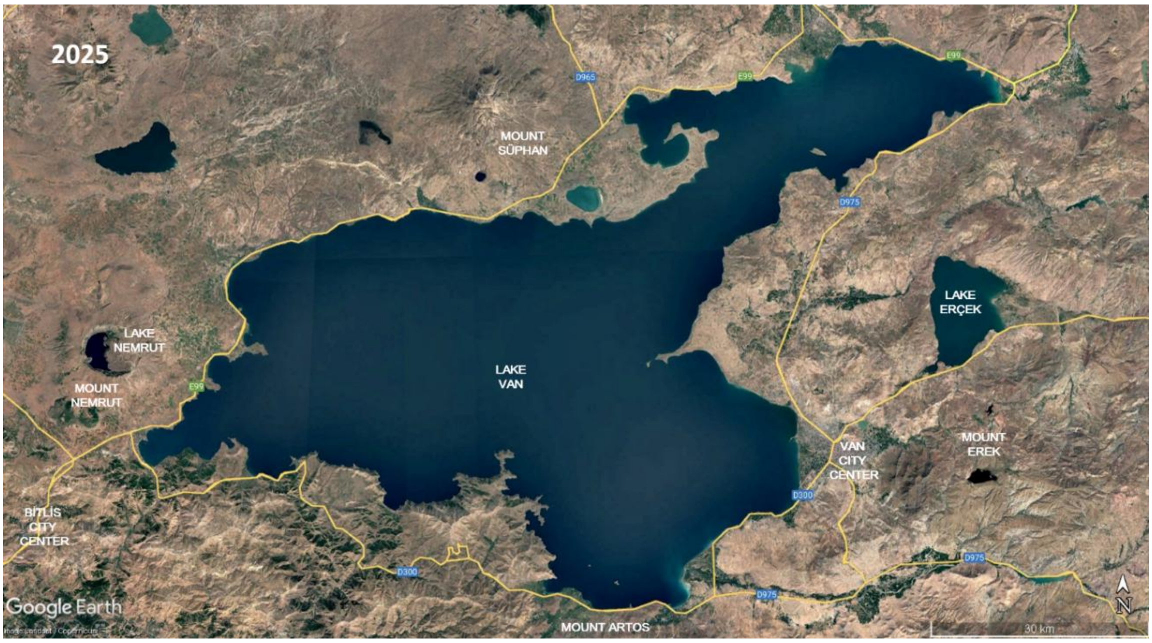

Fig. 7. GoogleEarth map of Lake Van, 2025. Marks are added by the author.

Fig. 8. Flood due to rising water level in Lake Van, İskele Neigbourhoud, 1995 (left: Deniz, 2003; right: Yıldız & Deniz, 2005).

Yıldız and Deniz (2005) studied the water level changes of Lake Van in 1990s and defined the effects on coastal settlements. Especially the rapid rises that had continued for several years in a row, caused great damage to the settlements, roads, agricultural areas and facilities belonging to public and private institutions around the lake. In the 58-year period between 1944 and 2002, as a result of the rise in the lake level, a total area of 52 km², 14.1 km² of which is urban areas, was occupied by lake waters. During this period, a greater or lesser amount of urban land was submerged in all the sides of Lake Van has been identified. A significant part of the 1413.7 hectares of urban land occupied by the lake waters belongs to the city center of Van (623 ha.). The level change caused great damage not only to coastal settlements and human facilities, but also to agricultural areas and wetlands around the lake (Yıldız & Deniz, 2005).

Yıldız and Deniz (2005) emphasised that the damages caused by the rapid rise in 1994-1995 were incomparably higher than in previous years (Fig. 9). A total of 1807 houses, 1178 of which were in urban spaces and 629 in villages, were exposed to disasters. Some of the dwellings were submerged in lake water, while others were affected by groundwater rise.

In 1995, the area was declared as a disaster area and İskele Neighborhood was evacuated. The Council of Ministers Decision No. 95/6925 of 8 June 1995 announced that 1655 meters level is the disaster level. Thus, city plans were revised and the 1655 meter level was declared as the disaster level where no new construction could be made. However, this decision became a matter of debate for those who had existing buildings and land in the area. With the decision of the Council of Ministers dated 20/02/2017, it was decided to reduce the lake water rise code from 1655 meters to 1653 meters and published in the Official Gazette. According to the decision published in the Official Gazette, the areas under the code of 1652 meters around Lake Van were considered as disaster areas. In the decision, it was stated that the existing structures between 1652 and 1653 meters codes will be preserved and no new settlements will be given. In addition, it was noted that in the buildings to be built on the 1653 meter code, the base code and the entrance codes such as buildings and parking lots are planned to be 1.00 meters above 1653 meters. With this decision, the Council of Ministers Decision No. 95/6925 of 8 June 1995 was also repealed (AFAD, 2025).

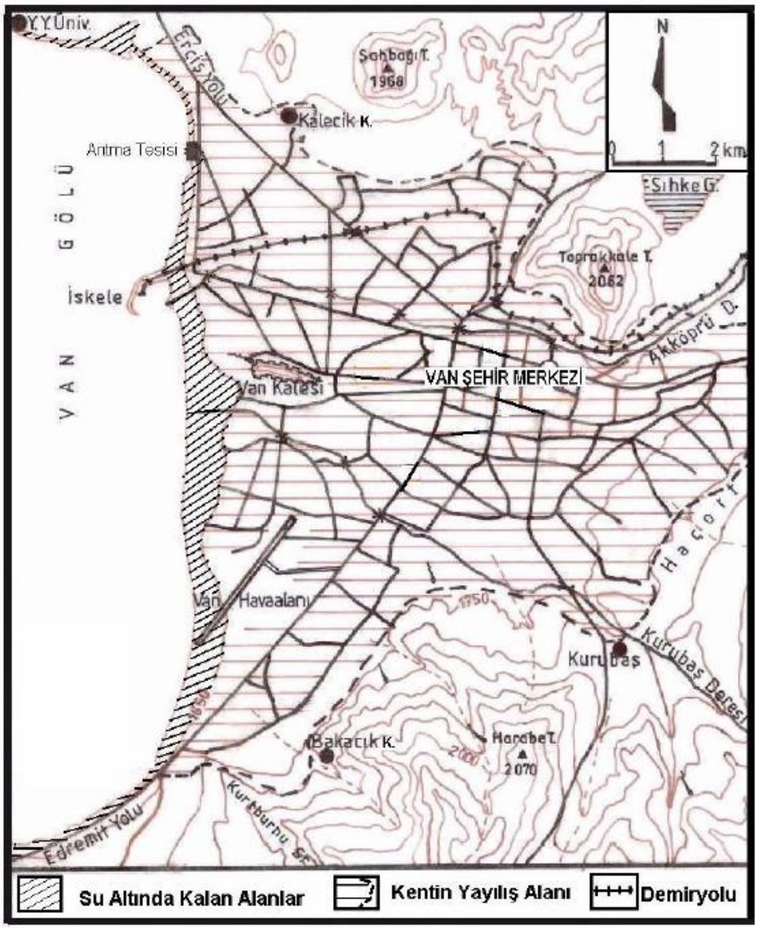

Fig. 9. Flooded lands in the Van city center, 1990s (Yıldız and Deniz, 2005).

Fig. 10. Retreat in Lake Van due to drought, 2023 (AA, 2023).

In the last few years, contrary to the 1990s, Lake Van is facing with drought risks (Fig. 10). It is not directly affected the built environment yet. However, the landscape of the lakeside is changing accordingly. Shallow and murky waters begin to appear along the lakeside. Since climate change might cause drought worldwide, the decrease in the level of Lake Van might continue. On the other hand, the IRAP report of Van AFAD stated that the problem of water level rise in 1990s, might most likely be repeated in the future. Hence, for the design and construction of new built environmets, both scenarios should be considered.

5. Results and discussion

The water level fluctuations observed in Burdur Lake and Lake Van have significantly affected the construction patterns of the cities and the city silhouette.

Burdur Lake has shrunk greatly in the last 35 years. The fact that approximately one-third of the lake area was lost from 1990 to 2025 led to the city center of Burdur being directly affected by this change. With the decrease in the water level, new residential areas and industrial zones were built in areas close to the lakeside within the city limits. This situation has adversely affected both the natural environment and residential areas. For example, the current status of Çendik Motel, which was built on the lakeside in the 1990s, has remained in a higher and more remote position with the receding water level. In addition, with the decrease in the lake level, social areas and touristic facilities by the water were also adversely affected.

Lake Van experienced a significant rise in water level in the early 1990s with the increase in snowfall. This rise has led to floods, especially in lakeside settlements such as İskele Neightbourhood, and the region has been declared a disaster area. In Van city planning, new arrangements have been made to reduce the effects of these floods, and an area up to 1655 meters has been banned from construction. However, with an amendment in 2017, the disaster level was reduced to 1653 meters. In recent years, due to the drought in Lake Van, the formation of shallow and turbid waters by the lake has led to significant changes in the landscape. Although this has caused the lake landscape in the city to change shape, it has not had a direct impact on the structures that have yet to be built.

It can be said that the water level changes around both lakes have significant effects on the residential areas. Fluctuations in the lake level have directly affected both the location of existing structures and the construction of new residential areas. In addition, the negative impact of touristic and recreational areas, in particular, has the potential to affect the local economy.

6. Conclusion

This research aimed to examine the effects of water level changes in Burdur and Van lakes on the built environment. The results show that the effects of climate change on residential areas and urban planning are becoming more and more apparent. The impact of climate change on the water levels of lakes plays an important role in both the management of water resources and the planning of residential areas. While the loss of water in Burdur Lake led to the construction of new industrial facilities and residential areas, the increase in the water level in Lake Van and the subsequent drought necessitated the rearrangement of existing structures according to the settlement plans. Water level changes have affected not only the settlements directly, but also the construction strategies depending on environmental factors. The structural changes made on the lakeside settlements in the city centers of Burdur and Van reveal the importance of sustainable management of natural resources.

This study provides some findings on the effects of water level changes on built environment of cities. However, it is clear that more research needs to be done in similar residential areas in the future. This research can help local governments bring lakeside construction and infrastructure projects more in line with climate change scenarios. In addition, developing structures that are more resistant to water level changes and strategic settlement planning will help prevent such negative effects in the long run.

Abstract. Old urban textures that have deteriorated and become abandoned spaces are considered abandoned and inefficient neighborhoods and settlements. When urban life in an area of the city stagnates for any reason and no effort is made to revive it, the urban texture of that area becomes worn out. The basic necessity of renovating and improving old and worn-out urban textures is to develop the living environment for humans. Economic, socio cultural, and other factors shape this necessity. For this reason, in this research, while recognizing the characteristics of the historical texture of Tabriz and the factors involved in the abandonment and destruction of some areas, an attempt is made to present urban design strategies and policies to promote the sustainability of this area and its improvement. Based on data extracted from different stages of the research and using a combination of various methods and tools for validating and evaluating models and patterns, the findings of this study have appropriate analytical power. In this regard, the set of indicators presented for the evaluation and analysis of aesthetic components affecting the improvement of the old urban fabric, with the aim of developing a conceptual framework for this process, has a desirable efficiency and is capable of comprehensively examining all dimensions and aspects of the research subject. The list of indicators and components identified in this study provides a systematic framework for categorizing and analyzing aesthetic dimensions affecting the improvement of the old fabric of Tabriz. This framework allows for the refinement of effective indicators and the separation of different dimensions related to the improvement process.

Keywords: Aesthetics; Revitalization; Old fabric of Tabriz; Western upbringing

1.Introduction:

The origin of beauty and the understanding of aesthetics has often oscillated between the two main poles of objectivism and subjectivism. Many efforts have been made to resolve the separation between objectivity and subjectivity by thinkers such as Husserl, Heidegger, and especially Norberg-Schulz, in order to apply both objectivity and subjectivity to phenomena through phenomenology. More recent philosophical analyses, adopting an interactive perspective, believe that the sense of beauty arises from the patterns that connect people and objects. For example, it has been suggested that beauty resides in the perceptual experiences of the perceiver and results from the interaction between the features of stimuli and the perceiver's cognitive and emotional processes (Dewey, 1934; Beardsley, 1958). This view aligns with the idea that aesthetic qualities are not inherent but are credited to the experience of observers as they respond to the objective and formal features of artworks (Beardsley,1958). It has also been said that although beauty is not an objective matter existing independently within the artwork itself, it finds meaning in the realm of shape and form and is analyzed by the mind. Every artwork has a quality that is independent of the realization of its meaning and content in the mind of the audience, and it is not confined to the emotions of the viewers. Therefore, an artwork, through the autonomy of its form, can elicit various emotions in audiences who are unpredictable and may offer different interpretations of their perceptions (Norouzitalab, 2008). In fact, a reasonable (and common) resolution to the objective subjective debate in evaluating aesthetic quality acknowledges that aesthetic quality is a joint product of visible characteristics that interact with related perceptual, cognitive, and emotional psychological processes in the human observer (Lothian, 1999). Based on this, according to another categorization (Golkar, 2000) regarding the quality of urban design which can also be generalized to

* Corresponding author, E-mail: Sa.feizi@iau.ac.ir

https://doi.org/10.31462/icearc2025_a_arc_879

the component of urban aesthetics—the threefold theories concerning the existence of urban design quality are as follows:

- As a quality or attribute inherent in the physical environment and existing independently of the observer
- As a subjective and taste-based category constructed by the observer and unrelated to the structure and physical characteristics
- As a phenomenon or event that is formed in the course of an exchange between the tangible and physical characteristics of the environment on one hand, and the cultural codes and mental capacities of the observer on the other (Golkar, 2000).

It has been examined from an objectivist perspective, and for this reason, urban theorists and designers have proposed numerous formal criteria for creating beautiful places (Pakzad & Saki, 2014). Despite differences among theorists' views on aesthetics, most of the criteria expressed within the objectivist approach are taught in the fields of urban planning and architecture. However, in addition to these criteria, perceptual studies with a subjectivist approach have been conducted, which focus more on people's evaluations of the beauty of various spaces, in order to examine aesthetics and the characteristics of beautiful spaces from the perspective of the public.

With the rise of perceptual aesthetics research and the publication of their findings, the differences between earlier evaluations of beauty and these new studies became clear, prompting researchers to further explore these distinctions (Chen et al., 2009). Since then, various methods have been employed to address aesthetic issues; among them is aesthetics with an approach focused on public preferences (Keshtkaran et al., 2017). The old urban fabrics that have become worn out and abandoned are considered derelict and inefficient neighborhoods and settlements. When urban life in an area of the city declines for any reason and no effort is made to revive it, the urban fabric of that area enters a process of deterioration (Andalib & Haj Akbari, 2008: 23).

The concept of urban deterioration can be understood as the decline of the social, economic, and physical conditions of the urban fabric (Rosmani,2008: 9). Therefore, urban deterioration is the result of various factors that, over time, must be prevented from spreading through greater care and actions such as improvement, renovation, and reconstruction. The fundamental necessity of renovating and improving the old and deteriorated fabrics of cities lies in the development of the human living environment. This necessity falls under economic, socio-cultural, and other essential factors (Shamaei & Pourahmad, 2010: 43). Hence, urban deterioration is a national issue and one of the serious problems and important priorities in the country's development planning, which must be addressed with comprehensive determination and a committed outlook. For this reason, this study, while identifying the characteristics of the historical fabric of Tabriz and the factors involved in the abandonment and destruction of certain areas, seeks to provide strategies and urban design policies aimed at enhancing the sustainability of this area and its improvement.

Mansouri (2023), in the article Struggle with Aesthetics, emphasized the importance of what is considered "beautiful," which has been discussed since the fifth century BC when Plato distinguished between the rational and logical and the good, emotional, and perceptual. The passage through time and the experiences of various societal transformations opened the way for this phenomenon—before being scientifically defined and documented in philosophical literature and while societies held an intuitive understanding of it—to enter academic discourse. Afterward, the understanding and evaluation of the beautiful became known in the form of the science of "aesthetics," which, beyond being confined to the world of art and referring to subjective dimensions, gained an objective and functional scale. A well known example of this transformation in urban literature is the term "urban aesthetics." In another article, Daemi and colleagues (2023) examined the role of tourism dimensions in the sustainable regeneration of the old fabric of Yazd, with the aim of urban regeneration as an approach to updating the old fabric of the city—while preserving neighborhood identity and authenticity— and responding to daily needs and sustainable urban development. For this purpose, the present study, using four main tourism variables, investigated the role of urban tourism dimensions in the regeneration of the historical fabric of Yazd. The goal of this research is to understand the mutual relationships between urban tourism and the regeneration of the old fabric of Yazd.

2. Theoretical foundations

The understanding of aesthetics is essentially visual and dependent on beauty. Despite the growing attention to the effects of the visual qualities of the environment on sustainability and the enhancement of quality of life, many questions in the field of aesthetic studies remain unanswered. A review of the urban aesthetics literature over the past half-century shows how discussions on aesthetics have shifted from being visually and artistically focused to having perceptual and semantic tendencies. In this section, the definition of the terms "beauty" and "aesthetics" is first addressed, followed by an examination of aesthetic approaches (objectivist and subjectivist approaches), methods for evaluating beauty, the fundamental perspectives in urban aesthetics, key approaches in urban aesthetics (expert-centered and people centered), and finally, the principles of urban aesthetics are discussed.

2.1. Beauty and aesthetics

In the Moein Dictionary, beauty is defined as a state and quality. Beauty is the order and harmony that exists along with grandeur and purity in an object, stimulating the intellect, imagination, and higher desires of humans. In the Dehkhoda Dictionary, aesthetics is defined as the recognition of beauty and a branch of psychology whose aim is to identify beauty and art (Behzadfar & Ilka, 2009). The term "aesthetics" or "esthetic" is derived from a Greek word meaning sensory perception. In the 18th century, Alexander Baumgarten used this term in the context of the perception and evaluation of beauty. This new term gained widespread use among English speakers from the mid-19th century onward. In some modern philosophical movements, there is a tendency to use the term "aesthetics" in a broader sense than merely the evaluation of beauty—referring also to the nature of attraction and other aesthetic qualities in a comprehensive view. Khakzand et al. (2014) state that the Greek word Aisthetikos means sensory perception, and the word Aisthea includes what is perceived. Ahmadi (1996) mentions that the science of aesthetics also examines the structure of methods for sensing the environment and the individual's position in the process of this perception (Groter, 1996).

Aesthetics is a science that deals with the nature and essence of beauty. This question has received two different answers in the fields of art and philosophy; philosophy responds to questions such as whether the roots and constitutive factors of beauty are absolute or relative, their nature, and\ their relation to other sciences. In art, it refers to the rules and systems that govern the shaping of artworks in the process of their creation. Identifying examples and manifestations of beauty is a product of human artistic output. By examining beautiful examples in the artworks of each land, one can understand the general criteria governing them (artistic aesthetics) (Mansouri, 2012). Aesthetics, or the science of what is beautiful, studies a set of principles that make the viewer focus their attention on the work and enjoy the sense of unity and harmony in their sensory perceptions (Atashin Yār, 2012). Aesthetics, which was once a branch of philosophy, is in the contemporary era a combination of philosophy, psychology, and sociology of art (Naghizadeh, 2002).

2.2. The objective aesthetics versus subjective aesthetics

An examination of the existing approaches regarding the nature of aesthetics reveals two main perspectives: objective and subjective. Many views have been proposed regarding whether beauty is subjective or objective. There are differing opinions about whether aesthetic judgment pertains to the sender or is an interpretation by the receiver. Significant challenges have been made to bridge the gap between objectivity and subjectivity by figures such as Husserl, Heidegger, and especially Norberg-Schulz, in order to apply both objectivity and subjectivity to "things" based on phenomenology. However, what is commonly understood from the term Aesthetic today is based on both objective and subjective dimensions of beauty. Studies show that in relation to these two approaches in the urban landscape, the objective approach was initially dominant, followed by a growing focus on subjective approaches. For instance, picturesque, with its architectural emphasis on visual and artistic aspects of the landscape, such as attention to human scale diversity, naturalism, and organic order in form and composition, as well as color, was popularized by figures like Zittel, Gibert, and Halperin. Meanwhile, gradually, urban beauty shifted from the domain of objective, emotional, and specialized focus on visual qualities—such as form, color, and texture—to the domain of perceptual studies of the subjective experience of th urban environment.

2.3. The degree and gradation of beauty

The degree of beauty is the pleasure felt by the perceiver, which arises from the desire to repeat individual experiences within the realm of internal observation. This desire is formed in humans through experience in any given field. The degree of beauty can also be understood in terms of quantity and quality, with the artistic quality encompassing the criteria for evaluating aesthetic beauty, and the artistic quantity referring to criteria related to the magnitude and extent of beauty. There have been fundamental efforts throughout the history of art and architecture to define and determine the quantitative aspect of beauty, expressing beauty using mathematical formulas. Another measure of aesthetic criteria can be based on values such as "trend" and "style," where the valuation of beauty is divided into levels from authentic to fundamental, linked to the foundational "aesthetic values" (Behzadfar, Elika,1391). Questionnaire studies are widely used as tools to examine people's attitudes and preferences. The advantage of questionnaires is that they allow the gathering of opinions from a representative group of people within a short period, providing an opportunity to evaluate attitudes across individuals from diverse socio-economic and geographical backgrounds.

In the evaluation of the aesthetic quality of landscapes, "Aryaza" and his colleagues believe that landscapes have inherent or objective beauty, although the viewer's response is subjective. Based on the views of "Briggs" and "Franz," they believe that there are two main methods of evaluation: Direct Methods: People's scene preferences regarding landscapes are compared to reach a consensus. With this method, Aryaza and his colleagues sought to evaluate the scene preferences of observers. They used images of landscapes for this purpose. This approach was based on the assumption that aesthetic judgments from images provide a suitable criterion for the beauty of real landscapes. Indirect Methods: Landscapes are evaluated based on the presence or intensity of defined characteristics. These methods bring together the components of landscapes to derive an overall value. In this method, it is believed that the entire scene is a collection of its components. However, some researchers have criticized this approach for its tendency towards subjective theories in evaluating the components of landscapes. Furthermore, this method does not include the interactive effects of each of the components.

"Arthur" and his colleagues used the terms of general priority models and descriptive list methods. These classifications are similar to the classification of direct and indirect methods. "Shafer" and his colleagues proposed a combination of descriptive methods and holistic models such as psychophysical models and surrogate component models. In recent years, this approach has gained attention due to the use of statistical techniques to determine the relationships between landscape components and scene preferences (Karimi-Moshaver, 1392).

Urban Aesthetics The realm of the presence and manifestation of beauty is infinite and stretches between human and the world, between past and future, between object and subject, between "me" and "you," and between reality and imagination. Therefore, the manifestation of beauty possesses an astonishing variety. Nevertheless, the domain of beauty can be divided into four main areas, as shown in the attached framework. Main areas of the manifestation of beauty:

- Beauty in the appearance of nature
- Beauty in work, production, and industry
- Beauty in artistic works
- Beauty in the human-made environment

These four areas are interconnected and interact with each other, reflecting a kind of unity in diversity. The study of the nature and functions of beauty in different fields is the subject of aesthetics, which itself is divided into various branches such as philosophy of beauty, psychology of beauty, environmental psychology, philosophy of art, art history, art criticism, etc. However, here we focus on the study and role of beauty and aesthetics in the urban environment, which belongs to the fourth area (the human-made environment). From the perspective of sociology and psychology, the city is the most complex human settlement in which the broadest human-environment relationships are categorized into three main components: spatial perception, sense of belonging, and sense of beauty.

- Spatial perception: understanding the environment and feeling spatial identity
- Sense of belonging: creating attachment and memory toward the environment
- Sense of beauty: feeling pleasure and emotional harmony with the environment

These three phenomena are organically connected with one another and together lead to the creation of satisfaction, comfort, safety, and pleasure for human beings. In fact, without spatial perception and a sense of spatial identity in the urban environment, it is not possible to develop attachment and a sense of belonging to it. And without a sense of belonging, one cannot attain the feeling of beauty and aesthetic pleasure. Any disruption or failure in this process results in feelings of ugliness, suffering, and tension. The aesthetics of art differs from urban aesthetics, although there are also connections between them. An important point in the aesthetics of the urban environment or urban landscape is the spirit and character of the perceiving individual. In the 18th century, the concept of beauty had a psychological dimension. This means that the viewer was also considered part of the beauty perception process and played a fundamental role in it. The perception of beauty is to a large extent considered a subjective matter. That is, beauty is not a quality of an objective phenomenon independent of its perceiver, but rather a value that is added by the perceiving individual to an objective entity such as a natural landscape, a building, a painting, a poem, or a piece of music. Therefore, what is considered beautiful or ugly depends on the individual's opinion.

In the perception and evaluation of the beauty of an environment and urban landscape, in addition to the usual and common physical criteria such as rhythm, order, proportion, etc., many factors and criteria within the realm of semantic perception also influence the assessment of beauty. Among them, one can point to the presence of nature and natural elements in human-made spaces, which, in addition to softening the environment and preparing it to play the role of a desirable space, is one of the main methods of conveying beauty to the environment — in other words, creating a beautiful space. A key factor that ultimately gives an urban landscape its charm and beauty is the life present within it. In landscape architecture, two elements are addressed: one is the urban space, and the other is the natural space. Natural beauty is perceptible unintentionally and spontaneously, but the urban landscape can only be perceived when it is free from chaos and possesses unity and harmony (Javadi, 2013). District 8 of Tabriz is located in the city center of Tabriz and is adjacent to Districts 4, 10, 11, 2, and 3, and is, in a way, surrounded by these districts. The area of this district, which is also considered the smallest in terms of size, is 388.4 hectares, and its population is28,006 people. Meanwhile, the per capita total land use in this district is 138.7 square meters. This district, with a population of 28,006 people, has about 18 hectares of service land use up to the regional level, and its total per capita service land use amounts to 6.43 square meters. The highest share of service land use in this district pertains to educational, administrative & law enforcement, and religious uses, amounting to 7.3, 3.3, and 2.8 hectares respectively, which together account for approximately 75% of the district's services. According to standard per capita criteria, there is a total shortage of about 21.4 hectares of services throughout the district, of which about 34% relates to a shortage of neighborhood-level services,48% to a shortage of district-level services, and about 18% to a shortage of regional-level services. Based on the collected data, the highest service shortages in the district are related to park and green space uses, healthcare services, and urban facilities, amounting to approximately 11.6, 2.5, and 0.5 hectares respectively. At the neighborhood and district level, the greatest shortage relates to healthcare land use, totaling about 1.9 hectares.

3. Location of Western Tarbiat Street in the old texture of Tabriz

Tarbiat Street is located in a neighborhood of the same name in the city center, within the old urban fabric, and to the south of the historical bazaar. Spatially, it forms a commercial system. Its length is 283 meters and its average width is 15 meters. This street is bounded on the northwest by Jomhouri Street and on the southeast by Ferdowsi Street. Before the construction of this street, the area served as a passage and was known as a famous branch of the Silk Road or Ipak Yolu, and it held particular renown (Khamachi, 2005). In those times, it was the passageway for the city's residents from the Nobar, Maqsoudieh, and Charandab quarters and the "Laleh Beig" path to the Darbandi Gate toward the Shaterban bazaar and the residence of Ali Qapu. On the other side, it also functioned as a route and access to the Shishegar Khaneh bazaar and later to Haft Kachal Square, which today is known as the Tarbiat-Ferdowsi intersection (see Fig. 1).

3.1. Historical and cultural characteristics of Tarbiat Street

Tarbiat Street has a historical background and an old urban fabric, housing several historical landmarks. This historic axis corresponds with a route that begins at the Nowbar Gate and connects on the other side to the Tabriz Bazaar. Nowbar Gate served as one of the external access points to the Tabriz Bazaar through this passage. The Tabriz Bazaar, with itsncenturies-old heritage, has long been a central hub for the city's commercial and economic activities.

Fig. 1. Position of Tarbiat passage with significant urban spaces

Table 1. Location of the Tarbiat passage in relation to the Nowbar Gate, Tabriz, Iran (Naqsh-e Jahan Pars Consulting Engineers, 2007)

Neighbourhood	Area	Population	Households	Role	Potential
Trabiat	26.6	1102	331	- Commercial with city-wide function - Workshop with urban, residential, and neighborhood-level function	- Proximity to the old city core - Presence of historical-cultural elements - Housing for middle-income populations - Rrelatively large average residential land plots

Fig. 2. The position of Tabriz Passage in relation to the Nowbar Gate (NaqshJahan Pars, Consulting Engineers, 2007)

3.1.1. Physical-spatial characteristics of Tarbiat Street

One of the key components of urban studies, especially at a micro-scale, is the study of physical structure. The physical form serves as both the basis for understanding and intervention in urban planning. In other words, although urban planners and designers analyze various dimensions ranging from history and culture to population and economy to understand a study area, the physical structure is ultimately what they can make decisions about and influence directly. Therefore, when the physical structure becomes the subject of study, it demands the utmost attention to detail from broad patterns to precise elements.

3.1.2. Access map and land use structure map

The architectural structure of Tarbiat Street, in terms of its physical and spatial characteristics, belongs to the architectural tradition of the late Qajar period, often referred to as the “Era of Architectural Transformation.” This period coincides with the arrival of automobiles and the introduction of streets into the traditional fabric of Iranian cities, which laid the foundations for modern street architecture and gradually introduced a new identity into this tradition. In terms of volumetric content, buildings from this generation typically have a two-story structure. The ground floor is primarily used for commercial purposes, while the upper floor is either residential or accommodates business and trade offices (Zekavat, 2010: 128). This era also marks the beginning of outward-oriented architecture, which, although greatly influenced by local criteria, still retains a strong indigenous character. It is no coincidence that the most valuable buildings of this period, representing high-quality architecture, are prominently located along major streets. This valuable architecture does not merely follow external concepts but localizes imported ideas and fully leverages the potential of the location to express its own values.

Fig. 3. Physical-spatial characteristics of Tarbiat Street
(Left: Map of access and structure, Right: Map of existing land uses)

4. Research Methodology

This research is of a quantitative nature. Quantitative research should be viewed as a systematic and scientific method of inquiry that operates based on the collection of data and information about the phenomena under study.

In this method, after categorizing and preparing data for processing, statistical, mathematical, or computational techniques are employed to model the behavior of phenomena.

Quantitative studies use sampling methods to focus on a portion of the target population and collect the required information through questionnaires (either online or paper-based). The statistical analysis of such data leads to the results of the quantitative research. These results, once accurately interpreted, allow for the prediction of a product or service's future based on the proposed model, making it possible to implement appropriate changes.

In this study, to evaluate citizens' opinions and prioritize the importance of each factor influencing aesthetics in the revitalization of the historic fabric of Tabriz, the Friedman test was used. Citizens were asked to rate each proposed aesthetic component based on the Likert scale. The Friedman test is a non-parametric statistical tool used when the data are measured at an ordinal level. It enables the analysis of two-way variance through ranking and comparison of average ranks among different groups (Habibpour & Safari, 2012). This method allows the researcher to assess the importance of each component entirely based on the opinions of the sample, independently of the relationships between variables (i.e., without assuming dependencies between independent and dependent variables).

To interpret the results of the test and determine whether there are statistically significant differences in the average opinions of citizens regarding the components, the results shown in Table 2 are used. With a test value of 150.862 and a significance level less than0.01, it can be concluded that the importance and role of each factor in defining the aesthetic concepts in the revitalization of Tabriz's historic fabric are statistically significant (p-value: 0.000). In addition to significance, the Friedman test also helps identify the ranking differences of the components from the perspective of respondents, thereby enabling the prioritization of criteria. In other words, the test shows which components have higher or lower average ranks. For this purpose, the results shown in Table 3 under the title "Ranks" can be used.

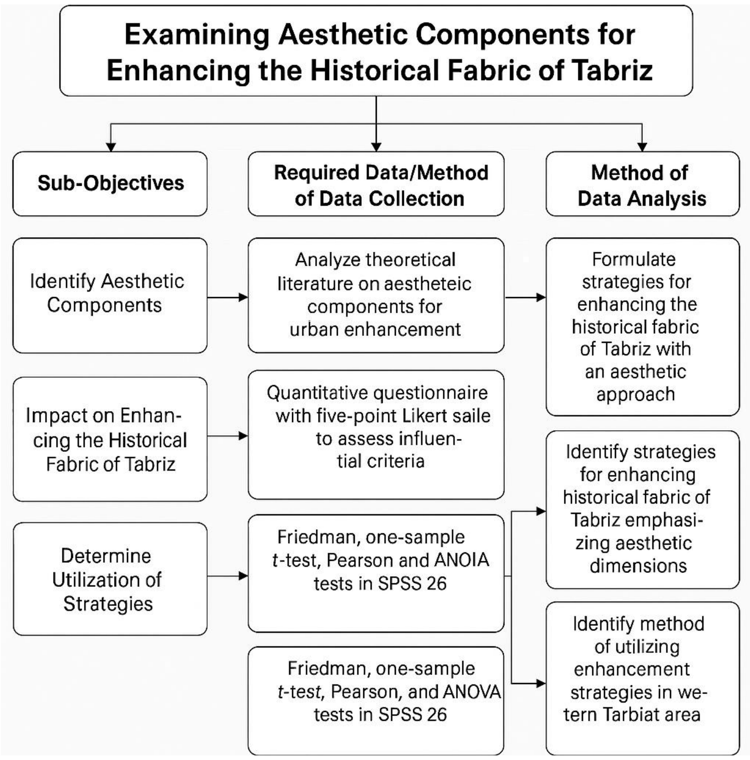

Fig. 4. Research methodology process

Table 2. Friedman test statistics

Value	Intact

Table 3. Mean rank assessment of key aesthetic components for revitalizing the historic fabric of Tabriz

Component	Mean Rank
Number of noisy land uses	17.34
Satisfaction with the compatibility of land uses in the area	15.27
Availability of gathering spaces and group activities	14.16
Variety of recreational activities	14.07
Quality of public restrooms in the area	13.42
Attractiveness of the space during the day	14.75
Attractiveness of the space at night	17.68
Spaces for children's play	15.43
Suitability of existing land uses for the area	17.75
Legibility of land uses	18.80
Quality of surface water drainage	17.02
Variety of urban furniture	15.96
Visual coherence of façades in terms of proportions	15.12
Design of shop windows	17.77
Identity-based detailing in the design	19.05
Unobstructed visibility of surroundings	16.86
Number of high-rise constructions	17.95
Use of local cultural symbols in urban signage	13.85
Quality of access routes to the area	18.45
Quality of existing buildings	17.49
Quality of street paving	14.03
Pleasantness of the spatial experience	17.45
Attention to human scale	19.95
Attention to balance and sequence in design	18.47
Noise pollution	19.68
Air pollution in the area	19.04
Diversity of green space usage	16.29
Presence of native and historic vegetation	15.47
Climate comfort	16.90
Traffic and car parking, social interactions in the area	17.20
Sense of safety	18.65
Sense of nostalgia	21.32

5. Interpretation of Findings

As shown in Table 3, based on the results of the Friedman test and the mean ranks of components influencing the revitalization of the historic fabric of Tabriz, the top three components with the highest mean ranks are:

- Sense of Nostalgia (21.32): This component, having the highest mean rank, highlights the deep importance of fostering emotional and cultural connections between citizens and the historical urban environment. A strong sense of nostalgia can reinforce place identity and attract people to the area.
- Attention to Human Scale (19.95): Designing with human scale in mind ensures that the environment aligns with people's needs and expectations, which significantly enhances comfort and satisfaction.
- Noise Pollution (19.68): This factor reflects the negative impact of disturbing sounds on the overall experience of the space. Reducing noise pollution directly contributes to improved quality of life and urban tranquility. The findings also show that components such as sense of safety (18.65), quality of access (18.45), and balance and sequence in design (18.47) are considered highly important by citizens.
- A sense of safety is crucial for shaping sustainable urban environments.
- Access quality reflects the role of infrastructure in improving connectivity and ease of access to historic areas.

Balance and sequence in design emphasize harmony between environmental elements, leading to a more cohesive spatial experience. Conversely, the three components with the lowest mean ranks are:

- Quality of public restrooms (13.42): This basic need was ranked lowest, possibly due to citizens prioritizing broader and more influential urban factors.
- Variety of recreational activities (14.07)
- Availability of gathering spaces and group activities (14.16)

These results suggest that while these elements are necessary, they are perceived as less critical compared to more identity-based and experiential components like nostalgia, safety, and urban scale Interpretation of Lower-Ranked Components. The quality of street paving, compared to other issues, has received relatively less attention.

The low ranking of “use of urban signs inspired by local culture” (13.85) may reflect a lack of public awareness or limited appreciation of the role cultural symbols play in enhancing the sense of place.

This lower perceived importance might also indicate the current state and performance of these cultural and functional infrastructures. However, overlooking such components can negatively impact citizens’ overall experience of the urban environment. Basic needs such as street paving quality and public restrooms should not be neglected in the revitalization process. Overall, findings suggest that emotionally driven components (such as sense of nostalgia) and environmental factors (such as noise and air pollution) carry higher priority in the minds of citizens. In contrast, more functional or secondary elements (like restrooms and paving quality) are ranked lower in terms of importance. This reveals that revitalization efforts should place greater emphasis on cultural and psychological needs of citizens, while still addressing essential infrastructural requirements. The following is the mean and the standard deviation obtained for all the More components of the review as shown in Table 4.

Table 4. The mean and standard deviation of each component affecting the old texture of Tabriz city, Iran

Component	Mean	Standard Deviation
Number of noisy land uses	2.64	1.030
Satisfaction with land-use mixing	2.48	0.904
Presence of gathering spaces and group activities	2.43	0.902
Variety in recreational activities	2.30	0.835
Presence of gathering spaces and group activities	2.43	0.902
Variety in recreational activities	2.30	0.835
Adequacy of public restroom facilities	2.28	1.026
Daytime spatial quality	2.37	0.939
Nighttime spatial quality	2.74	0.906
Availability of children’s play spaces	2.42	1.156
Suitability of existing land uses for the area	2.72	0.944
Legibility of land uses	2.83	1.074
Adequacy of surface water drainage system	2.63	0.849
Diversity of urban furniture	2.50	0.959
Façade design regarding visual proportions	2.48	0.969
Design of commercial storefronts	2.69	0.734
Identity-oriented detailing in local design	2.83	0.877
Unobstructed visual clarity of surroundings	2.70	1.059
Number of high-rise constructions	2.78	0.970
Use of local cultural urban symbols	2.32	0.839
Quality of accessibility to the area	2.80	1.044
Quality of existing buildings in the area	2.71	1.008
Quality of street paving	2.35	0.957
Noise pollution level	2.96	1.00
Air pollution level	2.89	1.034
Diversity in the use of green spaces	2.52	1.020
Presence of native and historic vegetation	2.46	1.058
Consideration of climatic comfort	2.62	0.962
Traffic and parking conditions in the area	2.83	1.256
Level of social interaction in the area	2.67	0.842
Sense of security	2.84	1.032
Sense of nostalgia	3.12	0.820

6. Conclusion

Based on the data collected through various stages of the study and the use of a combination of methods and tools for validating and evaluating models and frameworks, the findings of this research possess strong analytical and generalizability capabilities. In this context, the set of indicators presented for assessing and analyzing the aesthetic components influencing the renovation of historic urban fabric provides an efficient and comprehensive framework for conceptualizing this process. The identified list of indicators and components offers a systematic structure for categorizing and analyzing the aesthetic dimensions impacting the revitalization of the old fabric of Tabriz. This framework enables the refinement of influential indicators and the distinction of various dimensions related to the renovation process. To propose strategies for renovating the old fabric of Tabriz with an aesthetic approach, the analysis of data and findings reveals that various factors across functional, visual-physical, ecological, and socio-cultural dimensions—have diverse impacts on space quality and the overall desirability of the area. The results of the Friedman and Pearson tests specifically highlight the indicators that should be considered in developing the strategies including:

6.1. Functional strategies

Functional dimensions are among the most important factors in the renovation of old urban fabric. The Friedman test results indicate that indicators such as land use legibility (18.80), suitability of existing land uses for the area (17.75), and the desirability of spaces at night (17.78) play a vital role in enhancing the efficiency and performance of the area. The proposed strategies include:

- Improving the legibility and compatibility of land uses through systematic design and revision of incompatible functions
- Designing spaces with an emphasis on efficient performance to enhance spatial experience and foster a sense of belonging
- Separating noisy land uses and introducing mixed-use developments aligned with urban needs—such as integrating residential, commercial, and cultural functions— can increase social interaction and reduce environmental issues. In this regard, noisy uses should be located away from residential areas and placed in designated zones.
- Spaces for gatherings and social interaction: Designing areas for social gatherings and group activities—such as parks, plazas, and cultural centers—can foster social interaction and a sense of place. Especially, public spaces like cultural centers and cafes with thoughtful design can promote cultural and artistic activities in the old city fabric of Tabriz.

- Desirability of space during day and night: Urban improvement should include spaces that are attractive and functional both during the day and night. Appropriate lighting in public spaces at night, shaded areas during the day, and overall enhancement of urban scenery can add to the appeal of such environments

6.2. Visual-physical strategies

Indicators such as the design of commercial storefronts (17.77), attention to the visual proportions of facades (15.12), identity of architectural details (19.05), and the quality of access to the area (17.75) demonstrate the significance of visual-physical dimensions in the renovation process. The findings also confirm a positive and significant correlation between these dimensions and sociocultural aspects (r =0.236*). Based on this façade design. Emphasizing Tabriz's history and cultural heritage in spatial design can attract tourists and enhance the sense of belonging among residents. Renovating and upgrading building facades using visual harmony and local materials such as stone, wood, and brick can help revive the visual identity of Tabriz. Combining modern facades with traditional and vernacular architectural patterns will give these spaces a unique identity. Storefronts should be designed to harmonize with the city's historical architecture. Using natural materials, local colors, and traditional styles in the design of storefronts can significantly improve the visual and commercial appeal of the area. Attention to design details—including urban furniture, signage, and markers—can strengthen the area's identity. Incorporating cultural symbols and motifs of Tabriz into spatial design can showcase the region's cultural heritage while enhancing spatial aesthetics.

6.3. Ecological strategies

Although the Pearson test results show no significant correlation between ecological dimensions and other aspects, indicators such as the presence of native plants (15.47), consideration of climatic comfort (16.90), and the diversity of green spaces (16.29) highlight the necessity of improving environmental quality. Strategies include:

- Increasing vegetation cover with an emphasis on native species better suited to the local climate.
- Optimizing open space design to reduce air and noise pollution (especially considering the relatively high average levels of both in the area).
- In light of Friedman test results indicating existing pollution, developing green spaces and implementing modern public transport systems can reduce air and noise pollution. Moreover, urban design should prioritize reducing pollution sources, especially in high-traffic areas.
- Climatic design measures, such as creating natural shading and using heat-resistant materials, can offer more comfortable conditions for residents and visitorsand help reduce energy consumption in urban spaces.

6.4. Socio-cultural strategies

Socio-cultural dimensions are among the key components in renovating historical urban fabric. Indicators such as social interaction (17.20), sense of security (18.65), presence of gathering spaces (14.16), and the memorability of space (21.32) play a significant role in enhancing urban quality of life. Designing spaces for cultural, artistic, and social activities can help foster social interaction. Establishing cultural centers, exhibitions, and communal spaces in the Western Tarbiat area can increase the attractiveness of this district for both residents and tourists. Accordingly:

- Create appropriate public spaces for social interaction, such as plazas and local parks.
- Enhance spatial safety through proper urban design, lighting, and effective monitoring.
- Promote cultural and social events to strengthen social bonds.
- Introduce local culture through signage, symbols, and artworks in public spaces to reinforce Tabriz's cultural identity and deepen people's emotional connection to their place of residence

BIM-based construction quality management: A bibliometric analysis

Merve Cetin*[1], Fahriye H. Halicioglu[2]

[1] *Dokuz Eylul University, Graduate School of Natural and Applied Sciences, Department of Architecture, 35390 Izmir, Türkiye*
[2] *Dokuz Eylul University, Faculty of Architecture, Department of Architecture, 35390 Izmir, Türkiye*

Abstract. Building Information Modeling (BIM) has emerged as a transformative tool for the construction industry, offering significant potential to enhance design quality, minimize rework, and reduce conflicts. Integrating quality management within BIM applications ensures that construction processes are efficient, reliable, and aligned with project goals. Quality and its effective management are critical to the success of construction projects, ensuring efficiency, customer satisfaction, and compliance with standards. While "quality" spans various dimensions, including quality management, quality assurance, and quality improvement, its intersection with BIM applications has not been extensively explored. This study aims to conduct a bibliometric analysis of the existing literature to evaluate how BIM is integrated into construction quality management practices. The analysis identifies studies linking BIM with quality-related concepts, such as quality control, management, and continuous quality improvement. By examining publications indexed in the Web of Science (WoS) database from 1980 to 2025, this research aims to uncover patterns, trends, and key research gaps in the literature. Bibliometric tools like VOSviewer will facilitate the visualization of co-occurrence patterns, enabling a deeper understanding of thematic trends. 1,570 relevant articles were retrieved and analyzed, identifying 83 frequently used keywords grouped into six thematic clusters. Additionally, 25 highly cited and thematically relevant publications were reviewed in depth, revealing five dominant focus areas: BIM-based quality management systems, defect prevention and Zero-Defect Manufacturing (ZDM), organizational BIM maturity, process monitoring, and integrating emerging technologies. The findings indicate that BIM contributes to quality improvement across all project stages by enabling better collaboration, real-time monitoring, and process optimization. However, the literature remains largely conceptual, and future research should focus on empirical studies, comparative evaluations, and lifecycle-based assessments to establish measurable links between BIM implementation and quality performance outcomes.

Keywords: Building information modeling (BIM); Quality management; Construction industry; Bibliometric analysis.

1. Introduction

In recent years, Building Information Modeling (BIM) has emerged as a transformative technology within the construction industry, reshaping how projects are designed, managed, and executed. By enabling digital representations of buildings' physical and functional characteristics (Yan and Damian, 2008), BIM facilitates enhanced collaboration among stakeholders, reduces errors and omissions, and significantly improves decision-making processes (Azhar, 2011). One critical area where BIM has the potential to make a substantial impact is quality management, an essential component of successful construction project delivery.

Quality management in construction encompasses a broad range of practices to ensure that processes and outputs meet predefined standards, satisfy client requirements, and minimize rework and inefficiencies (Sun et al., 2017). These practices include quality planning, quality control, quality assurance, and continuous quality improvement. Despite the recognized importance of these concepts, integrating quality management principles into BIM applications has not been thoroughly investigated in the literature (Zhao, 2017). As the construction industry adopts digital tools and platforms, understanding how BIM can contribute to improving quality-related processes becomes increasingly vital. While several studies have explored the capabilities of BIM in areas such as cost estimation, scheduling, clash detection, and sustainability (Parsameh et al., 2023) fewer have directly addressed its role in supporting quality management frameworks. Given the complexity of construction projects and the multidimensional nature of quality, there is a growing need to assess how BIM is currently utilized in this context and identify gaps in the construction literature (Chen and Luo, 2014).

* Corresponding author, E-mail: merve.cetin21@ogr.deu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_884

This study aims to fill this gap by conducting a bibliometric analysis of scholarly publications related to BIM and quality management. By analyzing data from the Web of Science (WoS) database from 1980 to 2025, this research seeks to uncover patterns, trends, and emerging themes within the literature. Using bibliometric tools such as VOSviewer, the study will map out keyword co-occurrences and thematic clusters to provide a comprehensive overview of the current state of BIM-based quality management literature.

1.1 Quality in Construction and Its Relevance to BIM

Quality management in the construction sector is defined by its commitment to ensuring project deliverables meet client expectations, comply with regulatory standards, and are executed efficiently. It comprises four key elements: quality planning, assurance, control, and continuous improvement (Juran, 1992). Traditional practices in the construction industry have been predominantly reactive and paper-based, often leading to inefficiencies and overlooked quality issues. Recent research has highlighted the potential for integrating BIM into quality management processes for integrated and proactive quality management (Choi, Lee, and Kim, 2020). To understand BIM's contribution to quality in construction, it is essential first to define what "quality" entails. Sower and Fair (2005) noted that quality lacks a universal definition and is shaped by objective standards and user perception. Hoyer and Hoyer (2001) distinguish between two dimensions: one that aligns with technical specifications and another that emphasizes client satisfaction. This distinction is critical in BIM-enabled environments, where design outputs can be tailored through simulations to align with both performance metrics and user expectations.

Garvin (1984) outlines eight quality dimensions—performance, features, reliability, conformance, durability, serviceability, aesthetics, and perceived quality—that provide a structured approach to technically and perceptually assessing buildings. These dimensions gain practical relevance in BIM-integrated projects, where digital simulations can anticipate durability, energy use, and maintenance performance.

Juran's (1986) "Quality Trilogy"—comprising quality planning, control, and improvement—offers a useful lens for understanding how BIM supports quality at multiple stages.

- *Quality planning* involves setting project standards and ensuring alignment with client expectations. BIM enhances this by supporting early-phase scenario analysis, parametric design, and stakeholder engagement. Parasuraman et al.'s (1985) five quality gaps—understanding, design, process, operations, and perception—are also addressed through BIM's visual and collaborative features.
- *Quality control* is operationalized in BIM through real-time progress tracking, clash detection, and compliance verification, helping to detect deviations and correct them before costly errors arise. Juran (1986) highlighted that control is vital for maintaining output stability. BIM transforms this function from reactive inspections to anticipatory oversight.
- *Quality improvement* focuses on refining processes and outcomes. BIM supports two complementary strategies: income-oriented improvement through enhanced visualization and customization, and deficiency-oriented improvement by addressing root causes of inefficiency. Its simulation, data analytics, and feedback mechanisms enable a culture of continuous enhancement.

Golder et al. (2012) conceptualize quality as a dynamic process involving three interconnected stages: production, experience, and evaluation. BIM enhances each of these. During quality production, BIM facilitates stakeholder collaboration and simulation during early design phases. In quality experience, it ensures alignment with user needs via walkthroughs and performance modeling. In quality evaluation, it offers measurable post-occupancy data and benchmarks for assessing performance and guiding improvements.

2. Materials and Methods

This study aims to review the literature concerning the relationship between BIM and quality management through bibliometric methods. Analyzing publications indexed in the Web of Science database investigates how this relationship has been conceptualized, which dimensions and disciplines have been engaged, and what methodologies and research themes have been utilized. The study maps frequently used keywords and thematic clusters.

Bibliometric analysis utilizes various indicators and methods to evaluate the productivity, impact, and structural dynamics of scientific research, with productivity measured by publication volume across individuals, institutions, or countries, and impact assessed through citation counts, the h-index, and journal impact factors; structural analysis, on the other hand, employs techniques like citation analysis, co-citation, bibliographic coupling, co-authorship, and co-word analysis to reveal influential works, research clusters, collaboration networks, and thematic developments, offering a holistic view of knowledge generation (Zupic and Čater, 2015).

The reliability of such analysis depends heavily on high-quality bibliographic data from sources like the Web of Science, Scopus, and Dimensions, which provide detailed metadata. Tools such as VOSviewer, developed by Van Eck and Waltman (2010), enable the visualization of co-authorship, co-citation, and keyword networks.

In the context of this study, bibliometric analysis serves as a methodological foundation through which the integration of BIM into quality management practices within the construction industry is explored. Through a structured examination of academic publications, this approach aims to uncover:

- The evolution of research on BIM-related quality concepts (e.g., quality control, quality assurance, continuous improvement),
- Emerging research clusters and thematic trends,
- Potential gaps in the current literature.

Rather than relying solely on narrative literature review, bibliometric analysis provides an objective and reproducible method to evaluate a domain's current state of knowledge (Zupic and Čater, 2015). It facilitates the identification of underexplored areas in which BIM's role in quality management may be expanded, thereby contributing to forming a conceptual framework for future integration. The subsequent section presents the specifics of data collection, such as the selection of search terms, publication years, and database parameters. It outlines the practical implementation of the method adopted in this study.

3. Results and Discussion

In this research, the initial aim was to identify keywords related to the concept of quality to understand the relevant literature better. Thus, the goal was to access the term "quality" and other thematically related concepts. The search was conducted on the Web of Science database using filters for article type, English language, and inclusion in "SCI-Expanded" and "SSCI" indexes. Under these criteria, 2,481,042 records were retrieved. Using the refined tools of Web of Science—namely Web of Science Categories, Citation Topics Meso, Citation Topics Micro, and Research Areas—the dataset was narrowed down to 23,536 articles. When these were transferred to VOSviewer, 48,047 keywords were detected. Applying a minimum threshold of 35 occurrences, 271 keywords, and 6 clusters were identified. After eliminating unrelated terms, 38 keywords remained, which were grouped into five thematic categories: 1) Quality Management and Evaluation, 2) Project and Process Management, 3) Construction Sector and BIM-Related Terms, 4) Organizational Structures and Management, and 5) Optimization and Decision-Making Tools. These terms laid a foundation for evaluating the relationship between BIM and quality.

To further explore this relationship, a new search was conducted using the query TS=("building information modeling" OR "building information model" OR "BIM" OR "digital twin" OR "bim") AND TS=("quality" OR "tqm" OR "continuous improvement" OR "process improvement" OR "performance evaluation" OR "performance measurement" OR "six sigma" OR "taguchi method"). Applying the same filters (English, article type, SSCI/SCI-Expanded indexes), the search yielded 1,570 articles. (When the keyword "digital twin" was excluded, only 795 articles remained, thus justifying its inclusion.) In the conducted research, it has been revealed that the fields contributing to quality within the context of building information modeling (BIM) extend across a wide range of disciplines. these include management, computer vision & graphics, sustainability science, supply chain & logistics, knowledge engineering & representation, remote sensing, artificial intelligence & machine learning, statistical methods, optical electronics & engineering, design & manufacturing, software engineering, automation & control systems, and thermodynamics. This finding demonstrates the multidisciplinary nature of quality enhancement in BIM-based systems and emphasizes the importance of integrating technological, managerial, and analytical perspectives for effective implementation. The 1,570 retrieved articles were transferred to the VOSviewer tool. When the option "Create a map based on bibliographic data" was chosen, and the analysis type was set to "co-occurrence" and "author keywords," the program identified 5093 keywords that appeared at least once across the articles. These 5093 keywords may include repetitions. Therefore, to determine which keywords were used more frequently and to perform a density analysis, the minimum number of occurrences for a keyword was set to "10" using the "choose threshold" tab. By applying a minimum occurrence threshold of 10, the program filtered the initial 5093 keywords down to 83 with sufficient frequency for analysis. Fig. 1 illustrates the distribution and interrelations of these 83 terms. When examining the keywords of studies conducted on BIM and quality (Table 1), six thematic categories emerge: BIM, digital models and visualization, construction management and BIM application, quality management and assessment, digital technologies and industry 4.0, AI, simulation and data analysis, and sustainability.

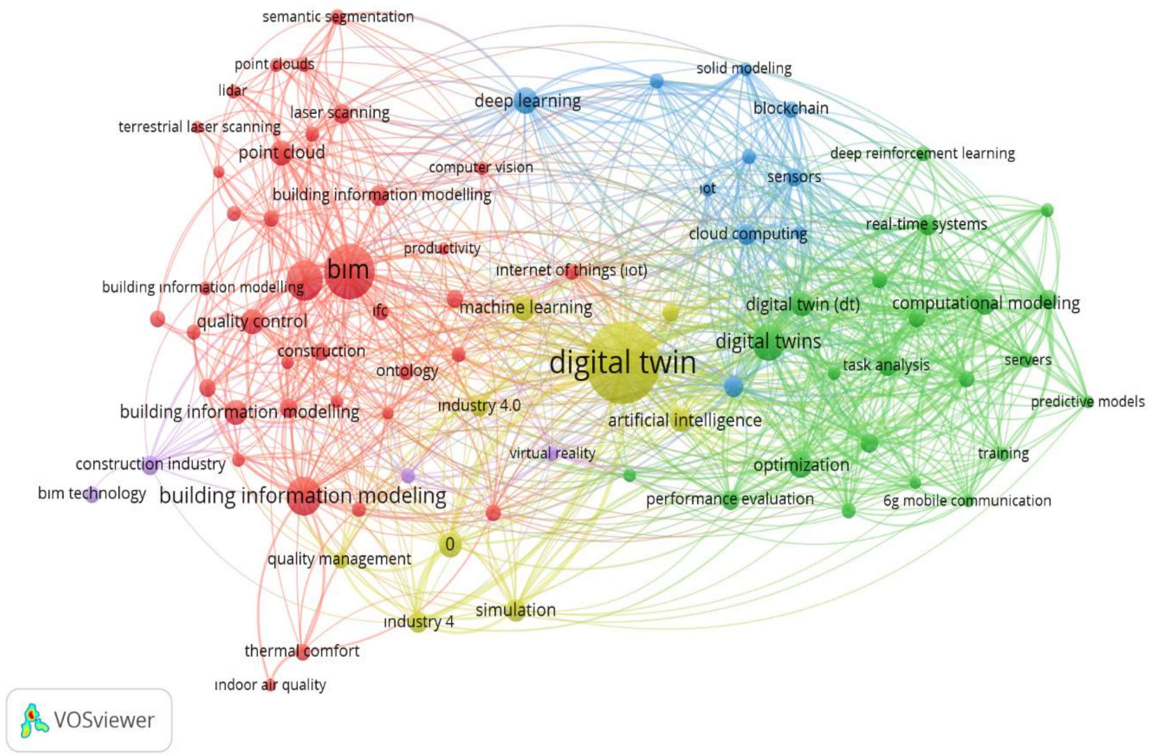

Fig. 1. Keyword Co-occurrence Map of 83 Terms (from 5093 keywords in 1,570 articles; min. occurrence: 10)

Table 1. Thematic Classification of Keywords in the Context of BIM and Quality Management

BIM, Digital Models & Visualization	Construction Management & BIM Application	Quality Management & Assessment	Digital Technologies & Industry 4.0	AI, Simulation & Data Analysis	Sustainability
digital twin	task analysis	quality control	cloud computing	deep learning	sustainability
building information modeling (bim)	construction industry	performance evaluation	internet of things(iot)	optimization	energy efficiency
point cloud	resource management	costs	real-time systems	machine learning	thermal comfort
laser scanning	facility management	quality of service	industry 4.0	computational modeling	indoor air quality
industry foundation classes (ifc)	construction management	quality management	servers industry 4.0	computer vision artificial intelligence	
3d reconstruction	automation	monitoring	edge computing	simulation	
three-dimensional displays	project management	quality assurance	sensors	data models	
augmented reality	resource allocation	quality	smart manufacturing	ontology	
building ınformation modeling	interoperability		blockchain	deep reinforcement learning	
virtual reality lidar	collaboration		internet of things (iot)	semantic segmentation	
point clouds	prefabrication		digitalization	predictive models	
scan-to-bım	productivity		mobile edge computing		
solid modeling			wireless communication		
terrestrial laser scanning			6G mobile communication		

As seen in Table 1, this classification highlights the multidimensional nature of the literature on the relationship between BIM and quality management, illustrating the technological, managerial, and analytical concepts that are most frequently addressed. It also provides researchers with a roadmap to explore in-depth analyses of datasets aligned with these thematic focuses.

According to the VOSviewer analysis, the concept of quality is frequently explored in conjunction with topics such as zero-defect manufacturing, quality management, modular construction, quality assurance, progress monitoring, automation, and point clouds, particularly within the domain of quality control. Fig. 2 visualizes the connections between "quality control" and 82 related keywords. Beyond its associations with BIM and digital twins, quality control exhibits thematic development through its links to point clouds, automation, modular construction, project management, progress monitoring, quality assurance, and zero-defect approaches. Similarly, Fig. 3 shows that quality assessment and its connection to BIM and digital twins evolve thematically through their ties to laser scanning and modular construction. Fig. 4 reveals that quality management, likewise associated with BIM and digital twins, is thematically linked to system dynamics, Industry 4.0, simulation, digitalization, sustainability, and zero-defect manufacturing.

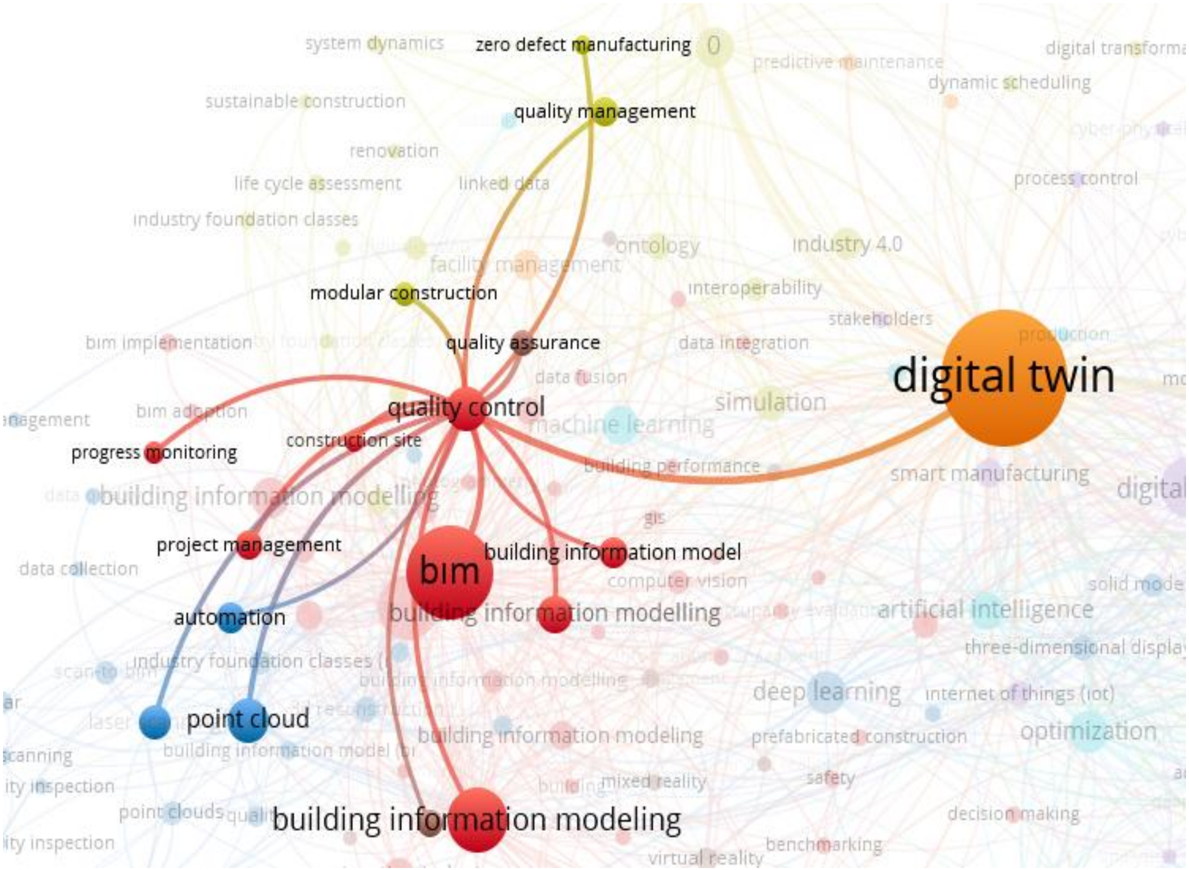

Fig. 2. Thematic Network of Keywords Associated with "*quality control*" Based on Co-occurrence Analysis

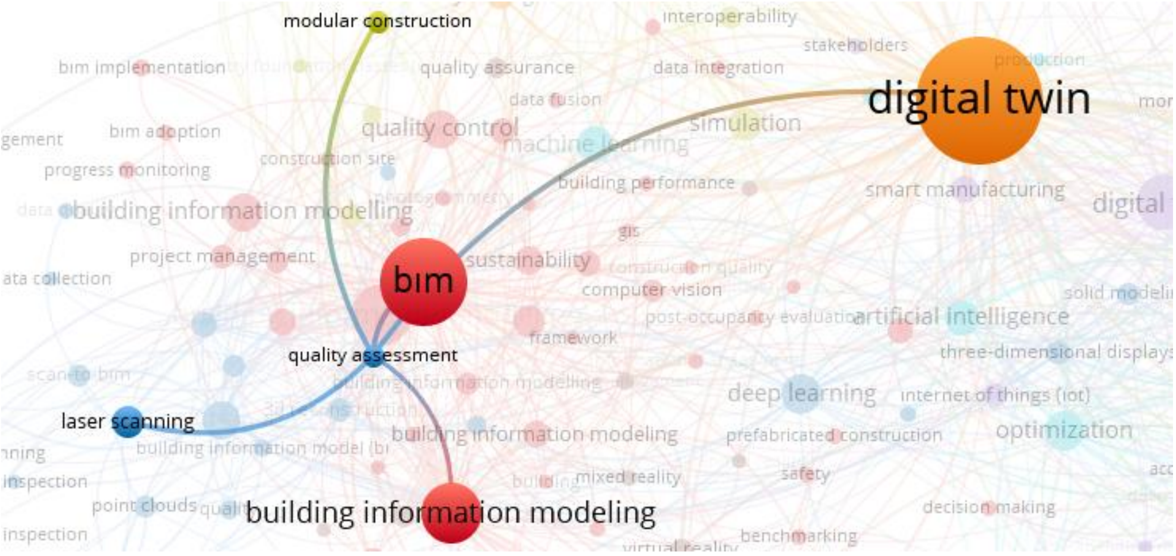

Fig. 3. Thematic Network of Keywords Associated with “*quality assessment*” Based on Co-occurrence Analysis

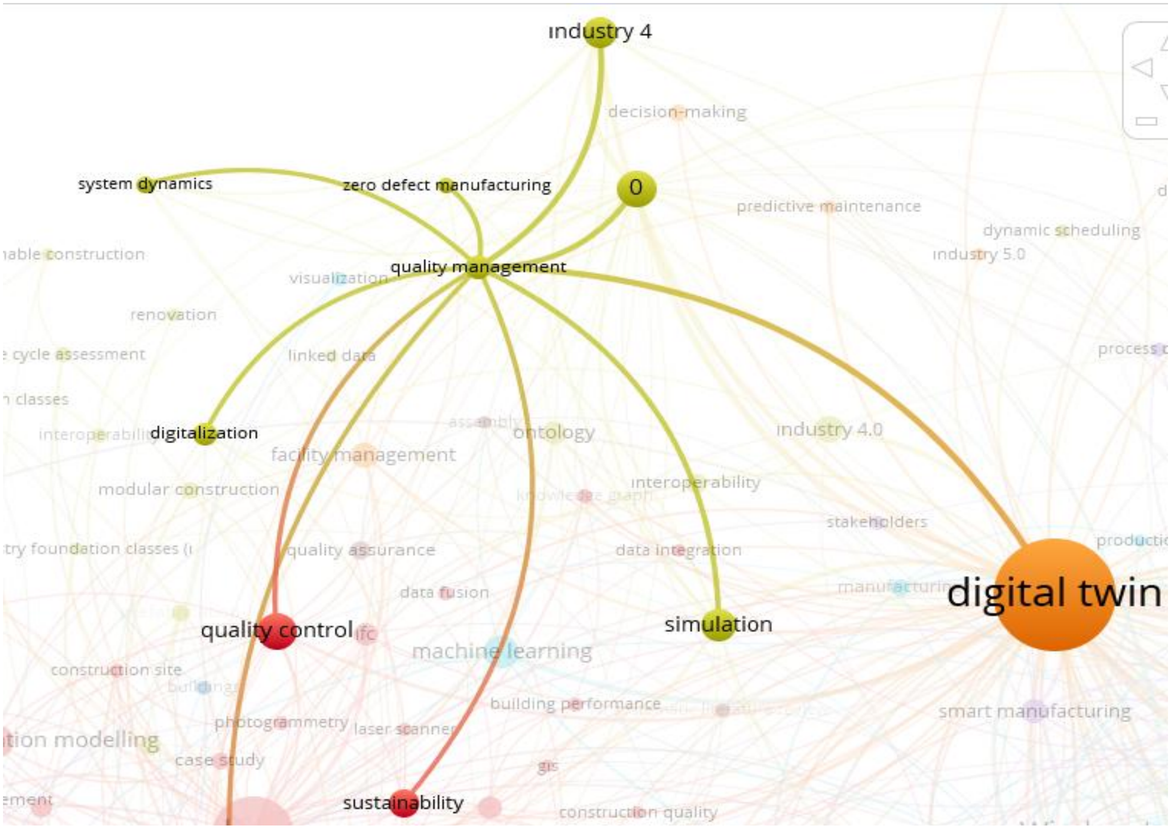

Fig. 4. Thematic Network of Keywords Associated with “*quality management*” Based on Co-occurrence Analysis

The thematic analysis of Fig.s 2, 3, and 4 reveals that quality-related concepts in the construction industry (namely *quality control*, *quality assessment*, and *quality management*) are strongly associated with digital technologies such as *BIM* and *digital twin*. A recurring theme across all three categories is integrating modular construction and pursuing *zero-defect* objectives, highlighting the industry's shift toward precision-driven and standardized production models. Moreover, while *quality control* is primarily linked to operational tools like *automation* and *point cloud*, *quality assessment* focuses on evaluation technologies such as *laser scanning*. In contrast, *quality management* demonstrates a broader strategic scope, aligning with system dynamics, Industry 4.0, and sustainability concepts. These findings suggest that quality in the construction sector is evolving through a multi-dimensional framework that combines real-time data, digital workflows, and long-term system optimization.

In this paper, a detailed review was also conducted on 25 thematically relevant papers selected from the top 200 most-cited among the 1,570 articles. Of these, 25 papers were chosen based on thematic relevance and reviewed in depth. The results are presented in Table 1, where the "Findings" column summarizes how each publication addresses the connection between BIM and quality.

Table 2. Summary of Key Findings from Selected BIM and Quality Management Studies

Source	Title	Findings
Psarommatis et al. (2022)	*"Zero-defect manufacturing: the approach for higher manufacturing sustainability in the era of industry 4.0: a position paper"*	This position paper establishes the conceptual foundation for Zero-Defect Manufacturing (ZDM) as a superior alternative to traditional quality improvement methods in the Industry 4.0 era. While it does not directly address BIM integration, it promotes a systemic shift in quality thinking that provides a valuable reference point for quality-driven BIM applications and smart construction environments.
Powell et al. (2022)	*"Advancing zero defect manufacturing: A state-of-the-art perspective and future research directions"*	The article positions Zero Defect Manufacturing as a transformative evolution of traditional quality management philosophies, aiming for systematic defect prevention and compensation across manufacturing and construction workflows. It highlights how moving towards a zero-waste, high-quality value chain strategy significantly strengthens sustainable and resilient quality assurance practices.
Yuan et al. (2022)	*"Digital twin-driven vehicular task offloading and IRS configuration in the Internet of Vehicles"*	While the article discusses digital twin and quality-related concerns such as latency and energy efficiency, it focuses entirely on vehicular networking in 6G environments, rather than construction or BIM-based quality improvement.
Wu et al. (2021)	*"On-site construction quality inspection using blockchain and smart contracts"*	This article proposes a blockchain-based framework for construction quality inspection, ensuring immutability, transparency, and automation in quality-related data management. Integrating smart contracts and IoT paves the way for real-time, secure, and reliable quality assurance, minimizing human error and enhancing accountability in on-site construction processes.
Psarommatis (2021)	*"A generic methodology and a digital twin for zero defect manufacturing (ZDM) performance mapping towards design for ZDM"*	The article proposes a forward-thinking ZDM methodology using digital twin simulations and Taguchi experiment design. This methodology enables real-time strategy mapping and performance optimization across manufacturing stages. Shifting from reactive to predictive quality control presents a strategic, data-driven framework for designing quality from the start of the production process.
Sheng et al. (2020)	*"Construction quality information management with blockchains"*	The article presents a blockchain-based framework that enables secure, transparent, and decentralized management of construction quality information. Improving traceability and accountability among stakeholders directly strengthens quality assurance processes and provides a digitally trustworthy infrastructure for managing nonconformance data in construction.
Franciosa et al. (2020)	*"Deep learning enhanced digital twin for Closed-Loop In-Process quality improvement"*	The article introduces a self-correcting, intelligent quality system by integrating a digital twin, deep learning, and CAE simulation to enable real-time defect prediction and mitigation. Its closed-loop framework supports continuous, automated, and in-process quality improvement, marking a shift from reactive to proactive quality control in manufacturing.
Maskuriy et al. (2019)	*"Industry 4.0 for the construction industry—how ready is the industry?"*	The article highlights how integrating BIM within Industry 4.0 cyber-physical systems enhances automation, optimizes data management, and improves construction lifecycle quality. Increasing accuracy, reducing errors, and promoting efficient workflows significantly contribute to continuous quality improvement and productivity gains in construction projects.

Table 2. continued.

Ma et al. (2018)	***“Construction quality management based on a collaborative system using BIM and indoor positioning”***	**The article enhances construction quality management by integrating BIM and indoor positioning technologies to enable more accurate, efficient, and collaborative inspection processes. Minimizing human errors and improving real-time stakeholder collaboration significantly support continuous quality assurance throughout the construction phase.**
Chen et al. (2018)	*“Construction automation: Research areas, industry concerns, and suggestions for advancement”*	Although the article does not propose a direct quality management model, it highlights how construction automation contributes to process consistency, error reduction, and improved productivity, all of which are fundamental quality aspects. It supports the strategic integration of automation into construction workflows to enhance process quality and overall performance.
Franz et al. (2017)	*“Impact of team integration and group cohesion on project delivery performance”*	The article demonstrates that higher team integration and cohesion significantly improve project quality, schedule, and cost outcomes. It highlights that quality management in construction is not only a matter of technical standards but also critically depends on organizational structure, communication efficiency, and collaborative practices, particularly those enabled by early contractor involvement and multidisciplinary BIM usage.
Gerrish et al. (2017)	*“BIM application to building energy performance visualization and management: Challenges and potential”*	The article explores how BIM can be utilized as a performance management tool by linking it with building management systems to visualize and optimize building operations. It improves quality by addressing data integration, behavioral adaptation, and technological alignment, enhancing operational building performance and overall quality outcomes.
Zadeh et al. (2017)	*“Information quality assessment for facility management”*	This article introduces a structured framework for evaluating the information quality of BIM models used in facility management. Aligning BIM content with FM user needs and operational demands provides a systematic and practical approach to ensuring model quality conformance, directly supporting long-term building performance and maintenance efficiency.
Smits et al. (2017)	*“Yield-to-BIM: impacts of BIM maturity on project performance”*	The article highlights that only strategic maturity in BIM implementation significantly predicts time, cost, and quality performance improvements. It emphasizes that BIM’s impact on quality depends on how strategically and intentionally it is embedded within organizational practices, not merely on its technical adoption.
Shalabi and Turkan (2017)	*“IFC BIM-based facility management approach to optimize data collection for corrective maintenance”*	The article demonstrates how leveraging BIM’s visualization and interoperability capabilities enhances the quality and efficiency of corrective maintenance data collection in facility management. Integrating maintenance alarms with related operational data in a 3D IFC-BIM environment improves response times, maintenance quality, and overall operational performance throughout the building lifecycle.
Giel and Issa (2016)	*“Framework for evaluating the BIM competencies of facility owners”*	The article provides a structured framework for building owners to evaluate and improve their BIM competencies, enhancing post-construction quality, data accuracy, and decision-making efficiency. Fostering lifecycle-oriented BIM strategies ensures quality is maintained and optimized beyond the design and construction phases.

Table 2. continued.

Oesterreich and Teuteberg (2016)	***"Understanding the implications of digitisation and automation in the context of Industry 4.0: A triangulation approach and elements of a research agenda for the construction industry"***	**The article investigates how the productivity—and quality-enhancing effects of digitisation and automation in manufacturing can be adapted to the construction industry. In this respect, it contributes to quality through a political and technological infrastructure perspective. Although it does not propose a direct quality model, it establishes a framework that promotes quality awareness.**
Abanda et al. (2015)	*"A critical analysis of Building Information Modelling systems used in construction projects"*	The article evaluates how different BIM systems impact information management, workflow efficiency, and project quality in the construction industry. Promoting more informed selection and strategic use of BIM software indirectly supports enhanced project outcomes and higher quality standards in construction projects.
Göçer et al. (2015)	*"Completing the missing link in building design process: Enhancing post-occupancy evaluation method for effective feedback for building performance"*	The article proposes integrating post-occupancy evaluation results into BIM models to create a continuous feedback loop for improving performance. Embedding operational insights into future designs directly supports long-term quality enhancement across the building's lifecycle, not just at the construction phase.
Wang et al. (2015)	*"Integrating BIM and LiDAR for real-time construction quality control"*	The article develops an integrated BIM and LiDAR-based system that enhances real-time defect detection and construction quality control. Enabling proactive quality management through real-time data processing significantly improves construction quality assurance efficiency, accuracy, and responsiveness.
Oh et al. (2015)	*"Integrated system for BIM-based collaborative design"*	The article enhances design phase quality by developing an integrated BIM-based system that addresses data loss, communication challenges, and workflow inefficiencies. Strengthening collaboration and ensuring data consistency across stakeholders significantly contributes to higher design quality and process efficiency in construction projects.
Al Hattab and Hamzeh (2015)	*"Using social network theory and simulation to compare traditional versus BIM–lean practice for design error management"*	The article introduces a novel framework for managing design errors by emphasizing team dynamics, early error identification, and communication patterns. Integrating BIM and lean methodologies supports a proactive and systemic approach to error prevention and quality improvement throughout the design phase.
Miettinen and Paavola (2014)	*"Beyond the BIM utopia: Approaches to the development and implementation of building information modeling"*	The article advocates for adopting local experimentation and organizational learning beyond normative standards in BIM implementation. This approach provides realistic and sustainable pathways for improving design and construction quality. While it does not propose a direct quality model, it establishes an intellectual foundation supporting organizational quality maturity development.
Chen and Luo (2014)	*"A BIM-based construction quality management model and its applications"*	The paper proposes a 4D BIM-based framework for integrated quality control during construction, linking design, organizational, and process data through a POP structure. By visualizing and managing quality requirements in real time, the study demonstrates how BIM can be an effective tool for proactive quality management beyond the design phase.
Park et al. (2013)	*"A framework for proactive construction defect management using BIM, augmented reality, and ontology-based data collection template"*	The article proposes an integrated system combining BIM, augmented reality, and ontology to enable proactive defect prevention in construction processes. It improves quality by enhancing data accuracy, defect traceability, and real-time field management.

This study conducts a thematic analysis of 25 high-impact, peer-reviewed articles (as presented in Table 2) investigating the intersection of Building Information Modeling (BIM) and quality management within the construction industry. Drawn from an initial pool of 200 highly cited publications, these selected studies offer critical insights into BIM's multifaceted contributions to quality enhancement across various dimensions of construction processes. The analysis identifies five overarching thematic categories emerging from the literature, as follows:

- *BIM-Based Quality Management Systems:*

Articles in this group focus on integrating BIM with quality workflows using technologies such as blockchain for data integrity, IFC-based data modeling, and BIM–Facility Management (FM) platforms. These systems help automate inspections, standardize documentation, and ensure traceability throughout the building lifecycle, supporting transparency and accountability.

- *Defect Prevention and Zero-Defect Manufacturing (ZDM):*

These studies align with Industry 4.0 paradigms, proposing proactive and predictive models that prevent quality issues rather than merely detect them. Digital twins, AI-enhanced real-time monitoring, and closed-loop defect control mechanisms are central to this theme, enabling early detection and response within construction or manufacturing processes.

- *Organizational BIM Maturity and Strategic Integration:*

Several articles emphasize that the success of BIM in quality enhancement is highly dependent on strategic maturity, institutional readiness, and integrated workflows. Without organizational alignment, BIM adoption may yield only partial benefits. This theme underscores the need for investment in training, culture change, and long-term digital strategies.

- *Process Monitoring, Feedback, and Lifecycle Evaluation:*

This cluster includes real-time progress monitoring, performance evaluation, and post-occupancy feedback studies. BIM manages construction and gathers operational data that informs future design and operation decisions, promoting a continuous improvement cycle.

- *Emerging Digital Technologies and Quality Enhancement:*

The final group explores advanced digital integrations including blockchain, IoT, AR, and AI. These technologies provide enhanced visibility, data security, and automation to the quality process, making quality management more responsive, accurate, and decentralized.

An in-depth analysis of the selected 25 articles reveals a diverse application of BIM tools in quality management. The most frequently employed features include 4D BIM, IFC-based modeling, BIM–FM integration, and digital twin systems. Additionally, advanced technologies such as augmented reality (AR), blockchain-enabled quality tracking, indoor positioning systems, and AI-driven analytical tools are increasingly utilized in quality control processes. These tools facilitate faster information flow, reduce defect rates, and enhance inspection traceability. As for quality indicators, the reviewed studies commonly emphasize traditional performance criteria such as cost control, schedule adherence, and defect/error rates. However, digital transformation-oriented metrics such as data accuracy, rework reduction, user feedback integration, preventive maintenance efficiency, and automation levels in quality assurance are also prevalent. In terms of methodology, the studies predominantly rely on case study analyses and conceptual framework proposals, while also incorporating simulation models, prototype system designs, systematic literature reviews, surveys, and the Delphi method. This variety highlights the multidimensional nature of BIM in addressing quality management both theoretically and practically.

4. Conclusions

To investigate how BIM is integrated into quality management practices, a bibliometric analysis was conducted using the Web of Science (WoS) database in this study. The findings indicate that the relationship between Building Information Modeling (BIM) and quality management in the construction industry has evolved through a multidimensional framework that integrates technological, managerial, and analytical perspectives. The bibliometric analysis of 1,570 articles identified 83 frequently used keywords, categorized into six thematic clusters, reflecting the key areas where BIM intersects with quality concepts. *Quality control*, *quality assessment*, and *quality management* are thematically connected with concepts such as BIM, digital twin, modular construction, automation, point cloud, laser scanning, simulation, Industry 4.0, and sustainability. A detailed review of 25 highly cited and thematically relevant studies revealed five dominant themes: (1) BIM-based quality management systems, (2) defect prevention and Zero-Defect Manufacturing (ZDM), (3) organizational BIM maturity and strategic integration, (4) process monitoring and lifecycle evaluation, and (5) emerging digital technologies in quality enhancement. These studies showed that while BIM tools like 4D modeling, IFC-based data exchange, and digital twins improve efficiency and quality oversight, the success of BIM in quality outcomes also depends on strategic planning, organizational culture, and integration with advanced technologies such as blockchain, IoT, and AI. The reviewed 25 studies mostly emphasized cost, time, and defect reduction improvements, highlighting new digital performance indicators such as data accuracy, process automation, and post-occupancy feedback integration.

BIM's role in quality should not be viewed solely as a technological innovation but as a comprehensive digital transformation strategy encompassing data management, organizational change, and capacity-building initiatives, such as training programs. Although the reviewed studies provide valuable conceptual frameworks and proof-of-concept applications, there is a noticeable lack of empirical evidence that links BIM usage to quantifiable quality outcomes. The majority of the existing contributions are either exploratory or theoretical in nature. Future research should focus on establishing empirical correlations between BIM implementation and specific quality indicators, such as cost reductions and defect rates. Additionally, there is a need for comparative studies that examine the impact of BIM across various project types, countries, and organizational settings. Extending quality management research beyond the construction phase to include operational, maintenance, and sustainability aspects within the BIM ecosystem will further enhance the holistic understanding of BIM's influence on quality across the project lifecycle.

Non-formal learning environments and their importance in architectural education

Merve Uluçay Temel*[1], Derya Elmalı Şen[1]

[1] Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye

Abstract. Non-formal learning refers to the processes through which individuals acquire knowledge via experiential, social, or everyday practices that occur outside of a structured curriculum or formal instructional setting. Particularly in the context of higher education, it enables individuals to enhance their personal competencies, strengthen critical thinking skills, and improve their capacity for creative problem-solving. In disciplines that encompass both technical and artistic dimensions, such as architectural education, classroom-based formal education alone is often insufficient. Therefore, non-formal learning environments serve as a vital complement to formal education by providing flexible, participatory alternatives that support individual development. This study focuses on non-formal learning within architectural education. As a literature-based investigation, it explores the limitations experienced by architecture students engaged in formal learning processes and examines the contributions that non-formal learning environments offer. Within this context, the concepts of formal, non-formal, and informal learning are defined, and the specific contributions of non-formal learning to architectural education are discussed.

Keywords: Architectural education; Learning environments; Formal learning; Non-formal learning; Informal learning.

---

1. Introduction

While vocational education processes provide individuals with certain knowledge and skills, the deepening of expertise and competencies acquired through these processes depends on personal experience and the assimilation of knowledge across diverse contexts. Although many of these requirements are addressed during traditional formal education, it is crucial for individuals to engage with experience-based learning opportunities offered by non-formal environments to further develop their expertise. In particular, individuals seeking to gain competencies in diverse domains should actively participate in less formal, flexible, and practice-oriented learning processes alongside structured educational experiences (Johnson & Majewska, 2024). Considering the rapidly evolving demands for knowledge and skills in today's world, integrating these two structures in a complementary manner presents important opportunities for developing more adaptable and learner-centered educational models. In this regard, the supplementary role of non-formal learning environments in supporting formal education warrants further investigation.

In today's educational landscape, where pedagogical paradigms are becoming increasingly flexible and multidimensional, the transformation of vocational education has become inevitable. Architectural education, in particular—a field that is both creative and practice-oriented—is significantly affected by this shift. It aims to foster students' active engagement in conceptualization, design, critical thinking, and construction processes, while simultaneously enhancing individual expression and representational abilities (UIA, 2023). However, acquiring these skills solely through formal, classroom-based instruction is insufficient due to the inherent nature of architectural education. As a discipline, architecture necessitates the continuous monitoring of technological innovations, sociocultural transformations, and environmental dynamics. Consequently, a learning approach confined strictly to the parameters of a structured curriculum cannot fully accommodate the dynamic demands of the profession or lifelong learning (Cantürk Akyıldız & Özgüven, 2024).

Against this backdrop, the present study focuses on the role of non-formal learning environments within architectural education. This literature-based research examines the limitations faced by architecture students engaged in formal learning processes and explores the ways in which non-formal environments address these challenges. To this end, the study first defines formal, non-formal, and informal learning types, outlining their similarities and differences. It then identifies the shortcomings of formal education within architectural pedagogy

* Corresponding author, E-mail: ulucay.merve@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_941

and highlights the potential of non-formal environments as a supportive mechanism for addressing these gaps. The analysis explores how students incorporate non-formal learning environments into their broader learning ecosystems and how such environments help them to navigate and overcome the limitations of formal instruction. Ultimately, the study aims to illuminate the complementary relationship between the rigid structure of formal education and the flexibility provided by non-formal learning environments.

A further aim of the study is to clarify the conceptual ambiguities identified in the existing literature. In Turkiye, particularly in studies focused on architectural education, notable inconsistencies exist in the terminology used to define learning processes. It is frequently observed that all learning outside of formal education is broadly labeled as “informal learning environments” (Yılmaz, 2009; İmamoğlu, 2019; Sarman, 2021; Özdemir Gökmen, 2023). The significance of this research lies in its effort to provide a clearer conceptual framework for distinguishing non-formal learning in the context of architectural education. By critically analyzing and differentiating these learning types—often conflated under generalized terms—the study contributes a more nuanced theoretical perspective to the field.

2. Types of Learning

Education is a multidimensional process that supports the cognitive, affective, and social development of individuals. In the literature of educational sciences, learning is commonly categorized under three main headings: Formal Learning, Non-Formal Learning, and Informal Learning (OECD, 2010). These learning types differ in terms of the learner’s level of participation, the context in which learning occurs, and the modes of assessment. However, they are often regarded as complementary components within a broader educational ecosystem (Rogers, 2014). Therefore, in order to define non-formal learning meaningfully, it is essential to explore its relationship with both formal and informal learning.

Formal learning occurs within structured and institutionalized environments, follows a defined curriculum, and typically results in a diploma or certificate (UNESCO, 2012). A formal curriculum represents a written program organized around specific content areas, topics, and learning resources, assessed through theoretical or practical examinations (Leask, 2009, p. 207). In this model, the roles of the instructor and the learner are clearly defined, and the content, learning objectives, and assessment criteria are predetermined. Every phase of the learning process is planned and intentional, and student participation is regulated by certain obligations.

Through its structured framework, formal learning contributes to standardizing knowledge and skills, thereby promoting equality and accessibility in education. It enhances social mobility and provides disadvantaged individuals with opportunities for upward movement in society. Additionally, it plays a crucial role in preserving and transmitting society’s collective knowledge—such as history, science, and culture—across generations. Formal education also ensures the traceability and accountability of learning through systematic evaluation processes (Johnson & Majewska, 2022). Nevertheless, despite these strengths, formal learning can bring about various structural and functional limitations that may negatively impact students’ academic performance and learning motivation. Hence, integrating formal education with other learning types is essential for a more effective and holistic learning experience.

Informal learning, in contrast, refers to lifelong learning processes through which individuals acquire knowledge, skills, attitudes, and insights from everyday experiences and environmental interactions (Coombs & Ahmed, 1974). This form of learning is unstructured and typically lacks a defined curriculum, teaching plan, or formal assessment (OECD, 2010). It occurs spontaneously and naturally, with outcomes that are not predetermined. Instructors are often not professional educators, but rather individuals such as parents, grandparents, peers, or experienced community members. Informal learning extends beyond institutional settings and may take place at home, in workplaces, community centers, or during leisure activities. Despite the absence of formal organization, it significantly contributes to cognitive, social, and emotional development. Notably, informal learning represents a substantial portion of lifelong learning and remains impactful even among individuals with advanced formal education (Coombs & Ahmed, 1974; Johnson & Majewska, 2022).

Non-formal learning encompasses structured, planned, and organized learning processes that occur outside the formal education system and do not lead to an official diploma or academic degree. While it is goal-oriented and systematic in nature, participation is voluntary and often aims to enhance the learner’s social, cultural, or professional development.

In non-formal learning, learners typically steer the process based on their interests and needs, while the instructor serves as a facilitator or guide. Effective peer communication and collaboration are central to this approach, which fosters individual motivation and strengthens social cohesion (Özsoy et al., 2017). Examples of non-formal learning environments include online or in-person courses, workshops, summer schools, volunteer projects, and seminars (Harris & Wihak, 2018). Furthermore, the flexible structure of non-formal learning supports learner autonomy and contributes to the cultivation of a lifelong learning culture by enabling individuals to tailor their educational pathways.

Formal, non-formal, and informal learning differ in terms of structure, methodology, and objectives. However, it is not always possible to draw strict boundaries between these forms, as they often demonstrate overlapping features and complement one another. Table 1 provides a comparative overview of the key characteristics of these three learning types, highlighting both their similarities and distinctions.

Table 1. Comparing structural and formal characteristics of learning types (Johnson & Majewska, 2022).

Features	Formal Learning	Non-Formal Learning	Informal Learning
Structure	Structured (includes linear objectives)	Can be structured	Not structured
How Learning is Incentivized	Promoted through direct teaching behaviors	Promoted through indirect teaching behaviors	Learning is encouraged in the natural process
Defining Learning	Defined by the trainer and the learner	Defined in line with the learner's purpose	Learning is shaped by the needs of the learner
Motivation	Extrinsic motivation is dominant	Intrinsic motivation is an important element	Intrinsic motivation is naturally part of the process
Realization Location	Takes place in educational institutions	Can take place inside or outside educational institutions	Can take place in any setting (home, work, community)
Participation Status	Mandatory	Can be voluntary	It is based on volunteerism
Measurement and Evaluation	Defined and measured through competencies	Identifiable or measurable through competencies	Outcomes of learning are not always measured or assessed by qualifications
Cognitive Dimension	High emphasis on cognitive knowledge	Includes cognitive, affective and social elements	Cognitive, affective and social development is supported in the natural process
Curriculum	It is written down and mandatory	Can be written down	No written curriculum
Learning Process Aspect	Top-down: transferring specific knowledge and skills	Bottom-up: focused on the needs of the learner	It develops completely spontaneously according to the needs of the individual
Relationship with Curriculum	Follows the official curriculum	Can complement the formal curriculum	Often not directly linked to the formal curriculum
Relationship with Socialization	Linked to socialization	May or may not be linked to socialization	Often strongly linked to socialization

An examination of the key characteristics compared in the table reveals that formal, non-formal, and informal learning styles possess distinct structural features; however, these differences do not establish rigid boundaries. Informal learning occurs spontaneously at every stage of the learning process, as it is shaped by unplanned and unstructured experiences that naturally unfold throughout an individual's life. Therefore, informal learning is not the opposite of formal education but rather a natural complement to it, often interwoven with formal structures. Conversely, non-formal learning occupies an intermediate space between formal and informal learning styles. It combines a degree of structure and intentionality with voluntary participation and flexibility, thus forming a common ground between the two extremes (Fig. 1). In this sense, formal, informal, and non-formal learning exhibit a complementary and integrative relationship.

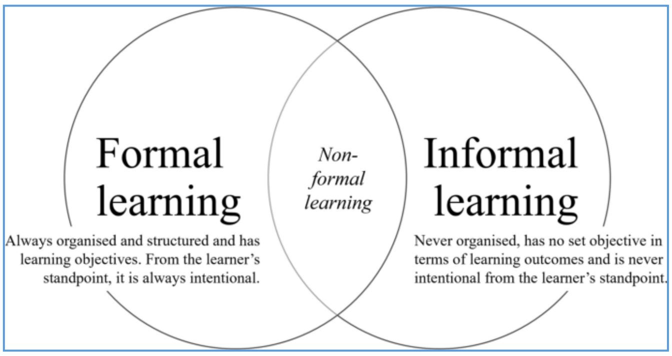

Fig. 1. The interrelatedness of learning styles (Johnson & Majewska, 2024).

3. Limitations of formal learning and its relationship with non-formal Learning

Formal learning is a fundamental model that enables individuals to develop knowledge and skills through a systematic and structured process, thereby supporting equality, accessibility, and quality in education. However, its focus on a predetermined structure and standardized objectives can, in some cases, hinder the ability to fully address students' diverse learning needs and individual development processes. In this context, the literature increasingly supports the view that formal learning should be complemented by other modes of learning.

To begin with, the grade-centered assessment systems inherent in formal education can negatively affect students' motivation and attitudes toward learning, and performance-driven approaches may at times limit the depth of learning. One of the most significant psychological factors that creates pressure on academic performance is grade anxiety. This form of anxiety, which intensifies during exam periods, may prevent students from reaching their full potential (Von der Embse et al., 2018). By fostering performance-based stress, such assessment systems shift the focus from intrinsic to extrinsic motivation. Consequently, particularly in programs heavily reliant on exam success, students tend to experience mental fatigue, avoid deep learning, and adopt surface-level knowledge acquisition habits.

Additionally, delays in curriculum updates and the inability of academic content to keep pace with sectoral changes challenge students' adaptation to evolving knowledge and skill requirements. In an era marked by rapid technological and methodological transformation, the slow pace of curricular revision in higher education institutions can lead to decreased student interest, lower motivation, and diminished practical competence. Moreover, it weakens the alignment between academic content and real-world needs (Alsadoon, 2020).

The lack of technological infrastructure and limited access to digital resources also constitute significant barriers to contemporary learning experiences (Assefa, 2025). Particularly in university settings, access to online learning materials, audiovisual content, and digitally supported practical applications is contingent on robust technological infrastructure. When lacking, students face challenges in accessing educational content, thereby diminishing the effectiveness of interactive learning processes.

Furthermore, the excessive volume of course content presented within formal curricula can act as a suppressive factor for learning (Kaya & Erdem, 2021). Dense academic schedules limit students' ability to engage in self-directed learning and hinder the development of high-order cognitive skills such as critical thinking and independent research. As a result, students are driven away from creative thinking and pushed toward an exam-oriented learning style.

Another limitation of formal learning is its lack of interdisciplinarity. Interdisciplinary learning environments encourage students to transcend the boundaries of their primary fields, embrace contributions from other disciplines, and critically analyze potential conflicts among diverse approaches—fostering deeper intellectual engagement. In this regard, interaction-based, interdisciplinary education plays a critical role in addressing today's complex and multifaceted knowledge demands (Corbacho et al., 2021). However, traditional formal education models often remain confined within single disciplinary frameworks, offering limited opportunities to cultivate a holistic perspective.

Finally, attendance policies enforced in higher education institutions can also negatively affect students' learning experiences. Although intended to encourage class participation, such policies may overlook individual learning styles and flexible working arrangements (Zhu et al., 2019). For students capable of managing their own learning, conducting research-based studies, or balancing academic life with professional commitments, rigid attendance requirements may restrict motivation and academic autonomy.

In contrast to all these limitations, non-formal learning environments offer flexible, participatory, and experience-based structures that play an important complementary role. With voluntary participation, personalized content tailored to individual interests, accessible technological tools, and a pressure-free approach that fosters intrinsic motivation, non-formal learning provides alternative and effective opportunities where formal education falls short. In addition, through online modules, hybrid activities, and self-paced planning, non-formal settings can alleviate constraints such as attendance requirements. Furthermore, workshops, summer schools, and competitions that bring together participants from various disciplines contribute to interdisciplinary interaction. In this way, students can engage in a more holistic learning process that prioritizes creativity, problem-solving, communication, collaboration, and personal development rather than focusing solely on academic achievement (Fig. 2).

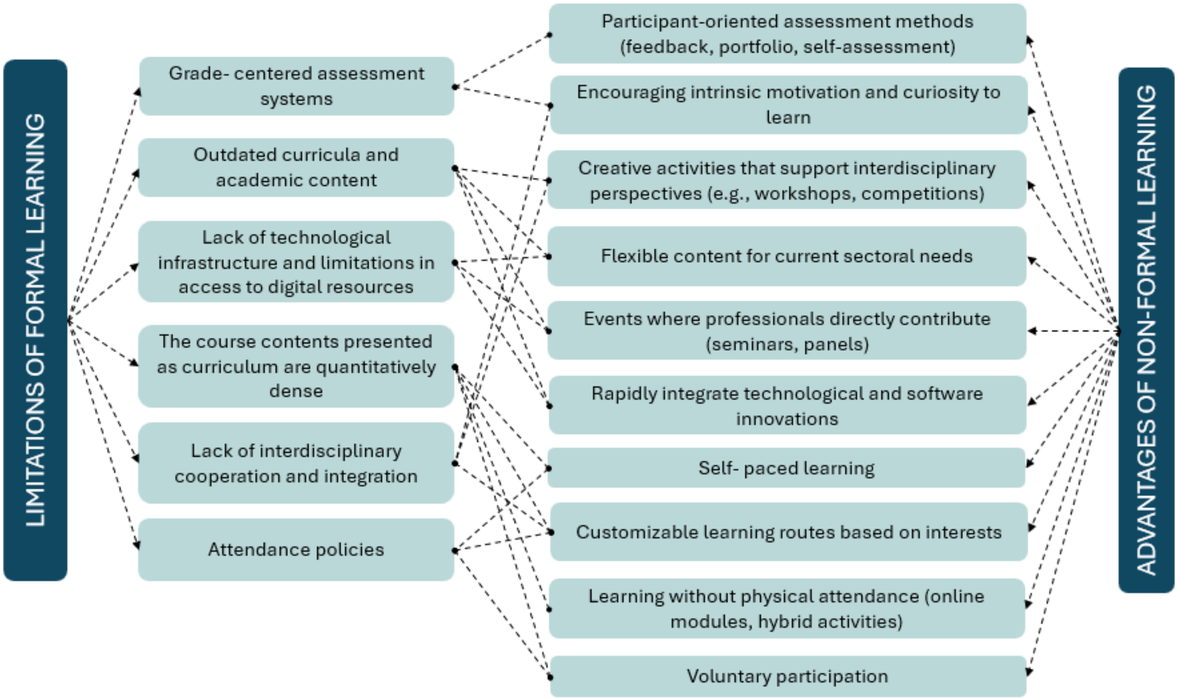

Fig. 2. A comparative illustration of the advantages of non-formal learning in response to the limitations of formal learning

4. Architectural education and non-formal learning

In Turkiye, the Turkish Higher Education Qualifications Framework (TYYÇ), established by the Council of Higher Education (YÖK), defines the knowledge, skills, and competencies that individuals are expected to acquire at all levels of vocational programs, including architecture. According to this framework, architectural education should equip future architects not only with theoretical and factual knowledge related to the field but also with cognitive and practical skills. Additionally, architecture students are expected to develop competencies in independent work and responsibility, learning ability, communication and social interaction, as well as professional ethics and behavioral awareness (URL 1, 2025). Among these, the learning competency category includes the following objectives: "Acts with future orientation, possesses the motivation and learning skills required for personal and professional development, identifies learning needs, makes and implements plans accordingly" and "Acts with an awareness of lifelong learning." Thus, the TYYÇ suggests that learning should not be limited to formal education and that future architects are expected to be capable of complementing their formal learning through other modes of education.

From Vitruvius to the present, architecture has been defined as a multidimensional design discipline that integrates functionality, durability, and aesthetic values while organizing spaces in line with human needs, blending artistic, technical, and social processes in a holistic manner. Since antiquity, it has been widely accepted that an architect is not merely a builder, but a well-rounded intellectual with deep knowledge across multiple domains. An architect is expected to demonstrate competence in fields such as geometry, mathematics, history, philosophy, music, medicine, and astronomy; combine aesthetic sensitivity with technical knowledge; and produce structures that adhere to natural laws while serving human needs. Moreover, they are expected to possess the ability to translate theoretical knowledge into practice, supported by an artistic perspective (Vitruvius, 1993: 4–5). In this sense, the definition of design proposed by Bremner and Rodgers (2013)—as a concept nourished by cultural, professional, economic, and commercial disciplines—can also be adapted to the field of architecture (Fig. 3). Accordingly, architecture maintains direct and indirect connections with numerous fields, ranging from social sciences such as art, history, archaeology, anthropology, psychology, and sociology, to disciplines such as civil engineering and biology (Şensoy & Yamaçlı, 2015). This multifaceted nature of architecture compels architectural education to evolve into a dynamic process that is responsive to diverse problems and continuously adapts to technological advancements.

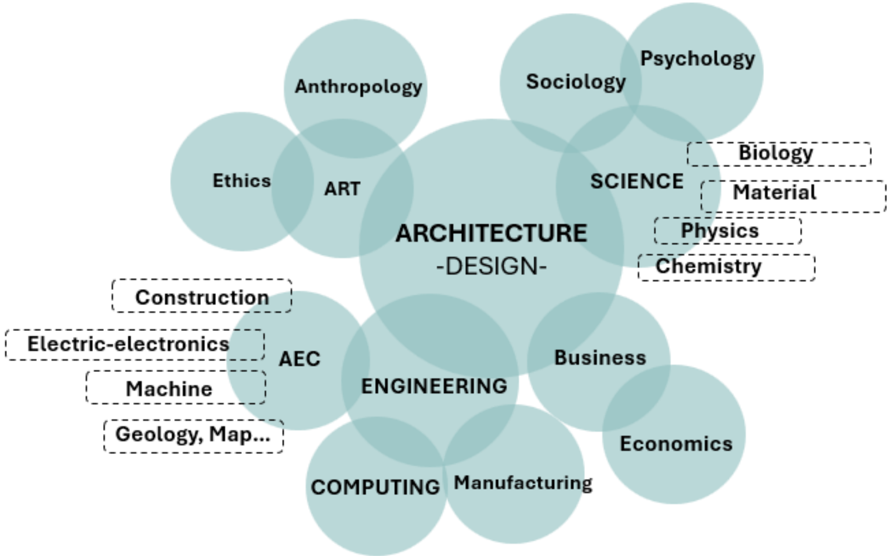

Fig. 3. An architectural adaptation of Bremner and Rodgers' (2013) design scheme

As a discipline situated at the intersection of multiple fields, architecture offers a formal education framework that combines theory and practice within a comprehensive curriculum. However, it is difficult for architecture students to acquire all the knowledge, skills, and competencies expected of them solely within the limited scope of a four-year undergraduate program. In this regard, it is well recognized that students voluntarily support their education and contribute to their professional development through non-formal learning environments. Particularly in light of ongoing technological advancements, there is increasing debate about the extent to which architectural education programs can adequately respond to the evolving demands and conditions of the contemporary world. As such, architecture education is currently undergoing one of its most extensive and rapid periods of transformation (Sancar Özyavuz, 2012). Consequently, there is a growing need to revise and adapt the overall curricular structure of architectural education (Soliman et al., 2019). Nevertheless, the limitations of formal education also manifest in this process. It is highly challenging for curricula to keep pace with the rapid flow of technological, hardware, and software developments. Moreover, expecting the curriculum to include diverse course content tailored to the interests and curiosities of each individual student over a four-year program is simply unrealistic. At this point, the importance of non-formal learning environments in architectural education becomes evident.

In contrast to formal education, which is tied to a specific curriculum and primarily centered around theoretical instruction, non-formal education not only focuses on the development of vocational skills but also fosters attitudes and competencies critical for future career success (Dib, 1988). Research shows that non-formal education can more effectively respond to students' individual needs and their expectations for better understanding themselves and their environments. Accordingly, non-formal learning presents a flexible, interest- and needs-based educational approach capable of rapidly adapting to the changing conditions of individuals and society (Todaro, 1995).

Non-formal learning in architecture encompasses a broad range of extracurricular activities that encourage individuals to participate in out-of-school experiences aimed at enhancing their skills and competencies. Such activities include workshops, conferences, design marathons, summer schools, design competitions, and exhibitions, each offering diverse formats and methods (Bratuškins et al., 2018, p. 46). Workshops, in particular, have become indispensable within architectural non-formal learning environments by providing a platform for discussing design practices, exchanging ideas, and fostering collaboration. Conferences and seminars enable students to interact with professionals and academics, keep up with current developments in the field, and engage in critical discourse (Fig. 4). These collaborative and informal settings also help students develop teamwork and communication skills, and facilitate networking by engaging with various stakeholders (Cantürk Akyildiz & Özgüven, 2024).

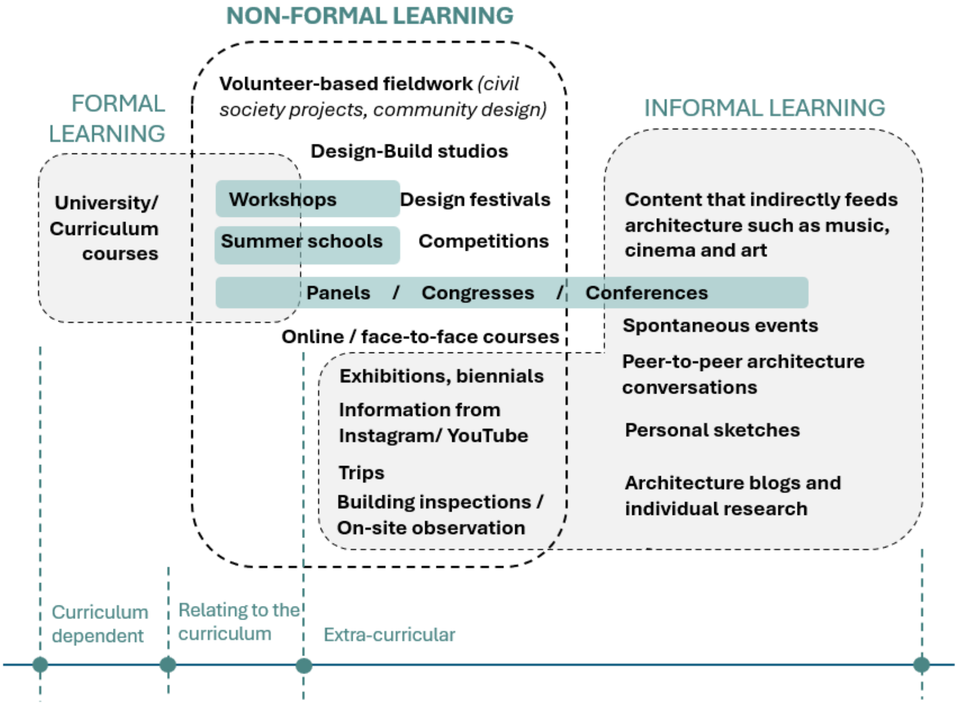

Fig. 4. Formal-non-formal-informal interaction in architectural education (Adapted from Özdemir Gökmen, 2023).

5. Conclusion

Traditional academic structures have long positioned formal learning as the central reference framework for education, emphasizing school-based knowledge transmission. However, with the rise of digitalization and socially interactive learning tools, profound transformations have occurred in how individuals access, process, and produce knowledge. This shift has fostered a new learning ecosystem that extends beyond formal education, elevating the significance of non-formal and informal learning modalities (Harris & Wihak, 2018). Particularly today, technological advancements have blurred the boundaries between formal and non-formal learning, leading to a continuous evolution of learning ecologies (Nygren et al., 2019).

Within this framework, non-formal learning emerges as an important alternative approach that complements the structured and institutional framework of formal education by offering flexible and individualized learning opportunities. Non-formal learning environments—through voluntary participation, adaptable content tailored to individual interests, experiential learning activities, and socially interactive formats—hold the potential to diversify and enrich educational processes.

It is well documented that learning experiences directly linked to students' areas of interest and real-life problems significantly increase their motivation and engagement (Afeldt et al., 2018). When knowledge is acquired in direct connection with practical contexts, learning becomes not only more lasting but also more meaningful (Badger, 2021). Non-formal learning environments empower individuals to focus on areas they enjoy, thereby strengthening intrinsic motivation and enabling them to develop flexible thinking skills by forming connections across various contexts (Johnson & Majewska, 2022).

Non-formal activities such as site visits, workshops, summer schools, and volunteer projects have been shown to generate holistic cognitive, affective, and social impacts on learners (Badger, 2021). On the emotional level, they increase students' interest and engagement; on the cognitive level, they enhance access to information and support long-term memory formation; and on the social level, they foster the development of skills such as communication, collaboration, leadership, and social responsibility (Frappart & Frède, 2016). In particular, non-formal learning environments play a critical role in the development of higher-order cognitive skills such as critical thinking, problem-solving, comparative analysis, and evaluating multiple perspectives (Badger, 2021). This dynamic structure enables students to approach learning not merely as an academic obligation but as an opportunity for personal growth and lifelong learning, allowing for more active, engaged, and meaningful participation in learning processes.

In conclusion, while the systematic structure and academic standards provided by formal learning continue to serve as the foundation of educational systems, non-formal learning—with its responsiveness to individual differences, flexible design, and experiential focus—assumes a complementary and enriching role. Therefore, a balanced and integrated application of both approaches is essential to support holistic student development and strengthen lifelong learning competencies within contemporary higher education.

This study, which highlights the importance of non-formal learning in architectural education, clarifies the structural distinctions among formal, non-formal, and informal learning modalities. Accordingly, it addresses the conceptual ambiguity in the architectural literature, where out-of-school learning processes are often grouped under the umbrella term "informal learning." The analysis demonstrates that informal learning corresponds to unstructured, spontaneous, and unplanned processes, whereas non-formal learning comprises activities that are organized with specific goals and structures, relying on voluntary participation. Consequently, applications such as workshops, seminars, summer schools, design-build studios, architectural design competitions, and online education modules—due to their planned and organized nature—should be categorized under non-formal learning environments. By clarifying these distinctions, the study not only emphasizes the significance of diverse learning types in architectural education but also contributes a theoretical framework to resolve the conceptual confusion in the literature.

Multidisciplinary sustainability model in post-disaster housing recovery: user-oriented and energy-efficient strategies

Melody Safarkhani *[1], Feride Şener Yılmaz[2]

[1] *Istanbul Okan University, Department of Architecture, 34959 Istanbul, Türkiye*

Abstract. The increasing frequency and complexity of disasters have posed significant challenges across environmental, economic, social, and cultural domains, bringing the sustainability of post-disaster housing to the forefront of policy discussions and recovery efforts. In response to these challenges, this study introduces a multidisciplinary model that integrates energy-efficient and user-oriented strategies, aligned with the principles of sustainable development and relevant goals. To develop this model, a systematic literature review of 59 academic sources was conducted using the PRISMA framework, enabling the identification and synthesis of key strategies. The review is guided by two central questions: (1) What are the key energy-efficient strategies that reduce environmental impact and minimize energy consumption? Moreover, (2) What user-oriented design strategies enhance the adaptability and livability of post-disaster housing to meet the diverse needs of affected populations?. The findings are thematically categorized into eleven strategic themes: five related to energy efficiency and six to user-oriented approaches. Energy-efficient strategies encompass passive design, improved thermal comfort and reduced energy consumption, the utilization of both traditional and advanced materials, life cycle assessment (LCA), and cost-effective design and economic feasibility. In parallel, user-oriented strategies emphasize human rights, psychological well-being and social cohesion, socio-cultural resilience and community-based practices, technology and innovative design, evaluation and optimization frameworks, and governance, strategic planning, and community participation. These strategies provide a comprehensive foundation for developing context-sensitive, inclusive, and sustainable solutions for post-disaster housing recovery.

Keywords: Post-disaster recovery; Temporary housing; Sustainability model; User-oriented; Energy-efficient

1. Introduction

Disasters, whether natural, human-made, or hybrid, threaten lives and communities. Natural disasters, such as meteorological, geophysical, hydrological, biological, and climatological events, and human-made disasters, resulting from human activity, negligence, or conflict, can severely impact the built environment and lead to sociopolitical unrest, technological failures and infrastructure collapse (Galderisi & Ceudech, 2013; Shaluf, 2007; The & Khan, 2021). In recent decades, disasters' growing frequency and complexity have intensified post-disaster management challenges across environmental, economic, political, social, and cultural dimensions (Shaw, 2014; Safapour et al., 2021). Yi et al. (2020) identify the core phases of post-disaster management as "relief, reconstruction, rehabilitation, and recovery" (p. 1), which together encompass physical reconstruction, socioeconomic and socio-cultural rehabilitation, and policy-driven strategies to strengthen resilience against future hazards (Berke et al., 1993; Peacock et al., 2018; Mukherji, 2014). Housing recovery has emerged as a critical priority (Berke & Campanella, 2006). As one of the most vulnerable components in disasters, housing serves as a physical shelter and a foundation for social life (Tas et al., 2007; Félix et al., 2013). Its destruction displaces populations, fragments communities, and undermines overall well-being. Post-disaster housing recovery requires balancing immediate and long-term needs by integrating emergency shelter, transitional housing, and permanent reconstruction efforts that not only provide safe, adequate homes but also reduce future vulnerabilities and foster community resilience (Johnson & Olshansky, 2016; Peacock et al., 2018). To achieve this, post-disaster housing recovery must be grounded in principles that align with the pillars and goals of sustainable development. In the housing context, sustainable development's environmental and economic pillars focus on energy efficiency and resource-conscious rebuilding. In contrast, the social and cultural pillars emphasize a user-oriented approach that addresses affected communities' specific needs and values. Building on this, the study aims to systematically

* Corresponding author, E-mail: melody.safarkhani@okan.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_951

review literature to identify post-disaster housing strategies that integrate user-oriented and energy-efficient approaches. It synthesizes this knowledge to develop a multidisciplinary sustainability model that enhances recovery efforts. The following questions guide the review process and ensure the findings align with the goal of promoting sustainable housing recovery solutions in post-disaster contexts.

- What are the key energy-efficient strategies that ensure reduced environmental impact and energy consumption?
- What are the key user-oriented design strategies that improve the adaptability and livability of post-disaster housing, ensuring that it meets residents' diverse needs?

2. Method

The systematic literature review was conducted using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework to ensure the inclusion of relevant studies. PRISMA, developed by Moher et al. (2010), provides a structured approach for conducting systematic reviews by identifying, selecting, and evaluating studies to answer a specific research question. It ensures comprehensive and unbiased analysis, highlights research gaps, and follows four phases: identification, screening, eligibility, and inclusion, guided by a 27-item checklist. This study conducted a literature search using the Scopus database, recognized for its comprehensive and credible coverage (Mongeon & Paul-Hus, 2015; Singh et al., 2021), on February 16, 2025, using advanced queries across titles, abstracts, and keywords without time restrictions. The search strategy included three main term categories. Category A focused on "post-disaster," while Category B covered terms like "temporary housing" and "shelter." Although conceptually distinct, these terms are frequently used in the literature to describe the provision of adequate living spaces in post-disaster situations. As Quarantelli (1995) highlights, the blurred line between sheltering and housing, with sheltering meeting immediate survival needs and housing supporting the return to normalcy. Montalbano and Santi (2023) outline a typical recovery timeline: emergency sheltering (12–48 hours), temporary sheltering (2–30 days), temporary housing (3 months–5 years), and eventual permanent housing within a few years. Category C refers to terms related to approaches in post-disaster housing; C1 included "energy" and "energy efficiency," while category C2 focused on user-oriented terms such as "user," "human," "human-oriented," and "user-oriented." The keyword categories are demonstrated in Table 1. The search process was conducted using two query sets, refined with Boolean operators to ensure comprehensive coverage. Table 2 presents these query sets used during the identification phase. The PRISMA flow diagram (Fig. 1) illustrates the systematic process of identifying, screening, assessing, and selecting studies for inclusion in the review.

Table 1. Keyword Categories.

Category	Keyword
General	Post-disaster
Specific	Temporary housing, Shelter
Approach	User-oriented, Energy Efficiency

Table 2. The query sets used during the identification phase.

Keyword A		Keyword B		Keyword C1	Keyword C2
		Temporary Housing		Energy	User
					OR
		OR			Human
Post-Disaster	AND		AND		OR
					Human-oriented
		Shelter		OR	OR
				Energy Efficiency	User-oriented

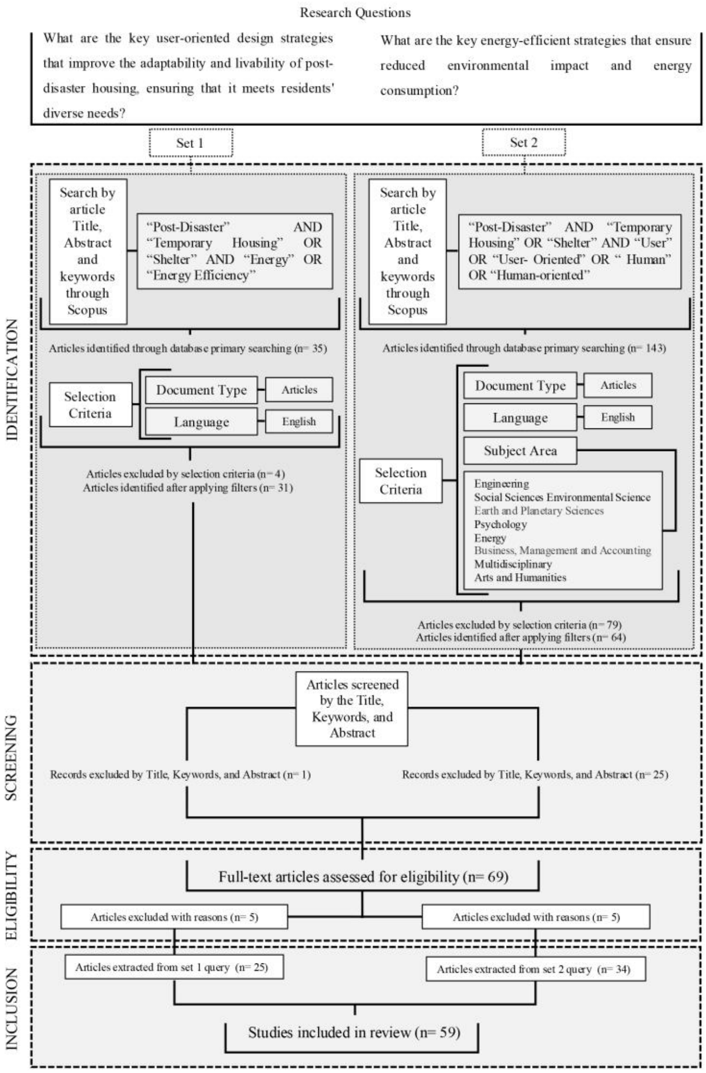

Fig. 1. PRISMA diagram.

3. Results and findings

The systematic literature review results were analyzed using thematic classification, allowing for the identification and organization of concepts across the selected studies. This approach facilitated a structured synthesis of findings for each set (energy-efficient and user-oriented) by grouping them into key themes, which revealed patterns and variations in the existing literature. In each set, several studies span multiple themes, reflecting their broad relevance across various disaster response and recovery aspects.

3.1. Results on the energy-efficient approach in post-disaster temporary housing

This part of the study addresses the research question: *What are the key energy-efficient strategies that ensure reduced environmental impact and energy consumption?* Through a comprehensive review of 25 scholarly sources from the first query set, which are classified into five themes.

3.1.1. Passive design strategies (I)

Post-disaster shelter design now prioritizes climate responsiveness, energy efficiency, and cultural adaptability to enhance relief and long-term recovery. Numerous studies utilize simulation tools and prototypes to evaluate how design choices perform in varied climatic and socio-economic settings. Mojahedi et al. (2019) and Mojahedi et al. (2021) demonstrate through EnergyPlus and DesignBuilder tools that architectural forms like domes and barrel vaults improve thermal comfort and reduce heat gain. Their research also underscores the value of vernacular knowledge in achieving culturally suitable designs.

Nocera et al. (2020) apply Passive House standards in modular shelters for post-earthquake Italy, integrating energy modeling with carbon footprint analysis to advocate for durable, adaptable housing. In tropical settings, da Costa et al. (2023) assess insulation performance in container shelters using BES, linking thermal comfort with economic returns. Modular innovations like the ASH module (Pusceddu et al., 2017) and 3D-printed walls (Khadka et al., 2024) show how flexible systems enhance scalability and climate resilience. Lee et al. (2025) evaluate photovoltaic-integrated mobile homes across Japan, emphasizing passive-active energy strategies for off-grid autonomy. Atmaca (2018) and Moreno-Sierra et al. (2020) focus on climate-responsive envelopes and passive cooling, while Maracchini & D'Orazio (2022) highlight EPS walls for minimizing mechanical reliance. Perrucci and Baroud (2020) stress the relevance of LEED and STEP programs in guiding sustainable temporary housing. Collectively, these studies argue that effective shelter design must go beyond structural safety, embracing passive performance, cultural relevance, and adaptability to climate and disaster types.

3.1.2. Improved comfort and reduced energy consumption (II)

Thermal comfort is a vital element of post-disaster shelter design (Li et al., 2024). Recent research emphasizes performance modeling and simulation tools to enhance energy efficiency, especially in extreme climates. Ibrahim et al. (2023) studied refugee shelters in Iraq, showing that incremental and low-impact construction strategies improve thermal conditions. Similarly, da Costa et al. (2023) and Ibrahim and Baranyai (2021) highlighted the use of PET wool and straw-cob-earth insulation in enhancing comfort when paired with sustainable building methods. Studies by Salvalai et al. (2017) and Pusceddu et al. (2017) demonstrated that recycled materials and multilayer insulation improve heat control in deployable modules, especially where HVAC systems are absent. Song et al. (2016) and Atmaca (2018) emphasized that poor insulation contributes significantly to lifecycle energy consumption, underscoring the need for efficient thermal envelopes. EnergyPlus and DesignBuilder tools are widely used for modeling energy use and optimizing building envelopes. Researchers, including Lee et al. (2025), Mojahedi et al. (2019), Song et al. (2016), and Rapone et al. (2024), applied EnergyPlus to simulate the performance of insulation systems, phase change materials, and shelter forms across multiple climate zones. DesignBuilder, as a visual interface for EnergyPlus, was used by Mojahedi et al. (2021), Moreno-Sierra et al. (2020), and others to evaluate solar gain, form sensitivity, and passive strategies. IDA ICE was applied in studies by Ibrahim et al. (2022, 2023) to validate passive envelope techniques like thermal mass and ventilation for low-tech shelters in Iraq. TRNSYS was used by Pusceddu et al. (2017) and Salvalai et al. (2017) for dynamic thermal simulations of modular shelters using recycled and multilayer materials. Additional tools include eQuest (da Costa et al., 2023), OpenStudio (Khadka et al., 2024), and SketchUp Pro for operational energy modeling. Several scholars combine simulations with experimental tests for real-world validation, including Lv et al. (2024) and Maracchini and D'Orazio (2022).

3.1.3. Traditional and advanced materials (III)

Recent studies highlight the importance of material selection and innovation in post-disaster shelters, focusing on lifecycle performance, cost, and sustainability. Ibrahim and Baranyai (2021) and McConnell and Bertolin (2019) stress local, climate-adapted materials for durability and affordability in resource-constrained settings. Comparative studies by da Costa et al. (2023) and Pusceddu et al. (2017) analyze wall assemblies and insulation systems to optimize thermal efficiency. Material innovation includes recycled plastic, EPS panels, cork insulation, and phase change materials (PCM). Moreno-Sierra et al. (2020) and Salvalai et al. (2017) developed prototypes using waste materials like plastic and skis, while Maracchini and D'Orazio (2022) and Barreca et al. (2022) paired these with passive cooling and prefabrication for better performance.

LCA studies by Zea Escamilla and Habert (2015) and Song et al. (2016) evaluate embodied carbon and energy use, while Atmaca (2017) and Atmaca and Atmaca (2016) compare containers, prefab, and lightweight shelters, showing that lifecycle outcomes often outweigh upfront costs. Cost-focused research, including Nocera et al. (2020) and Lee et al. (2025), reveals that investing in insulation and renewable systems yields long-term savings. Lv et al. (2024) tested a solar-powered emergency shelter (SPES) using flexible PVs and ANSYS-Fluent simulations, showing high thermal resilience in hot, humid climates with mechanical ventilation and evaporative cooling. Solar systems are central to off-grid solutions. Lee et al. (2025) and Li et al. (2024) found PV-powered mobile shelters effective in moderate zones but less viable in colder climates, emphasizing climate-specific energy strategies.

3.1.4. Life cycle assessment (LCA) analysis (IV)

Life Cycle Assessment (LCA) is essential in post-disaster temporary housing studies as it provides a comprehensive evaluation of environmental impacts across a shelter's entire lifespan, from material sourcing to deconstruction. Across reviewed studies, LCA supports informed decisions on materials, energy strategies, and sustainability trade-offs to design low-impact, resilient shelters. Nocera et al. (2020) apply LCA to Passive House shelters in seismic zones, linking thermal performance with environmental footprint. Mojahedi et al. (2021) evaluate nomadic-inspired shelters using LCA principles, emphasizing material and energy efficiency. McConnell and Bertolin (2019) assess container housing in the Bahamas, integrating spatial mapping and life cycle thinking to address both environmental and social impacts.

Atmaca (2017) and Atmaca and Atmaca (2016) compare prefabricated and container units, showing that prefabs offer superior environmental outcomes, with operational energy being the main emissions driver. Song et al. (2016) highlight timber walls as a lower-impact alternative, while Khadka et al. (2024) integrate LCEA with thermal modeling to assess 3D-printed panels. Zea Escamilla and Habert (2015) benchmark 20 global shelter types through multi-criteria LCA to guide material and deployment decisions across contexts. Barreca et al. (2022) examine modular timber shelters with cork insulation and PCM, confirming low carbon and high thermal performance. Together, these studies show that combining LCA with innovative materials and cost analysis is key to creating efficient, adaptable post-disaster housing.

3.1.5. Cost-effective design and economic feasibility (V)

Economic feasibility plays a crucial role in post-disaster housing, particularly when large-scale deployment is needed under limited budgets. Studies increasingly adopt life cycle cost analysis (LCCA), energy modeling, and material evaluation to inform cost-effective designs. Nocera et al. (2020) highlight the balance of energy efficiency and affordability in a passive house prototype for post-earthquake reconstruction in Italy, integrating both operational and embodied carbon considerations for rural modular use. Lee et al. (2025) explore photovoltaic-based mobile housing in Japan, using regional simulations to optimize costs and energy yield. In Brazil, da Costa et al. (2023) compare PET wool and mineral wool insulation in container shelters. While PET wool offers quicker payback (~4 years), mineral wool proves more cost-effective over eight years due to better thermal performance. In Turkey, Atmaca and Atmaca (2016) show that prefabricated shelters outperform containers, with 29.7% lower lifecycle costs and 25.1% lower energy consumption. Zea Escamilla and Habert (2015), comparing 20 designs across 11 countries, found that locally sourced materials reduce embodied costs and emissions, whereas imported steel and concrete raise upfront and long-term expenses. Maracchini and D'Orazio (2022) advocate for EPS-based shelters with passive strategies, natural ventilation, and cool coatings offering the best cost-performance outcomes, especially in hot climates. Overall, long-term affordability is prioritized over short-term savings. Integrating LCCA, regional energy modeling, and localized materials is essential for scalable, sustainable housing.

3.2. Results on the user-oriented approach in post-disaster temporary housing

This part of the study addresses the research question: *What key user-oriented design strategies enhance the adaptability and livability of post-disaster housing to meet residents' diverse needs?* Through a comprehensive review of 34 scholarly sources from the second query set, which are classified into six themes.

3.2.1. Human rights (VI)

Several studies stress that post-disaster housing must be understood as a human rights issue rather than merely a technical response. George et al. (2022) emphasize the importance of recognizing shelter as a space that ensures dignity, privacy, and protection, while Carver (2011) critiques the ambiguity in international law concerning a clear right to post-disaster housing, calling for stronger legal frameworks. Roosli and Baharum (2012) similarly view the failure to deliver appropriate housing in post-disaster recovery as a violation of basic living standards and a disregard for community agency. Juran (2012) underscores how disasters exacerbate gender-based inequalities, leading to heightened violations of women's rights in shelter access, sanitation, and safety. Imperiale and Vanclay (2019) argue that centralized disaster governance that undermines public participation and transparency erodes civic rights. Likewise, Kennedy et al. (2008) highlight that the "build back better" agenda often failed to include marginalized groups, limiting its ability to fulfill the promise of equitable and rights-based recovery. Together, these works call for a rights-based, inclusive, and participatory framework in post-disaster housing and recovery.

3.2.2. Psychological well-being and social cohesion (VII)

Psychological well-being and social cohesion are increasingly recognized as central to in the context of post-disaster housing recovery. Researchers emphasize that when displaced individuals are able to adapt or personalize their temporary housing, it fosters a sense of control and emotional stability (Duru & Sarıkaya, 2024). Well-regulated housing environments characterized by thermal comfort and spatial openness play a vital role in alleviating stress and enhancing psychological recovery (Li et al., 2023). Prolonged displacement can result in social isolation and emotional strain, underscoring the need for housing environments that encourage social connection and community engagement (Gagné, 2020). Design strategies that balance privacy with shared spaces can promote interaction and reduce tension among residents (Kim et al., 2022; Bris & Bendito, 2019). Social capital, whether among close-knit groups or wider community networks, plays a vital role in emotional recovery and reintegration, particularly when supported by environments that facilitate ongoing interaction and support (Rahill et al., 2014). Moreover, involving residents in the planning and design of shelters improves satisfaction, fosters trust, and strengthens the collective sense of community (Opdyke et al., 2019).

3.2.3. Socio-cultural resilience and community-based approaches (VIII)

Socio-cultural resilience and community-based approaches are widely recognized as essential to effective post-disaster housing recovery. Scholars emphasize that housing must go beyond physical shelter to support cultural continuity and community identity. Designs informed by local traditions and shaped through participatory processes foster a stronger sense of belonging and long-term usability (Hadafi & Fallahi, 2010; Rahmayati, 2016; Idham & Andriansyah, 2021). Engaging residents in planning helps reconcile professional design strategies with lived experiences, ensuring housing solutions are relevant and respectful of local values (Tan & Özcan, 2024; Opdyke et al., 2019). Additionally, bonding and bridging social capital reinforce emotional recovery and enable communities to mobilize resources and support systems (Rahill et al., 2014). Several scholars emphasize that standardized, top-down recovery models often overlook these dynamics, undermining local agency and cultural relevance (Kennedy et al., 2008; Curato, 2018). A systems-based perspective further underscores the importance of integrating cultural, social, and adaptive dimensions into the built environment to achieve sustainable recovery (Elinwa & Moyo, 2018).

3.2.4. Technology and innovative design (IX)

Technology and innovative design play a critical role in advancing post-disaster housing by enabling flexible, efficient, and locally appropriate solutions. Computational tools such as genetic algorithms and automated planning systems improve layout optimization, site allocation, and decision-making under constraints (Karaoğlan & Alaçam, 2019; El-Anwar et al., 2009). Prefabricated and modular construction methods help expedite reconstruction without compromising quality, making them suitable for large-scale deployment (Gunawardena et al., 2014). Mobile and reconfigurable shelters offer logistical advantages and adapt to changing user needs over time (Cerrahoğlu & Maden, 2024; Torus & Şener, 2015). Innovations in material use, such as 3D printing with local soil, demonstrate how sustainable practices can be combined with advanced techniques to reduce environmental impact and enhance self-sufficiency (Venturi et al., 2019). Moreover, integrating passive design strategies with culturally appropriate forms ensures that housing supports both immediate functionality and long-term community relevance (Shih & Ravina, 2020). Together, these approaches underscore the importance of design innovation in creating effective and inclusive housing responses to disaster.

3.2.5. Evaluation and optimization frameworks (X)

Evaluation and optimization frameworks are essential for ensuring informed, context-sensitive decisions in post-disaster housing recovery. These approaches often incorporate computational models and decision-support tools to optimize factors such as cost, location, and resource allocation, thereby improving the overall planning process (El-Anwar et al., 2009; El-Anwar, 2013). Some frameworks are grounded in sustainability or performance requirements, linking housing design to environmental efficiency, user needs, and adaptability (Hosseini et al., 2020; Montalbano & Santi, 2023). Others use indicator-based methods to assess shelter quality regarding safety, affordability, and cultural relevance, providing practical guidance for policy and implementation (Nath et al., 2016). Additionally, comparative evaluations of spatial and structural criteria offer adaptable standards that can be applied across varying disaster contexts (Beatini et al., 2022). Collectively, these frameworks enhance the reliability, sustainability, and responsiveness of housing recovery strategies.

3.2.6. Governance, strategic planning, and community participation (XI)

Effective governance and strategic planning are essential for equitable and coordinated post-disaster housing recovery. Scholars emphasize the value of participatory processes that integrate community knowledge, ensure transparency, and strengthen institutional trust. Involving local populations in planning improves satisfaction and supports the long-term success of housing solutions (Omidvar et al., 2011; Montalbano & Santi, 2023). Governance models that encourage deliberation and shared agency are considered more effective than centralized approaches, which often lack accountability and exclude those most affected (Curato, 2018; Imperiale & Vanclay, 2019). The importance of planning before disaster strikes is also underscored, particularly for defining responsibilities and preventing fragmented responses (Johnson, 2007). Bridging technical expertise with community perspectives further enhances the relevance and responsiveness of recovery strategies (Kelman et al., 2011). Ultimately, post-disaster housing governance should be guided by frameworks that promote dignity, inclusion, and proactive collaboration across sectors (George et al., 2022).

* Disaster Type Codes: 1 = Natural and Man-Made; 2 = Natural

4. Discussion

The reviewed literature in set 1 indicates that effective post-disaster housing is contingent on incorporating energy-efficient strategies that align with sustainable development's environmental and economic pillars. The derived strategies include adopting passive design techniques; improving comfort and reducing energy consumption; utilizing both traditional and advanced materials to support contextual adaptability and resource efficiency; and developing cost-effective design solutions that are essential for ensuring financial sustainability, particularly in resource-constrained post-disaster settings. Additionally, the integration of life cycle assessment (LCA) is a critical tool for evaluating the long-term environmental performance and overall sustainability of housing systems throughout their lifespan. The reviewed literature in set 2 consistently emphasizes the integration of psychological, emotional, and ethical considerations into post-disaster housing, aligned with the social and cultural pillars of sustainable development. The derived user-oriented strategies are: human rights; psychological well-being and social cohesion; socio-cultural resilience and community-based approaches; technology and innovative design; evaluation and optimization frameworks; and governance, strategic planning, and community participation.

Consequently, the model for sustainable post-disaster housing recovery (Fig. 2) centers on energy-efficient and user-oriented strategies, aligned with the four pillars of sustainable development and relevant goals to ensure holistic, long-term recovery. The energy-efficient strategies align with several sustainable development goals (SDGs), including SDG 7- Affordable and Clean Energy, SDG 9- Industry, Innovation and Infrastructure, SDG 12- Responsible Consumption and Production, and SDG 13- Climate Action. The user-oriented strategies support SDG 3- Good Health and Well-being, SDG 5- Gender Equality, SDG 6- Clean Water and Sanitation, and SDG 10- Reduced Inequalities. Both energy-efficient and user-oriented strategies align with SDG 11- Sustainable Cities and Communities, which advocates for the inclusive, safe, resilient, and sustainable built environment. Accordingly, these strategies support recovery efforts that are socially and culturally inclusive, environmentally responsible, and economically viable while also being better equipped to withstand future challenges.

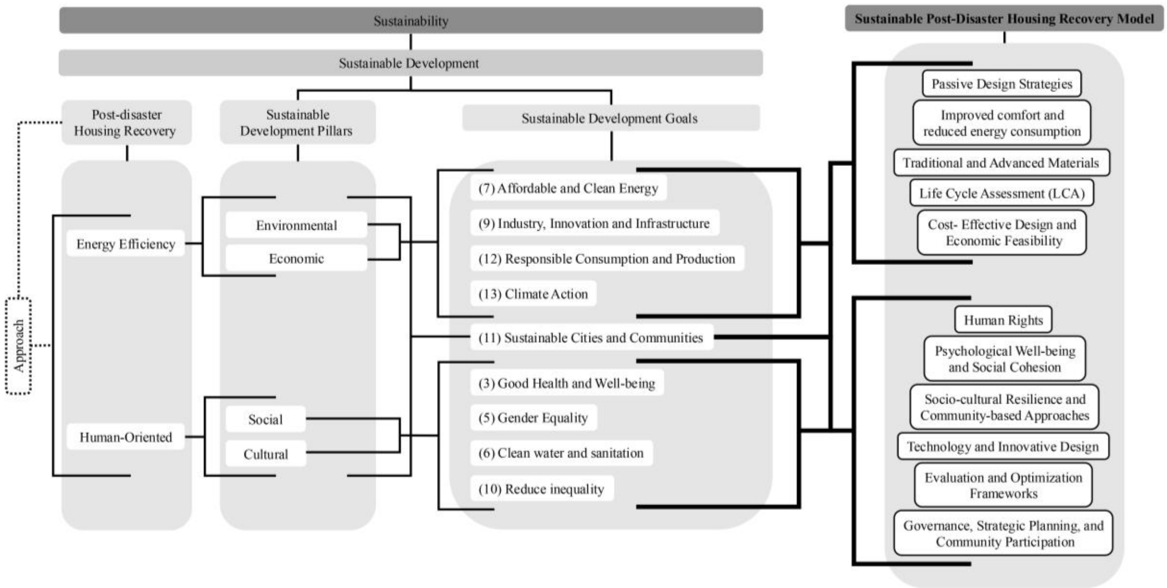

Fig. 2. Multidisciplinary sustainable post-disaster housing recovery model.

5. Conclusion

This study contributes to the field of sustainable post-disaster housing recovery by proposing a multidisciplinary model that integrates energy-efficient and user-oriented strategies. Based on a systematic review of 59 academic sources, 11 strategic themes were identified, five related to energy efficiency and six to user-oriented strategies. These themes highlight the need for recovery approaches that address environmental, economic, social, and cultural dimensions. Collectively, these strategies offer a foundation for sustainability in post-disaster contexts and inform a comprehensive, SDGs-aligned model adaptable to diverse settings. The study provides practical insights for researchers and professionals in architecture and urban studies, supporting the development of equitable, adaptable, and context-sensitive housing recovery solutions. Future research could further validate the proposed model through empirical case studies, simulation-based evaluations, or stakeholder-based participatory assessments to examine its applicability and effectiveness across different post-disaster contexts.

Definition and typology of nomadic architecture (Case study: Iranian nomads)

Soleimani Amirshekari Amin Reza*[1], Akhondi Farhad[1]

[1] *Tabriz Islamic Art University, Faculty of Architecture and Urbanism, Tabriz, Iran*

Abstract. Nomadic architecture is one of the significant aspects of Iran's architectural heritage, encompassing both tangible and intangible cultural values. This study aims to define "Nomadic Architecture" in a comprehensive manner that includes all nomadic structures. A better understanding of nomadic architecture requires attention to its diverse forms and should not be limited to temporary housing. Information for this study has been collected through library research and field surveys of nomadic habitats. The research methodology is descriptive-analytical, focusing on analyzing the collected data. The case study of this research includes nomadic communities in Iran. The nomadic community exhibits diverse and valuable architectural forms. Temporary housing structures (such as black tents, shelters, and yurts) are just one type of nomadic architecture. A typology of nomadic architecture should be based on models or frameworks that encompass all architectural forms. Nomads, due to their migratory nature, construct temporary, semi-temporary, and permanent structures. These various types of nomadic architecture can be categorized based on a spatial-temporal model. Additionally, nomadic architecture is multifunctional, providing spaces for housing, livestock shelters, fortresses, marketplaces, playgrounds, and tombs. These architectural types can also be classified using a functional model. Nomadic architecture is not limited to temporary housing structures such as black tents and shelters. It encompasses a wide range of diverse structures, including black tents, shelters, yurts, fortresses, tombs, marketplaces, masonry housing, playgrounds, and livestock shelters

Keywords: Architecture; Nomads; Nomadic architecture; Nomadic structures

1. Introduction

Modes of human existence, currently encompasses an estimated 30 to 40 million people worldwide (Vundi and Koome, 2023). Practiced across various continents for the efficient use of natural resources and environmental stewardship, this lifestyle has not only fulfilled the subsistence needs of human societies but has also endured as a cultural, economic, and social system. Core features of nomadism—mobility, continuous interaction with nature, and adaptable livelihood strategies—have distinguished it as a unique form of human life.

In Iran, the nomadic lifestyle has a deep-rooted history, with some sources tracing its origins to eight thousand years ago (Amanollahi Baharvand, 2004). The distinct natural and climatic conditions of the Iranian plateau have long facilitated the development and continuity of nomadic practices. Even the migration of Aryan tribes to this region and their choice to settle there highlight its climatic compatibility with nomadic life. Up until the early 14th century CE, Iranian governance was closely linked to nomadic societies, whose influence on the nation's economic, military, and social transformations remains undeniable (Shabani, 2011). Through activities such as animal husbandry, agriculture, and sustainable resource management, Iranian nomads have historically played a key role in ensuring food security and defending territorial boundaries (Mirtaghian Roudsari, 2023; Darvishi and Khodadad, 2022).

Among the most significant elements of nomadic culture is the architecture specific to these communities. Designed in response to the evolving needs of nomadic life and in harmony with the climate, these structures are simple, portable, lightweight, and efficient. They serve not only as seasonal and mobile shelters but also as spaces for livestock, food storage, religious practices, protection, and subsistence activities.

Nomadic architecture—such as the Siah Chador, Koper, Alachiq, and other forms—represents a synthesis of lived experience, indigenous knowledge, craftsmanship, and environmental adaptation. The use of local and renewable materials, efficient resource utilization, and climate-responsive spatial design are key characteristics.

* Corresponding author, E-mail: ar.soleimani@tabriziau.ac.ir

https://doi.org/10.31462/icearc2025_a_arc_975

Beyond its practical and ecological aspects, this architecture also conveys aesthetic, symbolic, and cultural meanings.

Despite its significance, nomadic architecture has often been narrowly defined in previous studies, primarily as temporary housing, with its broader forms and functions overlooked. This research seeks to redefine "nomadic architecture" more comprehensively and to classify the diverse architectural expressions found among Iranian nomadic groups. Through the analysis of documentary and field data, this study aims to provide a holistic understanding of nomadic architecture and to establish it as an essential component of Iran’s cultural, historical, and architectural heritage.

Table 1. Research background

Researcher(s) / Year	Title of Research	Findings / Results
Filberg (1993)	Black Tent: The Shelter of Nomads and Semi-Nomads in the Course of History	The researcher explores the types of nomadic tents in various regions, studying similarities and differences in nomadic dwellings among different tribes.
Kiani (1997)	Black Tents: A Study of the Life of the Qashqai Tribe	Nomadic housing is divided based on color into 'black tents' and 'colored tents,' differentiated by size, material, and function.
Danaei-Nia and Il-Begipour (2017)	Cultural Landscape Features of the Bakhtiari Nomads and Its Impact on Nomadic Architecture	The study identifies cultural factors affecting Bakhtiari nomadic housing and categorizes the architecture of seven major Iranian tribes based on these cultural landscape elements.
Aghai, Karami and Hasari (2018)	Typology of Architecture in Pastoral Nomadic Communities	This research classifies nomadic settlements using three models: spatial-temporal, socio-economic, and historical-cultural. It also compares parts of the black tent across different types.
Ranjbar and Mahmoudi (2020)	Morphology of Black Tents Among Nomads in Southwest Iran	The study analyzes cultural differences and similarities in black tent morphology among Kurdish and Bakhtiari tribes, considering climate, hospitality, ceremonies, protection, and aesthetics.
Turkmen and Sultan-Zadeh (2020)	Cultural Reflection in the Architecture of Nomadic Settlements – Case Study: Turkmen Nomads	The research identifies cultural components of the Turkmen tribe through symbols and signs in architecture and categorizes Turkmen tents into 'Chatma,' 'Got Takma,' and 'Aq Owi and Qara Owi' based on function, color, and duration of stay.
Mohsen Afshari (2021)	Typology of the Black Tent Architecture of the Qashqai Tribe	The research introduces and analyzes Qashqai black tent architecture and examines its different types across four scenarios: summer, winter, migration, and sudden weather changes.
Andrews (1997)	Nomad Tent Types in the Middle East: Framed Tents	Covers a wide range of nomadic tents in the Middle East, categorizing them into 56 types based on structural form and ethnic group.
Hassas and Borucka (2020)	A Comparative Study of Iranian Nomadic Housing	Investigates black tents as 'homes,' comparing and classifying them in seven different Iranian tribes by form, material, structure, space, and interior design.
Mojahedi, Vafamehr and Ekhlassi (2021)	Designing Post-Disaster Temporary Housing Inspired by Indigenous Nomadic Housing in Iran	Proposes replacing standard temporary shelters with indigenous nomadic models (Kapar, Moozif, Alachiq), highlighting energy efficiency and comparing their consumption.

2. Research background

Research on nomadic architecture has predominantly centered on identifying, documenting, and classifying the temporary dwellings of nomadic communities—especially structures such as the Siah Chador (black tent) and Alachiq, which serve as central elements of seasonal settlements. These studies have primarily examined temporary nomadic architecture from cultural, climatic, structural, and functional perspectives.

In this regard, Filberg (1993) was among the earliest scholars to study the tents of Middle Eastern nomads, classifying them based on cultural and climatic patterns. Kiani (1997) focused on the tents of the Qashqai nomads, categorizing them according to their structure and morphology. Building upon this foundation, Danaeinya and Ilbegipour (2017) examined nomadic housing through the lens of cultural patterns.

Other notable contributions include the work of Aghaei, Hesari, and Karami (2018), who analyzed Qashqai nomadic settlements using a spatial-temporal framework, proposing a five-fold classification. Similarly, Afshari (2021) developed a typology of Qashqai Siah Chador architecture in four distinct categories. Ranjbar and Mahmoudi (2020) investigated Siah Chadors among Kurdish and Bakhtiari nomads from both cultural and climatic standpoints. Torkaman and Soltanzadeh (2020) also classified the Alachiqs of Turkmen nomads into three groups based on their functional and cultural characteristics.

Internationally, several studies have engaged with this subject as well. Andrews (1997), for example, examined nomadic architecture in the Middle East from structural and climatic perspectives. Hassas and Borucka (2020) classified Siah Chadors used by nomads across various countries according to structural typologies. Similarly, Mojahedi, Vafamehr, and Ekhlassi (2021) conducted a comparative study of temporary nomadic architecture among three different tribes.

A review of this body of research reveals that most investigations have focused almost exclusively on the residential and temporary aspects of nomadic architecture. Few have addressed the broader scope of nomadic built environments, including non-residential structures, communal spaces, livestock-related facilities, and the cultural or social functions embedded within these architectural forms.

Accordingly, the present study seeks to move beyond the traditional framework of temporary housing by addressing the central question: "What is nomadic architecture, and on what basis can its various types be identified and classified?" With this objective, the research aims to identify and categorize all forms of nomadic architecture—both residential and non-residential. In doing so, the study employs cultural, climatic, structural, and functional approaches, as well as spatio-temporal patterns, as the primary analytical frameworks.

3. Research methodology

This study adopts a qualitative methodology and pursues a dual objective—both fundamental and applied. On the one hand, it seeks to expand theoretical knowledge in the field of nomadic architecture; on the other, its findings aim to support the identification, conservation, and promotion of the tangible and intangible cultural heritage of Iranian nomads. Accordingly, the research exhibits a hybrid nature, combining theoretical inquiry with practical application.

For data collection, a combination of library research and fieldwork methods was utilized. In the initial phase, written sources—including books, academic articles, field reports, and historical documents—were reviewed to establish the theoretical foundations of the study and to examine prior research. In the subsequent phase, the researcher conducted extensive fieldwork across various nomadic regions in Iran. Through direct observation and immersion in nomadic environments, qualitative data were gathered regarding different types of handmade nomadic structures. These data capture the physical, structural, functional, and cultural characteristics of architectural forms used by nomads during different phases of seasonal migration.

The collected data were then analyzed using a descriptive-analytical approach, which allowed for detailed documentation of nomadic architecture and examination of the interrelations among its cultural, climatic, functional, and structural components. This process facilitated the identification of recurring patterns as well as architectural diversity within nomadic life.

Ultimately, the study synthesized these findings to address its central research question and to identify and classify various types of nomadic architecture. The result is the formulation of a conceptual and practical framework for analyzing nomadic architecture in the Iranian context.

4. Geographical scope

The geographical scope of this research covers various regions across Iran where nomadic communities are traditionally based. These areas primarily include mountainous terrains, plains, and seasonal pastures (yaylāq and qishlāq), which offer a wide range of natural and climatic conditions favorable to nomadic lifestyles. Field investigations and sampling of handmade nomadic structures were carried out in these diverse settings.

The selected regions span several provinces, each chosen for its distinctive climatic, cultural, and historical relevance to nomadic habitation. These include:

The western provinces of East Azerbaijan and West Azerbaijan, home to Shahsevan, Kurdish and other nomadic groups.

The central and southern provinces of Fars and Kohgiluyeh and Boyer-Ahmad, where Qashqai and Bakhtiari nomads have historically resided.

This geographical coverage was intentionally chosen to represent the enduring diversity of nomadic cultures in Iran, making it well-suited for identifying and analyzing a wide array of nomadic architectural typologies.

5. Research findings

According to the Amid Dictionary, the term Ashāyer (nomads) refers to tribal groups who earn their livelihood primarily through pastoralism (Amid, 2014). Nomadism denotes a lifestyle in which people sustain themselves by raising livestock and using agricultural products, migrating seasonally in search of natural pastures. This way of life has existed in Iran since ancient times and continues to persist today. In the Iranian context, several terms—such as Ashāyer (tribes), Kuchneshin (nomads), Eliyāti (tribal people), Biābangard (desert wanderers), Gallehdār (herders), Goluneh, and Māldār-e Chādarneshin (tent-dwelling herdsmen)—are used to describe different aspects of nomadic life (Emanollahi Baharvand, 1981). In this study, the term Ashāyer is employed to refer to nomadic communities.

5.1. Nomadic architecture

Nomadic architecture is not merely a form of shelter or a temporary structure—it is an inseparable component of the broader nomadic way of life (Trisno, Husin, and Lianto, 2023). Nomadic communities across all continents design and build structures tailored to their living needs, often using locally available materials. Like other forms of informal architecture, nomadic architecture centers on human needs and prioritizes practicality and adaptability. It encompasses a wide spectrum, from simple utilitarian forms to elaborate cultural expressions (Trisno et al., 2023).

The origins of nomadic architecture trace back to early human societies that migrated in search of food, water, and shelter. In diverse geographical settings, nomadic groups developed unique architectural traditions suited to their specific environmental and cultural conditions. Well-known examples of such adaptive architectural forms include the Mongolian yurt, North African tents, and Native American tipis.

Hassas (2021) defines nomadic architecture as the “home” of nomadic people, challenging the notion that tents are merely temporary shelters. She provocatively asks: how can a structure that meets human needs day and night for centuries still not be regarded as a 'home'?

Aghaei, approaching the subject from an archaeological standpoint, argues that nomadic architecture is shaped by the need to adapt to the environment—prioritizing energy conservation, protection from the elements, and the safety of both people and livestock (Aghaei, Hesari, and Karami, 2018).

Nomadic architecture specifically refers to structures designed and constructed by nomadic societies. These structures vary in form and function according to cultural traditions, climatic conditions, livelihoods, and the scale of migration. Due to the mobile nature of nomadic life, this architecture typically emphasizes transportability, simplicity, lightness, and flexibility (Soleymani Amirshkari, 2019).

In this study, nomadic architecture is defined as the art and practice of designing and building all types of structures created by nomadic communities. This encompasses a diverse range of spaces and forms, including Siyāh-Chādor (black tents), masonry dwellings, Ālāchigh (felt tents), Pilevari caravanserais, fortresses, animal shelters, communal gathering spaces, and play areas.

5.2. Typology in architecture

In architecture, a type is defined as a schema or prototype in which the common characteristics of a group of buildings are identifiable (Memarian and Tabarsa, 2013). The concept of type and typology in architectural discourse was first introduced by Ghiyath al-Din Jamshid Kashani in the 9th century AH (15th century CE). In his book Miftah al-Hesab, he referred to various traditional architectural elements—such as arches, vaults, and domes—using the term “qesmat” (meaning section or category), which conceptually aligns with the contemporary notion of type.

Architectural typology as a formal discipline began in 18th-century France, focusing on both form and function. During this period, Laugier explored the concept of the primitive hut, and later, in collaboration with professors at the École Polytechnique in Paris, developed typological classifications based on theories of independent origins and the gradual evolution of architectural characteristics (Durand, 2000). His definition of type was largely quantitative and mechanistic, utilizing coded systems to analyze architectural forms. The rationalist logic of that era in typology laid the foundation for later eclectic movements (Moneo, 1978).

In general, architectural typology serves as a framework for organizing and analyzing buildings based on shared features. This approach enables broader interpretations by integrating various chains of thought and diverse perspectives. In Iran, over the past three decades, typological studies—especially in the field of vernacular architecture—have garnered increasing attention, supported by institutions such as the Building and Housing Research Center and the Housing Foundation of the Islamic Revolution (Soltanzadeh and Ghaseminia, 2011).

In this context, Ardalan and Bakhtiar emphasize the symbolic and semantic dimension of typology from the perspective of the archetype. They assert that the archetype possesses a transcendent essence that is reflected in various physical forms within the material world (Ardalan and Bakhtiar, 1973). In sum, researchers have explored architectural typology from both morphological and physical as well as semantic and symbolic perspectives.

5.3. Nomadic architecture and its typology

Nomadic architecture, as a tangible reflection of the culture of nomadic communities, symbolizes human adaptation to the natural environment and innovation in utilizing local resources. This architectural form embodies both tangible and intangible cultural heritage, encompassing diverse values and dimensions, including historical, aesthetic, social, and environmental aspects. To gain a comprehensive understanding of nomadic architecture, typological analysis must consider not only the morphological and physical dimensions but also the structural and foundational (genotypic) characteristics. In this study, the typology of nomadic architecture is based on its genotypic features, with a particular focus on its fundamental structures.

Nomadic communities rely on the natural resources available in their ecosystems to construct their architecture (Trisno et al., 2023). One of the most distinctive aspects of nomadic architecture is its close relationship with the environment. By utilizing local and natural materials such as wool, wood, and reed, and designing structures that adapt to climatic conditions, this architecture exemplifies sustainability and respect for nature. Additionally, the flexibility of these designs enables easy relocation and effectively responds to the seasonal and livelihood needs of nomadic life.

Today, nomadic tourism is recognized as a distinct form of tourism characterized by unique spatial patterns. This type of tourism, particularly in the form of ecotourism, has gained significant importance and attracted substantial international investment (Yousefi, Tamassoki, and Tamassoki, 2022). Nomadic ecotourism, in particular, plays a beneficial economic and cultural role, generating positive impacts for both nations and nomadic communities.

To understand nomadic architecture more precisely, it is essential to systematically classify the structures used by these communities based on a range of distinct characteristics. This typology is influenced by factors such as the level of mobility among nomads, patterns of pasture ownership, climatic conditions, cultural traits, livelihood strategies, and the spatial functions of the structures. One of the most important distinguishing features of nomadic architecture, in contrast to sedentary architecture, is mobility. Nomadic groups are constantly on the move, responding to seasonal changes and environmental conditions, and establish temporary settlements in specific parts of their territory.

Unlike the architecture of rural and urban communities, nomadic architecture is more dependent on natural, geological, and climatic factors. The materials used in constructing these structures are sourced from local and natural environments, including goat hair and wool, wood, reeds, soil, lime, stone, and tree branches. These materials are not only accessible and renewable but also fulfill the needs of a mobile and temporary lifestyle.

5.4. The "Spatio-Temporal" and "Functional" models in nomadic architecture

Nomadic architecture is a direct reflection of the nomadic lifestyle—a way of life shaped by regular and seasonal migrations within natural landscapes, closely intertwined with the environment, climate, and subsistence economy. In this context, space functions not only as a physical container for habitation but also as an integral part of survival mechanisms, production systems, and cultural rituals. Therefore, typologizing nomadic structures requires a model capable of effectively capturing this complexity and dynamism. The "spatio-temporal" and "functional" models provide appropriate analytical frameworks for this purpose, as they align with the ecological and cultural realities of nomadic communities.

Typologizing nomadic architecture based on these two models aims to identify and classify the fundamental structures and spatial orders governing this architectural tradition. Despite differences in form, material, and climatic context, these structures follow a shared internal logic. This typology can be situated within the conceptual realm of the "genotype," as it analyzes the deep structural layers of nomadic architecture by focusing on stable patterns and space-organizing algorithms. In contrast, the external and variable manifestations of this architecture—shaped by interactions with the environment, climate, and local cultures—can be interpreted as "phenotypes." In other words, typology based on spatio-temporal and functional models reflects a shared spatial and conceptual system among nomadic communities, expressed in diverse forms and indicative of genotypic characteristics.

5.5. The Spatio-Temporal Model

The spatio-temporal model, rooted in the inherently mobile nature of nomadism, allows for the classification of structures based on their geographic location (summer pastures, winter pastures, and migratory routes) and the duration of their use (temporary, seasonal, semi-permanent, or permanent). This model also considers the adaptability of structures to climatic conditions, access to natural resources, and the need for portability or durability. In other words, nomadic architecture cannot be understood or analyzed without considering the spatial and temporal context of settlement.

This section of the study investigates the spatio-temporal model in the context of Iranian nomadic architecture. One of the key characteristics of this architecture is its strong connection to seasonal mobility and climatic variability. That is, at each stage of migration, pastoral nomadic communities adapt their architectural structures significantly in response to factors such as weather conditions, pasture availability, and subsistence needs.

Iranian nomadic groups typically occupy different geographical zones throughout the year. Specifically, during winter, they settle in low-altitude winter pastures (qeshlaq); in autumn, they move to mid-altitude slopes;

in spring and part of the summer, they migrate to highland summer pastures (yaylaq); and during the remainder of the summer, they occupy cold intermountain plains. These spatial shifts not only directly influence their lifestyle and livelihood strategies but also result in significant architectural transformations in the structures they use.

A notable example of architectural change during seasonal migrations is the transformation in the design and structure of the black tent (siah chador). At each stage of migration (yaylaq, qeshlaq, and transition), black tents exhibit specific features, including variations in platform shape and the location of hearths, based on the geographic and climatic context. These changes demonstrate the nomadic architecture's precise adaptation to the spatio-temporal conditions of nomadic life.

Consequently, Iranian nomadic architecture can be categorized into three general types based on spatial and temporal conditions: temporary, semi-temporary, and permanent. This classification aligns with the three main stages of nomadic settlement—yaylaq, migration, and qeshlaq—and accurately reflects the architecture's responsiveness to the shifting spatial and temporal conditions of nomadic existence.

This typology, based on geographical locations and usage duration, comprehensively explains the complex processes underlying nomadic architecture and illustrates how these communities' structural systems adapt to seasonal and climatic changes.

5.6. Typology of nomadic structures in Iran

Based on research findings, nomadic architectural structures in Iran can generally be classified into three categories: transportable, immovable, and semi-transportable structures. Each category reflects specific features shaped by subsistence needs, geographical locations, and seasonal changes inherent to nomadic life.

5.6.1. Transportable structures

Transportable structures are those designed for easy assembly and disassembly due to their temporary nature, allowing for mobility by nomadic groups. These structures are typically made from soft, natural materials readily available to nomads. Notable examples include black tents (siah chador), kapar huts, kuar, and various animal shelters—all made from materials such as leather, specialized fabrics, and wood. These structures are primarily used during migration and seasonal relocation, and are characterized by simple, functional designs that accommodate quick and easy movement.

5.6.2. Immovable structures

Immovable structures are usually constructed in fixed locations within yaylaq or qeshlaq areas and remain permanently in place. These are typically built in regions revisited annually by nomads and often include winter structures in cold mountainous areas. Built from locally sourced and durable materials such as wood, stone, mud, and lime mortars, they include khan residences, shrines, village-like homes, animal shelters, and small fortifications. Along migratory routes, defensive shelters were also constructed—used by armed guards to protect the tribe during transit.

5.6.3. Semi-transportable structures

Semi-transportable structures combine features of both mobile and immobile architecture. Typically, the foundation and walls—requiring durability—are built from hard materials, while the roof and coverings are made from soft, temporary materials. A prominent example includes the stone-enclosed black tents used in cold qeshlaq regions, where traditional fabric covers (chugh) are replaced by stone barriers to better resist cold and wind. These hybrid structures provide resistance in harsh environments while maintaining the flexibility needed for seasonal reconstruction or relocation.

This classification clearly illustrates the diversity and complexity of nomadic architecture in Iran—ranging from simple, temporary shelters to resilient, permanent constructions. Each structure is crafted from specific materials in response to seasonal needs and geographical conditions. This categorization enhances our understanding of how nomadic architecture interacts with the environment and supports efforts to preserve and sustain these unique architectural forms.

5.7. Functional pattern of nomadic architecture

The functional pattern of nomadic architecture is one of the most important aspects of this architectural style, directly linked to the daily needs of nomadic communities. This pattern, as one of the fundamental components of nomadic architecture, takes into account not only the physical needs but also the cultural, social, and environmental dimensions of nomadic societies. Nomadic architectural structures are designed to meet all livelihood and cultural needs at each stage of movement and settlement in various regions.

5.7.1. Design of residential spaces
Residential structures in nomadic architecture typically consist of spaces designed for temporary yet comfortable habitation. These spaces are specifically built for short-term movement and settlement in different areas. The design of these spaces considers essential needs such as heating, ventilation, and protection against climatic conditions. For instance, black tents, one of the most recognized residential structures in nomadic architecture, are designed with flexible structures and indigenous materials like wool and leather, specifically to adapt to various climatic and geographical conditions.

Black tents, as temporary living spaces, are commonly used during the migration from one region to another. The design of these structures is such that they can be easily erected and dismantled, which is an essential feature for nomadic life. This type of architecture enables nomads to adjust their living space at any time and place as needed.

5.7.2. Livelihood and productive spaces
Alongside residential spaces, there are other areas in nomadic architecture specifically designed for livelihood activities. Since animal husbandry and agriculture are the main sources of income for nomads, nomadic architecture includes spaces for livestock housing, food storage, workshops, and even small areas for food preparation and cooking.

Livestock spaces are of particular importance and must be designed to protect animals from natural threats and wild animals while also providing for their nutritional needs. Typically, these spaces are designed as storage areas made of wood or matting, allowing for proper ventilation and protection from extreme temperature changes.

5.7.3 Ritual and social spaces
Another aspect of the functional pattern of nomadic architecture is the social and ritual spaces. These areas, in addition to meeting daily needs, serve as places for social interaction and cultural and ritual activities. In nomadic societies, many cultural rituals, such as festivals, religious ceremonies, and social gatherings, take place in these spaces.

These spaces may include larger tents or pavilions used for holding ceremonies and social gatherings. In some cases, these structures are considered gathering places for tribes and clans and are temporarily constructed in specific areas of the nomads' territory.

5.7.4. Service-commercial structures
Nomadic architecture, aside from residential aspects, also includes service and commercial dimensions. Nomads create spaces for temporary markets, rest stops at caravanserais, and trade connections with other groups. Nomadic markets are among the prominent examples of these structures, often set up in early spring in some areas. These markets not only serve as places for buying and selling nomadic products but also offer opportunities for cultural and social exchange between nomads and other segments of society.

Finally, the architecture of Iranian nomads, particularly in structures such as yurts, black tents, defensive structures, and livestock spaces, reflects the social, cultural, and climatic needs of nomads. These structures, in addition to being functional tools for survival and daily life, symbolize the identity and cultural beliefs of the nomads. Documenting and preserving these structures not only helps preserve a cultural heritage but also leads to a deeper understanding of the way of life and culture of nomads.

4. Conclusion

This paper analyzed nomadic architecture as an essential component of the cultural and social identity of nomadic communities. This architecture, which has evolved through continuous interaction with the environment and the use of natural resources, is recognized not only as a temporary shelter but also as a symbol of awareness, adaptability, and resilience in the face of climatic and cultural changes. Classifying nomadic architecture based on functional, spatial-temporal patterns and the biological needs of nomadic communities provides a more precise and comprehensive understanding of this architectural style.

This research, by categorizing nomadic structures into three main groups—movable, semi-movable, and immovable—and identifying various functional patterns such as yurts, livestock spaces, storage areas, recreational spaces, service-commercial spaces, tombs, and defensive structures, illustrates the complexity of nomadic architecture in terms of spatial, climatic, social, and cultural dimensions. Furthermore, these analyses help understand the internal logic of nomadic architecture, laying the foundation for preservation and documentation policies for this invaluable heritage.

In conclusion, it is evident that nomadic architecture is not just a historical cultural heritage but should also be regarded as a living part of contemporary culture, deserving of protection and documentation. By utilizing this indigenous knowledge, sustainable development and nature-friendly architecture can be achieved in today's world. Therefore, protective and research-oriented efforts must be prioritized to preserve this heritage and ensure that the rich identity and culture of nomadic communities are passed on to future generations.

Unveiling the hidden meanings of transparency: Fondation Cartier's structural reading as an art-cell

Nazlı Taraz Varışlıaslan*[1]

[1] *Bursa Technical University, Department of Architecture, 16320 Bursa, Türkiye*

Abstract. In 1994, a globally known luxury goods-manufacturer Cartier collaborated with Jean Nouvel to design a multi-functional building that integrates branding and art in a single space. The architect skeletonized a super-transparent box in Paris with an interlocked structure of glass and steel. By placing transparent and elongated surfaces on facades, Nouvel created real-time changing interplays with ongoing environmental and urban flow. Behind these screens, the transparent mass of the Fondation Cartier melts boundaries between the city and the citizen by providing various spaces for art pieces, exhibitions, installations and besides, working offices. Majorly, the building is valued for its generous opportunities and supportive approach to artists all over the world and, blurs the barriers standing between the artist and the audience by paving visible and accessible ways for everyone. The Fondation Cartier is also identified as an ideological apparatus with its "accessible", "visible" and "honest" structure as a continuation of the comprehensive construction process of Paris called *Grand Projets*. Hence, attentive combination of the modern architectural tendencies, materials and construction techniques are supposed to underline new, light and transparent urban silhouette of the city as a symbolic reflection of the ongoing political agenda. Thus, in this study, it is aimed to unveil the hidden meanings of the Fondation Cartier through semiotic analysis to construct a multilayered perspective on structural and representational stances of the the building which becomes a monumental, light and transparent art-cell in Paris from the mid-1990s until today.

Keywords: Fondation Cartier; Jean Nouvel; Transparent structures; Semiology; Art spaces.

---

1. Introduction

Paris has undergone two significant transformation periods since the 19th century. The first urban change occurred in the 1860s when the French Emperor Napoleon III and Georges-Eugene Haussmann agreed that a comprehensive urban transformation was necessary for Paris to prevent riots due to the ongoing discontent between the administrative leaders and the citizens (Fierro, 2003). Thus, Haussmann determined two main principles in the planning strategy of Paris: creating wide boulevards for controllable and visible circulation and decreasing the intensity of mass buildings in the urban context to increase the city's accessibility. Naturally, those superstructural transformations brought about a grand amendment in the infrastructure (Fierro, 2003). This way, the city's wide boulevards provided a safe circulation in urban life, and possible riots and meetings were largely prevented. Compared to the former urban structure of Paris, consisting of narrow streets, the new and lively arteries of the city became concrete representations of a safe urban life. As a result of the grand change in the city, Paris transformed into a vast theater stage where the historical buildings were met with new governmental edifices and housing zones on the two sides of the wide boulevards where the citizens could be easily governed, controlled, and observed.

The second reconstruction period of Paris began during François Miterrand's presidency, and the president initiated a comprehensive regulation program for Paris, called *Grand Projets*, from his selection in 1981. Like Haussmann, Mitterrand aimed to re-create Paris as a commodious city for the citizens. However, as a complementary advantage, Mitterand considerably benefited from the era's modern and improved construction technologies and production techniques. Mitterand's reconstruction process could be summarized as the maintenance of historical artifacts, relocation of existing buildings, and construction of new buildings designed for Paris by the key architects of the time (Fierro, 2003). Thus, *Grand Projets* were conducted by Mitterrand and the architects with a great collaboration of the new materials, especially using glass and steel with the new construction techniques. Musee d'Orsay (1986), Parc de la Villette (1987), Grande Arche la Defense (1989), Louvre Pyramid (1984), Opera Bastille (1989), Ministere des Finances et de l'Economie (1988), Bibliotheque

Nationale du France (1996), Tjibaou Culturel Centre (2000), and Arab World Institute (1987) were among *Grand Projets* which were designed and built to create a new city silhouette, built environment and urban life for Paris.

Jean Nouvel, the French architect, became a key figure in the grand transformation of Paris during the *Grand Projets.* As a grad student of Ecole des Beaux-Arts, Nouvel's architectural design philosophy is largely fed from the transition of perceptions, visual plays, and multi-layered space concepts. Thus, Nouvel frequently used visual possibilities of glass and steel as light and reflective structural complements (Boissiere, 1996). In his words, "the way of learning should not be based on copying, but on being able to diagnose a specific situation" (Cambert, 2004). Accordingly, the main target of architecture is to respond to people's demands at specific times, and geographies properly comply with Nouvel's design attitude. Thus, architecture is always considered within specific contexts, cultures, climates, and people. Otherside, architects could not easily be freed from facsimile and mechanization. Here, mechanization does not correspond to "mechanics" but to stereotyped designs that ignore personal, cultural, and geographical specificities (Cambert, 2004).

2. An Architectural Reading on Fondation Cartier

Jean Nouvel's attentive design philosophy shows itself in Fondation Cartier pour l'Art Contemporain. Before its design in 1994 by Nouvel, Fondation Cartier was established in 1847 by well-known jewelry manufacturer Cartier S.A (Fierro, 2003). Until a group of investors bought the Cartier in 1972, the brand was located at the Rue de la Paix in the 2nd Arrondissement. In 1984, Alain Dominique Perrin, who collaborated with those investors, founded the art museum with its new name, Fondation Cartier pour l'art Contemporain, to give opportunities to young artists worldwide. In 1994, Fondation Cartier moved its new site to 261 Boulevard Raspail in the 14th Arrondissement of Paris with its new building designed by Jean Nouvel. In accordance with *Grand Projets,* the building's structural characteristics, material usage, and construction novelties reflect the technological improvements of the era, including the use of glass and steel to create 12.000 square feet and a 6-storyed monumental building for the office and art spaces of the Fondation Cartier. The reflective construction materials created a continuously changing urban silhouette of Paris on the surfaces of the building, and the vision is constantly re-produced in accordance with ongoing urban density, climate conditions, and changing daylight. This way, Fondation Carties became one of the city's most outstanding symbolic edifices in the urban context with its complex perception, monumentality, and hidden meanings in design and material choices (Fig.1).

Fig. 1: View of the Fondation Cartier (ArchDaily, 2025)

With its garden penetrating the building and its huge, transparent glass walls on the façade, Fondation Cartier differs from its counterparts by proposing an unconventional exhibition space. Around the glass walls, trees in the garden reach the museum's top and create stunning botanic influences on visitors' perceptions. The Lebanese Cedar, which was planted by French author, politician, and diplomat François-Rene Chateaubriand in 1823, behaves like a gate for the building (Asensio ed., 2002). Also, it determines a symmetry axis in front of the transparent glass façade and contributes to increasing blurred space perception. In this way, Jean Nouvel generates a perception that incites visitors into a transparent and reflective complexity (Baudrillard & Nouvel, 2002). This sort of illusion, which incites curiosity and discovery, strengthens the relationship between the visitor and the building and transforms Fondation Cartier into a living art-cell between perception, reality, reflection, and illusion.

3. Transparency as a Sign for Citizenry / City and Wealth / Honesty
In semiology, a *sign* consists of a signified and a signifier. The sign delivers a specific meaning by substituting and representing a certain entity, philosophy, idea, or object. However, the signified cannot be directly perceived; perceived¸the signifier can easily be conceived (Rifat, 2018). Signs could vary in different circumstances such as a *qualisign* – as a qualitative sign-, *signisign* – as a singular sign – , a *legisin* – as an order sign – , *icon* – as a visual sign –, *index* – as a relative sign – , and a *symbol* – as a compromised representation – (Rifat, 2018). Accordingly, meaning is defined as an entity consisting of certain signals and symbolization methodologies to convey defined information (Preziosi, 1979). From this perspective, the built environment and a city transform into "a bricolage of daily life," which is composed of harmonious signalization and symbolization (Preziosi, 1979). In the architectural discourse, each part of the built environment and architectural products are evaluated as signs to convey a defined language of their era (Kalpaklı, 1990). Accordingly, architectural concepts and the composition of materials could be used in certain methods to convey and symbolize hidden meanings in daily life. Moreover, due to the transparent character of glass, the blurring boundaries between inner and outer spaces were easily produced (Richards, 2006) (Fig.2).

Fig. 2: View of the reflective transparent façade of the Fondation Cartier (Archdaily, 2025)

Transparency is the key concept for the Fondation Cartier, which is achieved by strategically using glass to create a multi-sensory perception of the built environment from history onwards. In the middle of the 13th century, glass was found as a chemical product made of silicon dioxide, which shows liquid characteristics despite its firm and stable quality. Following the 17th century, glass was re-processed into glass-making and glazing technologies, which resulted in a shift in the production industry. Because of its penetrability, cheapness, and ampleness, glass became an important material after its discovery (Wigginton, 2002). Moreover, the spiritual and sacred understanding of glass is also another powerful philosophy that affected the use of glass, especially in Gothic architecture (Richards, 2006). Thus, glass became one of the most prominent architectural materials actively used in structural productions and design philosophy (Elkadi, 2006).

As a novel perspective, Scheerbart proposes that architecture and culture have a reciprocal relationship. Accordingly, more qualified architectural environments can generate a higher level of culture and create a new understanding of design. The material qualities of glass provide a wide range of advantages in the built environment. In this way, the use of daylight could be increased while wide openings were designed in buildings. Moreover, heating and cooling issues could easily be controlled in glass structures to design healthy and livable environments. Additionally, Scheerbart integrates iron skeleton with glass to produce wide openings and high-ceilinged comfortable interiors (Scheerbart, 1972). Thus, special importance is attached to glass and transparency in different fields, such as architecture, painting, and poetry. As a result of glass's material characteristics, transparency became a critical output. Particularly, the Industrial Revolution and developed technological improvements accelerated the application fields of glass, and its transparent and bilateral effects on spatial perceptions became prominent in different design areas (Betsky, 2016). In this way, transparency gave opportunities to glass users, especially architects and space designers, to create extraordinary ambiguities in inside-outside apprehensions and to generate or destroy the boundaries in space (Glass, 2002).

This sort of use shows itself in Fondation Cartier's huge glass walls and trees in the garden. The aggregation of glass walls and the reflective character of the materials create an unclear experiment, and this uncertainty shakes the spatial perception. Novel explains this sensation "… if I look at a tree through the three glass panels, I can never determine if I am looking at the tree through the glass, in front of it, behind it, or the reflection of the tree" (Baudrillard & Nouvel, 2002). With the loss of certainty, the sign becomes an active factor in constructing the building's visual appearance and the perception of its functional units, such as meeting rooms, offices, and exhibition spaces (Fierro, 2003). As Hertzberger defines space, "shaped by what is that surrounds it and otherwise by the objects within it and perceivable by us, at least when there is light… A space is determined as finite and fixed by its periphery and/or the objects in it." However, the glass walls of the Fondation Cartier provide synchronous surveillance both inside and outside (Hertzberger, 2003). Three huge transparent and reflective screens are gathering the city silhouette and the interior of the building as an art-cell in the heart of the city. This telescopic image consists of the Boulevard Raspail, the Place Denfert Rochereau, the Saint-Germain area, and the artworks in one glance (Fierro, 2003) (Fig.3).

Fig. 3: View of the Fondation Cartier (ArchDaily, 2025)

In addition to the bilateral perception of visitors, Parisians can acquire unexpected accessibility to the museum from the streets of Paris. With its huge, transparent façade, Fondation Cartier supports the relationship between artworks and people walking around the street. The reflective and easily seen façades transform the building into a showcase of the city by symbolizing prosperous citizenry in Paris with clarity, accessibility, and visibility. In this way, the building becomes a characteristic piece that gives its character to a city (Rossi, 2006). The artistic performances, installations, and exhibitions pour out Fondation Cartier by composing an art-cell with its legendary garden and reflective, transparent screens. Thus, Fondation Cartier proposes an unlimited design and artistic space in Paris in contrast to the massive and historical edifices of the city (Fig.4).

Fig. 4: View of the Fondation Cartier’s light and transparent façade (ArchDaily, 2025)

In this way, the building became a self-standing art object that continuously changes in accordance with the dynamism of time, sunlight, or climatic alterations of the day. Nouvel values dynamism as an unavoidable and necessary transformation for evidence of vitality (Baudrillard & Nouvel, 2002). Moreover, the exterior of the building and its mass organization lightly contribute to the built environment while reflecting the urban life around the green areas and city sidewalks.

Additionally, glass can be considered a sign of wealth and honesty in the urban context. During *Grand Projets,* Mitterand aimed to show governmental honesty by using transparency with glass-steel structures of the era. Here, in addition to the clarity of the glass, steel signs France's firm and improving stance on a symbolic level. Glass’ symbolic meaning, as a sign, also captivates a “hygienic” perception related to its inner objects. It requires high quality and assurance to show everything without covers or enclosures. It is necessary to be sure about the qualities of products to display them with all their nakedness. A glass of wine must be clear, or a bottle of olive oil must be crystalline to exhibit them in transparent pots. These concepts of prosperity and purity could be defined as semiotic consequences of glass and its transparency. With the transparent facades showing inside with all clarity and revealing the quality of objects inside it, Fondation Cartier glorifies the art.

4. Conclusion

In order to unveil an architectural edifice, it is crucial to understand its representative formations, interpretations, and signs (Kalpaklı, 1990). On the one hand, the site of a building, its urban context, environmental circumstances, design principles, material choices, production technologies, and usage scenarios constitute the overall construction; on the other hand, the hidden meanings of an edifice, the spatial use of the building, the use activity in and out of the structure complete the life story of an artifact. Accordingly, the physical qualities of a building and its perceived meaning play a strategic role in its participation in urban life. Because all factors have been continually changing within the ongoing agenda of the era, the character of an architectural edifice as a sign has also changed in accordance with those changing circumstances. In this way, signs replace the hidden meanings of a phenomenon while unveiling and substituting them. (Erkman Akerson, 2023).

From this perspective, the major transformation periods of Paris are evaluated as critical ruptures in history by bringing out critical changes in the urban context upon signs. Following Haussmann’s reconstruction period, by widening the city's main arteries to increase accessibility, visibility, and safety, Mitterand’s period generated an urban scale symbolization of a prosperous, firm, and honest administration. While each notion is signified by one or more signifiers, a complex and compositional sign appears in the urban context as an architectural edifice specific to this study. Jean Nouvel’s Fondation Cartier is a striking example of the signifier and signified relationship with its transparent and light structure, melting concrete boundaries between the citizen/administration, regular/artistic, and unaccessible/accessible. As Grosz proposes, space is perceived not only by perceptions but also by the body in space itself, which continually enriches with infinite virtual possibilities (Grosz, 2001). The controversial question “does transparency represent real accessibility or not?” Fondation Cartier represents an alternative response to the question of accessibility with these two basic points related to transparency and its signified meanings. The building's huge, transparent glass screens and meaningful garden create a monumental edifice for the city. In this way, Fondation Cartier has been an important interaction space for Parisians, from its first location as a jewelry shop in the 2nd Arrondissement to the present. Nouvel's illusion tactics and complex space perceptions put forward the building as a new spatial concept that can be experimented with ad infinitum by visitors and people who walk around the Paris streets. While the multiple usage supplies a continuous interaction between the city and the art museum, Fondation Cartier is valued as a locus for Paris and its inhabitants by creating a complex interaction space with its transparent characteristics and becoming a living transparent art cell for Paris.

The relocation and preservation issues of Hasankeyf

Elif Yılmaz*[1],Mazlum Kalak[2]

[1]Gazi University Institute of Science,Ankara,Türkiyes
[2] Gazi University, Faculty of Architecture, Department of Architecture,06570 Ankara,Türkiye

Abstract. Hasankeyf, located in Turkey's Southeastern Anatolia Region along the Tigris River, is a unique cultural heritage site with a history spanning 12,000 years. Due to the Ilısu Dam project, which posed the threat of submerging the area, many significant structures, including the Zeynel Bey Tomb, Artuqid Hamam, Middle Gate, İmam Abdullah Shrine, and Roman-era columns, were relocated to new settlement areas through specialized engineering projects. This effort aimed to preserve historical landmarks but also introduced various challenges, both physical and symbolic.

The displacement of these structures from their original context led to a loss of cultural and historical integrity. This separation disrupted the connection between the sites and their natural and historical surroundings, diminishing their authenticity. Additionally, the relocation process caused damage to some structures, further fueling criticism. Beyond architectural concerns, the Ilısu Dam project had profound socio-economic and environmental consequences. Local communities were displaced, losing their homes, agricultural lands, and centuries of cultural memory rooted in Hasankeyf. Such losses deeply impacted the social fabric of the region.

Environmental repercussions were also significant. The dam's construction altered the local ecosystem, leading to biodiversity loss and the submersion of a unique natural landscape. While the project proponents emphasized economic benefits and energy production potential, the long-term costs to heritage and ecology have been substantial.

The Hasankeyf case highlights the tension between development and heritage preservation. It underscores the necessity of prioritizing in situ conservation and integrating inclusive, long-term planning into such projects to safeguard cultural sites and affected communities.

Keywords: Hasankeyf, Ilısu Dam, cultural heritage, relocation process, preservation

1.Introduction

Hasankeyf is a settlement area located in the Southeastern Anatolia Region of Turkey, stretching along the Tigris River, with a history of 12,000 years, holding significant value as part of humanity's heritage. Throughout history, the region has hosted numerous civilizations, and it has a culturally rich heritage, featuring structures such as cave settlements, bridges, tombs, and palaces that carry the traces of these civilizations.

Despite being declared a natural conservation area in 1981, Hasankeyf faced the risk of submersion due to the implementation of the Ilısu Dam project. According to Çelik (2019), although the dam project is defended on the grounds of offering significant opportunities for energy production and economic development, it has sparked serious debates regarding the preservation of cultural heritage and environmental sustainability.

Although efforts were made to preserve the historical structures in the region by relocating them, this process has been criticized by many experts. The structures that were relocated were physically preserved, but they faced the risk of losing their cultural integrity as they were separated from their original contexts and historical settings. Experts on cultural heritage preservation emphasize that maintaining structures in their original locations is the most effective approach for the sustainability of historical and social memory. However, the relocation process implemented within the Ilısu Dam project did not fully adhere to this principle, and as Demir (2021) states, it has resulted in irreversible changes to Hasankeyf's historical identity.

The construction of the dam is considered one of the key factors threatening the region's historical identity and ecological structure. Specifically, the process of relocating historical structures has sparked various debates regarding the proper way to preserve cultural heritage (Erdoğan, 2018). International organizations such as UNESCO, ICOMOS, and WWF argue that cultural heritage preservation should be carried out on-site. However,

* Corresponding author, E-mail: yilmazelif03@gmail.com

https://doi.org/10.31462/icearc2025_a_car_031

the challenges of balancing economic development and the preservation of cultural heritage are clearly observed in the case of Hasankey (UNESCO, 2020).

This paper will address the historical and cultural significance of Hasankeyf, discuss the impacts of the Ilısu Dam on the region, and examine the preservation processes, offering alternative solutions. The paper will particularly explore whether the relocated structures have lost their authenticity, the technical details of the relocation process, and the engineering and preservation strategies applied during this process.

2. The Historical and Cultural Heritage Value of Hasankeyf

Hasankeyf is considered one of the oldest settlement areas in Mesopotamia. The region, which bears the traces of numerous civilizations such as the Sumerians, Assyrians, Persians, Romans, Byzantines, Artuqids, and Ottomans, has historically been a key point on trade routes (Fig. 1.). As a result, Hasankeyf has been an important stop not only for its architectural significance but also due to its strategic and economic importance. The region has served as a military, commercial, and religious center at various times, and throughout this process, it has built significant structures while maintaining its cultural diversity. (UNESCO, 2020).

Fig. 1. The Original Site of Hasankeyf

However, with the Ilısu Dam project, Hasankeyf's historical and cultural heritage has been placed under serious threat. While some significant structures in the region have been relocated and preserved, many historical elements have been submerged under the dam's waters. This situation raises the debate regarding the balance between cultural heritage preservation and development projects. (ICOMOS, 2017).

2.1 The Strategic Location and Historical Significance of Hasankeyf

Hasankeyf, due to its location along the Tigris River, has held strategic importance throughout history. Its position on trade routes extending from Mesopotamia to Anatolia has facilitated the region's economic and cultural development. An important settlement since ancient times, Hasankeyf became one of the significant cities of the Islamic world during the Middle Ages. Throughout this historical continuity, Hasankeyf's urban layout has been shaped in harmony with the natural topography and water resources. The castle, city center, and religious structures located along the banks of the Tigris River reflect the region's strategic role in both defense and commerce. Gabriel's (1932) map illustrates the spatial relationships among these structures, forming the historical core of Hasankeyf, shedding light on the physical organization of the city. The map also visualizes the integrated structure of historical buildings with the river, walls, and the urban fabric (Fig. 2).

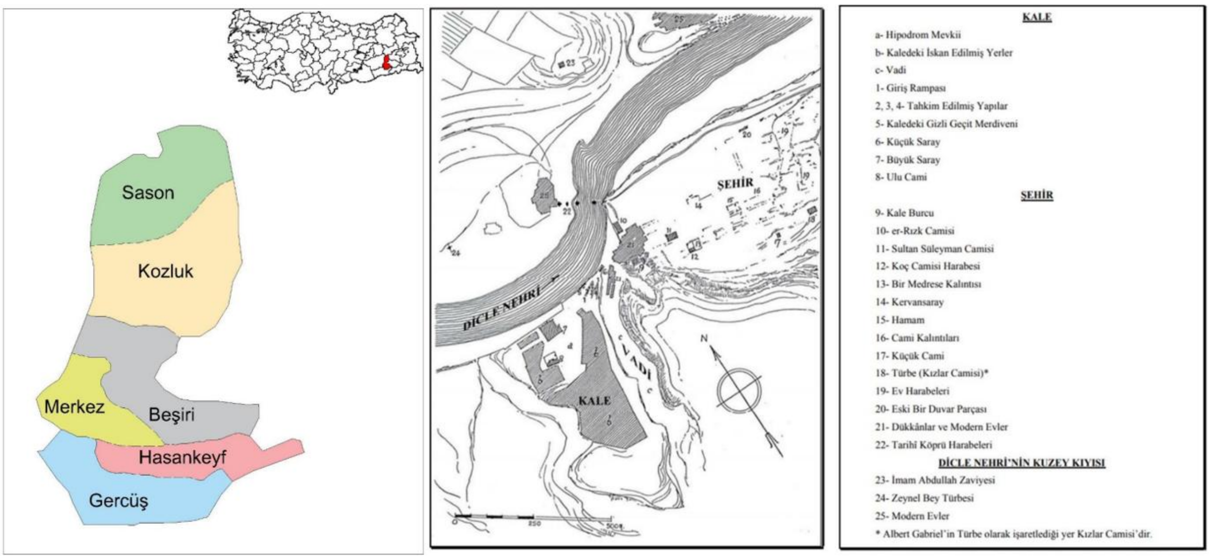

Fig 2.Location and Settlement of Hasankeyf (Gabriel, 1932)

The region's geographical structure, with natural rock formations providing a defensive advantage, led to its use as a "fortress city" throughout history. During the Artuqid and Ottoman periods, this strategic location was also utilized, and the city developed as an important administrative center in the region. During this process, numerous palaces, mosques, bridges, and underground structures were constructed (Atalay, 2021).

2.2 Important Buildings and Architectural Features in Hasankeyf

Located at the crossroads of various civilizations, Hasankeyf has embraced many cultural layers throughout its historical development, resulting in a unique architectural diversity in the region. The structures that span from the ancient period to the Ottoman era are not only significant in terms of historical identity but also stand out for their architectural and engineering features. These buildings serve as important documents reflecting the technical capabilities, aesthetic understanding, and socio-cultural structure of their respective periods. Below, key structures that have emerged throughout Hasankeyf's historical development are presented chronologically, along with their architectural features (Fig. 3).

- Cave Settlements: Hasankeyf contains approximately 6,000 cave dwellings, which were used by different civilizations from the 8th century BC to the Middle Ages. Cave settlements are considered an important part of Hasankeyf's natural and cultural heritage (WWF, 2021).
- Roman Columns and Bridges: Dating back to the 2nd-3rd centuries AD, these structures are key elements that strengthen Hasankeyf's historical context. Particularly, the bridge over the Tigris River highlights the region's importance on ancient trade routes (Zeybek, 2021).
- Castle: Initially constructed during the Byzantine period (4th-5th centuries), Hasankeyf Castle was strengthened by the Artuqids and Ayyubids during the Middle Ages and served as a strategic defensive structure. Its commanding position over the Tigris River provided protection from attacks for many years (UNESCO, 2020).
- Ulu Mosque: Dating back to the 12th century, this mosque belongs to the Artuqid Dynasty and is a significant example of Islamic architecture in the region. The mosque's minaret and interior decorations reflect the development of Islamic art in Anatolia (Yılmaz, 2022).
- Artuqid Bathhouse: This bathhouse from the 12th century is one of the important examples of Artuqid architecture. The bathhouse's original heating and water distribution systems showcase the engineering knowledge of the period (Karahan, 2020).
- Palaces: Numerous palace remains, built from the 13th century during the Artuqid and later Ottoman periods, reflect the region's historical identity. These palaces provide important clues about the administrative structures of the time (Atalay, 2021).
- Zeynel Bey Tomb: Built in 1473 for Zeynel Bey, the ruler of the Akkoyunlu dynasty, this monumental tomb is one of the most recognized structures in the region and carries the influences of Central Asian architecture (Erdoğan, 2018).

Fig 3. Ancient Structures of Hasankeyf (Yılmaz, 2019)

The structures in Hasankeyf have been shaped by the contributions of various civilizations throughout history, resulting in a rich cultural heritage. However, due to dam projects and modernization processes, much of this heritage is now submerged under the reservoir. Although conservation efforts are underway, more comprehensive policies need to be developed to ensure the long-term sustainability of the cultural heritage. Given Hasankeyf's historical and cultural significance, it is essential to adopt more effective conservation strategies at both national and international levels (ICOMOS, 2017).

Hasankeyf has hosted numerous civilizations throughout history, contributing to the accumulation of a rich cultural heritage. However, with the completion of the Ilısu Dam, many significant structures in the region have been largely submerged, and the old settlement area has been drowned. The new settlement area has been built approximately 3 kilometers away from the original settlement, with 710 houses and 98 workplaces completed and handed over to the rightful owners. According to the Ministry of Agriculture and Forestry (2019), efforts to protect the cultural heritage in Hasankeyf are ongoing; as of 2024, volunteers have been encouraged to participate in these activities, and it has been emphasized that this process could create new employment opportunities for the local population through sustainable tourism. Given Hasankeyf's historical and cultural significance, it is evident that more comprehensive and effective strategies for the region's preservation must be implemented at both national and international levels.

3. The Ilısu Dam Project and Its Impacts

The Ilısu Dam is one of Turkey's largest hydroelectric projects, designed to provide economic benefits such as energy production, irrigation, and flood control. However, its impact on cultural and natural heritage has sparked significant debate. The submergence of a historically significant settlement like Hasankeyf under the dam's waters serves as a notable example of the tension between the preservation of cultural heritage and the demands of development. With the completion of the dam, irreversible changes have occurred in the local settlements, ecosystem, and historical structures.

In this context, it becomes evident that the Ilısu Dam is not merely an economic and energy-focused project, but also one that brings about cultural and environmental consequences. Fig. 4 illustrates the overall view of Hasankeyf, most of which has been submerged by the dam's reservoir. In the foreground, the historical settlement area and cave dwellings are visible, while in the background, the transformation of the Tigris River into a reservoir is highlighted. This situation underscores the disconnection of cultural heritage from its natural context and the irreversible spatial changes it has undergone. This section will detail the scope of the project, its effects on physical and cultural heritage, its environmental outcomes, and the socio-economic transformations that have ensued.

Fig 4.The situation after Hasankeyf was flooded by Dam waters

3.1 The Objective and Scope of the Ilısu Dam Project

The Ilısu Dam is a large-scale infrastructure project implemented to enhance Turkey's energy production, improve irrigation systems, and provide flood control. Constructed as part of the Southeastern Anatolia Project (GAP), the dam is situated on the Tigris River and has an annual electricity production capacity of 4.12 billion kWh (DSI, 2020). With the completion of the dam, the objective has been to meet the region's energy demands and accelerate economic development.

However, the construction of the dam has sparked significant debates concerning the preservation of cultural heritage. The risk of flooding historical sites in Hasankeyf and its surrounding areas necessitated various relocation and conservation measures within the scope of the project (Ersoy, 2021). Nonetheless, there are differing opinions regarding the adequacy and impact of these measures. Some experts argue that the relocation of specific historical structures represents a crucial step in protecting cultural heritage, while others contend that this process results in the loss of the structures' original context and disrupts the integrity of the historic fabric. Furthermore, submerging many irreplaceable artifacts is emphasized as a significant loss for the region's historical identity. In addition, criticisms have been raised regarding the conservation efforts, which are confined mainly to physical structures, while the cultural memory of the area and the way of life of the local population have been overlooked. Consequently, ongoing discussions persist within academic circles and the public regarding the long-term effects of the dam on cultural heritage.

3.2 The Effects on Physical and Cultural Heritage

With the construction of the Ilısu Dam, many historical structures in Hasankeyf have been submerged. Although some structures were relocated to new settlement areas using modern engineering techniques, this process has resulted in various physical and cultural changes to the buildings (ICOMOS, 2019). For example, during the relocation process, material loss occurred in some structures, and the buildings were disconnected from their original locations, losing their historical context (Karahan, 2020).

Moreover, cave dwellings and natural rock formations, which are of significant historical and archaeological value in Hasankeyf, could not be preserved and were submerged by the dam waters. These caves, which have been used as living spaces by various civilizations over thousands of years, are among the key structures that reflect the region’s cultural and historical continuity. The natural rock formations, which held not only aesthetic and geological significance but also served practical purposes in the past, such as defense, shelter, and worship, are of considerable importance. However, with the dam’s construction, these unique natural and cultural heritage elements have been irreversibly lost, severely damaging the integrity of Hasankeyf’s historical fabric. This situation is regarded as a significant loss by archaeologists, historians, and environmentalists, highlighting the urgent need for more comprehensive and sustainable measures to protect cultural heritage (UNESCO, 2020).

3.3 Environmental Impacts

The construction of the Ilısu Dam has impacted not only the cultural heritage but also the natural environment of the region. The formation of the reservoir has led to significant changes in the local ecosystem, with the rise in water levels causing damage to agricultural lands and natural habitats (WWF, 2021). Endemic plant species and aquatic ecosystems in particular have been adversely affected by these changes.

Moreover, the dam's water retention capacity has altered the natural flow regime of the rivers, leading to considerable ecological consequences. The changes in the flow rate and discharge of the rivers have negatively impacted the life cycles of many plant and animal species that are dependent on these water sources. Specifically, migration routes of certain fish species have been interrupted, resulting in a decline in their populations and disruptions in the food chain within the ecosystem. In terms of agricultural production, the need to control water levels has forced local farmers to modify their traditional irrigation practices, which has led to fluctuations in crop yields and economic uncertainty. Additionally, changes in soil structure and the effects on the microclimate are posing long-term threats to the region's agricultural potential. The long-term outcomes of these environmental changes are still under investigation, and comprehensive scientific studies are ongoing to fully understand the ecological impacts (Doğan, 2021).

3.4 Socio-Economic Impacts

One of the most significant impacts of the dam project is the socio-economic changes it has caused among the local population. According to UNESCO (2020), thousands of people living in Hasankeyf and surrounding villages were forced to migrate due to the construction of the dam, which resulted in their relocation to new settlement areas. This situation has led to substantial changes in the social and economic structure of the local community.

As noted by Çelik (2022), the displaced population has faced economic difficulties in their new living areas, with communities particularly dependent on agriculture and livestock suffering significant financial losses. According to Yıldırım (2022), the inadequacy of infrastructure and social services in the new settlement areas has negatively affected the quality of life of the local population.

In general, while the Ilısu Dam Project has brought significant benefits in terms of economic development and energy production, it has also sparked considerable debate due to its impacts on cultural and environmental heritage. There is a strong consensus in academic circles and among international organizations that a more balanced approach between the protection of cultural heritage and sustainable development should be adopted (ICOMOS, 2019).

4. The Relocation Process of Historical Structures: Engineering Solutions and Preservation Challenges

The relocation process of historical structures in Hasankeyf is considered a significant example in the preservation of cultural heritage both in Turkey and globally. With the completion of the Ilısu Dam project, many historical structures in Hasankeyf faced the risk of being submerged. As a result, several important buildings were relocated using specialized engineering methods and placed in new conservation areas. However, while this process ensured the physical preservation of the structures, it also caused them to lose their cultural and historical contexts (UNESCO, 2021).

The engineering techniques employed during this process were supported by modern technologies, with the goal of relocating the structures with minimal damage. However, as noted by Ersoy (2021), debates have arisen regarding the detachment of the relocated structures from their original locations and their adaptation to new environments. These discussions have raised the question of whether the preservation of historical buildings should be limited solely to physical relocation or if other aspects of their historical and cultural significance should also be considered.

4.1 Relocated Structures and Applied Engineering Techniques

As part of the Ilısu Dam project, several significant structures were relocated using specialized engineering methods. The relocation process was carried out by various engineering firms under the supervision of the Turkish Ministry of Culture and Tourism. During the relocation, modern engineering techniques were employed, whereby the structures were cut into blocks and transported to new settlement areas (Akgün, 2020). Detailed information on the relocation process of Hasankeyf and the techniques employed is provided below.

The Zeynel Bey Mausoleum: The Zeynel Bey Mausoleum is one of the most notable cultural heritage structures relocated as part of the dam project in Hasankeyf. This monumental structure, weighing approximately 1,100 tons, was transferred to its new location using an integral (monolithic) relocation method. Advanced engineering solutions were implemented to preserve the structural integrity of the mausoleum during the process. First, the connection between the mausoleum and the ground was severed, and steel platforms were placed underneath. These platforms were then gradually lifted using hydraulic jacks. The structure was subsequently integrated into a rail transport system and moved approximately two kilometers to its new location in a controlled manner. Throughout the process, engineering measures such as vibration control, load distribution, and structural stability analysis were meticulously applied to preserve the original structural characteristics and integrity of the mausoleum. The relocation of the Zeynel Bey Mausoleum represents one of the few successful applications of integral transport techniques and reflects the use of modern engineering practices in the preservation of cultural heritage.

Artuklu Bath **:** The relocation of the Artuklu Bathhouse required a different engineering approach. Weighing approximately 150 tons, the structure was dismantled and relocated using a modular relocation method. Initially, architectural and structural analyses of the building were conducted, after which the structure was carefully dismantled into stone blocks. Each block was numbered and mapped to ensure accurate reassembly during the restoration process. High-capacity crane systems and specialized stabilization techniques were employed during the transport, including shock-absorbing cushions and steel support systems to prevent damage to the blocks. This method enabled both the preservation of the building materials and the faithful restoration of the structure at its new location. The relocation of the Artuklu Bathhouse serves as a successful example of the secure relocation of cultural structures using the modular transport method (Fig. 5).

Fig 5. The holistic relocation of the Zeynel Bey Mausoleum and the Artuqid Bathhouse to their new site (CNN Türk, 2018)

Fig 5.Transportation routes of the flooded area and related structures after the Ilısu Dam (medium, 2021)

These relocation processes are of great significance not only from an engineering perspective but also in terms of cultural heritage preservation. Although each structure was moved using different techniques, the overarching objective was to safeguard the historical and cultural value of Hasankeyf without compromising its integrity during the transfer to new locations. The map on the left illustrates the original locations of the Zeynel Bey Mausoleum (in red) and the Artuklu Bath (in blue), while the map on the right depicts their new positions and the routes along which they were relocated. These operations were meticulously planned to ensure the preservation of the structures and the transmission of cultural heritage to the newly established settlement area (Fig. 6).

Eyyubi Mosque Minaret: The minaret of the Eyyubi Mosque was preserved with great care during the relocation process. To prevent any damage during transport, the structure was encased in a steel frame designed to shield it from external forces. The minaret was subsequently lifted and moved to its new location with the aid of a crane. Due to their height and slender construction, such structures pose significant risks during relocation. The steel frame ensured the structural integrity of the minaret, enabling a safe and stable transport process.

Hasankeyf Castle and City Walls**:** Hasankeyf Castle, one of the oldest and most significant structures in the region, presented a particularly complex relocation challenge. Portions of the castle walls were dismantled and reassembled at a new site. However, some of the transported stones suffered damage, and elements of the original structure reportedly lost their authenticity during the reassembly process. Breakage or detachment of stones during transport likely prevented the complete reconstruction of the original form. This highlights a major challenge in cultural heritage preservation: while relocating a historic structure aims to conserve its material presence, such interventions often entail structural and visual compromises.

The relocation of structures in Hasankeyf under the Ilısu Dam project serves as a significant example of heritage preservation through engineering. Historical monuments such as the Zeynel Bey Mausoleum, Artuklu

Bath, Eyyubi Mosque Minaret, and Hasankeyf Castle were relocated using various techniques, drawing on modern engineering solutions. Depending on each structure's specific architectural characteristics, monolithic, modular, or reinforced relocation strategies were employed. Comprehensive planning ensured the protection of structural integrity, the retention of authenticity, and minimal exposure to environmental damage. Nonetheless, certain structures inevitably experienced physical or aesthetic losses during the process. This situation underscores the limitations of engineering in cultural heritage preservation and highlights the sensitivity required in such interventions. Ultimately, the large-scale relocation operations undertaken in Hasankeyf contributed significantly to the physical preservation of cultural assets, but also sparked debates concerning authenticity and the severance of place-based identity. These processes offer a multifaceted experience that must be considered both technically and ethically in future projects of a similar nature. The following section will expand upon this discussion by exploring critiques related to the loss of authenticity and the broader implications of relocation.

4.2 Criticisms of the Relocation Process and the Loss of Authenticity

A significant portion of the criticisms surrounding the relocation efforts emphasize the detachment of these structures from their original historical and cultural contexts, leading to a considerable loss of their spatial and symbolic meanings (Doğan, 2021). These structures are not merely physical entities but are integrally connected to the socio-cultural identity of the region, having been historically embedded within their natural and built environments. In this regard, the relocation process signifies not only a physical displacement but also a transformation of the historical and cultural fabric that these structures embody.

According to Öztürk (2022), there remains uncertainty as to how these relocated monuments will adapt to their new environmental and climatic conditions. Differences in microclimate, soil characteristics, and humidity levels may affect the long-term conservation of the structures, though the extent of such impacts has yet to be fully understood. Therefore, focusing solely on the physical aspects of relocation is insufficient; comprehensive conservation and maintenance strategies must also be developed to ensure the structures' resilience in their new settings.

Yıldırım (2022) argues that the relocation of historic structures results in severance from their original context and cultural significance, as these monuments are not only architectural artifacts but also integral components of collective memory and social identity. Similarly, Şahin (2023) stresses that the relocation of the Zeynel Bey Mausoleum has completely disrupted its spatial and historical relationship with its original surroundings.

Several academic studies have revealed that the relocated structures have, in many cases, been transformed into touristic and economic commodities, often at the expense of their cultural identities (Çelik, 2023). Furthermore, it has been noted that these monuments may become increasingly vulnerable to natural wear and deterioration in their new locations. The long-term environmental impacts of the new settlement areas on the relocated heritage remain uncertain (Şahin, 2023).

In light of these critiques, diverse perspectives within the academic literature reveal that cultural heritage relocation is not merely a technical intervention but a complex and multilayered issue with profound social and cultural implications. Smith (2006) argues that cultural heritage comprises not only physical structures but also the social practices, rituals, and collective memories associated with them. From this perspective, although a monument's physical integrity may be maintained, its contextual and symbolic significance can be severely diminished through relocation.

Similarly, Jokilehto (1999) emphasizes that cultural heritage must be evaluated in a holistic relationship with its spatial context, warning that relocation may disrupt this essential integrity. Research conducted in the Turkish context supports these arguments. For instance, Kaya (2021) contends that although the relocation of Hasankeyf's structures was technically successful, these monuments do not retain the same meaning in their new locations, as their emotional connection with the local community has been significantly weakened.

In this regard, preservation strategies for cultural heritage should not be limited to the technical aspects of relocation but must also incorporate comprehensive approaches that consider historical context, local identity, and collective memory. While the relocation process implemented in Hasankeyf involved noteworthy engineering solutions for heritage protection, it has largely remained confined to physical preservation, failing to fully address the contextual values of the cultural assets. Although the structures continue to exist in material form, the relocation has not ensured the preservation of their authenticity and historical identity.

Therefore, future projects of a similar nature must include more holistic planning that safeguards the historical and cultural contexts of relocated structures. Additionally, to ensure the long-term sustainability of the relocated monuments, the development of regular monitoring and maintenance programs is essential.

5. Conclusion and Recommendations

Although the cultural heritage relocation process carried out in Hasankeyf is considered a significant achievement in terms of technical and engineering aspects, the cultural, historical, and sociological dimensions of this process should also be addressed comprehensively. Iconic structures such as the Zeynel Bey Mausoleum, the Artuklu Bath, and the Minaret of the Eyyubi Mosque have been relocated to new areas with their physical integrity preserved; however, this relocation has led to the disconnection of these structures from their historical context. These structures derive their meaning not only from their architectural features but also from the landscape in which they were situated, their social environment, and their past functions. Therefore, the relocation process represents a physical transfer and a transformation of spatial memory, identity values, and collective meaning.

The preservation of cultural heritage, as emphasized by international organizations such as UNESCO and ICOMOS, is possible not only through the sustainability of the physical existence of the structure but also through the continuity of its original context, social functions, and societal relationships. In this context, the process carried out in Hasankeyf has brought ethical and methodological debates concerning cultural heritage preservation to the forefront beyond the engineering achievements. Indeed, the relocated structures cannot fully sustain their meaning in the new settlement areas, and their historical ties with the local community are weakening. This demonstrates that it is not sufficient to reduce cultural values to their material characteristics alone; cultural heritage's social and symbolic aspects must also be preserved.With the advancement of technology, methods such as digital archiving, 3D modeling, and virtual reality have become increasingly important in preserving cultural heritage. Especially for assets that cannot be relocated or are at risk of destruction, documentation in digital environments will enable their future use for academic and cultural purposes. As in the case of Hasankeyf, such digital documentation projects play a significant role in preserving the lost original context and historical value of relocated structures. The reconstruction of these structures in virtual environments and their presentation to the public through interactive displays can help cultural heritage reach broader audiences. In this regard, it is necessary to increase digital documentation projects for the preservation of Hasankeyf and to raise public awareness of these processes. In addition, the participation of the local community in the preservation of cultural heritage is of great importance. The exclusion of the local population from the relocation process jeopardizes the sustainability of preservation policies. As UNESCO emphasizes, the active participation of local communities in these processes is a critical factor for maintaining and embracing cultural heritage. In this framework, developing sustainable development models for Hasankeyf and supporting cultural tourism projects will strengthen the regional economy and encourage the local population to take ownership of the cultural heritage.

On the other hand, adapting relocated structures to new environmental conditions is another issue that must be carefully monitored in the long term. Environmental factors such as different soil types, humidity levels, and microclimatic effects may negatively impact the relocated buildings' structural integrity. This situation indicates that the physical relocation and subsequent protection, monitoring, and maintenance processes should be conducted with a comprehensive and sustainable strategy. For long-term success, the physical integrity of relocated structures must be preserved along with their cultural contexts and connections to social memory.

Many academic studies highlight that the relocation process not only aims to preserve the structures but also transforms them into touristic elements and economic commodities in their new settlement areas. This indicates that the understanding of cultural heritage preservation is increasingly acquiring a commercial dimension. Furthermore, it is stated that the environmental and climatic conditions the relocated structures will face—particularly factors such as differences in soil, humidity levels, and microclimate effects—create uncertainties regarding their long-term durability. The discussions in academic literature suggest that cultural assets cannot be preserved through engineering interventions alone and that holistic preservation strategies enabling adaptation to their new locations must be developed. When separated from their natural and social environments, these structures experience significant losses not only in physical terms but also in symbolic and cultural contexts.

The transformation experienced in Hasankeyf emphasizes that technical solutions alone are insufficient in cultural heritage preservation and that historical structures must be addressed holistically within their environmental, cultural, and social contexts. Although modern tools such as engineering techniques and digital documentation are essential for preserving structural integrity, the process should not be limited to the physical relocation and recording of the structures. Historical buildings are deeply connected with the cultural and socio-economic structures of the geography in which they are located. In this context, relocated structures should be preserved not only through construction techniques but also through the social memories, cultural identities, and relationships with the local population inherited from the past. The exclusion of the displaced community from the relocation process may result in the loss of the social and cultural contexts of cultural heritage. It may also have long-term negative impacts on its sustainability. The preservation of cultural heritage requires a multidimensional approach that encompasses not only the physical structures but also the surrounding natural and social environment. As in the case of Hasankeyf, the adaptation of relocated structures to their new environments, considering environmental factors (microclimate, soil conditions, humidity levels) and social structures, will ensure the sustainability of not only the physical but also the cultural values of this heritage. Therefore, the participation of the local population in the preservation of cultural heritage is of great importance; the community's sense of ownership and belonging contributes to the conservation of social memory and regional history. The preservation process implemented in Hasankeyf reveals the necessity of a multidisciplinary approach that considers the relocated buildings' structural features and their social contexts.

Conservation assessment of historical healthcare facilities: An investigation of Cebeci Hospital in Ankara University Faculty of Medicine

Furkan Başaran*[1],

[1] *Istanbul Gedik University, Architecture and Design Faculty, Interior Arcihtecture and Environmental Design, 34876, Kartal/İstanbul, Türkiye*

Abstract. Ankara University Faculty of Medicine is a significant institution in Türkiye's medical education history, reflecting the modernization efforts of the early Republican period. Established under Mustafa Kemal Atatürk's directive, the faculty played a key role in shaping the country's healthcare system. Constructed during the First National Architectural Movement, its architectural character reflects the era's emphasis on national identity, functionality, and the use of local materials. However, during the last decades, for the sake of responding to the modern needs in healthcare buildings, new annexes have been added to the hospital.
This study examines the architectural changes the faculty went through over time. It does so by analyzing the architectural features of the different building blocks, new and old, Cebeci Hospital in Ankara University Faculty of Medicine. Hospitals, beyond their medical function, represent institutional trust, state authority, and the accessibility of public health services in the architectural language of their time. The case study-based assessment of the historical building conservation showed that while initial structures are aligned with the principles of the First National Architectural Movement, later structures reflected modifications that impacted the historical integrity. The research highlights the need for future recommendations for adapting contemporary healthcare needs to the heritage conservation strategy of the hospital complex.

Keywords: republican architecture; healthcare architecture; built heritage conservation; Turkish National Architecure

1. Introduction

Ankara University Faculty of Medicine is one of the most historically and culturally significant institutions where the foundations of modern medical education in the Republic of Türkiye were established. Examining and understanding this meaningful structure, which holds great importance in the country's history is critical for comprehending the development of healthcare buildings during the early Republican era. Beyond their medical function, hospitals represent institutional trust, state authority, and the accessibility to public health services.

Public buildings constructed for healthcare purposes during the initial years of the Republic reflect the characteristics of the First National Architectural Movement. In the capital city of Ankara, ministerial buildings serve as symbolic structures representing political authority (Gürdağ & Koca, 2020). From this perspective, the building can be considered a bridge connecting the past to the future, serving as a significant vessel of memory for understanding the period, which constitutes the central focus of this study.

This article aims to evaluate the architectural period of the building and associate it with the characteristics of Ankara University, Faculty of Medicine, Cebeci Hospital. Rather than treating the building merely as an architectural work, the study seeks to align the building with the history of the Republic and interpret it as a culutural heritage asset. Furthermore, this investigation aims to highlight the contributions of the biulding to the modernization of healthcare buildings in the Republic of Türkiye. In this context, by analyzing the transformations and additions the building has undergone since its establishment, the study aspires to contribute to the preservation of Turkish historical and cultural h.eritage and ensure its transmission to future generations. Despite the significant role of Cebeci Campus in the formation of modern medical infrastructure in Türkiye, its architectural transformations have not been extensively documented. This paper addresses this gap by offering an analytical perspective on its spatial evolution and conservation needs.

2. The First Turkish National Architectural Movement and Ankara University Faculty of Medicine

The building of Ankara University Faculty of Medicine reflects the features of historical educational and healthcare institutions from the Ottoman period such as *Darülfünun* and *Darüşşifa*. The history of the Faculty extends back to the foundation of the Republic. The Cebeci Research and Practice Hospital is the first hospital of the first Faculty of Medicine established under the directive of Mustafa Kemal Atatürk during the early years of the Republic (Arda, 1996).

Influenced by Islamic civilization, the Turks combined the Arabic term *"dār al"*, meaning "house," with *"shifā"*, meaning "healing" or "recovery," to name public health structures *"Darüşşifa"*. The purpose ıs to indicate buildings that provided healthcare services to the community. During the Ottoman period, there were numerous *Darüşşifa* buildings established to offer free medical services to the public (Umar & Sarı, 2020). These institutions also played significant roles in the provision of healthcare services in Ankara. However, during the Independence War, these structures became insufficient, leading to the adoption of provisional solutions. The establishment of Ankara University Faculty of Medicine was a response to the growing awareness of such deficiencies and a part of the modernization efforts carried out during the Republican era, aimed at providing contemporary medical education and healthcare services (Arda, 1996).

Although the Faculty's foundations were influenced by the Ottoman health system, it is evident that its establishment faced shortcomings imposed by the needs of the pre-Republican period. Ankara University Faculty of Medicine holds a special place in the history of medicine in Türkiye as a pioneering institution in laying the foundations of the Republic's modern healthcare and medical education system. Due to its historical and national significance, the Cebeci Hospital (Fig. 1. & Fig. 2.) is considered a "Veteran Hospital (*Gazi Hastane*)." The Chief Physician's building and the U-shaped campus behind it were designated as a "Preservation Area" in 2005 by the Ankara Regional Board for the Conservation of Cultural and Natural Assets under the Ministry of Culture and Tourism (AKVMGM).

Fig. 2. Ankara Medical Faculty Cebeci Campus, URL1, 2000

2.1. Architectural Characteristics of Ankara University Faculty of Medicine and Its Relationship with the First National Architectural Movement

The First National Architectural Movement of the Republican Period coincides with the early phases of Türkiye's modernization process. Led by architects Kemaleddin and Vedat Tek, this movement was referred to by

Kemaleddin himself as the "National Architecture" (*Milli Mimari*) and was defined as follows: "This movement is similar to the Neoclassical movement in Europe. It features works that combine the forms of Classical Ottoman architecture with new interpretations. It incorporates the forms and styles of the Ottoman Classical period and bears traces of the transitional era. It was inevitably influenced by Western architecture" (Çaha, 2022).
In the early years of the Republic, an approach that blended national architectural elements with modern styles was adopted. Unique examples of Turkish Neoclassicism were produced during this period (Kızıldere & Sözen, 2005,). Significant contributions to the movement were also made by Ahmet Hikmet Bey (Koyunoğlu) and the Italian-born architect Giulio Mongeri (Hasol, 2017).

Compared to previous periods, the architecture of this era was much simpler and more minimalist. Functionalism was prioritized, and buildings emphasized practicality and usability. Structures built during this time were more modern and Western-oriented than other Ottoman-era buildings within the country's borders (Kızıldere & Sözen, 2005). Simple forms were employed, and there was a tendency toward geometric shapes. The emphasis was placed on highlighting national architecture, and particular attention was given to the use of local materials and regional products (Bozdoğan, 2003).

The buildings constructed during this time of social transformation were especially prominent in the healthcare, public, and educational sectors. In this context, the Second Turkish Grand National Assembly (II. TBMM) (Fig. 3.) Museum and Ankara Palas (Ankara Vakıf Hotel) (Fig. 4.), which are located in front of each other, are considered exemplary buildings from this era. Ankara Palas, in particular, is one of the best representations of the period with its symmetrical plan aligned along the entrance axis, wide eaves, dome, and tile cladding (Hasol, 2017).

Fig. 3. Second Grand National Assembly Building, URL2, 2021

Fig. 4. Ankara Palas, URL2, 2021

Ankara University Faculty of Medicine was built during the First National Architectural Movement of the Republican Era. Buildings from this architectural period are known for reflecting the national identity of the Republic of Türkiye and frequently incorporating local elements (Fig. 5.) (Çubukçu, 2021).

The architectural design of Ankara University Faculty of Medicine (Fig. 6. and Fig. 7.) also reflects the principles of this national architectural movement. The building was designed and constructed in accordance with the stylistic features of the First National Architecture. Local elements were included in the design process, and the use of local materials was prioritized. The incorporation of native stone and natural building materials is a direct reflection of the architectural approach of this period. The building features design elements that reflect Turkish national identity and emphasize national values. It is significant lies at its contribution to Türkiye's struggle for independence and the strengthening of national consciousness.

Fig. 6. Ankara Medical Cebeci Hospital, URL1, 1950

Fig. 7. Ankara Medical Cebeci Hospital, URL1, 2013

3. Evolution of the Building's Changes Overtime

The campus was established in 1945 and has served as the main building of the Faculty of Medicine since ever. It covers an area of 70 acres and stands out with its location close to the city center. In addition to the Faculty of Medicine, the campus also houses various research units, laboratories, a library, and student accommodation facilities (URL1, 2023) (Fig. 8.).

Fig. 8. Location of Ankara University Campuses, URL1, 2023

The Cebeci Campus takes its historical significance from the function of healthcare facility it served during the Turkish War of Independence. Backthen, the building was used as a cavalry barracks. The threat of World War II led to the adoption of various precautionary measures and policy reviews in Türkiye. In this context, due to the risk of Türkiye entering the war, it was decided to relocate the Gülhane Military Hospital from Istanbul to Ankara. While Cebeci Hospital was established in 1941, it began to operate in 1945 as the first Faculty of Medicine of the Republic of Türkiye. In 1953, by the decision of the Ministry of National Defense, the Cebeci Buildings were prepared and officially transferred to the Faculty of Medicine. This developmental process continued with the opening of İbni Sina Hospital in 1985 and the establishment of specialized clinics within the General Surgery Building. Alongside modernization and increasing medical infrastructure, the Surgery Building was reinforced and the laboratory facilities were improved (URL1, 2023).

The primary reason for the additions and modifications made to the Faculty was the growing demand for medical education and the need for modernization. Since the hospital was initially designed for military purposes, the post-war transformation into a center focused on medical education and necessitated the construction of new buildings. The relocation of clinics from Numune Hospital to the Cebeci Campus allowed for a more efficient use of space. The modernization objective was to integrate technological advancements and to make the physical structure more effective for both medical education and healthcare services. During the restoration period from the 1970s to the 1990s, the use of older clinics was altered, and the U-Block began to host various medical departments. Restoration and renovations during this period aimed to create a more compatible working environment having contemporary healthcare standards (URL1, 2024).

With its rich history, the building has become one of the symbols of modern medicine and stands as a prominent emblem of Ankara University Faculty of Medicine in the centennial year of the Republic. The architectural evolution of the campus may also be interpreted as a reflection of the continuing advancements in the field of medicine to the present day (URL1, 2024).

4. Preserved and Preservable Sections

The Cebeci Campus is notable for its U-shaped layout (Fig. 9.). This architectural form accommodates recreational spaces at its center, offering ample green areas for visitors. Similar U-shaped structures can also be observed in other parts of the campus. These configurations are creating spaces for social interaction and recreation in the campus (Fig. 10.).

Fig. 9. Gynecology Department Block (Source: the author, 2024)

Fig. 10. Rectorate Resting Area, P.A. (Source: the author, 2024)

During the construction of the campus, particular emphasis was given to the use of local materials, and it has been identified that andesite stone—commonly known as Ankara Stone (Fig. 11.) —was frequently utilized. The ornamental elements used in the window details and the prominent red color aimed at emphasizing the architectural characteristics of the buildings (Fig. 12.).

Fig. 11. Use of Ankara Stone (Source: the author, 2024)

Fig. 12. Blood Center (Source: the author, 2024)

In addition, sculptures with symbolic meanings are located at various points throughout the campus. For example, the sculptures featuring Angora goats (Fig. 13.) reference the historical heritage of Ankara, while the statue of a pregnant woman (Fig. 14.) placed in front of the maternity hospital symbolizes birth. These sculptures are intentionally positioned to better reflect the cultural value and historical significance of the original structure.

Fig. 13. Angora Goats Sculptures (Source: the author, 2024)

Fig. 14. Sculpture Titled Dressing (Source: the author, 2024)

Design of entrance in the campus building shows noticeable differences. In addition to the entrances constructed as part of the original structure, there are also modern entrances added in later periods. The use of metal and glass materials (Fig. 15.) reflects these temporal modifications and emphasizes the architectural transformation over time. However, renovations carried out over the years—particularly the installation of air conditioning units and exposed piping (Fig. 16.) —have caused significant damage and led to a loss of aesthetic value in the building's original design.

Fig. 15. Oncology Building Entrance (Source: the author, 2024)

Fig. 16. Radiotherapy Outpatient Clinic (Source: the author, 2024)

Over time, additional buildings have been constructed within the campus to support the growing needs of the hospital. One such example is the "Pediatric Emergency" building. By utilizing facade materials similar to Ankara Stone, efforts were made to ensure architectural coherence with the overall identity of the campus. The use of colored glass on the exterior was intended to evoke a link to children (Fig. 17.). A similar design approach can also be observed in the Gastroenterology Building (Fig. 18.).

Fig. 17. Pediatric Hospital Perspective (Source: the author, 2024)

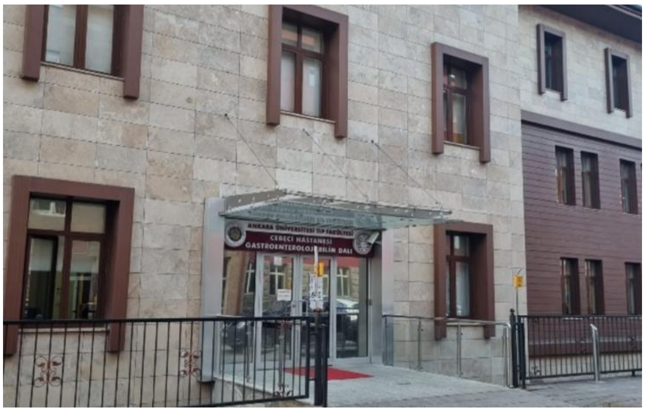

Fig. 18. Gastroenterology Outpatient Clinic (Source: the author, 2024)

However, not every additional building has been constructed in harmony with the historical character of the campus. Structures such as the security post, cafeteria, and childcare center (Fig. 19.) —located near the main entrance—were added later. They, however, failed to reflect the historical architecture due to their material choices. Similarly, the Faculty Dining Hall Building (Fig. 20.), which houses banking and dining facilities, also diverges from the campus's historical texture due to its use of incompatible materials.

Fig. 19. Security and Cafeteria Area (Source: the author, 2024)

Fig. 20. Faculty Dining Hall (Source: the author, 2024)

5. Conclusions

This study examined the architectural structure of Ankara University Faculty of Medicine and aimed to highlight its significant place in the history of medicine in Türkiye by reflecting the characteristics of the First National Architectural Movement of the Republican Era. It was determined that the changes and additions made to the building were intended to meet the increasing demands of medical education and healthcare services. The preserved and preservable sections of the Cebeci Campus represent a rich cultural heritage, enriched by the use of local materials and symbolic sculptures.

However, it has been observed that the modern entrances and buildings added later have compromised the aesthetic integrity of the original structure. While preserving the historical character of this significant site is crucial, these additions have been inadequate in maintaining the integrity. Future restoration efforts should prioritize the architectural coherence between old and new structures, ensuring that new additions do not compromise the symbolic and historical integrity of the original building.

This study was conducted with the aim to understand the architectural evolution of Ankara University Faculty of Medicine and supporting efforts for its conservation. The preservation of the Cebeci Campus is not merely about maintaining individual buildings, but it is also about sustaining a tangible legacy of Türkiye's medical and architectural modernization. This legacy holds educational, cultural, and symbolic value. As such, conservation strategies must be informed by a long-term vision—one that balances healthcare innovation with historical responsibility. By respecting, both the past and the present, the Cebeci Campus should continue to serve as a meaningful and functional heritage space for future generations.

Acknowledgments

The research described in this paper was supported by İstanbul Gedik University.

4th International Civil Engineering & Architecture Conference
17-19 May 2025, Trabzon, Türkiye

Comparison of wooden masonry (çantı) technical mosques in near geographies: Georgia Adjara Region and Trabzon rural architecture

Feyza Halı Kabataş*[1], Mazlum Kalak[1], Özlem Sağıroğlu Demirci[1]

[1] *Gazi University, Department of Architecture, 06570 Ankara, Türkiye*

Abstract. Wooden masonry mosques in Turkey, especially in the Black Sea Region, are under the threat of extinction due to reasons such as the disappearance/degradation of wood, inadequacy of construction artisans, and natural disasters. It is also possible to see examples of mosques built with this technique in geographies close to the Black Sea Region. Georgia, whose mosque architecture was shaped by the adoption of Islam during the Ottoman period, and the rural architecture of Trabzon in the Eastern Black Sea Region are two prominent regions with wooden mosques with unique values. Especially in Georgia and the Black Sea Region, centuries of cultural exchange and architectural and artistic style interaction have led to the emergence of similarities and differences in the mosque architecture of the regions (plan schemes, materials, construction techniques, etc.). In this study, the primary mosque structures built with the wooden masonry technique in the Adjara Region of Georgia and Trabzon countryside were evaluated in terms of the construction system, material properties, and plan schemes by analyzing the qualitative data obtained as a result of literature reviews. The similarities and differences of the mosques selected within the scope of the study have been examined, and their comparative analyses have been made by analyzing them vectorially. Although some architectural solutions in close geographies are similar to each other, cultural and regional differences and the necessity of building appropriate to the region have increased the architectural diversity of both regions.

Keywords: Wood Masonry; Construction System; Mosque; Georgia; Trabzon

1. Introduction

Wooden mosques stand out as important architectural works of art in our country, especially in the Black Sea Region. With the architectural style specific to the region, construction techniques based on master-apprentice relationships, and the use of local materials, original examples of wooden mosques have survived to the present day. Wooden mosques built according to the nature of the region and local traditions may show different characteristics depending on the diversity offered by the Black Sea geography.

The wooden mosques in the region have survived to this day as a reflection of a culture that has lasted for centuries. While mosques made entirely of wood are frequently seen around Samsun and Ordu, wooden masonry (çantı/çandı) mosques are mainly dated to the 18th and 19th centuries in the central and eastern parts of the Black Sea Region (Zorlu, 2017).

The studies on wooden masonry mosques in different provinces of the Black Sea Region have dealt with detailed documentation, structural and spatial analysis, ornamental features, and typological analyses. These studies analyzed the mosques on a single-building scale or specific to a particular region. At the same time, there is also a study in the literature on determining the risks arising from nature and using wooden masonry mosques (Yücel, 2022).

In the city of Trabzon and its districts, which reflect the unique nature of the Eastern Black Sea region, it is possible to come across the wooden masonry technique mosques mentioned in the present study (Karpuz, 1990). In this study, the structural and architectural features of these mosques, which have become an important part of rural architecture and wooden architecture and have survived to the present day with the repairs and restoration works, will be examined through the data obtained from the literature and archives. The study included Uzungöl Filak Mosque, Güney (Kondu) Neighborhood Mosque, Dereyurt Village Merkez Eski Mosque, Masele Mosque, Kuşluca Mosque and Taşkıran Neighborhood Mosque.

* Corresponding author, E-mail: feyzahali8@gmail.com

https://doi.org/10.31462/icearc2025_a_car_130

The architectural style of the Eastern Black Sea wooden masonry mosques continues in the Adjara Region of Georgia in the nearby geography. Especially during Ottoman rule, the increase in Islam in the region allowed the increase in the number of mosques in the countryside and the use of construction techniques learned due to cultural interaction in the construction of mosques. In this context, the wooden masonry mosques of the rural Trabzon and Adjara Region were examined in detail in terms of architectural plan, structural features, materials, and construction system. It aims to reveal the architectural and artistic values by determining the similar and different aspects of the mosques with original woodwork through the selected examples. The study utilized information obtained from literature, architectural drawings taken from the archive of the Trabzon Foundations Regional Directorate (TVBM), inventory studies, and photographs determined within the scope of the Eastern Black Sea Project (DOKAP).

2. Wooden Masonry (Çantı) Technique Mosques in Trabzon

Wooden mosques have an important position in the historical development of Turkish architecture. The first known examples of wooden mosques in Central Asia can be seen in cities such as Samarkand and Bukhara during the Ghaznavid and Qarakhanid periods. In Anatolia, Sivrihisar and Afyon mosques dating to the 13th-14th centuries, Ankara Arslanhane and Beyşehir Eşrefoğlu Mosques are the surviving wooden mosques (Karpuz, 1989).

Looking at the general characteristics of the wooden mosques in the Eastern Black Sea region, most of them are located on a sloping terrain. Stone material was used in the subbasement to protect the wood from excessive rainfall. In single-story mosques, stone walls rise to the entrance level, while in two or three-story mosques, the upper floors are built as wooden masonry or carcass.

According to Ayverdi (1972), wooden çandı or çantı structures were constructed by joining long logs together without nails (Ayverdi, 1972). The skeleton of the wooden masonry system consists of horizontal and vertical bearing trees. The wooden masonry walls between the carriers are generally made of 4-5 cm thick chestnut and yellow pine trees (Karpuz, 1989). The boards placed on top of each other are joined in different ways. Different names are used for corner joints depending on whether they are round or rectangular (Fig. 1). In the mosques of the region, the kurtboğaz technique is mostly preferred. (Fig. 2). In cases where the length of the window and door edges and the wooden element was not sufficient, poles called armoz were placed in the middle of the walls. The number of channels opened to these posts varies according to the place of use (Fig. 3).

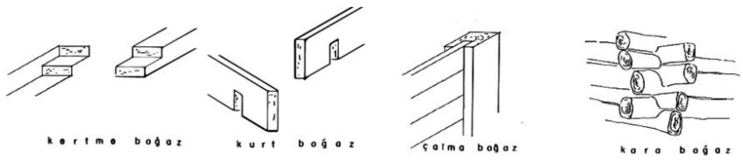

Fig. 1. Types of wooden masonry throat joints (Özgüner, 1970)

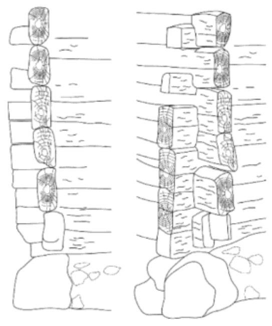

Fig. 2. Drawing of rectangular section kurtboğaz technique (Halı Kabataş ve Sağıroğlu, 2021)

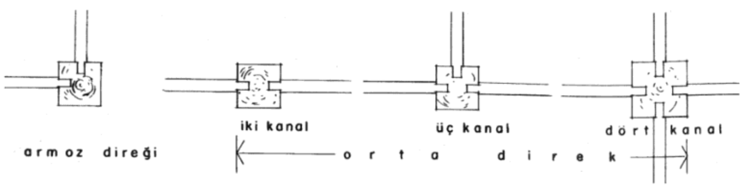

Fig. 3. Armoz pole and center pole connection types (Özgüner, 1970)

In this part of the study, six mosques of Trabzon built with wooden masonry technique were examined, and their spatial characteristics, materials, and construction techniques were typologically analyzed in the light of literature reviews and information obtained from the Trabzon Regional Directorate of Foundations.

2.1. Çaykara, Uzungöl Yeni Neighborhood, Uzungöl Filak Mosque (1813/1819)

Filak Mosque is located in the center of Filak Neighborhood, which is within the borders of Uzungöl Yeni Neighborhood of Çaykara. There is a distance of 2 km from Uzungöl. The construction date of the mosque is known as Hijri 1235, Miladi 1819 (Aydın & Perker, 2017).

The mosque consists of three floors: basement, harim, and mahfil floor. The entrance to the building, which is located on a sloping land in the north-south direction, is provided from the north façade. While there is direct access to the harim from the last congregation, the mahfil floor is reached by stairs. The harim is entered through a door made of walnut wood with two wings. The mahfil floor has a U-plan at the entrance and is carried by wooden pillars (Karpuz, 1990).

The building was constructed using the wooden masonry technique and was over two floors. While the walls of the north, south, and east façades of the basement floor are stone walls, the wall of the west façade was built with the göz dolma technique. The thickness of the stone walls varies between 70-80 cm. Wooden masonry technique is seen at the corner points of the walls surrounding the harim. The timbers with rectangular sections ranging between 6-8 cm are joined at the corners with the kurtboğaz technique.

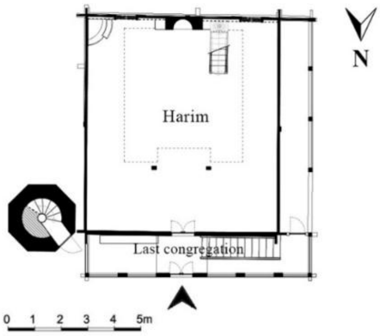

Fig. 4. Uzungöl Filak Mosque (Drawing: TVBM; Url 1)

2.2. Dernekpazarı, Güney (Kondu) Neighborhood Mosque (1819)

Dernekpazarı is located on the Çaykara-Of highway after crossing the Soğanlı Mountains that separate Anatolia and the Eastern Black Sea. The mosque is located on a sloping terrain on the steep slopes of the Güney (Kondu) neighborhood of the Dernekpazarı district. According to written sources, the mosque dates back to 1819. Gregorian terms correspond to 1883-84 (İren, 1983).

The mosque has three floors: basement, harim, and mahfil floor. There is a two-storey madrasah to the south. Due to the fact that the land where the building is located is quite sloping, the entrance to the harim is provided from the west façade. Therefore, the location of the last congregation is also in the west direction. Measuring 8.5 x 8.62 m, the entrance to the square harim is provided by a double-winged wooden entrance door. Wooden stairs from the harim lead to the U-planned mahfil floor. A separate entrance to the mahfil is given from the closed area above the last congregation from the north façade (Çalık and Konak, 2021).

Due to the sloping terrain, the basement floor is also under the ground except for the south façade of the basement floor, which was built with masonry rubble stone with a thickness of approximately 1 m (TVBM, 2019). The walls of the harim floor were built with a wooden masonry system using the kurtboğaz technique at the corners. Centre posts were placed between the wall system from the beginning of the ground floor to the mahfil floor. In this system, called çalma boğaz, in cases where the wood's length is insufficient, there is a wall mesh that is extended by passing it to the intermediate pillar elements. Another construction system seen in the mosque is found on the upper floor of the last congregation place with a few overhangs carried by wooden poles. The entire south façade and more than half of the west façade of this overhang were constructed with the muskalı dolma technique.

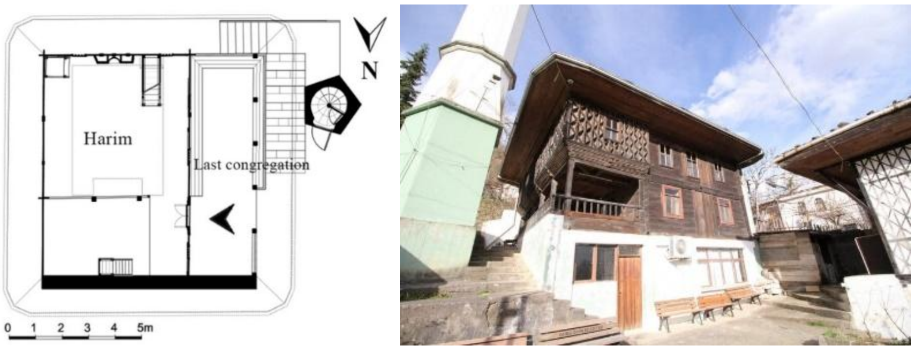

Fig. 5. Güney (Kondu) Neighborhood Mosque (Drawing: TVBM; Url 2)

2.3. Hayrat, Dereyurt Village, Merkez Eski Mosque (1832)

Dereyurt village is located 3 km from the center of the Hayrat district of Trabzon. The Merkez Eski Mosque is located in the central position within the sloping land of the village. The construction date of the mosque dates back to 1832-33 in Gregorian (Yıldırım, 2016).

The mosque was built with two floors, the harim and the mahfil floor. It has a seating area of approximately 10 x 9.6 m and is close to the square (TVBM). The entrance to the harim floor of the building is provided by a two-winged wooden door with round arches from the west façade. Both the harim and the imam rooms adjacent to the north wall of the harim are reached by the last congregation. Wooden stairs access the mahfil floor above the imam's room in the north-east of the harim. When the construction system of the mosque was analyzed, a wooden masonry system was used throughout the floors. The corners of the building were joined with the kurtboğaz technique, and intermediate pillars were placed along the wall system, especially on the sides of the window and door openings.

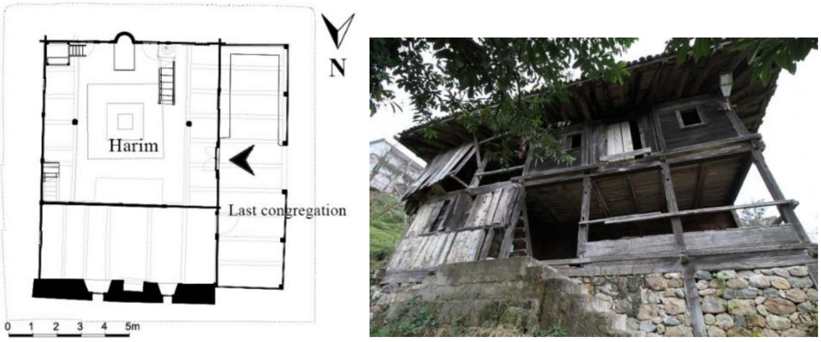

Fig. 6. Merkez Eski Mosque (Drawing: TVBM; Url 3)

2.4. Araklı, Bereketli Village, Masele Mosque (1867)

Masele Mosque is located in Bereketli village of Araklı district of Trabzon. According to the inscriptions on the building, it was built in H.1283 / M.1867. The mosque, which was known as 'Mesele Mosque' among the people because the people of the neighborhood solved their problems in the mosque, was later recorded as 'Masele Mosque' (Sarı, 2021).

The mosque was built on a single storey, including the harim floor, on a sloping land on a stone foundation up to the subasman level (Önal and Köşklü, 2020). The harim measures 5.60 x 6.36 m internally and is close to a rectangular form. The last congregation place and the imam's room are placed side by side to the north of the harim. The entrance to the harim is provided by a wooden door with round arches and a single wing from the last congregation. The building was rebuilt in its present location with the materials salvaged as a result of a fire (Sarı, 2021). The fact that it was built with a wooden masonry technique makes it possible to dismantle these mosques and move them from one place to another. The corner points of the harim, the last congregation place, and the imam's room were joined with the kurtboğaz technique. Intermediate pillars were placed on the window edges and the sides of the mihrab in sections varying between 10x15/10x20 cm.

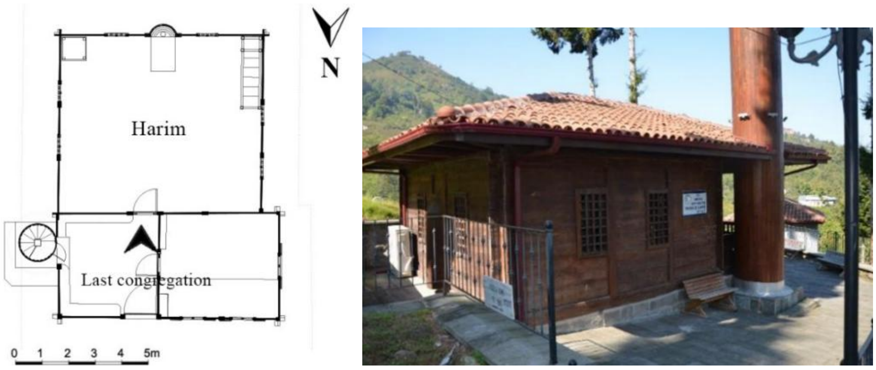

Fig. 7. Masele Mosque (Drawing: TVBM; Sarı, 2021)

2.5. Sürmene, Çamburnu Neighborhood, Kuşluca Mosque (1893)

Kuşluca Mosque is located in Çamburnu Neighborhood, east of the coastal part of the Manahos Stream Valley. According to the documents in the archive of the Trabzon General Directorate of Foundations, the mosque was built in 1893 (Önal and Köşklü, 2020).

The building has two floors, harim and mahfil floor. The last congregation is located on the north façade of the building and on the mihrab axis. The top of the last congregation is designed as an open sofa carried by six wooden pillars (Kazaz, 2016). A double-winged wooden door from the façade of the last congregation provides the entrance to the mosque. The semi-U-shaped mahfil floor is carried by four main pillars with a 20x20 cm section. A wooden staircase L placed in the northwest direction of the harim is used to reach this floor. The mosque was built with wooden masonry techniques throughout the harim, and the mahfil floor, and the kurtboğaz technique was used at the corners. Intermediate pillar elements were placed at an average of 2 m intervals along the wall.

Fig. 8. Kuşluca Mosque (Drawing: TVBM; Url 4)

2.6. Çaykara, Taşkıran Neighborhood Mosque (1897/1898)

The mosque is located on a sloping land in the east-west direction. According to written sources, the building was built on Hijri 1315, Gregorian 1897/1898 (DOKAP, 2019). It is the last example of the traditional mosques identified (Karpuz, 1990).

It was built with two floors, the harim and the mahfil floor. While there was no last congregation place in the original building, this section was added later. The entrance to the mosque, which has a rectangular plan along the mihrab axis, is provided from the west façade (Kazaz, 2016). A staircase from inside the harim accesses the mahfil floor. The entire perimeter of the upper floor is designed as a mezzanine. While the harim floor of the building is approximately 80 cm thick stone wall, the mahfil floor is made of wooden masonry. Kurtboğaz technique was used at the corners.

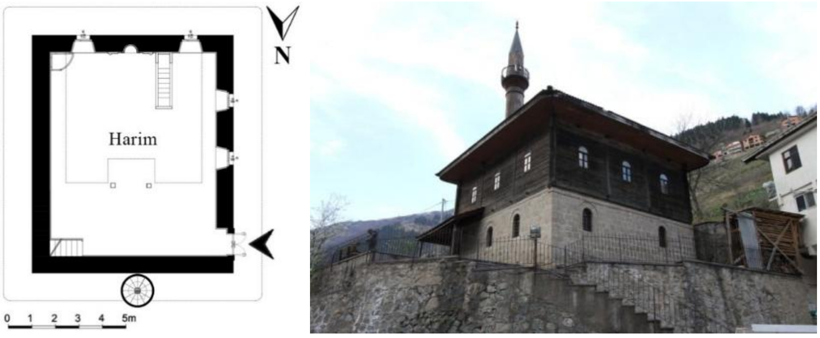

Fig. 9. Taşkıran Mosque (Drawing: TVBM; Url 5)

It can be said that the main elements that determine the typologies of the six mosques built with wooden masonry technique in rural Trabzon and evaluated within the scope of the study are the form of the main worship space, the presence, and location of the last congregation place, the presence and shaping of the mahfil section, construction technique and material use.

In this context, for these mosques, the main worship space shaped in the direction of the north-south mihrab axis, Uzungöl Filak Mosque, Güney (Kondu) Neighborhood Mosque, Kuşluca Mosque and Taşkıran Mosque have rectangular forms. In the Merkez Eski and Masele Mosque in the center, the harim has a form close to the square. The common point in the mosques with a square main worship space is the addition of another room to the north of the harim

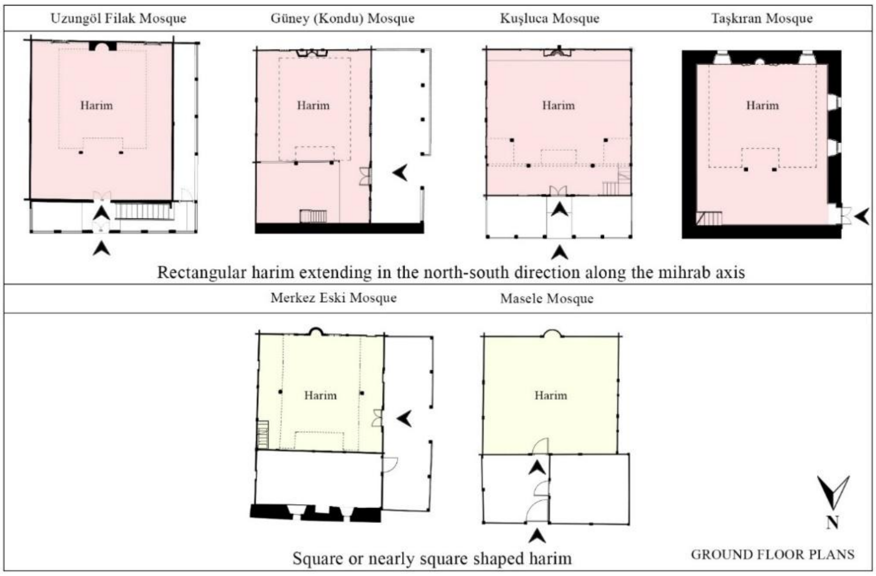

Fig. 10. Harim dimensions of rural mosques in Trabzon region (Drawing: Reproduced from TVBM archive)

The last congregation space is not present in some of the mosques in the region, and its position changes according to the mihrab axis. In Taşkıran Mosque, the last congregation area was added later, and this section was not present in the original building. In Uzungöl Filak Mosque, Kuşluca Mosque, and Masele Mosque, the last congregation place is on the mihrab axis and is located in the north direction. In the Güney (Kondu) Neighborhood Mosque and the Merkez Eski Mosque, this section is located on the west wing of the harim. Depending on the land conditions and the buildings' topography, the last congregation's location are varied. In mosques, if there is another room other than the harim, entrances to this space are provided from the last congregation place.

In some of the mosques of the region, the last congregation place was designed as an outer sofa with a function similar to the 'hayat' of rural houses. This area, with wooden poles and a covered roof, has turned into a place where the congregation socializes before and after prayers, waits for the time of prayer, has conversations and classes are held when the weather conditions are appropriate (Karpuz, 1989; Karpuz, 1990). Uzungöl Filak Mosque, Kuşluca Mosque, Güney (Kondu) Neighborhood Mosque, and the Merkez Eski Mosque are examples of this kind of use of the last congregation place.

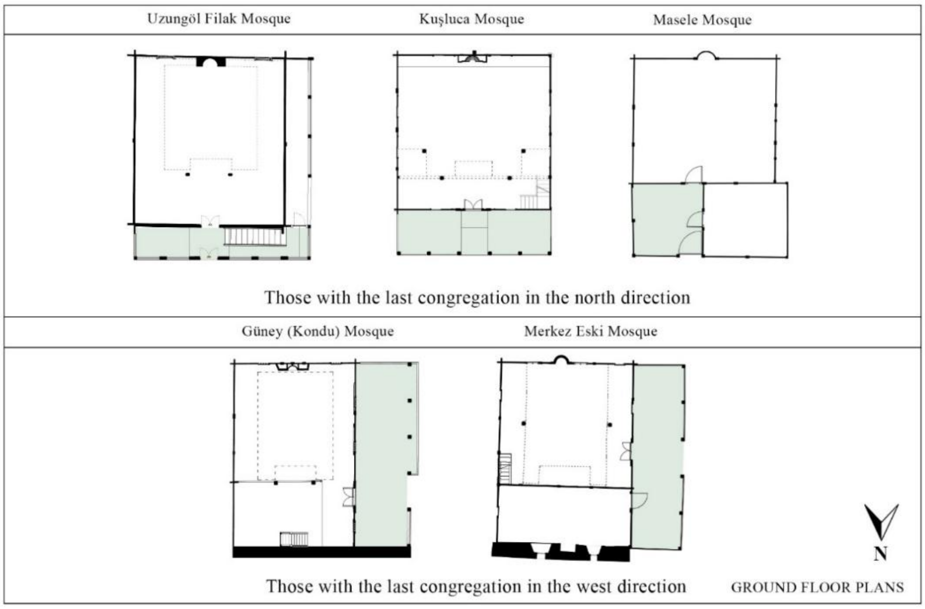

Fig. 11. The location of the last congregation place of rural mosques in the Trabzon region (Drawing: Reproduced from TVBM archive)

The system of use of the mahfil in mosques, a mahfil layout with a U-plan and surrounding the harim from three sides, is not a normal situation (Karpuz, 1989). This practice is seen in the Güney (Kondu) Neighbourhood Mosque and Merkez Eski Mosque, which are mosques in the region. In Kuşluca Mosque, the extending arms of the mahfil floor do not continue along the harim walls and are left halfway. The situation is quite different in Uzungöl Filak Mosque and Taşkıran Mosque. In these two mosques, the mahfil floor continues on the mihrab wall and surrounds the harim from four sides. This area above the mihrab is not wide enough for prayer. This situation has been stated as the allocation of the difference between the floors due to the different achievements of the ground and upper floors (Kazaz and Tuluk, 2021).

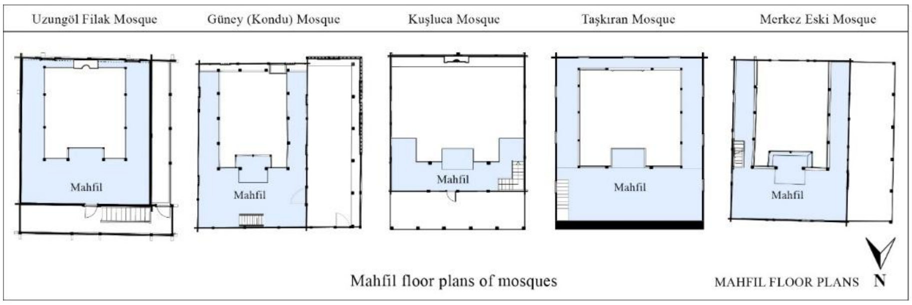

Fig. 12. Mahfil formations of rural mosques in Trabzon region (Drawing: Reproduced from TVBM archive)

The materials and construction techniques used in mosques should be evaluated together. Wood was used as the main material of the structure of the buildings. Mosques that were formed by joining 4-5 cm thick and rectangular wooden boards at the corners with the kurtboğaz technique (Özgüner, 1970) and have completely wooden masonry system walls are Masele Mosque and Kuşluca Mosque. Stone was used only in the main wall of the single-storey Masele Mosque. Although the main building structure is wooden masonry, it is possible to see different construction systems in the other four mosques. Göz dolma technique was preferred on the western wall of the basement of Uzungöl Filak Mosque, and the muskalı dolma technique was preferred on the mahfil floor of Güney (Kondu) Neighborhood Mosque. Stone masonry system was used in the basement floors of these two mosques. The harim floors of Taşkıran and Merkez Eski Mosques were built with a stone masonry system, and the mahfil floors were built with a wooden masonry system. The fact that many techniques are seen in a single mosque can be explained by factors such as the slope of the land where the building is located, its positioning, the function of the interior space, and material possibilities.

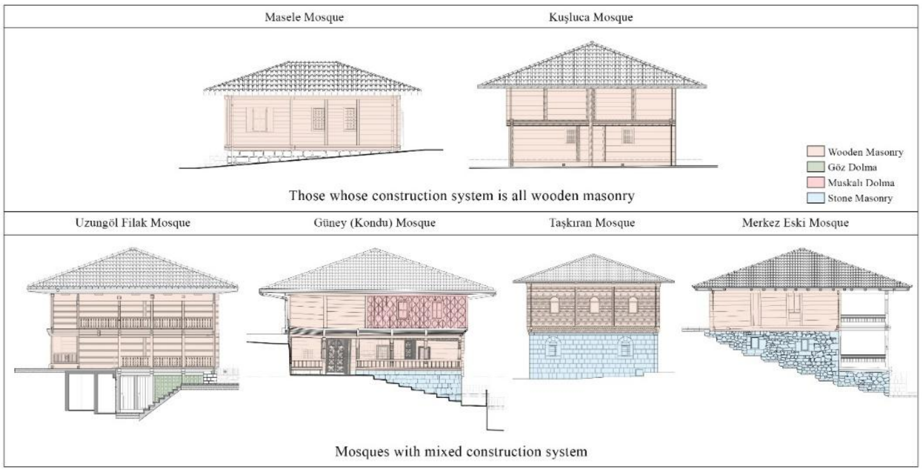

Fig. 13. Use of wood and stone materials and different construction techniques in rural mosques in the Trabzon region (Drawing: Reproduced from TVBM archive)

3. Comparison of Wooden Masonry Mosques in Georgia Adjara Region and Trabzon

When the administrative regions of Georgian geography are examined, the Adjara Region is important in terms of its proximity and border neighbor with Turkey in terms of geography, history, and socio-culture. Adjara Region came under Ottoman rule in the late 15th century. Batumi, the region's capital under Ottoman rule, was a sanjak attached to the province of Trabzon. 1921, the Autonomous Republic of Adjara was established as an autonomous republic. Apart from the capital, the large settlements called districts are Keda, Şuahevi, Kobuleti, Hulo, and Helvaçavuri (Seçkin, 2018). Islam increased in this region during the Ottoman rule. Therefore, there are examples of traditional mosques built with appropriate plans and architectural schemes under the influence of Islam that have survived to the present day (Kaya, 2022).

Fig. 14. Map of Georgia and Adjara Region (Url 6)

As a result of the literature research, it has been determined that there are similarities and differences between the original wooden masonry technique mosques built in the rural area of Trabzon province in the Eastern Black Sea Region of our country and in Georgia during and after the Ottoman Period. Within the scope of the study, a few examples of wooden masonry technique mosques in the Adjara Region of Georgia were selected to be compared with the rural area of Trabzon. The mosques will be examined comparatively under subheadings such as plan scheme, harim and mahfil arrangement, presence and characteristics of the last congregation place, material, and technique.

3.1. Plan Scheme

In the plans of rural mosques in the Adjara Region, the land conditions, the materials used, and the knowledge of the master builders are decisive. As in the mosques in Trabzon, the mosques in the region basically consist of a harim, mahfil, and last congregation place. Mosques have a rectangular plan scheme and are close to square in width or length according to the mihrab wall.

The harim is designed in mosques as a rectangular plan close to the square along the north-south mihrab axis. There are wooden poles and a wooden staircase in the harim that carry the mahfil on the upper floor. The last congregation place can be positioned in three directions except for the south side of the harim.

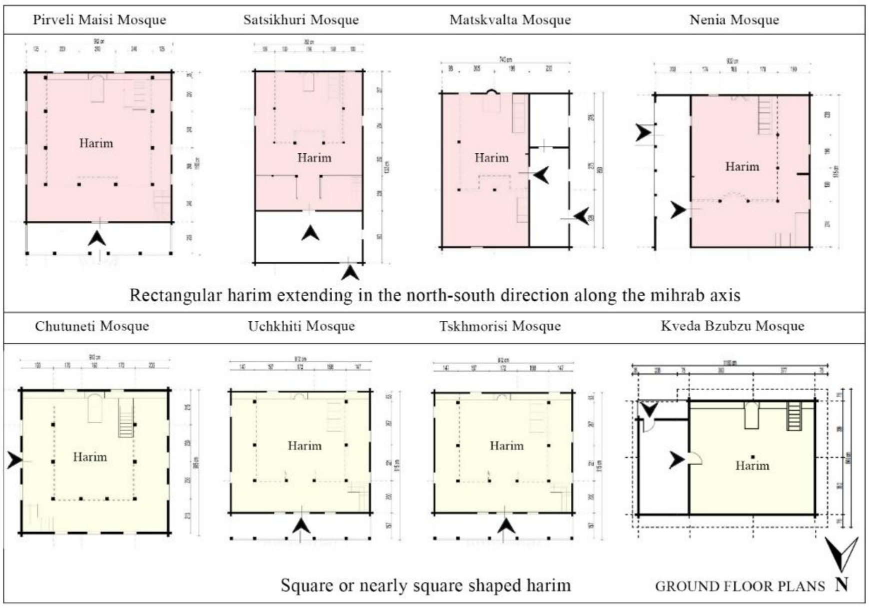

Fig. 15. Dimensions of the harim of rural mosques in Adjara Region (Drawing: Kaya, 2022)

In mosques, the north-south oriented and rectangular planned mosques on the qibla wall axis can be given as Pirveli Maisi Mosque (1720), Satsikhuri Mosque (1831-32), Matskvalta Mosque (1842), Nenia Mosque (1887), Medzibna Mosque (1910), Beghleti Mosque (1909). In these mosques, the harim has a rectangular plan regardless of the location of the last congregation place and entrance door. Examples of mosques with prayer spaces shaped almost like a square are Chutuneti Mosque (1826), Uchkhiti Mosque (1903), Tskhmorisi Mosque (1891), Kveda Bzubzu Mosque (20th century), Akho Mosque (1818), Agara Mosque (1809-10) (Kaya, 2022).

3.2. Last Congregation Place

When we look at the last congregation place of the wooden masonry technique mosques in the Adjara Region, it is possible to come across examples that are open or semi-open spaces supported by wooden poles that remain in the interior of the mosque, that are later closed or completely closed, or that do not have last congregation place. In some examples, the ample space left inside the harim and at the entrance is called the last congregation place. The location of this place varies due to factors such as the entrance door of the mosque, different rooms added to the mosque, topography, and slope of the land. In cases where the last congregation place is designed as a closed space, the wooden stairs leading to the mahfil floor are placed in this space.

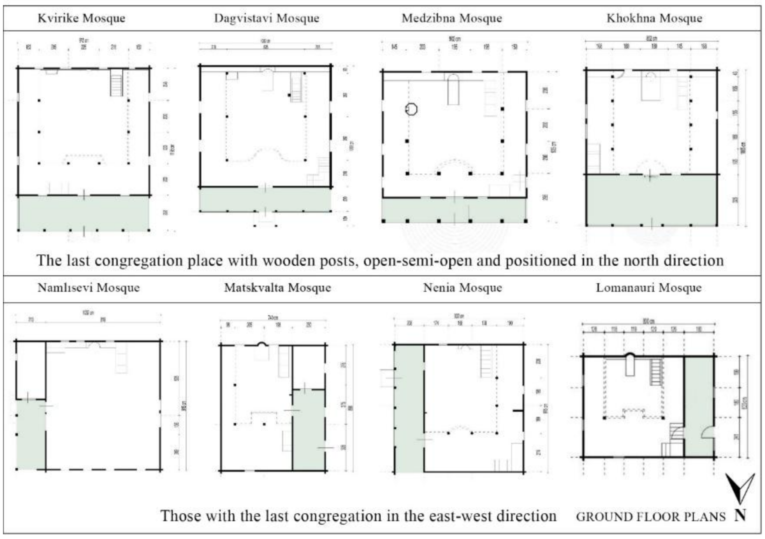

Fig. 16. Last congregation places of some rural mosques in Adjara Region (Drawing: Kaya, 2022)

Similar examples to Uzungöl Filak Mosque and Kuşluca Mosque, where the last congregation place is on the north side and has the feature of an entrance with wooden pillars, are Kvirike Mosque (1859), Dagvistavi Mosque

(1914), Pirveli Maisi Mosque (1720), Uchkhiti Mosque (1903), Medzibna Mosque (1910), Zundaga Mosque (1903), Khokhna Mosque (1900). Examples of mosques where the last congregation place is on the east or west axis, as in Güney (Kondu) Neighborhood Mosque and Merkez Eski Mosque, are Namlısevi Mosque (19th century), Kveda Bzubzu Mosque (20th century) Matskvalta Mosque (1842-43), Nenia Mosque (1887), Lomanauri Mosque (20th century). In Zeda Agara Mosque (19th century) and Beghleti Mosque (1909), the last congregation place was built as a closed entrance space, and there is a direct passage between it and the harim without an entrance door. In Ghorjomi Mosque (1902), the last congregation place has a different layout and makes a T-shaped protrusion to the north. In addition to these, there are examples in the mosques of the Adjara Region where the last congregation place is not defined as a separate space and is inside the harim. Tago Mosque (1900-15), Darchidzeebi Mosque (1840), Mahalakidzeebi Mosque (1760), and Kviakhidzeebi Mosque (1889) are among these types of mosques. In addition, there is no narthex in Chutuneti Mosque (1826) as in Taşkıran Mosque (Seçkin, 2018; Kaya, 2022).

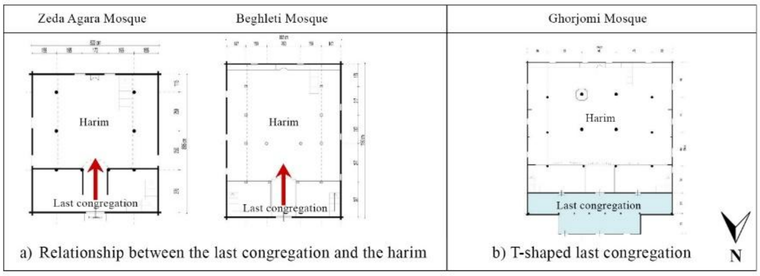

Fig. 17. Zeda Agara Mosque and Beghleti Mosque last congregation-harim relation b) Ghorjomi Mosque T-shaped last congregation (Drawing: Kaya, 2022)

3.3. Mahfil Arrangement

Mahfils were developed in small-scale rural mosques due to the insufficiency of the congregation and the idea of creating a space suitable for women, which is seen in mosques in the Adjara Region (Kaya, 2022). The mahfil arrangements of these mosques mostly have a U-shaped form surrounding the harim. The mahfil is carried by wooden poles rising in the harim on the upper floor. The mahfils, whose north side is wider, are left narrower on the east-west sides and end at the qibla wall. There are protruding kiosks on the north wing, as in the rural mosques of Trabzon. The mahfil example extending only along the north façade is found in the Zeda Bzubzu Mosque (1820-60). There is no mahfil arrangement in the Kveda Bzubzu Mosque (20th century).

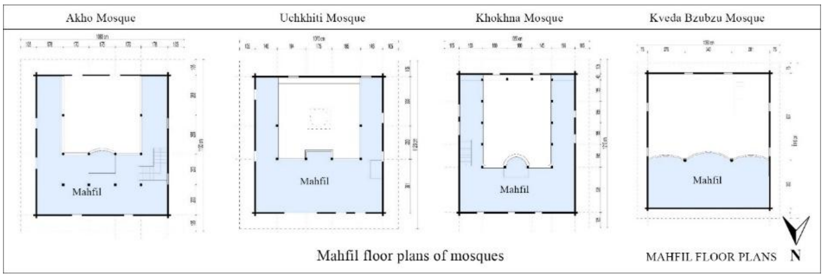

Fig. 18. Mahfil arrangements of some rural mosques in Adjara Region (Drawing: Kaya, 2022)

3.4. Material and Technique

The main construction material of the exterior and interior architecture of the regional mosques, except for the basement, is wood. As in the Eastern Black Sea region, chestnut, walnut, pine, oak, spruce, beech, and elm (tela) trees, which are resistant to heat, humidity, and external conditions for a long time, were used in the structures (Aytekin and Kaya, 2024). Stone material is seen in the basements of the regional mosques and in the basements of sloping lands. Like the mosques examined in the Trabzon countryside, the wooden masonry system was applied intensively in the mosques of Adjara. Some of the mosques that can be included in this group are given in Fig. 19.

In mosques, the wooden stacking system continues for two floors, including the harim and mahfil floors. Examples of mosques that are rarely three-storey and are entirely constructed of wooden masonry include the Darchidzeebi Mosque and the Medzibna Mosque. The common point in these mosques is the use of stone instead of wood on the façades where the basement is buried due to the slope of the land. As in Trabzon mosques, wooden walls are stacked on top of each other between the main beams and joined at the corners with the kurtboğaz technique. In cases where the length of the wooden boards is not sufficient, intermediate posts are placed, and a complete wall appearance is achieved by using the two or three-channel çalma boğaz technique. Unlike the rural mosques of Trabzon, some façades of Adjara mosques are covered with aluminum material to protect the structure from external factors. At the same time, examples have been seen where all of the wooden surfaces on the façade are painted. While there are thicker wall sections in Trabzon mosques where the göz or muskalı dolma technique is used in addition to wooden masonry, it is impossible to come across these techniques in the Adjara Region. However, from the oldest façade photograph of the Tago Mosque, it is thought that the wall where the entrance door is located has features similar to the göz dolma technique.

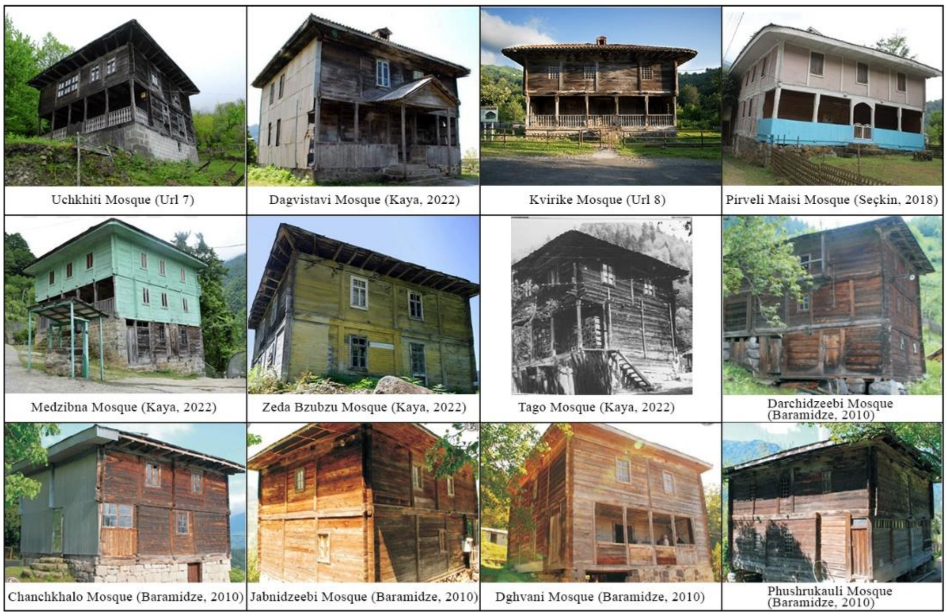

Fig. 19. Adjara Region mosques built with wooden masonry technique

The çantı mosques are seen in two different types in the Black Sea Region in terms of the plan, spatial features, façade, mahfil arrangement, and construction system. The Seljuk and Early Ottoman Period I. group çantı mosques have a longitudinal rectangular plan and are single-storey, and the mahfil is to the north of the harim. The 18th-20th century Late Ottoman Period II. group mosques have a rectangular or nearly square plan, are two-storey, and are built in the form of a mahfil floor surrounding the U-shaped harim from three sides (Kaya, 2023; Aytekin and Kaya, 2024). Wooden çantı mosques continue to exist in both Trabzon and Georgia regions with similar typologies to their traditional original forms. The vast majority of these mosques have the characteristics of group II.

4. Conclusion

Within the scope of the research, other typological analyses can undoubtedly be made regarding the nature of the rural mosques of Trabzon and Adjara that are not included in the text. For example, architectural elements such as ornamental features, door and window details, façade arrangements, and permanent components of the interior such as the pulpit and mihrab can be evaluated. The study is limited to the distinctive typological analyses between the basic components of the mosques in question, such as plan arrangement, last congregation place, use of the mahfil, materials, and construction techniques.

This study examined specific examples of wooden masonry (çantı) mosques, which are an important part of the rural architectural heritage of Trabzon and Adjara Region, which have a cultural past and geographical proximity throughout history. It was determined that these sample mosques have very similar plans, architectural features, and construction techniques. It is possible to explain this relationship between the regions with the increasing cultural exchange between the two geographies, especially during the Ottoman Period, the interaction of the construction masters, and the understanding of art and style similarities.

Due to the slopes of the land settlements, both regions' mosques were built on a high basement or basement floor. This situation increased the possibilities of using stone and wood together. It was also a solution to prevent the wood from rotting because of rainwater and humidity.

In Trabzon and Acara mosques, the last congregation area has gone beyond being a functional place for the congregation to pray, as in monumental mosque architecture. In most of the mosques in both regions, this area has become a transition and socialization area for the congregation and has been designed as a dış sofa. In addition, local masters have not been insensitive to the environmental elements in which the mosques in the region are located and have positioned the last congregation area not only in the north but also in different directions.

In both regions, all mosques are wooden masonry. Masonry walls relate to kurtboğaz at the corners and the middle of the walls with the çalma boğaz technique. It is seen that the masonry technique used in the mosques of Adjara as a result of the stylistic unity with the Black Sea Region was continued from the Seljuks to the Ottoman Period and later. However, in the rural mosques of Trabzon, the use of the muskalı and göz dolma techniques and the wooden masonry system is a characteristic specific to the region.

Mahfil floors generally surround the harim in a U-shaped manner on three sides in the Trabzon and Adjara Region mosques. According to the style of the master builders, there are examples of mosques in Trabzon with mahfils on the mihrab in addition to the three sides, and in the Adjara Region, there are examples of mahfils only on the north side. Different typological solutions can be encountered in the plan plane for mahfil floors in this context.

As a result, the wooden masonry mosques of Trabzon and Adjara Region, which are part of the regional building tradition, are rural architectural heritages that should be protected and transferred to future generations without deterioration. Today, due to the limited number of these mosques in rural areas, their deterioration due to lack of maintenance and natural conditions increases the risk of their extinction day by day. In mosques that have undergone repairs due to use, unconscious interventions have been made to the original elements. Cultural cooperation should be ensured between the two neighboring countries to repair and restore mosques. Thus, the architectural tradition of the wooden masonry mosques of the Trabzon rural area with their general layout plan, harim and mahfil floor arrangements, building materials, and construction solutions will be able to continue its continuity in the Adjara Region in distant geographies.

The effect of Russian Era buildings on today's Kars City identity in terms of socio-cultural sustainability

Yusuf Yıldız*[1], Hande Akarca[1]

[1] Duzce University, Department of Architecture, 61080 Konuralp, Düzce, Türkiye

Abstract. Cultural heritage reflects the society's social, economic, and cultural values, and serves as a bridge between the past and the future. The socio-cultural sustainability of cities is possible with the common culture, history, and nature consciousness of the people living in the city. It is seen that today's urban sustainability studies are generally focused on environmental and socio-economic issues, while the socio-cultural sustainability aspect is quite neglected. In this study, the significance of the Russian period buildings in the city centre of Kars and their contribution to the city's identity were examined in terms of sociocultural aspects and architectural value. Russian buildings, which have undergone physical and functional changes for over a hundred years, were analysed thoroughly with their cultural, historical, and architectural features. The subject of the research is to examine the effects of physical changes on urban identity in terms of socio-cultural sustainability. In this study, historical photographs and engravings, projects, maps, and archive documents, as well as related literature, were utilised. The current conditions of the buildings were documented based on photographs, surveys, and restoration drawings. Questionnaires and in-depth interview techniques were used to determine the urban identity and socio-cultural sustainability relationship. As a result, historical Russian buildings are seen as a value by the local community and should be protected by giving them appropriate new uses and conserving the physical characteristics of the buildings. This approach would help enhance the urban identity and contribute positively to the socio-cultural sustainability.

Keywords: Socio-cultural sustainability; Urban identity; Urban memory; Urban conservation

1. Sustainable Development and Sociocultural Sustainability

Ideas such as using today's needs in a way that does not harm the resources that future generations will need, and harmonizing between human and natural order are the basis of sustainable development. Sustainability aims to reduce our future carbon footprint through sustainable development principles and sustainability criteria, increase economic efficiency, protect and repair ecological systems, and increase the welfare of everyone on a social and environmental scale (Sırkıntı, 2012).

With the Industrial Revolution, mechanization in production processes accelerated in the 18th and 19th centuries; this development led to the dissolution of rural life, cities becoming centers of attraction and large-scale migration movements. With this transformation in production, environmental problems have also increased, natural resources have been overexploited and unplanned urbanization has brought new social and ecological problems

The concept of sustainable development, which has the characteristics of a solution after the negative conditions experienced, started to show itself in the 1990s with sensitive and respectful policies in the economy and the studies carried out in the protection of the natural environment, and it aimed to serve egalitarian, egalitarian, goals on a social, economic and environmental scale with human-oriented studies, to make joint decisions with the participation of everyone in all studies that will benefit and to allow equal opportunities (Şenel, 2010). There are policies that countries need to carry out to achieve the efficiency they aim for in the sustainable development process. Among these, global responsibilities, participatory approaches, common approach strategies, and sustainable urbanization policies constitute some of the basic principles.

The concept of sustainable development was officially defined in the document called Our Common Future, known as the Brundtland Report, published by the United Nations World Commission on Environment and Development in 1987 (Bulut & Taş, 2017). In the report, sustainable development is defined as a development model that aims to meet the needs of the present without jeopardizing the opportunities of future generations.

*Corresponding author, E-mail: yildiz.yusuf3634@gmail.com

https://doi.org/10.31462/icearc2025_a_car_224

In this context, sustainability is an environmental approach and a multidimensional way of thinking that includes economic and social responsibilities. This understanding aims to create change in consumption habits, solidarity based on equality, and a future-oriented development approach. Sustainability is evaluated on three main axes: environmental, social, and economic, and these dimensions are considered as a whole (Şenel, 2010).

The framework of environmental sustainability aims to use the raw material resources that meet the basic needs for vital activity, which exist spontaneously in nature, in line with the necessary needs, and to avoid unnecessary use and waste that cause great destruction on an environmental scale. In economic sustainability, as in environmental sustainability, the aim is to monitor the process by taking into account the ecological balance in the supply and use of basic raw materials. With every development, an undisturbed living space and usable raw material resources should be considered together with the economic accumulation to be left to future generations, and strategies should be followed in this context. Social sustainability is the development of social structure and environment, beliefs and lifestyle, education, and personal attitudes following social balances. It aims to ensure fairness in the level of welfare and to have equal social status. The basis of social sustainability is the provision of constitutional rights and basic vital activities such as the opportunity to work in appropriate criteria, suitable living space, health, access and transportation, social environment, right to education, regardless of the status in the society (Özçuhadar, 2007).

Societies that want to continue to exist in future generations care about the evaluation of cultural values, structures, and environments within the social and cultural framework and aim to leave these values as a legacy for the future. Environmental sustainability on an environmental and ecological scale to create a livable environment and social space, economic sustainability in the development of systems that allow the long-term use of raw materials and existing resources, socio-cultural sustainability that provides opportunities in standard quality of life under the rules of social order of societies and ensures that cultural heritage is maintained without losing its material and spiritual values.

Socio-cultural sustainability includes the preservation of the physical integrity of buildings with historical and traditional textures as well as their cultural meanings. In this process, it is of great importance not only to preserve the buildings but also to document their original qualities such as architectural plans, construction techniques, and material properties, and to shape conservation policies in line with these documents (Yazıcı, 2020).

Sociocultural sustainability, which is formed by social and cultural values, which are among the important phenomena that make up the urban structure and culture, is evaluated with different qualities and criteria. In this context, these criteria are considered as social, cultural, and physical dimensions. The physical dimension covers issues such as physical spaces, urban environments, energy efficiency, natural environment, and the proper use of the natural environment. The social dimension covers issues such as ownership, belonging, justice, social values, and equality. The cultural dimension covers issues such as tradition, custom, cultural values, and historical environment (Çahantimur and Turgut Yıldız, 2008). Although these dimensions have different meanings, they have many points that serve a common purpose. By protecting and sustaining the physical environment, the values attributed to the social dimension are also protected, and in the cultural dimension, the historical environments and cultural values in question have survived to the present day (Barke, 2018).

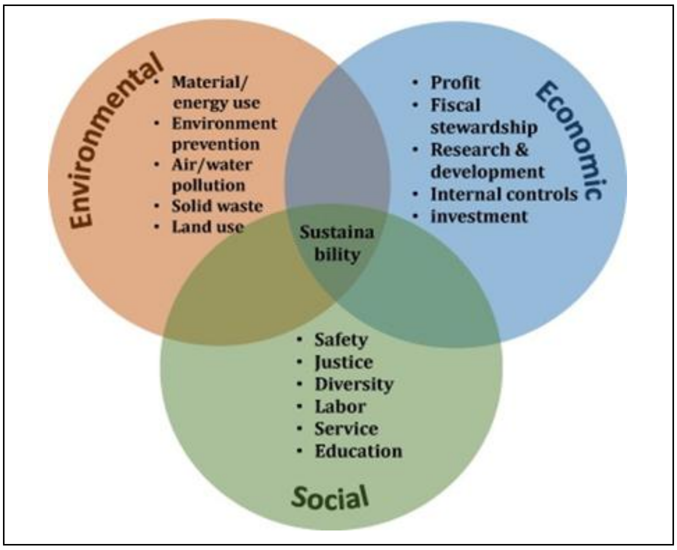

Fig. 1. Dimensions of sustainability (Şenel, 2010).

2. City Identity

The most important features that allow cities to have an identity and show different characteristics from each other are the unique features of the city. These features can be expressed as the location, population density, demographic structure, traditions, customs, architectural style, and socio-cultural conditions of the city. The thoughts that come to mind about a city or, in other words, the way the city is described in the mind and the thoughts determined about the city in the mind when visiting the city express the city's identity (Kaya Özdemir, 2016).

The role of architectural features in the identities of cities is quite high. Architectural features of the periods, materials used, plan shapes, facades, windows, and ornamental elements all provide information about the city's identity (Kaya Özdemir, 2016). However, with the industrial revolution and the invention of the steam engine, developments in cities, job opportunities, quality living options, and the attractive features of urban life resulted in rapid and intensive migration of people from rural areas to cities and increased the population in cities. To meet the housing needs of the population density in the cities, fast-production housing constructions have become widespread with the help of developing technologies, and uniform and similar buildings have emerged as a result. In addition to the positive contributions provided by technology, such an application at the urban scale has made cities fit into a certain scale and has confronted them with the possibility of becoming uniform over time. This situation is a phenomenon that damages the identities of cities and de-identifies them.

Today, de-identification and the lack of identity in cities have become one of the most important problems. This situation has negative consequences for the city in social, economic, cultural, and environmental dimensions and causes users to move away from a sense of belonging.

It is an important fact that the city is far from being alive and static, as opposed to being an abstract and inanimate formation. It is important to adopt the traces of the past, historical roots and cultural values, to protect the identity of the city, to protect its identity (Bingül, 2004).

2.1. Sustainability of Architectural Identity

It should be said that the structures that best reflect the architectural style in cities are historical places, monuments, squares, parks, and gardens. These structures, which constitute the unique architectural style of each city, should be transferred to future generations, and the urban identity should be sustainable. Therefore, this sustainability is possible through conservation, restoration, and transformation projects. Revitalizing historical buildings that have lost their original function with new uses suitable for the needs of the age contributes to the preservation of architectural character and increases social awareness. Such interventions reinforce the public's attachment to cultural heritage and keep alive the historical and cultural meaning of the building beyond its physical existence. These buildings, which bear traces of different civilizations, thus build a bridge between the past and the present, becoming the common values not only of the present but also of the future. In this way, cultural heritage can preserve its existence despite the corrosive effects of time and can be kept alive for generations.

3. Russian Period Buildings in Kars

Located in the extreme eastern part of Turkey, this city has a surface area of approximately 9,939 km² and is situated considerably above sea level with an average altitude of 1,756 meters. Most of its territory consists of the plains of the Kars-Erzurum plateau, which runs in a northeast to southwest direction. An analysis of its urban structure and architectural character reveals that the Russian rule, which lasted from the last quarter of the 19th century until the early 20th century, left deep traces on the city. Buildings and planning approaches from this period are still evident in the urban fabric today (Ekici & Şahin Gürcan, 2022).

3.1. Urban Development in Kars during the Russian Period 1878-1918

Kars, which has been the scene of many military conflicts throughout history due to its strategic location, has been one of the focal points of the Ottoman-Russian struggles. Russia considered Kars as a key region for the passage to Anatolia and fought three wars with the Ottoman Empire before the Treaty of Berlin in 1878. These conflicts caused great destruction in the city. The Russians, who annexed the region to their territory with the Treaty of Berlin, created a new administrative unit centered on Kars (Serbest & Savaş, 2012). The administrative structure in question consisted of four sub-regions, namely Kars, Ardahan, Kağızman and Oltu, and led not only to an administrative change but also to radical transformations in the city on social, economic, military and spatial levels. During the period of Russian rule, the influence of Russian culture spread rapidly in the city, and experts and entrepreneurs brought from Europe played an active role in the reshaping of the city through various projects for the modernization of Kars (Fig. 2) (Serbest & Savaş, 2012). The fact that the region was located on the border between the Ottoman and Russian Empires brought Kars to the forefront in terms of military logistics. Accordingly, a railroad line starting from Russia and extending to Sarıkamış was built in 1899 to facilitate future military shipments. This line, which was considered a continuation of the Batum-Tbilisi customs line, has historical significance as it was the first railway line built in Anatolian lands outside of Ottoman control (Yavuz, 2012).

During the 40 years of Russian sovereignty, which had a great impact on the formation of today's urban fabric in Kars, an urban phenomenon was created in a grid system that cut each other perpendicularly on the plain called

Tahtdüzü to the south of the castle and Kars Stream without touching the civil architecture built during the Ottoman period on the skirts of the castle (Ortaylı, 1978). The city started to be built around the grid plan system formed by the intersection of 8 streets, 4 in the north-south direction and 4 in the east-west direction (Fig. 3) (Kesici, 2022). In this urban planning, some corner parcels were used as public spaces, squares, and parks.

In the buildings constructed during the Russian period, entrances were mostly provided through the main façade of the building, while public and administrative buildings were generally located at the junction of streets and avenues. This layout was supported by wide pedestrian paths, adding both order and visual richness to the city skyline. Balconies, which are frequently encountered in the building plans of that period, stand out as an important aesthetic element, especially in official buildings. While these balconies added splendor to the buildings, a simpler ornamentation approach was adopted in the residences offered for public use. Compared to official buildings, more restrained decorations were preferred in residential areas, and it was aimed to provide access to residences through side entrances to courtyards as well as entrances to the street (Alınak, 2022).

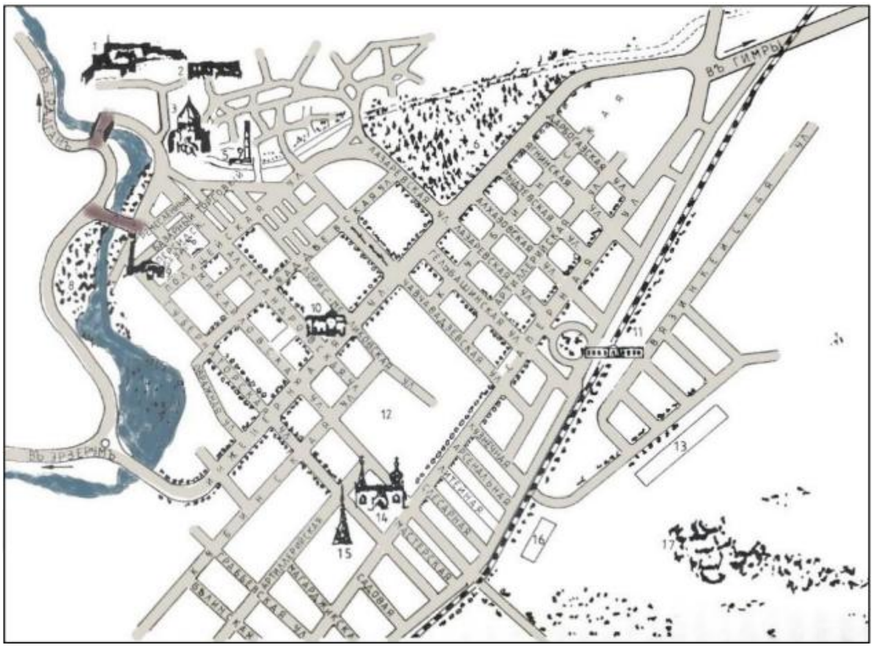

Fig. 2. 1910 Russian Period Kars City Plan (Alınak, 2022).

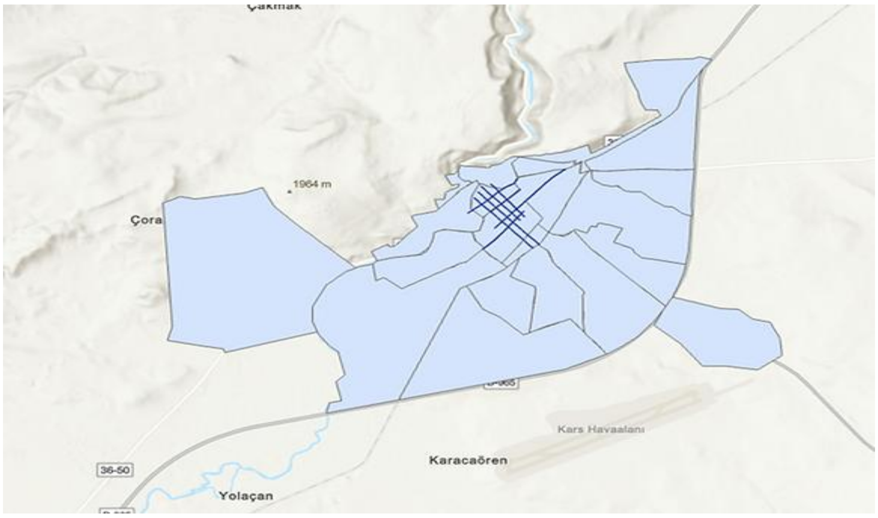

Fig. 3. Grid Plan Developed by the Russians in Kars (Kesici, 2022).

3.1.1. Russian Period Buildings in Kars City Center

The Russian period buildings in the city center of Kars have continued their existence by changing their uses over time and are still in use today. During this process, architectural features and strategic locations of the buildings contributed to the urban identity. Fig.s 4 and 5 show that many structures in the city center have different functions and have been transformed over time according to local needs. Within the scope of the paper, the physical, social, and cultural characteristics of the Kars Chamber of Commerce and Industry Building, the Kars Financial Affairs Directorate Building, and the Kars Municipality Building located on Karadağ Street are examined in terms of sociocultural sustainability and their effects on the identity of the city.

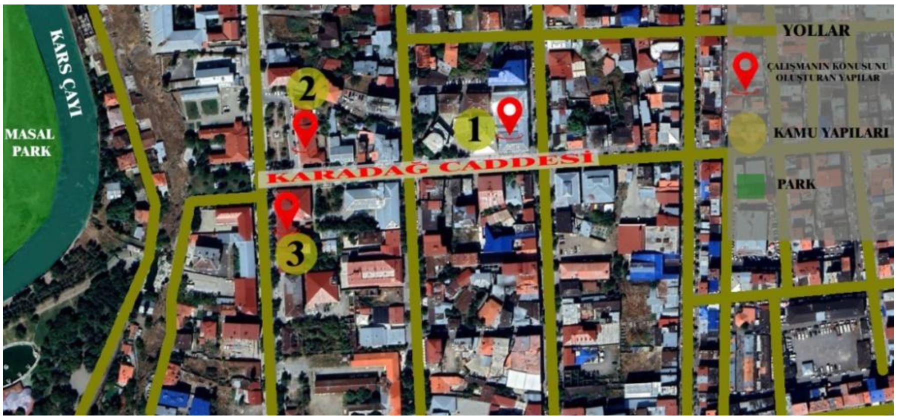

Fig. 4. Location of Buildings, Roads and Parking Areas are indicated on the map taken from Google Earth

Fig. 5. Location of the buildings to be examined in the study in the urban fabric

Fig. 6. Kars Chamber of Commerce and Industry Building

The building was built in the 19th century and its current use is as a public building and its first use was a public building. The building is planned in L-form and consists of two floors: the basement and the ground floor (Fig. 6). During the construction process, cut basalt stone and masonry rubble stone were preferred as the basic building materials (Fig. 7.A). Although no significant deterioration or intervention was observed on the facade of the building over time, significant changes were made in the interior space depending on the user needs. Interventions such as the removal of existing interior walls and the addition of new sections have drastically changed the original plan layout of the building (Fig. 7.B).

Due to urban development and changing needs, new buildings built around the existing ones are in a visual and functional competition rather than for integrity. This situation causes economic gain and profit-oriented approaches to come to the forefront; as a result, it has negative repercussions on urban identity at physical, cultural, and socio-economic levels. With the proliferation of similar buildings, an urban texture without identity is formed, far from the human scale. While this transformation causes the values that make the city unique to fade, it also makes it increasingly difficult to preserve cultural continuity and urban memory.

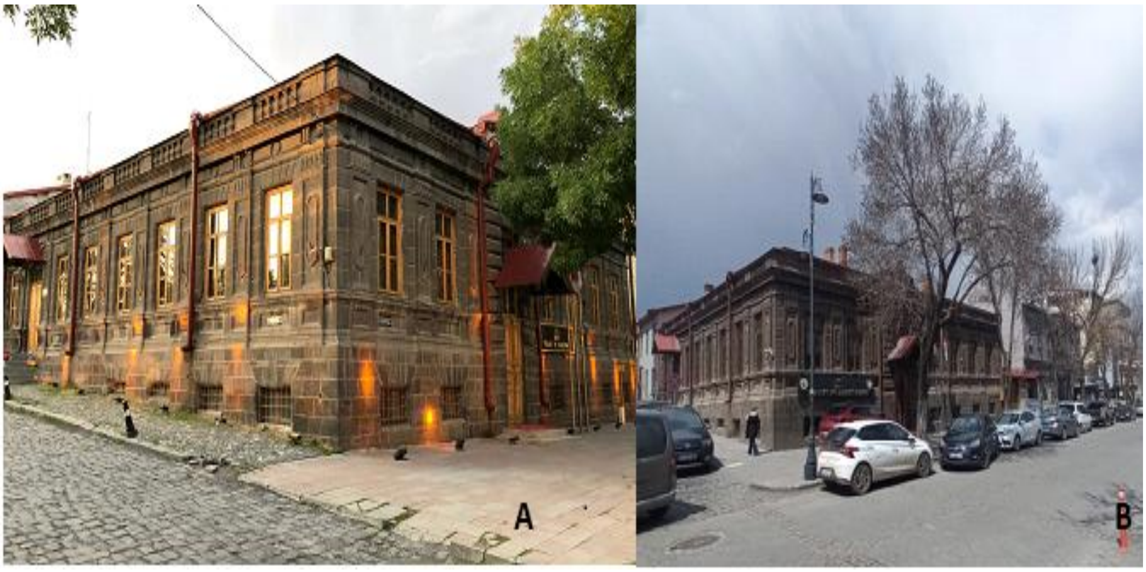

Fig.7. Kars Chamber of Commerce and Industry Building before (A) and after (B) adaptive re-use.

Fig. 8. Kars Treasurer's Office Building

Fig. 9. Kars Defterdarlık Building A. Original building, B. Current condition.

The building was built in the 19th century, and its current use is as a public building; and its first use was as a theater. The building has a total of three floors: basement, ground floor and first floor and is planned in a U-shape (Fig. 8). Different materials such as smooth cut andesite stone, black cut stone and rubble stone were used together in the construction of the building, which has entrances from two different points (Fig. 9.A). Among the architectural details, the cartouche-style ornaments concentrated especially around the windows and corners attract attention. This building, which stands out among the buildings from the Russian period with its magnificent architecture and large scale, has a symbolic value for both the people of the city and the visitors.

It is observed that the building is not in physical harmony with other buildings in its surroundings, and exhibits a fragmented and disconnected structure instead of forming a unity with the urban fabric (Fig. 9. A). Such incompatibilities lead to the emergence of irregular and unrelated architectural formations along urban axes, which negatively affect both the physical environment and the socio-economic, cultural, and demographic structures that make up the urban identity. Repetitive and unidentified construction examples that are far from spatial integrity pave the way for the formation of an environment that is foreign to the urbanites. This situation transforms the urban identity and the imaginary elements that constitute it, leading to a process of change that will weaken these values over time and threaten the sustainability of sociocultural heritage.

Fig.. 10. Kars Municipality Building

The structure was built in the late 19th century, and its current use is as a public building; and its first use was as a school. The structure, which is located on the corner parcel where Karadağ Street and Atatürk Street intersect, was built as a basement and ground floor during the period it was built, and later on, a first floor was added in the early 20th century. The plan of the structure has an L-shaped plan (Fig. 10). The facade of the structure, which has a significant value for locals and visitors to the city, bears very important traces from the period it was built with recessed columns, plant and geometric motifs, and balcony projections (Fig. 11.A).

After the declaration of the Republic, a new addition was added to the building that served as the municipality building, and the entrance to the building was provided through a glass door between the old and new buildings. The entrance leads to a courtyard with a glass ceiling on a lattice system. And from this courtyard, there are transitions to the building built during the Russian period and the addition added later (Fig. 11.B). There is another main entrance on the Karadağ Street side of the building, built during the Russian period. Although the section added later to the building complies with traditional systems, it disrupts the integrity of the existing structure. Due to investment-oriented urban policies, the transformation process of the structures makes it difficult to sustain socio-cultural values and preserve urban identities.

Three representative structures from the Russian period on Karadağ Street were examined (Fig. 12). There are structures built using new construction techniques along the street. The structures remaining from the Russian period domination process add a unique identity to the street and the city. However, the structures have undergone transformation and change with interventions and renovations in the process. Although these are not significant on the facade of the structure, they are dense in terms of plan and usage functions. There are two more historical structures examined along the street and the exterior. There is a structure and street plan that does not comply with the current texture and historical structures in terms of density. It is understood from the interviews that the structures that have historical value and heritage for the future also have cultural value for the city's people. Today, there are historical structures that keep the social and cultural values that are about to be forgotten alive in many parts of the country. Each structure carries an identity value. The Russian structures in Kars province are at a low damage percentage at this point.

The physical, social, cultural, and urban identity characteristics of Karadağ Street and the buildings on it will be evaluated (Table 1).

Fig. 11. Kars Municipality Building A. Original building, B. Current condition

Fig. 12. Views from the Karadag Street

Table 1. Evaluation of socio-cultural sustainability and urban identity of the buildings located on Karadağ Street

Building Name/Type	Construction Date	Social Sustainability Contribution	Its Relationship with Urban Identity	Current Use/Status
Kars Treasurer's Office	19th century	Provides social equality by increasing access to public services.	It is a part of the tradition of the state's continuity and public administration	It is still serving as a public building.
Kars Municipality Building	20th century	It serves as an important center for the local government to meet the citizens.	It is the building block of identity as the political and administrative representation mechanism of the city.	It is active as a municipal service building.
Kars Chamber of Commerce and Industry Building	20th century	It contributes to sustainable development by supporting the development of local economic institutions.	It strengthens the economic identity by reflecting the history of trade and production.	It continues its function as a Chamber of Commerce

4. Conclusions

In recent years, the rapid cultural and spatial transformations in our country have had a great impact on streets, one of the most important components of urban areas, and the urban images formed by these streets. Rapid changes in the city lead to the rapid loss of street texture, street structure, and the identity that forms a whole with the environment. Considering the interaction of old and new structures, the relationship between streets, transportation networks, and people should be reconsidered, and a sustainable urban life should be created in this context. In particular, the streets and surrounding urban areas, which have lost their identity, should be reshaped by adapting to the changing cultural structure. In this process, rational and logical approaches should be adopted in the reconstruction of urban identities and images, rather than aesthetic or fashion-based solutions.

The development processes and functional characteristics of cities are often filled with similar buildings shaped by economic concerns, rather than ensuring integrity with the buildings built around them. This situation negatively affects the physical, socio-economic, cultural, and demographic structure of urban identity and creates an alienated environment. The basic values that constitute urban identity and urban images are undergoing processes of change and transformation, which create great difficulties in ensuring the continuity of socio-cultural values and preserving urban identities. However, social sustainability is a topic that has been addressed less than other aspects of sustainability; comprehensive analyses and in-depth studies in this field will reveal important practical results both today and in the future.

Structural techniques of northern Iran: Traditional methods and sustainability

Niusha Ghanini*[1], Farhad Akhoundi[1]

[1] *Tabriz Islamic Arts University, Faculty of Architecture and Urban Planning, Tabriz, Iran*

Abstract.
This paper examines the traditional construction techniques of houses in the village of Asiabar in northern Iran, focusing on two types of walls: Zegali and Darvarjin. Each of these structures has been designed with unique features to adapt to the environmental and climatic conditions of the region. Zegali walls are typically built on Pakuneh foundations, utilizing carved wood and specific construction methods to ensure better stability and performance against environmental changes. In contrast, Darvarejin walls, which are older and now less common, are constructed on compacted earth or stone foundations, with horizontal logs and mud filling the gaps between them.
This study specifically analyzes the structural and functional differences between these two types of walls, examining factors such as the placement of wood and the types of foundations used. The construction of sloping roofs, supported by Bam Dar beams and covered with materials like Latte Sar or metal sheets, is also explored in the context of the village.
The aim of this paper is to provide a detailed analysis of these traditional construction techniques and their impact on the durability and stability of the structures. This research can contribute to the improvement of traditional design practices and the recognition of local architectural values in similar regions.

Keywords: Traditional construction, Zegali wall, Darvarejin wall, Pakuneh foundation, Local architecture.

1. Introduction

Providing affordable and resilient housing is one of the fundamental needs of any society. Achieving this goal relies heavily on the efficient use of materials and the application of engineering knowledge to optimize construction methods (Oliver, 2006). After the 1990 Gilan earthquake, it became evident that certain wooden houses, designed with appropriate frames and foundations, remained largely intact, suffering only minor and repairable cracks (Charkhtab Moghaddam & Roohanian, 2014). This highlighted the resilience of traditional construction methods in seismic regions. Wood, as a lightweight and environmentally friendly material, offers high resistance to both tensile and compressive forces and has been used for centuries in beams, roofs, and wall structures (Herzfeld, 2002). Its flexibility and energy absorption capacity make it a valuable material in earthquake-prone areas (Brzev, 2007). In Iranian vernacular architecture, wood and mud have been widely used due to their availability, low cost, and climate responsiveness (Memarian & Brown, 2006). Despite these advantages, traditional wooden techniques are now less commonly used, and their technical logic is at risk of being forgotten. Iranian vernacular architecture has historically adapted to local climates and available materials, producing solutions that meet both functional and environmental needs (Foruzanmehr & Vellinga, 2011). This study focuses on the traditional village of Asiabar in northern Iran, located in a humid, mountainous region. In the foothill regions of Gilan Province—characterized by a temperate climate, high humidity, and frequent rainfall—housing must address not only the basic need for shelter but also provide climatic comfort. The vernacular architecture of the village of Asiabar, like that of many rural settlements, has been profoundly shaped by environmental conditions. To prevent moisture infiltration from rain and snow, roofs are constructed with two or four slopes. Compared to the lowland areas, these mountainous regions experience lower humidity but colder temperatures, leading to more enclosed building envelopes and fewer semi-open spaces. Semi-open areas are typically limited to the main façade of the first floor and are often protected with wide doors and windows. Building orientation is carefully planned to benefit from desirable winds that help reduce humidity, while avoiding harsh winter winds, regional warm gusts,

* Corresponding author, E-mail: n.ghanini@gmail.com

https://doi.org/10.31462/icearc2025_a_car_225

and driving rain, thus fully responding to the region's climatic requirements. The aim of this paper is to analyze the construction techniques of two traditional wall types—Zegali and Darvarjin—through a detailed investigation of their structural systems, from the foundation to the roof. By examining elements such as the type of foundation, placement of wooden beams, wall composition, and roofing methods, this study seeks to highlight the structural logic and environmental adaptability embedded in local construction practices.details — from the foundation to the roof — are examined to gain a better understanding of these methods.

2. Materials and methods

The present study is based on a one-week field research conducted in the village of Asiaber, located in northern Iran. The research team voluntarily traveled to the region, and data collection was carried out through direct observation, architectural surveying, interviews with local residents, and on-site investigation and damage assessment of buildings. During the fieldwork, the physical condition of the structures, their construction characteristics, and traditional building techniques were carefully documented and recorded. Semi-structured interviews were conducted with local inhabitants, particularly the elderly, to supplement the historical and indigenous knowledge. Upon completion of the field stage, the collected data were analyzed and compared with library resources and verified documents. The final analysis included a detailed examination of the structural characteristics of Zegali and Darvarjin walls, types of foundations (Pakuneh and Compacted earth), and methods of constructing sloped roofs. The aim of this process was to gain a deeper understanding of the technical and climatic features of the village's traditional architecture to assess the sustainability of these construction techniques against the environmental conditions of the region.

3. Enviromental and climatic Characteristics of the Region

Asiabar is a village in the Deylaman District of Siahkal County, located in Gilan Province. According to the 2016 census conducted by the Statistical Center of Iran, the population of Asiabar was 384. The houses in this village, like most houses in northern Iran, are generally built from wood and are typically one or two stories high. Wood is a naturally abundant material in northern Iran and has been readily available to the residents. The commonly used woods in this village include beech, yew, and alder. Yew (known locally as "Noonj") is particularly used in the foundations due to its superior resistance to heavy loads, moisture, and insects. The majority of the population's occupations are agriculture, animal husbandry, and beekeeping. According to the latest archaeological findings in the region, especially governmental seals, the history of human settlement in this area dates back to millennia before Christ. The average annual temperature of the county is about 15 degrees Celsius, ranging from 2.4 degrees in January to 25.1 degrees in July. This indicates that in this area due to the relatively low humidity and high altitude, the occurrence of severe cold is very possible. *(Book: Gilan - Group of Iranian Researchers)* Traditional Iranian houses were built in various ways considering the region's climate, culture, and local traditions. These houses were designed to be compatible with the environmental conditions and the needs of the inhabitants. One of the most important methods was the use of local materials. In northern Iran, most structures were made from wood and mud. Wooden structures are among the oldest construction methods in human history and have been used in different parts of the world since ancient times. The earliest uses of wood as a building material date back to when humans used branches and tree trunks to build shelters. Due to its natural properties, including lightness, flexibility, insulation, and renewability, wood has always been a popular building material. Wood has good resistance to compressive and tensile forces and can retain heat effectively. However, as previously mentioned, low resistance to fire and insects are the main disadvantages of wooden structures ("Introduction to Wooden Structural Systems and Their Advantages - Construction Encyclopedia"). In Gilan province, where the prominent climatic characteristics are moderate temperature, high humidity, and prolonged rainfall, housing must provide climatic comfort after basic needs such as shelter and refuge. Undoubtedly, residential buildings in Asiaber, like other rural buildings, are significantly influenced by the climate. To better and more effectively combat rain and snow, the roofs of houses are made sloped (four-sloped and two-sloped) to prevent moisture penetration from above. In the foothill areas of Gilan compared to the plain areas, relative humidity and rainfall are less, and the cold is more severe. Therefore, while maintaining sloped roofs, the walls become more enclosed, and semi-open and transparent spaces like porches around the building are absent, with only the main facade of the first floor having a semi-open space, often protected from the cold by full-length doors and windows. All principles of building orientation are influenced by climatic characteristics and aim for optimal use of favorable moisture-repellent winds while avoiding harmful winter winds, the region-specific hot wind, and slanting rain. In the physical and philosophical structures of traditional and local architecture of Gilan, the first floor or ground floor is built on a platform (usually 80 centimeters to one meter high) and typically on wooden structures (Pakoonah) to protect the spaces from ground moisture and dampness. The main facade faces southeast to avoid western winds and seasonal rains and to benefit the most of the summer breeze. Gilan province, part of the Alpine system and located on its central northern edge, has not yet reached real equilibrium in terms of tectonic movements and, like other parts of Iran, can be considered an unstable and vulnerable zone. Therefore, Gilan is among the high-risk seismic areas, and the occurrence of multiple earthquakes in this region is neither unusual nor unexpected.

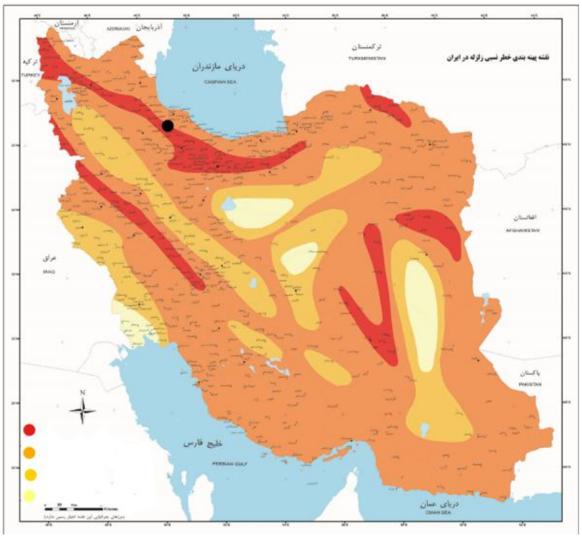

Fig. 1. Seismic zoning map of Iran and the location of Asiabar village

The 1990 Rudbar and Manjil earthquake can be considered the most significant earthquake in the area. This earthquake occurred at 00:30 Iran time (21:00 GMT) on Thursday, June 20, 1990, approximately 16 kilometers from Rudbar, centered in the village of Pakdeh and surrounding villages in Gilan province, causing extensive loss of life and property within a 100-kilometer radius. The earthquake's intensity caused at least four villages to disappear entirely along with their inhabitants. However, based on interviews with the elderly residents of Asiaber village, there were no casualties or complete structural collapses, but approximately 25 percent of the structures suffered partial damage. *(Asiaber Village Master Plan Revision Report)*

4. Traditional Construction Techniques in Asiabar Village

Asiabar houses consist of three main parts, foundation, walls, and roof. We will examine each of these components separately. The foundations were constructed in three ways: compacted earth, Pakuneh, and stone. In northern Iran, to prevent rising damp, most houses are built elevated above the ground. This is primarily achieved using the Pakuneh foundation, which allows for a raised structure, while a stone foundation can somewhat prevent direct contact between the moist soil and wood. However, compacted earth, remains in direct contact with the wood (Image3). The walls in Asiabar are of two main types: Zegali and Darvarjin. The Darvarjin wall is older and has become nearly obsolete, with only a handful still remaining in the village. The construction method involves placing a horizontal tree trunk on the compacted earth or stone foundation, followed by positioning the first wall trunk perpendicular to the first trunk. This process continues until the desired wall height is achieved, and then the gaps between the wood are filled with mud.

Fig. 2. Pakoune foundation and the way of its connection to Bone Nal

Fig. 3. A House constructed with Darvarjin Wall

The Zegali structure is typically built on a Pakuneh foundation. In this method, a trimmed horizontal trunk, known as Bone Nal, is placed on the Pakunehs. Then, several vertical trimmed woods are secured onto the Bone Nal. Thinner woods are then placed diagonally, horizontally, and cross-diagonally between the two columns and nailed to the columns. Finally, the wall is plastered with mud on both sides. Another method involves building two closely spaced rows of columns and filling the space between them with mud, which is referred to as double-layered Zegali.

Fig. 4. A Half-Built House with a Zegali Structure

Due to the heavy rainfall in northern Iran, the roofs of houses are made sloping. In this village, the roofs were also constructed with either two-sided or four-sided slopes. The primary material for the roof was originally Latte Sar, but over time, the villagers have replaced it with tin. To construct the roof, the main beams, Bam Dar, were first placed on the columns. Then, triangular or rectangular trusses were used to create the roof's slope, and finally, the tin or thin wooden boards (Latte) were placed on top as the covering.

Fig. 5. Four-sided roof with Latte

4.1. Construction Technique of House No. 1

Based on the interview conducted with one of the former apprentice builders from the mentioned village, the construction method of House No. 1, begins with digging pits approximately one meter deep and wide, locally referred to as sakat chah or sakteh chal. These pits serve as the foundation for installing the main vertical wooden posts called pakuneh. The pakuneh is typically made from durable tree trunks such as beech or yew (locally known as nonj). The wooden post is leveled in the center of the pit, then the surrounding space is filled with soil and stones. A process called Bako follows, during which the earth is compacted to secure the wood firmly in place. Once the Pakuneh posts are set, horizontal wooden beams known as Bone Nal are placed on top and nailed into the vertical posts. These beams support the main structural columns of the building, referred to as Geleh Sotoun, which are installed vertically and topped by another horizontal beam called Sar Nal. At this stage, the primary wooden framework of the building is complete up to the roof level. For the roof structure, main load-bearing beams called Bamdar—which serve as ridge beams—are placed over the Sar Nal beams. These elements are essential for maintaining structural stability, especially in snowy regions where snowfall can reach up to two meters. On top of the Bamdar, vertical wooden elements called Kulak are installed, forming part of the pitched roof truss. Over the Kulak, thinner horizontal wooden slats are placed, which help bind the four sides of the structure together and create a secondary lattice for the roof.

To form the pitched shape of the roof, inclined beams called Sarchou are added. In Latteh Bam (wood-planked) roofs, wooden planks are inserted intermittently into the Sarchu to lock them in place. The rest of the planks are laid overlapping each other without nails to prevent water penetration.

In the final roofing stage, additional wooden elements are installed perpendicular to the Sarchu. These elements differ depending on the roof type: if the roof is made of metal sheets, they are called Zir Halab, while in Latteh Bam roofs, they are known as Bigan. For bigan, simple round wood is used, whereas Zir Halab requires cut timber planks.

For wall construction, a technique called zegali is used. In this method, the space between the structural columns is filled with wooden elements to form a mold. A mixture of straw and clay, locally called shekeleh gel, is then poured into the mold. This method results in walls with thermal properties that keep the interior cool in summer and warm in winter.

4.2. Construction Technique of House No. 2

This building is the former local structure of Asiabar. The structure is rectangular or square in shape and was constructed using the Darvarjin technique. In this method, wooden beams called Varjin are placed alternately on top of one another. At the contact points where the beams overlap, shallow grooves were carved—locally referred to as Katoh—to allow better seating and stability of the beams.

On the southern side of the building, there is a balcony with windows also facing south. The windows were positioned in that direction to avoid the strong winds from the other sides. Another reason for constructing the balcony was to prevent snow from entering the openings. The preparation of timber beams and columns followed a three-step process: first shaping the cross-section with an axe, then refining it with an adze, and finally smoothing the surface using a hand planer.

The roof structure was also constructed using the Darvarjin method. According to one of the oldest architects of the village, when the height of the structure increased, the length of the beams decreased, resulting in a pyramid-like roof form. And he noted that the roof's outer covering, Darvarjin started above the main roof level and was built with thinner wooden elements. Experienced carpenters executed this roof type with four sloping surfaces.

4.3. Comparison of House No. 1 and House No. 2

Materials and Structural System:

• House No. 1: Combines timber and stone. Vertical wooden posts known as Pakuneh are placed in pits filled with soil and stones, which form the base. Horizontal beams are then installed on top of these posts.

• House No. 2: Constructed using the Darvarjin technique, where wooden beams are stacked alternately. The walls are made from timber filled with a mixture of clay and straw.

Moisture Management:

• House No. 1: The use of soil and stone at the foundation prevents capillary moisture from rising. This enhances the building's durability and resistance to moisture-related damage.

• House No. 2: Thanks to its elevated walls and wooden beams (such as Bone Nal) being kept above moist soil, the structure minimizes direct contact with ground moisture.

Roof Structure:

• House No. 1: The roof consists of load-bearing wooden beams called Bamdar, which support pitched roofs like Latteh Bam. Thinner wooden slats are placed above to complete the roof structure.

• House No. 2: Uses the Darvarjin method for roofing as well, employing stacked wooden beams. The roof has a pyramidal form with four slopes, constructed with thinner elements at higher elevations.

Ventilation and Daylight:

• House No. 1: Features south-facing windows that help reduce exposure to harsh winds and minimize snow entry into openings. This orientation also improves indoor light and airflow.

• House No. 2: Similarly, has balconies and windows facing south, providing comparable benefits in terms of ventilation and natural lighting.

Weather Resistance:

• House No. 1: In snowy regions, its stone and timber construction and sloped roof design effectively protect the building from heavy snow and harsh weather.

• House No. 2: With its thick timber walls filled with straw and clay, this house also performs well against moisture and snow, offering sufficient resistance to weather extremes.

5. Conclusion:

The comparative study of House No. 1 and House No. 2 in Asiabar village reveals two distinct yet equally resilient approaches to traditional architecture in northern Iran. While House No. 1 relies on a combination of wooden frames and stone foundations with a vertical post system, House No. 2 is characterized by the Darvarjin technique, where horizontal logs are interlocked to form the structural body. Both methods demonstrate thoughtful responses to environmental challenges such as humidity, seismic activity, and heavy snowfall. House No. 1 mitigates ground moisture through stone-filled pits, whereas House No. 2 elevates its wooden base to avoid direct contact with damp soil. Structurally, the diagonal Zegali system of House No. 1 may offer better earthquake resistance due to the inclusion of angled braces, while the Darvarjin structure provides strong thermal insulation and simplicity in construction. These vernacular techniques reflect deep-rooted local knowledge, adaptability, and sustainability, offering valuable lessons for future architectural practices, especially in culturally and environmentally sensitive regions.

Design studio experiences in the context of a new building in a historic environment: the example of Fertek Hammam

Hasan Taştan*[1]

[1] *Niğde Ömer Halisdemir University, Department of Architecture, 51000 Niğde, Türkiye*

Abstract. The preservation of historical structures within the dense urban fabric and their continued existence in harmony with newly emerging structures is an important topic in today's urbanization debate.As part of the protection of cultural heritage, it is important to build additional modern structures to existing historic structures properly, to reuse historic structures or to preserve their original function and to continue their use in harmony with newly constructed groups of buildings.
In this study, the experiences of the architecture studio with the Fertek Hamam and its surroundings in the Fertek district of Niğde province were discussed. As part of the project course, the Fertek Hamam, which was in an unused state, was put back into use with the students of the design studio, modern additional structure proposals were developed and projects with different social functions were developed in the same building block as the hamam. Different usage scenarios were developed in the designs, and designs were developed to preserve the hamam structure and keep it alive by creating spatial relationships with new structures.
As a result of the study, proposals were made in relation to the construction of new structures in the historic environment, the conversion of historic structures and the construction of additional structures to historic structures. Firstly, the importance of historic structures for the preservation of the original collective memory was emphasized and that their original functions should be preserved or restored through a design that reflects their original functions, and that this can best be achieved through functional projects with social content and appeal to the general public. The study used examples to discuss the need to preserve the material characteristics of the historic structure, the development of design proposals for the recreational use of open and semi-open areas of the roofs, and the material characteristics of additional structures to be built on top of the historic stone structure. In addition, the study developed proposals that support and emphasize the historical and cultural richness in terms of residential culture and the use of public space in the Fertek district. Design proposals were made for the preservation and revitalization of the inactive hammam structure.

Keywords: Historic environments; Adaptive reuse; Appendices buildings; Cultural heritage

1. Introduction

The Turks, who were called Anatolian Christians, lived in Anatolia, spoke Turkish and worshipped in Turkish and belonged to the Orthodox sect of Christianity, were called Karamanlis. The Orthodox Turks, who spoke Turkish and wrote Turkish with Greek letters, lived mainly in the areas of Konya, Karaman, Nevşehir, Kayseri and Niğde in Central Anatolia (Ekincikli, 1998) Karamanli Orthodox Turks, was a community the majority of which lived in the Cappadocia Region in Anatolia. Were subjected to the forced emigration to Greece as of May 1st, 1923 in accordance with the "Convention and Protocol relating to Exchange of Greek and Turkish People" signed on January 30th, 1923 between the Grand National Assembly of Turkey and the Greek Parliament (Öger,2013).

In the early periods of the Ottoman Empire, non-Muslims were granted rights, but their ability to construct new buildings was restricted in various ways. With the new world order in the late 18th and 19th centuries, non-Muslim minorities were granted more extensive rights so that they could better express their religion and erect new churches and other buildings. During these centuries, the Greek Orthodox erected numerous religious buildings in many parts of Anatolia. In Niğde, many churches are known to belong to the Orthodox Turks from Karamanli. Some of the churches were used as mosques to meet the needs of the Muslim population that settled in the city after the population exchange. Some of them are currently inactive. There are three hammams in Niğde that presumably belong to the Karamanlis. One of these bathhouses is the Fertek Bathhouse in the Fertek district.

Historical buildings carry a lot of information and historical memories such as construction techniques, material properties and socio-cultural values from the past into the present (Taştan and Manisa, 2019).

On the other hand, cities are in a constant state of change. Historical structures that reflect the city's past may no longer be able to fulfill their original functions for many reasons, e.g. due to major social events such as war and migration, but also due to changes in living culture and living conditions, as well as changes in the types of structures needed by society. Today, one of the main topics of discussion is the evaluation of historic structures that are no longer able to fulfill their original functions, the preservation of which is of great importance for the transmission of collective memory to future generations and the survival of the city's identity. Freezing the historic structure in time and transforming it into an exhibit, defining a new function for the structure or adding modern additions while retaining the original materials and construction techniques of the structure are the main conservation methods used and discussed in today's architectural and planning world.

Within the framework of this study, the architectural design studio of Niğde Ömer Halisdemir University discussed the topics of new construction in historical surroundings, protection of historical buildings, conversion and modern additions to historical buildings specifically for the Fertek hammam, which was defined as the study area, and defined new functions for the use of the derelict historical buildings that meet the needs of the people in the neighbourhood. The study took into account the conceptual designs and ideas developed by the students during the 14-week workshop and developed design strategies for the construction of new structures in historic surroundings.

2. Study Area: Fertek Neighborhood

Fertek, which is 5 km away from Niğde city center, is one of the oldest settlements in the city (Fig. 1). It is a livable settlement area with vineyards, orchards and vegetation that includes different shades of green in the middle of the steppe. This historical settlement became one of the neighborhoods of Niğde with the legal regulations made in 2012 (Dinçer, 2008). Fertek neighborhood, which has a multi-layered settlement texture and dates back to the 3rd century AD, bears traces of the Roman, Byzantine, Seljuk and Ottoman periods (Dinçer, 2005). Narrow streets, stone houses with high ceilings and large courtyards, which exhibit traditional Anatolian architecture, reflect the architectural character of Fertek.

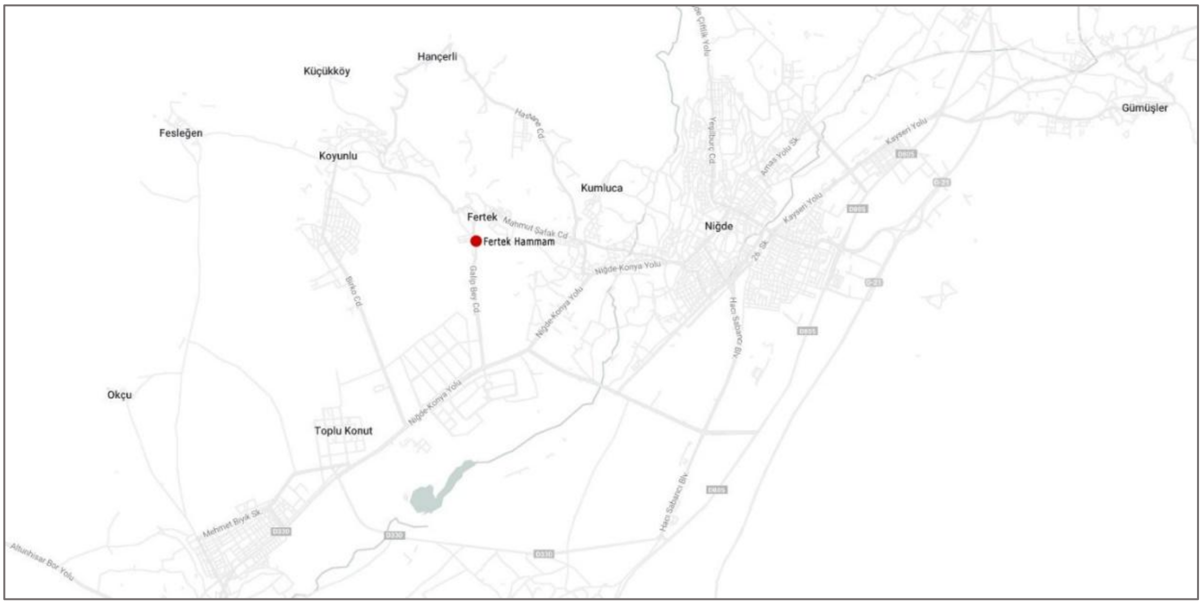

Fig. 1. Location of Fertek neighborhood (SnazzyMaps)

The Fertek district is home to important buildings such as churches, mosques, baths, underground cities, traditional houses and historic fountains (Fig. 2). The Fertek Church was converted into a mosque during the Republican period. The Fertek Bath, which is the subject of this study, was built in 1852-1853 and shows traces of Byzantine-Ottoman architecture, but is currently not in use. These buildings belong to the Turkish-speaking Orthodox Christians known as Karamanli. The Karamanli population emigrated to Greece as part of the Turkish-Greek population exchange in 1924, and Turkish immigrants from various parts of Anatolia settled in their place.

Fig. 2. Neighborhood texture in Fertek (Taştan,2025)

3. Fertek Hammam

The Fertek Bath is one of the buildings that have survived to this day from the Karamanlis, who immigrated to Greece as part of the population exchange. It is located on Hüseyin Avni Göktürk Boulevard, which connects the Fertek district with Bor Street. The bath is located on the border of the original neighborhood, in the area called "Hamamarkası". For this reason, its immediate surroundings are surrounded by newly developing residential areas. The structure, which is located on an area of 1650 square meters, is within the protected area boundary determined by the decision of the Kayseri Regional Cultural Heritage Conservation Authority dated 24.02.2022 with the number 5812. Within the scope of the study, two adjacent plots with an area of 430 square meters and 520 square meters together with the area where the bath is located were selected as the project area (Fig. 3).

Fig. 3. Location of Fertek hammam (GoogleMaps).

The inscription written in Karamanlidika indicates that the bathhouse was built in 1853 during the reign of Sultan Abdülmecid I. It was built on a rectangular ground plan on a slightly sloping terrain in a north-south direction about 2 meters below street level. Due to the street level, the bathhouse has an entrance that gradually slopes downwards as the ground level is lower (Ekiz, 2014).

Fig.4. Roof system of the Fertek hammam (Taştan, 2025)

The hammam is a domed building made of carved stone and bears the characteristics of Byzantine-Ottoman architecture (Dinçer, 2008). The Fertek Bath, whose rooms are arranged from south to north as a (soyunmalık) changing room, (ılıklık) warm room and (sıcaklık) hot room, was actively used until 1990. However, it is currently unused. The original plan of the structure is generally well preserved and has survived to this day. Extensions were built around the building over time, which have no historical value. The building materials used in the structure were mainly ordinary carved stone, a small amount of marble and a very small amount of brick (Ekiz, 2014). The (soyunmalık) changing room part of the building is covered with a dome resting on an octagonal drum. other areas are covered with skylights that protrude slightly from the ground (Fig. 4).

4. New Building Design in Historical Environment: a constitutive theme in Architectural Design Studio

This study deals with the strategies for the design of new buildings in historical environments developed within the framework of projects carried out with second-year students of the Architecture Department of the Faculty of Architecture at Niğde Ömer Halisdemir University. The main purpose of the 14-week architectural design studio is to create a discussion environment for students on topics such as the reuse and preservation of abandoned historical structures, the design of new buildings in historical environments, the design of additions to be made to historical structures and to develop students' awareness of historical structures. During the process, various literature research and analysis related to the field of study were conducted. As part of the course, an interim jury and a final jury were conducted with the participation of the course instructor and other academics and the students' work was evaluated. During the process in which modern protection, conversion and new building design approaches were discussed, theoretically applicable, conceptual idea projects were carried out in compliance with basic architectural protection rules. During the workshop process, five different design strategies were applied in the design of the projects, namely preserving the original function, adaptive reusing, building a modern extension, interventions that preserveor refer to the collective memory, and taking into account the needs of the region and the society to which it belongs.

4.1. Preserving the original function of the building

The most appropriate use of a historic building is to keep it alive by ensuring its continuous maintenance (Tunçoku, 2004). Preserving the original function of the building in modern times and adding various new functions that meet the needs of people today is the most efficient way to preserve a historical building. The bathhouse, that has served the Fertek district for years, is currently not in use. Ensuring that the bathhouse continues to fulfill its function today will keep not only the building but also the bathhouse culture alive. During the workshop process, some students preserved the original function of the bathhouse and supplemented this function with functions such as a spa, physiotherapy center, gym and day care center (Table 1.).

4.2. Adaptive reuse of the building

As a result of changing living conditions over time, most historic buildings are no longer able to fulfill their original functions. Due to the value, they have, their adaptive reuse offers not only environmental and economic, but also social and cultural benefits (Taştan and Manisa, 2019). In architecture, conversion or adaptive reuse is defined as the transformation of a building that can no longer fulfill its original function for some reason to fulfill another function. Adaptive reuse is a process of preserving the existing structure as much as possible while developing it to meet current user needs (Latham, 2000). Identifying the heritage values is an important factor in the decision-making process that directly affects the decision on the new function. The needs of the district should be defined to determine the most appropriate function for the heritage building. The heritage buildings should be evaluated in the context of the whole district (Mısırlısoy and Günce, 2016).

4.3. Adding a Modern Annex to a building

Contemporary conservation theory aims to preserve historic buildings primarily in their original function. If this is not possible, it provides for equipping the building with a contemporary function and intervening with methods that do not damage the building and with modern materials. The most important parameter of the contemporary conservation approach, which aims to intervene in the building in a minimal way, is the inclusion of approaches that separate the features of the period of origin from the original building by using architectural variables such as form, color, texture and material and not misleading the public. (Yapan and Büyükmıhçı, 2023). Any intervention in a historic building should be reversible without damaging the building. This strategy is particularly important for temporary sections or exhibition areas that are built inside. The materials used in new additions should be used in a language that respects the character of the historic building without imitating it. For interventions and extensions, the original form and materials of the historic building should be preserved and the necessary repairs and reinforcements made with a minimum of intervention; the newly added spaces should be such that they do not affect the existing building and can be easily restored to its former state.

4.4. Interventions that protect/reference the collective memory

The preservation of historic buildings in a way that reflects the characteristics of the period in which they were built, such as construction techniques, materials and living culture, contributes to the continuity of collective memory by allowing memories to be revived in social memory (Bandarin, Oers, 2012). It is therefore to be expected that any conservation intervention will contribute to the preservation of this collective consciousness.

4.5. Consideration of the needs of the region in which the building is located and the society to which it belongs

The heritage buildings should be evaluated in the context of the whole district (Mısırlısoy and Günce, 2016). Regardless of whether historic buildings are re-functioned, preserved with their original functions or treated together with new modern additions, the most important design element is that the building is treated in a way that serves the neighborhood and the society it belongs to. Buildings gain meaning when they are preserved by being included in daily life and not frozen in time like a museum object. Therefore, when dealing with a historic building, not only the physical but also the social needs should be considered. As a result of the studies carried out in the architectural design studio, the above-mentioned methods and design strategies were applied in connection with the Fertek Hamam and various designs were realized. During the design process, the question of whether the original function of the hamam should be preserved, what function the new building should have and how it should relate to the historical building were the main design decisions (Table 1).

Table 1. Projects and design decisions made in the architectural design studio.

	Project Name	Function of Historical Hammam	Function of New Building	Design Approach
1	Fertek Library and Coworking Center	The hammam was re-functioned as a library.	Co-working spaces and offices for rent.	The modern glass building, which was added to the historic bathhouse structure, created the entrance area for the library, café and social areas were created.
2	Fertek Çınaraltı Social Facility	Its original function has been preserved and it was intended to be used as a neighbourhood hammam.	A social facility with services such as workshops, libraries, cafes and gyms that can be used by the local people, especially the elderly and retired people.	While preserving the bathhouse culture, it is also aimed to preserve the culture where the elderly population socializes by drinking tea and coffee under the plane tree.
3	Fertek Spa and Natural Treatment Center	Its original function has been retained and it is to be used as a bathhouse with an integrated spa center.	Modern annex creating a sunken courtyard with spa, massage and physiotherapy functions.	The bath culture has been preserved by blending it with modern needs.
4	Fertek Elderly Care Center	Its original function has been preserved and it was intended to be used as a neighbourhood bath.	A centre where the elderly and people in need of care can receive health services, socialize and stay for a short time.	In addition to the recreation areas in the courtyard, which were created by the historic hammam and the new building, a winter garden with a modern glass extension was added to the hammam's wall.
5	Fertek Book Bazaar	The bathhouse building has been converted into a workshop and exhibition hall where traditional arts such as marbling are displayed.	It includes social areas such as workshops, bookstores and cafés.	The terrace roof of the restored hammam was used as a temporary exhibition and event area, allowing users to experience the building in a variety of ways.

Table 1. continued

6	Fertek Healthy Living Center	The original function of the bath has been preserved.	It consists of psychological support, sports and healthy life units.	The social spaces were designed by creating a common courtyard with the hammam's structure.
7	Fertek Youth Center	The structure of the hammam has been converted into a museum that reflects the bathing culture.	It includes socializing areas with a cafe, gym and swimming pool.	The social spaces were designed by creating a common courtyard with the hammam structure.

5. New Building Design in Historical Environment: experiences from Architectural Design Studio

5.1. Architectural form experiments

During the workshop process, various form experiments were conducted that relate to the architectural features of the historical building and bathing culture. One of these is the mass experiment, which was carried out using the example of the polygonal supporting wall supporting the dome in the "soğukluk" area of the hammam. In the study, in which workshop units with independent entrances and service units larger than the workshops gradually rise, semi-open areas are created in places and open areas that will function together with the historic structure are designed (Fig. 5)

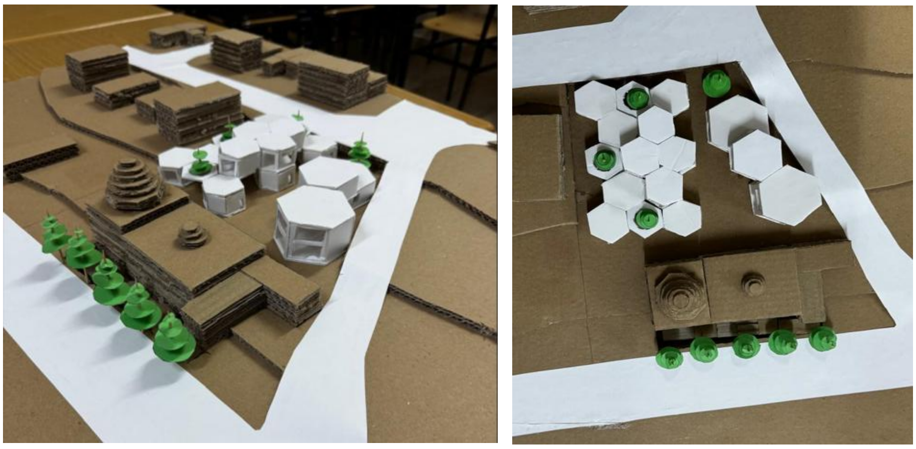

Fig. 5. Samet Bakır's attempt at architectural form.

5.2. Creating an inner courtyard

The courtyard not only provides a degree of privacy, but also forms a natural barrier for noise control. The use of a courtyard is considered an excellent solution as it creates a quiet area where various activities can be carried out away from noise (Beyoğlu, 2019). In public buildings, courtyards can be used as public gardens with controlled access and can be used by everyone. In the design proposals developed during the workshop process, the new buildings are not directly adjacent to the historic bathhouse, but are connected to a courtyard or transitional area, maintaining the distance and creating a visual connection with the historic building. In the courtyard, shaded areas, open space arrangements, seating and walkways were created and a lively intermediate area was designed between the historic bathhouse building and the social facility (Fig. 6).

Fig. 6. Project models of Yakup Tekin and Rıdvan Ercan.

Another student, Rulla Cellul, designed the courtyard in such a way that her spa project created a sunken garden 3 meters below ground level, preserving the original function of the historic bathhouse. This courtyard, which offers a high degree of privacy, combines the spa and bathhouse experience with tranquillity (Fig. 7).

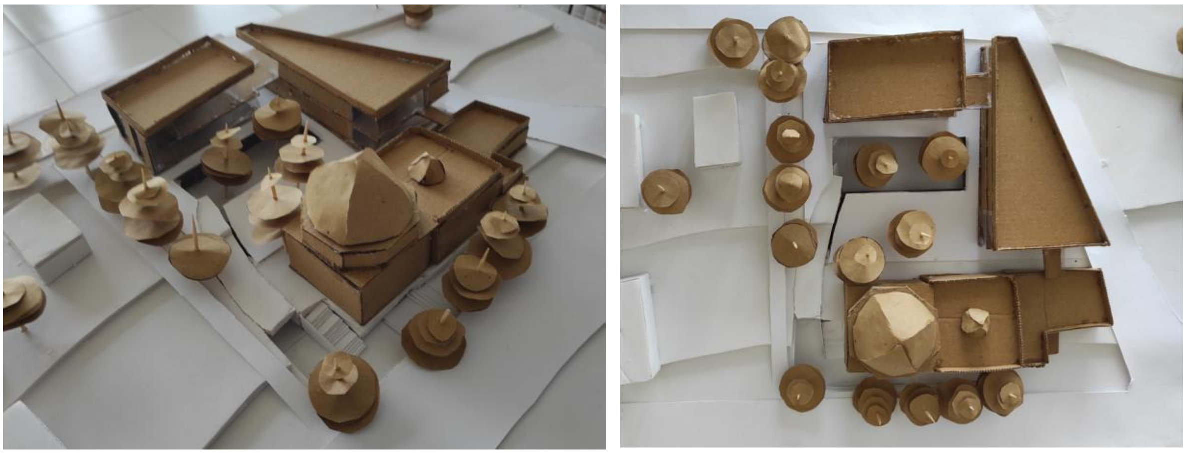

Fig. 7. Project model of Rula Cellul.

5.3. Touching the Historical Structure

The oven, the water tank and the 'sıcaklık' section of the historic hammam are covered with a patio roof. The wide roof of the hot section offers a perfect view of the dome of the cold section. The upper covers of these units, which rise in steps, are easily accessible via stairs. Spaces with various functions, such as an exhibition hall and a café, were designed as part of the project and are connected to this useful terrace area from the additional structure (Fig. 8). Historic buildings, which are interesting exhibits with their materials, construction techniques and façade details, are kept alive and used by people in some way, and a design that allows people to touch and look closely at them helps to create the desired natural atmosphere.

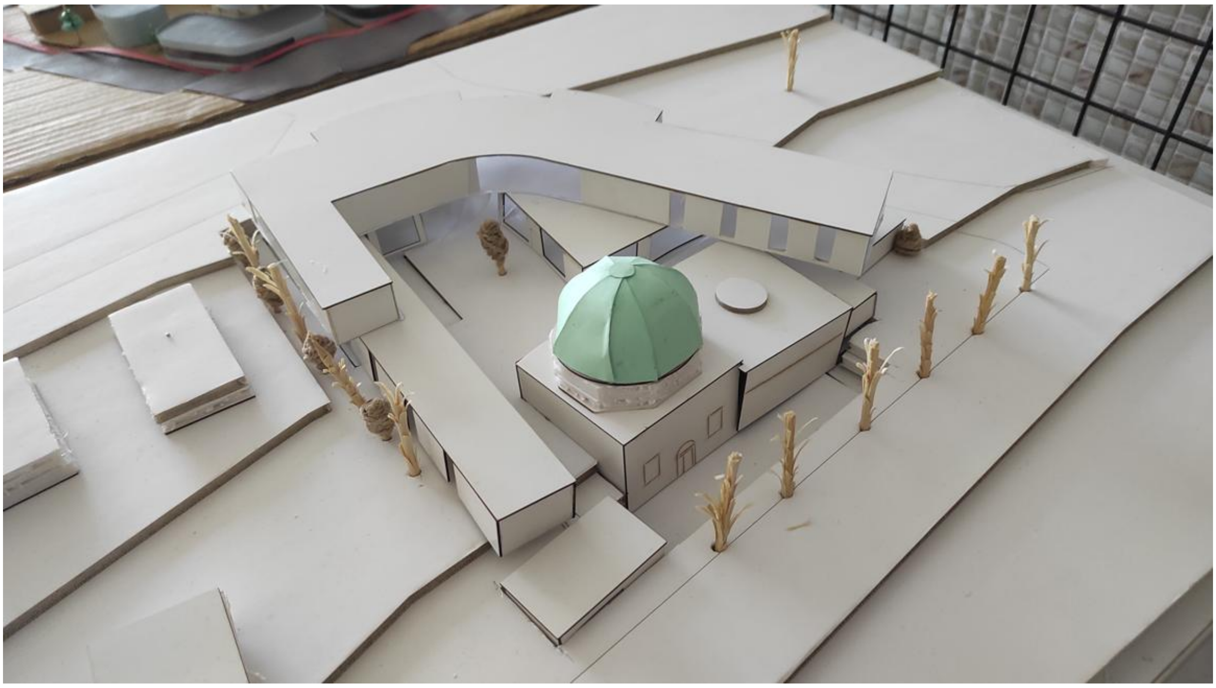

Fig. 8. Kübra Arslan's project model.

Besmele Dillo carried out a further study in which the upper cover of the oven, water tank and other units was achieved with a bridge and an open space design. The structure creates a courtyard by surrounding the bathroom and access to the courtyard is from street level, with the drains on the first floor. In addition, a winter garden made of a steel structure and completely glass facades were designed in the project, which serves the courtyard and uses the stone wall of the historic structure as a 4th Surface (Fig 9).

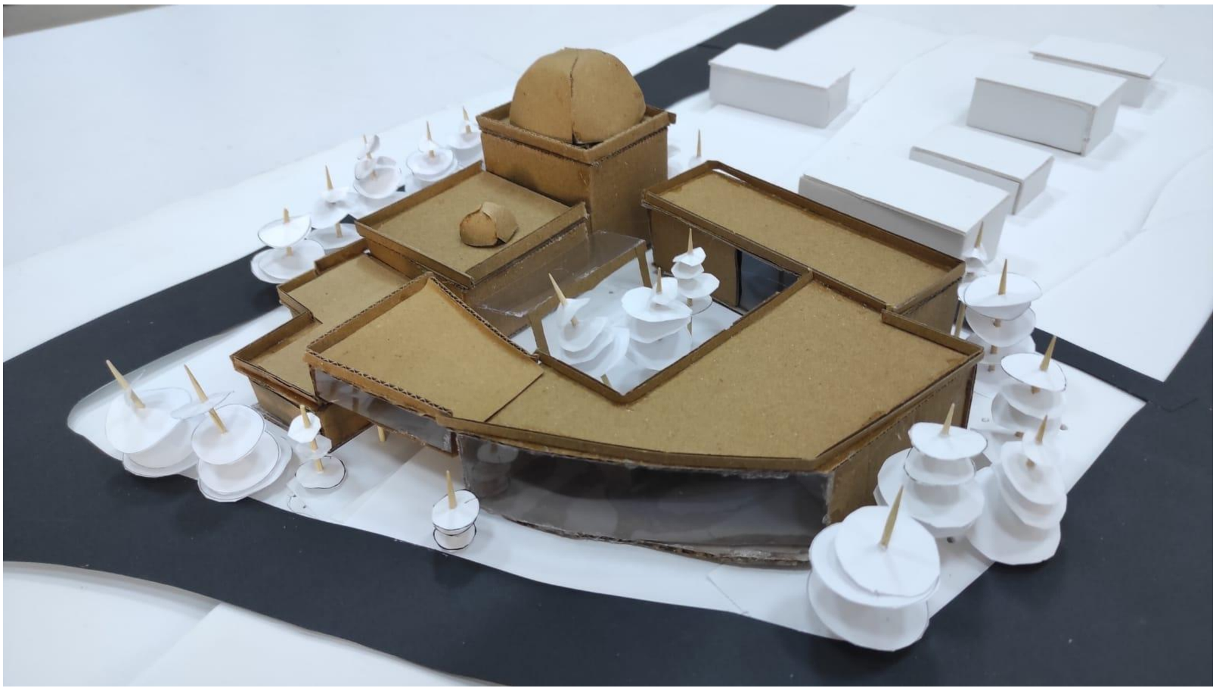

Fig. 9. Besmele Dillo’s project model.

5.4. Adding a Modern Annex

In Tunahan Günaydın’s project to convert the historic bathhouse into a library, the new structure includes shared workspaces and offices. In this project, a glass extension was added to define the entrance to the bathhouse and create a meeting area and open areas of the café. The annex, designed in relation to the café and office areas in the basement, is completely demountable and is made of steel and glass compatible with the stone, the original building material of the bathhouse (Fig. 10).

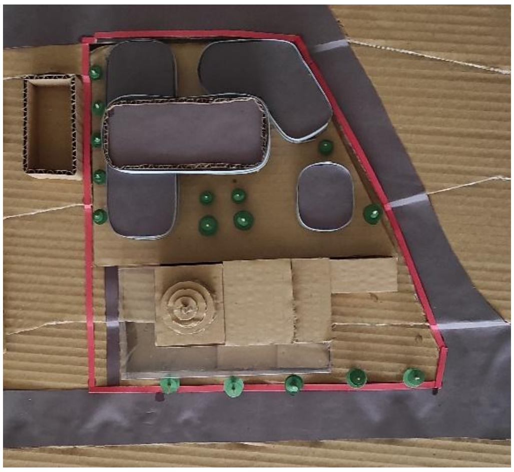

Fig. 10. Tunahan Günaydın's project model.

5.5. Keeping the collective memory alive

The Fertek bathhouse, which belonged to the Orthodox Turks known as the Karamanlis, bears many traces of collective memory to the present day. The bathing and bathhouse culture of the Karamanlis, who left the region as part of the population exchange, and the activities they carried out in the bathhouse should be kept alive by designing the building to fulfill functions such as an exhibition hall and a bathhouse museum. The use of the bathhouse, which was known to have been in operation until 1990, in its original function was also seen as another way of keeping the collective memory alive. One of the most important parts of daily life in the Fertek neighbourhood, where the elderly population is now densely packed, are the tea houses around the neighbourhood’s historic church and the seating areas under an associated tree. Muhammed Dalkılıç's project made reference to the culture of socializing under trees and designed the social facility around a plane tree. The plane tree was placed in the center of the conservatory to protect it from the harsh Niğde climate and create a semi-open area at any time of the year (Fig. 11).

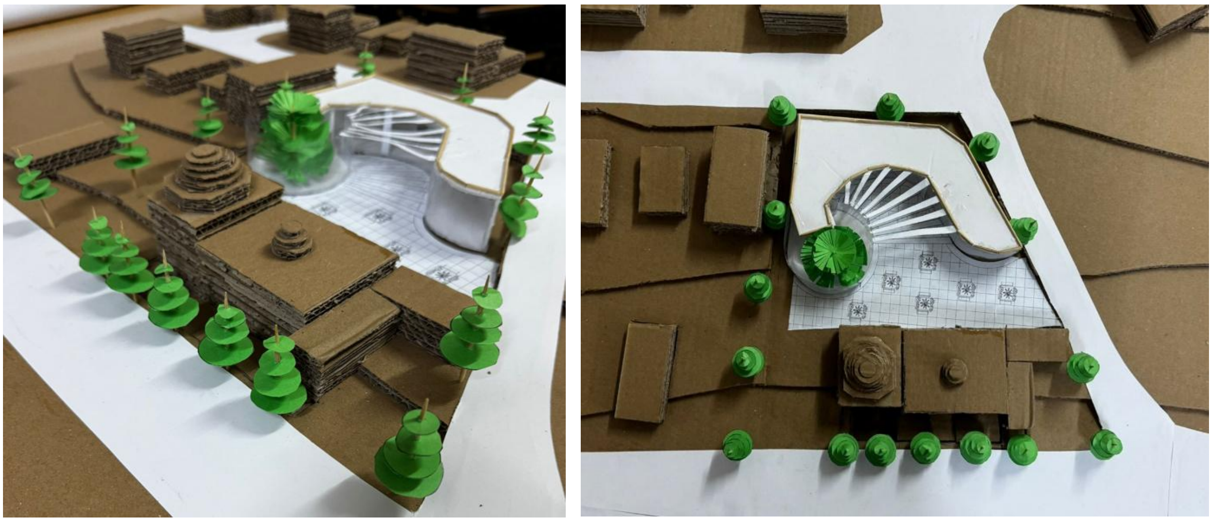

Fig. 11. Muhammed Dalkılıç's project model.

5.6. Ensuring environmental and social sustainability

When historic buildings are designed as spaces that are accessible to all people in society without financial constraints and where they can spend time, they go beyond being a shared value of society that needs to be protected and become meaningful and useful spaces for all. Transforming historical buildings into spaces that are accessible to all contributes to social sustainability. Azat Altın's project is characterized by sports areas, psychological care and health stations that can be used by the residents of the neighbourhood. The project, which retains the original function of the bathroom, includes design strategies aimed at environmental sustainability, such as a winter garden and the use of panels that generate electricity from solar energy (Fig. 12).

Fig. 12. Azat Altın's project model.

6. Conclusions

This study discusses design strategies developed to preserve the historic value of the vacant Fertek Bathhouse and revitalize it in a way that meets the needs of today's society, and draws conclusions for the protection of historic structures in similar situations.

- Preserving the original function of the structure: When protecting historic structures, the original function of the structure should be prioritized. When preserving the original function, it is important to maintain the structural and design integrity of the building. Instead of making structural interventions to maintain the original function, other solutions should be developed for the additional spaces required.
- Adaptive reuse of the structure: When reusing a structure that can no longer fulfill its original function, the original function of the structure, its historical value, the needs of the environment in which it is

located and the environmental, cultural, physical, economic and social conditions of the structure should be comprehensively analyzed.

- Adding a modern annex to the building: If a modern annex is to be added to a building of historic value, the principle of minimum impact should apply first and any addition should be designed to be reversible. The new building should be compatible in material and texture with the existing building, not imitate it in any way, but be visually and physically in harmony with the existing building. The façade, scale, proportions and finishes should be designed to match the existing structure.

All interventions in historic structures should take into account the social and physical needs of the environment in which they are located and the characteristics of the structure. It should be ensured that a historic structure is transformed into a space that can be experienced by all sections of society without physical or social barriers. In this context, the development of sustainable conservation and conversion strategies, taking into account social, economic and physical aspects, is becoming increasingly important.

Acknowledgments

I would like to thank the students of the architectural studio Samet Bakir, Muhammed Dalkiliç, Rıdvan Ercan, Tunahan Günaydin, Yakup Tekin, Azat Altin, Hatice Kübra Arslan, Besmele Dillo and Rula Cellul for their contributions to this study.

Abstract. The railway history of Türkiye can be analyzed under three headings: Pre-Republican period, Republican period: 1923-1950 period and the post-1950 period. The post-1950 period has different stages of development. Between 1950-1980, the construction of railways remained in the background as highway transportation gained momentum. In the 2000s, the integration of high-speed rail technology into national policy gained pace. The growing importance of high-speed railway transportation since the 2000s can be linked to the concept of sustainability. Sustainable development is one of the prominent concepts in the report "Our Common Future" (Brundtland), published by the World Commission on Economic Development (WCED) in 1987. In 1992, the Rio Earth Summit was held in Rio de Janeiro, the main outcomes of which were Agenda 21 and the establishment of the Commission on Sustainable Development. All these developments can be characterized as factors that accelerated the introduction of the concept of sustainable development into the agenda of international and national policies. Historic railway station structures have great importance in terms of providing economic and environmental benefits, as well as deep cultural and social ties to national history and urban identity. The continuous use of station buildings, with necessary maintenance and renovation interventions, offers many advantages in terms of reducing the consumption of energy and raw materials required for the construction of new buildings, reducing carbon emissions, preserving culture and history layers belonging to urban identity. It is clear historic station buildings have an critical role in achieving sustainable development goals. With the development of railway technology, historic railway lines and station structures have entered a process of transformation in line with modern technology and requirements. This global transformation is also having an impact at the national level. In this context, the issue of adapting historic station buildings to high-speed train technology has gained importance. Within the scope of this research, examples of international and national approaches to the integration of historic station buildings with high-speed train buildings will be examined. Then the selected examples will be evaluated conceptually in the context of sustainable development goals.

Keywords: Histotric train stations; Adaptive re-use; Sustainable development; Conservation of cultural heritage

---

1. Introduction

Railway transport has been one of the most important carriers of the technological and social transformations that accelerated with the industrial revolution on a global scale. Since the mid-19th century, railway lines and related station structures have not only shaped transport networks, but also deeply affected the physical structure, economic development and social dynamics of cities. Considering the railway history in Türkiye after the proclamation of the Republic, three main development phases can be defined: between 1923-1950, between 1950-2003 and after 2003. These periods are closely related to the economic, political and social changes and technological developments in the country. In the early Republican period (1923-1950), two significant policies were implemented, which had a considerable impact on the development of railway transport. The first of the aforementioned measures was the nationalisation of railway lines that were previously controlled by foreign capital. The second objective was to establish the essential transport infrastructure in regions lacking railway lines and integrating the existing network with the new infrastructure. The objective of this initiative is to establish an

* Corresponding author, E-mail: dilarazegerek@metu.edu.tr

https://doi.org/10.31462/icearc2025_a_car_294

independent transport network that would facilitate efficient connectivity between the eastern and western regions of the country (Yalçın, 2024 as cited in Ekizoğlu, 2012).

Especially after 1950, with the prioritisation of road transport, railway construction activities remained in the background and railway investments followed a stagnant course. However, since the 2000s, the integration of high-speed train technologies into national transport policies has accelerated and a renewed interest in railway transport has emerged (Pektaş, 2017). This process is also overlapping with the gaining importance of the concept of sustainability on a global scale. The process, which started with international studies such as the Our Common Future (Brundtland) Report published by the World Commission on Economic Development (WCED) in 1987 and the 1992 Rio Earth Summit, has placed sustainable development at the centre of contemporary development goals. In parallel with the developments in the international agenda, the concept of sustainability has started to be discussed at the national level in terms of environmental impact.

In the 7th Development Plan prepared in 1995, attention was drawn for the first time to the negative environmental impacts caused by the transport sector. The need to increase the importance given to railway transport in public investments in the transport sector in Türkiye was emphasised for the first time in the 7th Development Plan, and the concept of sustainability was officially included in the 8th Development Plan prepared in 2011 (Zeren, 2021). Railway transport, which is a sustainable and efficient method in terms of environmental protection policies as an alternative to road transport, which is dependent on fuel consumption with high carbon emissions in both global and national transport policies, comes to the forefront with the development of high-speed train technologies (Candan Demirkol & Gülpınar, 2023).

Railways are socio-technical systems morphologically composed of 'social' and 'technical' elements. These elements cannot be separated from each other. A holistic approach is needed to properly analyse the historical significance of railway systems (Coulls et al., 1999). As an industrial heritage, railway structures have a strategic importance as social spaces that stand out in the city identity with the technical infrastructure they offer in the field of transport. Evaluating the changing technical infrastructure and social conditions together with technology is of great importance for the conservation of these heritage sites. In the period from the 1950s to the 2000s, the problem of the existing railway structures becoming idle and losing their importance by losing their function due to the prominence of road-based transportation and the effect of modernisation has started to be discussed. Railway structures, which are considered under the title of industrial heritage, came to the forefront in the 1970s as an element of cultural heritage (Kösebay Erkan & Ahunbay, 2008 as cited in Ede & Çelen Öztürk, 2024).

Since 2003, conventional railway lines and station structures, where national passenger transport services are provided, have been transformed in line with modern needs. Construction of new lines and station structures serving high speed train technology has gained momentum. In the 2024-2028 TCDD Strategic Plan, the vision of using renewable energy resources to contribute to a cleaner world and implementing sustainable practices to minimise the negative environmental impacts of railways has been adopted. Within the definition of this vision, the concepts of economic and environmental sustainability come to the fore. The development of different design models in order to carry out applications without damaging the buildings with historical value is among the targets included in the plan (T.C. General Directorate of State Railways, n.d.). This approach can be associated with the cultural dimension of sustainable development. The construction of new technological transport infrastructure brings along a number of debates. In the period from the 1950s to the 2000s, the prominence of road-oriented transport and the inactivity of existing railway structures due to the effect of modernisation and the loss of importance by losing their function have started to be discussed. This situation brings the problems regarding the preservation of the national railway heritage to the forefront of the agenda of contemporary conservation debates. TCDD does not have an effective inventory of its cultural heritage building stock. Documents, photographs, maps or drawings related to the history of these buildings are not collected in a single archive. The absence of an effective archive system for the protection of railway heritage creates a disadvantage for the protection of this heritage. Problems such as the demolition of existing buildings if deemed necessary and the loss of importance of existing historical buildings by becoming dysfunctional with the commissioning of new buildings come to the agenda (Kösebay Erkan & Ahunbay, 2008). In addition, although the strategies developed include the development of innovative designs for the protection of historic buildings and the expression of sustainability, an effective conceptual framework for the planning and implementation of these designs has not been defined.

The 17 universal goals and 169 objectives determined as a result of the United Nations' efforts to include sustainable development in country policies and to create global goals are a guide for multilateral and collaborative development strategies at the international level (Gedik, 2020). The Sustainable Development Goals (SDGs) published by the United Nations in 2015 are planned to be achieved by 2030 (United Nations, 2015). The strategic plans and programmes developed to achieve these goals prove the power of these goals to take action. These goals can be defined as a dynamic action tool that covers multidimensional goals such as environmental protection, economic development, social justice and cultural heritage protection. The integration of historic stations with new transport systems requires the development of effective approaches that are environmentally, economically and socially sensitive to the preservation of cultural heritage, modern living conditions and human needs. Objective, versatile and binding SDGs can be used as a tool for the development of these effective approaches.

Within the scope of this research, examples of international and national approaches to the integration and re-functionalisation of historical station buildings with buildings built for high-speed railway lines are examined. This examination aims to develop a conceptual perspective based on the evaluation of the selected examples through the concept of sustainability.

2.Methodolgy

Qualitative research methods were adopted in this study. Within the scope of the study, national and international examples of the integration and re-functionalisation of historical railway stations with high speed train lines were examined through literature and archive review. In the literature review, primary and secondary sources such as academic articles, reports, project documentation and relevant policy documents were utilised. During the literature review, the history of railway development in the Republic of Türkiye was firstly researched. In order to facilitate the research and evaluation stages, the history of railway development was handled in periods. Accordingly, three main development phases were defined as between 1923-1950, 1950-2003 and after 2003. Then, focusing on the concept of railway heritage, literature and archive researches were conducted on the studies on the conservation of historical station buildings. In the next step, literature researches were conducted on the historical development of the concept of sustainability and sustainable development. Literature researches were carried out to analyse the place of railway transportation and cultural heritage conservation approaches in sustainable development. International and national examples for the integration of historical station buildings and high-speed rail transport have been analysed using literature and archival documents. In the next methodological stage of the study, the examples analysed were conceptually evaluated on the axis of sustainable development. In the last stage, all the findings obtained are evaluated and included in the conclusion section.

3. Evaluation of the integration of historical railway stations into high speed railway systems in the perspective of sustainable development goals

In this chapter, the integration of historical railway stations, which have been shaped within the framework of the development process from the early periods of its history to the present day, with high-speed railway (HSR) systems is evaluated in the context of sustainable development goals. In this context, the historical development of the Republic of Turkey's railways is discussed. Subsequently, an evaluation is conducted of international approaches to the importance of railway structures as cultural heritage. Furthermore, with reference to the architectural, technical and socio-cultural characteristics of railway structures, the protection of these structures, ensuring their functional continuity and integrating them with modern transport systems, is discussed within the scope of the United Nations Sustainable Development Goals.

Finally, in this framework, national and international examples are analysed to evaluate the technical, functional and conservation-oriented challenges encountered in the process of integrating historical stations with high-speed train technologies.

3.1 Historical development of Turkish Republic railways

Railway policies of the Republican period are generally considered in three main phases. The first period is the period between 1923-1950 when the railway had a priority position in transport systems. The second period covers the years 1950-2003, when Türkiye started to intensify its relations with the United States of America within the framework of the Truman Doctrine in 1947, which led to a change in the direction of transport policies and highway investments came to the forefront. The third period is the period in which the restructuring process in railway transport started as of 2003, high speed train projects were prioritised at the state policy level and railways were repositioned as a strategic transport model (Ekizoğlu, 2012).

The railway policy effective in the period between 1923-1950 was carried out in line with two main objectives. The first one was to build railway lines covering neglected regions as well as developed centres and to organise the entire transport infrastructure through an interconnected network system. In this way, it was aimed to support national unity and economic development. Secondly, the nationalisation of railway lines inherited from the Ottoman Empire and controlled by foreign companies was adopted as a strategic step towards the nationalisation of transport infrastructure (Öztürk, 2009). In the Early Republican period, political and strategic priorities were decisive in the approaches towards railway enterprises. In this period, the size of the station buildings was planned by taking into account the population and importance of the settlement through which the line passed. The buildings constructed in the 1920s have elements such as wide eaves, arched windows and tile decorations reflecting the architectural understanding of the period. The 1926 Ankara Gazi Station and the 1912 Adana Station are examples of this architectural approach. In the 1930s, the simple and massed forms of modern architecture were blended with an understanding symbolising the authority of the state. Ankara Station, designed by Şekip Akalın in 1937, and Afyon Station in 1939 are among the buildings of this period, where prismatic masses add mobility to the façade (Sezginalp & Sezginalp, 2021). According to the Truman Doctrine, which developed during the Cold War period after World War II, Türkiye was included in the Marshall Plan in 1948. In order to benefit from the Marshall Plan, Türkiye was required to accept a number of conditions. As a result of these conditions aimed at increasing the economic volume of private enterprises by reducing public entrepreneurship in the economy, it was put forward not to establish heavy industries such as iron and steel and heavy chemistry (Öztürk, 2009). This situation started the process that led to the railway lines being put into the background due to the emphasis on highway investments.

From 1950 to 2003, the importance given to railways gradually decreased. Road transport was encouraged through Marshall Aid and highway construction gained momentum. As a result of the road-oriented transport policies implemented in this period, highways took the first place among transport systems. Accordingly, the number of motorised vehicles increased rapidly in the following years. A completely foreign-dependent automotive industry was established for the necessary fuel and spare parts needs (Pektaş, 2017). In the 1996-2000 7th Development Plan prepared in 1995, attention was drawn for the first time to the negative environmental impacts of the road-based transport sector (Zeren, 2021). The increase in the use of motor vehicles has brought along the problems of excess fuel consumption, environmental pollution, accidents and traffic congestion in urban transport in Türkiye (Prime Ministry State Planning Organisation, 2010).

The EU harmonisation process has directly affected Türkiye's national policies, particularly in the field of transport. The development of the physical and economic infrastructure of the transport sector, which is directly related to the revitalisation of sectors such as trade and tourism, has become a priority issue. This priority status has directly affected the development plans prepared by the state, which also include transport policies (Zeren, 2021). In the Long Term Strategy 2001-2005 and the Eighth Five-Year Development Plan, the main objective is to strengthen the role of railway operations in the country's transport system by making them compatible with market conditions, commercially oriented and efficient.

With the effect of all these developments, 2003 was a turning point in railway transport and high speed train technology was included in national transport policies. In this way, railways were adopted as a priority transport model again as a state policy. In addition to Ankara-Istanbul and Ankara-Konya High Speed Train Projects, cooperation was established between the central government and local administrations for the development of urban rail public transport systems. In this context, large-scale urban rail transport projects such as Marmaray in İstanbul, Ege-ray in İzmir and Başken-tray in Ankara have been implemented (Karaman, 2010 as cited in Ekizoğlu, 2012). In the Ninth Five-Year Development Plan for 2007-2013, it is stated that the existing railway infrastructure is not suitable for high speed and high quality service between large populated cities. Within the scope of improvement works, restructuring of railway line and station structures to make them suitable for high speed train operation has been brought to the agenda (Ekizoğlu, 2012).

In the 19th century, train terminals built in many important cities of Europe attracted attention with their wide-span railway halls reflecting the developing engineering possibilities of the period. Today, these buildings are facing a 'station renaissance' process; some of them have been modernised and adapted to high-speed train (HSR) systems. In the last two decades, in line with the goals of revitalising city centres and expanding HSR networks, large-scale new generation station structures with multifunctional programmes have been built. These stations stand out not only as transport infrastructure but also as monumental structures within the urban space. Ankara HSR Station and Konya Selçuklu HSR Station, which have been commissioned in Türkiye in recent years, are among the local examples of this new generation of multifunctional and large-scale station buildings (Zeren, 2021).

3.2. Importance of railway structures as cultural heritage

The UK, which is at the forefront of the development of railway technology, has many examples in terms of the construction and preservation of railway structures. Therefore, analysing how railway heritage is handled in England is advantageous for studies in this field. Until today, railway heritage has not received the attention it deserves, including in the UK. The closure of many railway lines in the 1960s when coal mines became dysfunctional, and the structures lost as a result, have led to an awareness of railway heritage in the UK (Kösebay Erkan & Ahunbay, 2008).

The process of including railway infrastructure within the scope of cultural heritage initially encountered two main obstacles. Firstly, railway remains were considered as ordinary and functional infrastructural elements for a long time; this situation caused both their cultural and technological values to be insufficiently recognised. Secondly, due to this perception, the lack of an effective legal framework or regulation for the protection of railway structures has made the protection of these structures difficult. The acceptance of the concept of industrial heritage as a historical and cultural value came relatively late, resulting in a large number of industrial abandonments, including transport infrastructure that became dysfunctional with changing industry and technology. Abandoned railway lines, in particular, are often located in areas where coal mining or heavy industrial activities have ceased, leading to the dysfunctionalisation of the sites. Moreover, the gradual modernisation of railway systems resulted in the decommissioning of many historic lines of high engineering and architectural value (Merciu et al., 2022).

In the 1970s, in response to concerns about the potential environmental threats posed by the demolition of industrial buildings, meetings began to be organised under the leadership of various universities and conservation organisations. These reactions, which were initially shaped by environmental concerns, gained a different dimension in time with the effect of the sense of belonging of the workers who had worked in these buildings for many years. These developments paved the way for an increase in interdisciplinary studies on industrial areas and the emergence of concepts such as ‘industrial archaeology’, ‘industrial culture’ and ‘industrial area’. Thus, since the late 1970s, awareness for the conservation of industrial buildings has developed and these buildings started to be defined as a cultural value under the title of ‘industrial heritage’ in the second half of the 20th century. Since the mid-1980s, this conservation approach has expanded beyond the structural scale to include large-scale industrial areas (Gür, 2019).

In 1977, the exhibition ‘Off the Rails’, organised as part of the ‘SAVE Britain's Heritage’ initiative, contributed significantly to raising awareness of railway heritage in the UK. After this exhibition, the preservation of railway buildings with historical and architectural value came to the agenda; Manchester Central Station was re-functionalised instead of being demolished in 1980 and became one of the first applications that set an example for this process. By 1997, a total of 60 railway lines were under protection in the country, and by 2003, more than 2,000 railway structures were officially protected. Today, although railway heritage is generally evaluated within the framework of industrial heritage and industrial archaeology disciplines, historical railway lines and structures are specifically addressed under the title of ‘railway heritage’ within this inclusive framework (Kösebay Erkan & Ahunbay, 2008).

Railway heritage is not only an element reflecting the function of transport infrastructure in the past, but also a multi-layered cultural value bearing the traces of social, technological and spatial transformations. Railway structures, which played a central role in shaping the processes of urbanisation, mobility and economic development after the industrial revolution, constitute important reference points in terms of historical memory with their engineering achievements, architectural styles and urban locations. The preservation of this heritage is critical both for the reuse of environmental and economic resources in line with sustainable development goals and for ensuring cultural continuity. In addition, the re-evaluation of abandoned or defunct railway buildings is of great importance in terms of integration with modern transport systems, preservation of urban identity and urban aesthetics.

3.3. Evaluation of railway heritage from sustainable development perspective

The term sustainable development was first defined in the ‘Our Common Future’ report prepared by the United Nations' World Commission on Environment and Development (WCED) chaired by Gro Harlem Brundtland. In this report, sustainable development was defined as a development that meets the needs of the present without jeopardising the ability of future generations to meet their own needs (Basiago, 1999; Redcliff, 2005 as cited in Gedik, 2020). The Venice Charter, adapted and published by ICOMOS in 1965, emphasises that the protection of cultural heritage sites is a responsibility towards future generations (ICOMOS, 2023).In the early 1960s, the interaction between sustainability and conservation was emphasised by conservation experts and this relationship has been widely covered in the international conservation literature over time.In the following years, the Paris Declaration published by ICOMOS in 2011 stated that development-oriented investments and practices can lead to negative consequences that threaten heritage sites and their values. Therefore, it was stated that heritage sites, as fragile and non-renewable resources, should be protected for the benefit of future generations (ICOMOS, 2011). In this context, the expressions ‘future generations’ and ‘non-renewable resource’ clearly reveal the strong relationship of cultural heritage with the concept of sustainability.

With the development of conservation theory and sustainable development studies over time, the importance given to sustainability in heritage conservation policies has gradually increased. Following the 2030 Agenda adopted by the United Nations in 2015, the International Council on Monuments and Sites (ICOMOS) established the Sustainable Development Goals Working Group (SDGWG) to develop strategies related to sustainable development goals (ICOMOS, 2016). In the report published by this group, the role of tangible and intangible, natural and cultural heritage elements in achieving the Sustainable Development Goals is clearly emphasised. According to the report, integrating cultural heritage into various dimensions of sustainable development offers multifaceted contributions such as increasing social resilience, strengthening a sense of identity and belonging, and supporting environmental sensitivity (ICOMOS SDGWG, 2021).

This study aims to evaluate the process of integration of historical railway stations with high speed train systems from the perspective of the 17 Sustainable Development Goals (SDGs) announced by the United Nations in 2015. The SDGs that directly overlap with the scope of the study and the relationships established with them are explained below:

3.3.1. SDG 9 - Industry, innovation and infrastructure

This goal aims to develop sustainable infrastructure systems, promote inclusive and sustainable industrialisation and disseminate innovative practices. Within the scope of the study, the process of integrating historical stations into the existing railway infrastructure, transforming these structures in accordance with technological requirements and integrating them into high-speed train systems overlaps with the principles of ‘resilient infrastructure’ and ‘innovation-based transformation’ of the target. In this way, while cultural continuity is ensured by integrating historical buildings into modern transport networks without demolishing them, the functional efficiency of infrastructures is increased.

3.3.2. SDG 11 - Sustainable cities and communities

This goal aims to make cities inclusive, safe, resilient and sustainable. The preservation and re-functioning of historic railway stations contributes to strengthening cultural identity by ensuring the continuity of urban memory and architectural heritage. In addition, making transport systems sustainable with railway-based solutions helps to reduce urban traffic load and emission rates. Thus, both the quality of social life is improved and spatial sustainability is supported.

3.3.3. SDG 12 - Responsible production and consumption

This target envisages efficient use of natural resources, reduction of waste production and promotion of sustainable consumption and production patterns. Repurposing and adaptive reuse of existing historic stations, rather than new construction, helps to reduce the environmental burden of development. This approach not only reduces carbon emissions from construction activities but also minimises material and energy consumption.

3.3.4. SDG 13 - Climate action

This target aims to take urgent measures to combat climate change. Railway systems, especially high speed train lines, have a lower environmental impact in terms of carbon emissions compared to road and air transport. Therefore, prioritising railways in transport and integrating historical infrastructures into this system is important for reducing the carbon footprint. Moreover, such practices encouraging public transport are in line with long-term climate strategies.

3.3.5. SDG 8 - Decent work and economic growth

This goal includes elements such as increasing employment, supporting economic growth and ensuring inclusion in the labour market. The renovation of railway stations and their integration into modern transport projects creates new employment opportunities for various occupational groups in the planning, restoration, construction and operation processes. In addition, revitalised activities in these areas strengthen local economic dynamics and create new opportunities for the service sector and small businesses.

3.3.6. SDG 15 - Life on land

This goal aims to protect terrestrial ecosystems, sustain biodiversity and prevent the destruction of natural areas. The re-functioning of historic railway infrastructures means using existing areas without creating construction pressure on new areas. Indirectly, the reduced need to intervene in nature due to new development contributes to the protection of natural habitats.

3.4. Approaches to the integration and adaptive reuse of historical station buildings with high speed railway systems

This section explores how historic railway station buildings are integrated and adapted for use within high-speed railway systems. The goal is to balance heritage preservation with the demands of modern transportation. Using examples from different countries and cities, the section looks at architectural design, new uses, and planning strategies. It also assesses how these approaches support sustainable urban development, protect cultural heritage, and improve transport system integration.

3.4.1.Oslo central station & Nordic light (Norway)

Oslo Central Station, opened in 1854, originally served Norway's first railway line, the Christiania–Eidsvoll route. Over time, the station expanded and became one of the most important transportation hubs in Norway throughout the 20th century. Under the "Nordic Light" project, the station underwent a transformation that combines Scandinavian minimalism with environmental sustainability principles. The use of natural and recyclable materials such as wood, glass, and stone is notable, alongside open public spaces and interior arrangements designed to maximize natural light. Energy-efficient systems and green design strategies have endowed the station with new functionality. As a historical structure, Oslo Central Station has been reimagined with modern architecture, integrating sustainable materials, energy-saving systems, and public spaces under the Nordic Light project. Both functionality and environmental sustainability were given high priority in this redevelopment.

Fig. 1. Oslo Central Station & Nordic Light (Reiulf Ramstad Arkitekter, 2025)

3.4.2. Atocha station (Madrid, Spain)

Cultural continuity has been ensured through both the preservation of the historic terminal and the construction of a new terminal building serving high-speed rail lines. The botanical garden and interior spaces within the station reinforce the theme of sustainability. Atocha Station was built in 1851 and has since become Madrid's largest and busiest railway station. The monumental iron-and-glass entrance hall, designed in 1892 by Alberto de Palacio, is particularly notable. In 1992, with the integration of the high-speed rail system, the station was expanded, and the interior of the original building was transformed into a botanical garden. This intervention preserved the historic structure while creating a public space that enhances spatial sustainability. The new terminal building, designed by Rafael Moneo, establishes a balance between contemporary architectural lines and historical architecture.

Fig. 2. Atocha station (Freepik, 2023; The Wandering Passport, 2024)

3.4.3.Vilnius Railway Station (Lithuania,Vilnius)

Built in the late 19th century, Vilnius Station is one of the key hubs in Lithuania's railway history. Redesigned within the framework of the European Union's Green Deal principles, the station has been supported by open spaces oriented toward the city center and transportation routes prioritizing pedestrians and cyclists. The new design embraces a nature-integrated transport architecture that emphasizes green infrastructure. In this way, the station has been reimagined to establish a stronger connection with the urban fabric while also being integrated with sustainable infrastructure.

Fig. 3. Vilnius Railway Station(Godfrey, 2025)

3.4.4. California high-speed rail (USA, California)

This system, currently under construction, constitutes the first full-scale high-speed rail line in the United States. As part of the project, several historic train stations have been preserved and integrated with modern high-speed rail terminals. This approach establishes a hybrid station model that maintains local identity while addressing contemporary transportation demands.

Fig. 4. California High Speed Railway Station(The High Speed Rail Alliance, 2024)

3.4.5. Ankara railway station / Ankara high-speed railway station (Türkiye, Ankara)

Completed in 1937, Ankara Railway Station is a significant transportation structure reflecting the modernist architectural approach of its time and is considered a spatial representation of the Republican ideology. With its simple geometric masses, symmetrical layout, and monumental entrance axis—characteristic of Early Republican architecture—it has reinforced its symbolic position in the history of rail transport in Türkiye.

The Ankara High-Speed Rail (HSR) Station, which became operational in 2016, was positioned adjacent to the historic station complex to meet the increasing passenger demand and to accommodate the integration of high-speed rail lines. However, the new structure has been heavily criticized for its architectural language, façade character, and impact on the urban silhouette, particularly in terms of the relationship it establishes with the existing historical context. In line with conventional conservation principles, newly built structures in historic settings are expected to be sensitive to their surroundings, and to align in scale and materials; yet, Ankara HSR Station is argued to exhibit only limited compliance with these standards.

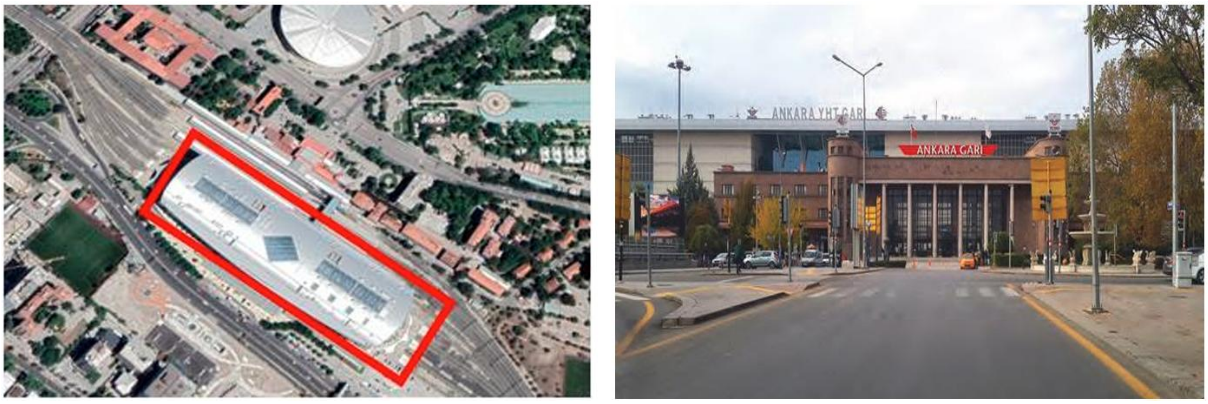

Fig. 5. Ankara high speed railway station (Altın, 2025)

3.4.6. Konya railway station / Selçuklu high-speed railway station (Türkiye,Konya)

Konya's historic railway station has served as a transportation hub since the Ottoman era. The new Seljuk High-Speed Train (HSR) Station was constructed at a separate location from the historic station. While this separation has been criticized in terms of physical and cultural continuity, it has enabled the efficient operation of high-speed rail services.

Fig. 6. Selçuk high speed railway station (Konya Büyükşehir Belediyesi, 2023)

3.4.7. Eskişehir railway station/ Eskişehir high-speed railway station project (Türkiye, Eskişehir)

Eskişehir holds a significant place in Turkey's railway history, spanning from the Ottoman Empire to the Republic. The city has made a significant contribution to the railway industry through its production and maintenance activities, a legacy that has been preserved to the present day. In accordance with this historical background, the Eskişehir High Speed Train Station (HSR) was designed by the renowned architects Orhan Uludağ and Prof. Dr. Zeynep Uludağ and completed in 2014. The newly constructed station building, which has been integrated into the city centre, aims to ensure the integrity of transport and urban structure. The edifice has garnered acclaim for its architectural conception, having been the recipient of the National Steel Structure Award in 2018 and the World Architecture Award from the World Architecture Community in 2020 (UMM, 2021). Nevertheless, concerns have been raised regarding the necessity to enhance the connection between the edifice and the historical station building, as well as the social memory of the city. This situation demonstrates that cultural heritage should be protected not only in physical but also in social aspects

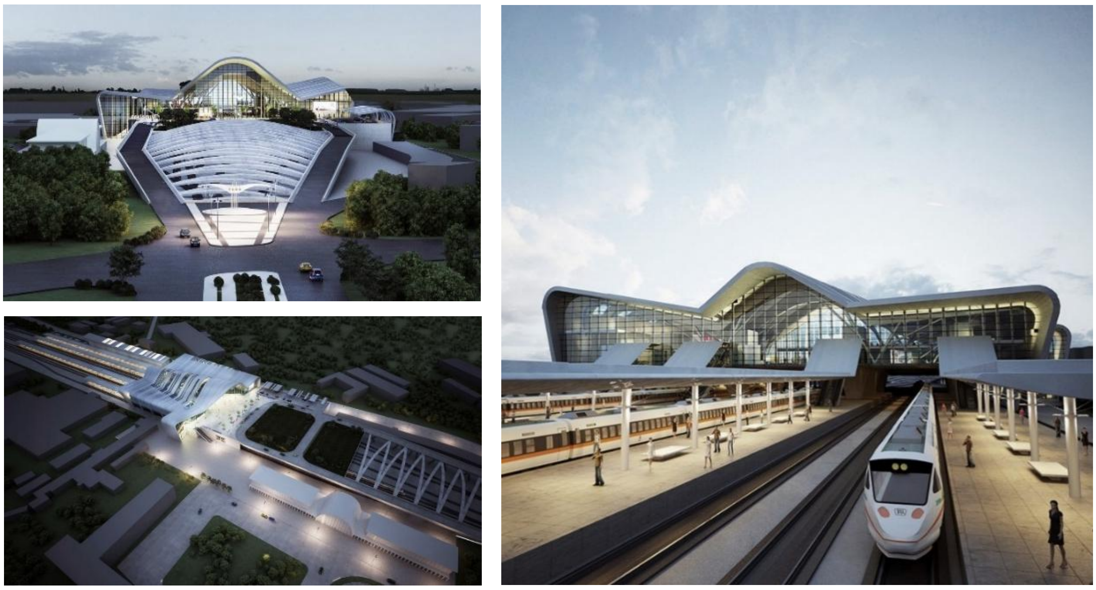

Fig. 7. Eskişehir high speed railway station (Arkitera Mimarlık Merkezi, 2025)

3.4.8. Adana railway station / Adana high-speed railway station project (Türkiye,Adana)

Opened in 1912, Adana Station has been one of the region's key transportation hubs during both the Ottoman and Republican periods. As part of the HSR project, efforts are being made to preserve the historic station and integrate it with the new infrastructure systems. Within the scope of the Adana HSR Station Project, adaptive re-use of the 1916-built historic warehouse building was proposed by the contractor. The original floor plan and façade design of the building have been preserved to ensure its integration with the new structure. The old warehouse building is intended to be refunctining as a restaurant. At the same time, the new HSR Station building has been designed with an architectural approach that respects the historical identity of Adana Station and its visibility within the city. The project's main principles include creating a balanced architectural transformation, taking into account the station's strategic location and historical significance.

Fig. 8. Adana High Speed Railway Station (Çizgi Hisar Mimarlık,2020)

4. Conclusions

This study examines the role of railway transport in the context of the Sustainable Development Goals (SDGs), with a particular focus on the integration and adaptive reuse of historic station buildings in high-speed rail systems. It highlights that historic buildings should not only be considered as aesthetic or nostalgic elements, but also as strategic assets that can contribute to sustainable urban development, environmental responsibility and economic resilience.

The SDGs approach heritage conservation not only as a matter of conservation, but also as a multidimensional development tool linked to social inclusion, economic vitality and environmental balance. In this context, the adaptive reuse of historic railway stations plays a crucial role in preserving urban identity and providing public spaces, in line with efforts to make cities more inclusive and sustainable. Furthermore, the reuse of existing structures reduces material consumption and construction waste, supporting resource efficiency and circular economy principles.

As a low-emission mode of transport, rail systems make a significant contribution to climate change objectives. By revitalising historic stations rather than demolishing and rebuilding them, the environmental impact is minimised. Integrating historic infrastructure with modern technology not only preserves architectural heritage, but also modernises transport networks in line with innovation and resilient infrastructure goals. In addition, such projects support local employment and stimulate economic activity through newly created functions and services, especially in sectors such as tourism and cultural industries.

Moreover, the reuse of existing buildings serves to reduce pressure on land development, thereby contributing to the protection of natural areas and terrestrial ecosystems. In essence, the adaptive reuse of historic station buildings signifies a comprehensive strategy that transcends mere physical transformation, embodying a holistic approach that seamlessly integrates the imperatives of cultural heritage conservation, urban sustainability, and integrated development.

By repositioning cultural heritage as both a driver and accelerator of sustainable development, the SDGs serve to dissolve the long-standing dichotomy between conservation and progress. Consequently, the integration of historic railway architecture into contemporary high-speed transport systems represents a strategic step towards the creation of more liveable cities and the safeguarding of cultural identity for future generations.

Damage observations of February 6th 2023 Earthquakes on historical buildings in Kahramanmaraş

Merve Büyükçelik*[1], Ömer Dabanlı[2]

[1] LL.M & M.Sc. Architect, İstanbul, Türkiye
[2] İstanbul Technical University, Faculty of Architecture, İstanbul, Türkiye

Abstract. The purpose of the study is presenting observations about the damages of some historical buildings because of the February 6th 2023 Earthquakes, which affected eleven cities including Kahramanmaraş. This study presents the observations about the damages of some historical buildings in Kahramanmaraş, carried out immediately after the earthquakes. In the study, the pre-earthquake conditions of damaged historical buildings were investigated and transformed into base data through literature reviews. Then, the post-earthquake conditions were determined by site observation carried out in the city. There are severely damaged cultural assets in Kahramanmaraş. The damage pattern of the monuments gives insight for the weaknesses of the structures. This study contains research, observation and preliminary results about the damages of some of the historical monuments in Kahramanmaraş after earthquakes. The documentation of many damaged historic buildings in the earthquake zone is quite crucial in respect to the evaluation of damage reasons and further repairs.

Keywords: Cultural heritage; Damage assessment; Earthquake; Historical monuments; Kahramanmaraş

1. Introduction

The February 6, 2023 earthquakes affected a huge area and caused severe damage in eleven cities. Kahramanmaraş was one of the most severely damaged cities in the region due to its epicenter. On the morning of February 6, the first earthquake in Pazarcık was followed by a second earthquake in Elbistan, further increasing the damage in the city.

Although Kahramanmaraş, which was established on a fault line in Anatolia, has experienced many earthquakes in its history, some of them caused the city to collapse completely (Gümüşalan, 2012, p.226). The earthquakes with the highest destructive power occurred in the 12th and 18th centuries and caused many casualties. In the earthquake on November 29, 1114, more than 40,000 people lost their lives, and then the cold intensified contrary to seasonal norms and the loss of life reached around 100,000 due to the effect of weather conditions when snow fell after the earthquake (Kesik, 2001, p.32). Mateos of Urfa, one of the most important historians of the period, stated that no one survived in this earthquake (Andreasyan, 1987, p.255).

Sources indicate that there were other earthquakes of mild intensity in Kahramanmaras region in the same century, but another earthquake of similar intensity occurred in 1114 and another in 1115 (Gökhan, 2008, p.150). The epicenter of this earthquake was the ancient city of Misis, 27 km from Adana, and it is known that Misis and Kahramanmaras were completely destroyed, while Antakya was severely damaged (Fulcher of Chartes, 1969, p.214). Mihail the Syriac, one of the most important historians of the period, described the severity of this earthquake as blowing up the foundations of Kahramanmaras and causing pieces of the buildings to fall to the ground (Syriac, 1924, p.60-61). In addition, many historians of the period such as Ibn al-Asir, Ibn al Kalanisi, Ibn al Adim, Simbat, Aynî recorded the 1115 earthquake and stated that the epicenter was in Syria, although they did not directly state that the earthquake was in Misis (Gökhan, 2008, p.150). Considering the locations of the historians during this earthquake, the size of the earthquake zone can be estimated.

In Kahramanmaraş and its surroundings, where many communities had settled, such as the Hittite Empire was established in the same lands (Gümüşalan, 2012, p.4). During the Assyrian period, Kahramanmaraş became an important trade route through which caravan routes crossed Mesopotamia, Northern Syria and Central Anatolia, thus making the region strategically important (Gümüşalan, 2012, p.6). This city, which was wanted to be included within its borders by many communities, was under the sovereignty of the Hittites, Assyrians, Medes, Persians, Macedonians and the Great Roman Empire respectively (Gökhan, 2008, p.21). Kahramanmaraş is known as

* Corresponding author, E-mail: mervebykclk@gmail.com

https://doi.org/10.31462/icearc2025_a_car_347

"Maraj" or 'Markasi' in Hittite sources and "Germenika" in Roman sources (Gümüşalan, 2012, p.4). After the conquest of muslims, the city kept its importance during Seljuks, Ottomans as well as until today.

2. Methodology

This study focuses on monumental cultural heritage structures classified within the first-degree protection category. Alongside on-site assessments, qualitative and quantitative data were gathered from a wide range of sources, including testimonies and reports from central and local authorities, public officials, institutions, media outlets (both national and local), and non-governmental organizations. To efficiently organize and interpret the information collected from multiple channels, a comprehensive database was developed.

Orthophotos obtained from the HGM Atlas—an application developed by the General Directorate of Mapping—were utilized during the evaluation process to determine the locations and conditions of damaged structures. All collected data were integrated into a cloud-compatible web-based Geographic Information System (GIS) platform, where they were visualized on a digital map. Upon completion of the data input phase, several distinct data sets were generated as output. Although the study area covers all 11 districts of Kahramanmaraş, this study focused on the Dulkadiroglu region, which is the center of the city, as it is more accessible than the other districts and has many buildings with damage. Observational damage assessments were made for the buildings in this district, which houses most of the cultural assets in the city.

Given the extensive geographic scope and the widespread distribution of cultural heritage assets across rural areas in the 11 provinces impacted by the earthquake, conducting a comprehensive damage assessment necessitates a large-scale organizational effort and a considerable investment of time. Accordingly, this study was limited to a selected sample area to enable focused and systematic analysis. Kahramanmaraş is one of the provinces that suffered heavy damage due to its epicenter. In light of the extensive scale of the disaster area and the prevailing challenges related to infrastructure and accessibility, the number of sites addressed in this study already represents a substantial fieldwork effort. Consequently, the scope was narrowed to focus specifically on principal cultural heritage structures within Kahramanmaraş. Nonetheless, due to access limitations, it was not possible to reach all targeted buildings; therefore, the findings presented should be regarded as partial and subject to the constraints of the available data (Dabanli et al., 2023).

3. Findings

3.1. Foundational cultural assets in Kahramanmaraş and damages

Dating back four thousand years, Kahramanmaraş and its surroundings are one of the oldest settlements in the Mesopotamia region and are known to have hosted many civilizations. The layers identified as a result of archaeological studies in this region date from the Ottoman Period to the Neolithic Age (Gökhan, 2008, p.42). As a remarkable case, it was determined that the region was an important settlement during the Persian, Hellenistic Roman and Byzantine periods according to the findings obtained from the studies carried out in Pazarcık in 1958 and 1969 (Kılıç, 1961, p.40).

There are 45 foundation works in Kahramanmaraş, including 27 mosques, 1 mosque-madrasa, 1 mosque-tomb, 1 inn, 1 caravanserai, 1 masjid, 9 minarets, 1 ribat, 2 tombs and 1 cemetery (Foundations Journal, 2023, p.22). While the majority of these works belong to the Dulkadir Principality period and preserved their authenticity for many years, disasters such as earthquakes and fires in the 19th century and the chaotic environment of the First World War caused many buildings to be damaged (Gümüşalan, 2012, p.281).

Dulkadiroğulları developed a unique architectural style by synthesizing the stonework of Aleppo and Damascus with Mamluk influence. Within the scope of this study, it was determined that 44 of these foundation buildings were severely damaged in the February 6 earthquakes. These damaged buildings are located 17 in Dulkadiroğlu, 7 in Onikişubat, 7 in Afşin, 7 in Elbistan, 2 in center, 2 in Pazarcık, 2 in Çağlayancerit. Although Kahramanmaraş consists of 11 districts, the damaged buildings that are old monuments are located in 7 districts.

3.1.1. Grand Mosque of Kahramanmaraş

Kahramanmaraş Grand Mosque was built between 1442-1454 during the Dulkadiroğlu Principality period and became the center of the city during the Dulkadiroğlu period with the construction around it and maintained its importance during the Ottoman period (Çetin, 2018, p.17). The mosque, as the largest mosque of the city in the 16th century (Gökhan, 2019, p.394), is also known as Cami-i Kebir, Cami-i Âtik, Alâuddevle Bey Mosque and Süleyman Bey Mosque (Çobanoğlu, 2012, p.111). This building, where many declarations were announced to the public during the National Struggle Period, has a special importance in terms of the history of the city as it is the place where sermons were given for the liberation struggle during Friday prayers (Çetin, 2018, p.13).

It is learned from the inscription on the main gate of the mosque that it was repaired in 1501-1502, 1780, 1853-1854, 1897 and 1945, and it is known that the repair in 1780 was due to fire (Çobanoğlu, 2012, p.111). In 1848, the minaret of the mosque was built by Hacı Halil Bey from the Zülkadir family, one of the elite families of Maraş, and the minbar of the mosque was built by Mehmet Esad Bey from the same family in 1899-1900, but these repair activities are not included in the inscription of the building (Gökhan, 2019, p.409; Alpaslan et al., 2008, p.55). In addition to the building in question, various demolitions were also realized. An example of this situation is the demolition of the muvakkithane, which was built as a period addition in 1945 (Çobanoğlu, 2012, p.111).

In 1960, the Italian city planner Puccinati was commissioned to draw up a new zoning plan for Maraş, which included the restoration of the Grand Mosque, Isa Divanlı Mosque and Elbistan Grand Mosque (Gökhan, 2019, p.796). Although the Grand Mosque was restored in 1945, the decision to restore the building again in 1960 is a separate issue that needs to be studied. Located in the Dulkadiroğlu region of Maraş, the mosque was damaged in the February 6 earthquakes. Some parts of the stones near the keystones of the arches inside the mosque fell on the floor of the building and the minaret of the mosque collapsed, while the minaret stones fell on the portico and caused damage to the roof of the building in various dimensions (Fig. 1.). Luckily the minaret did not collapse totally, remaining approximately half of it in its original state. But according to the recent information, the remaining part of the minaret was demolished and there is no trace of the minaret today.

Fig. 1. Grand Mosque, before (M.Cambaz) and after (F.Al) earthquake

3.1.2. Çukuroba Mosque

Çukuroba Mosque, also known as Hacı Hüseyin Efendi Mosque, located in the city center, was built in 1640. During the War of Independence, it was heavily damaged as a result of being bombed by Armenians and only its minaret survived (Başkan, 2006, p.90; Özkarcı, 2007, p.11; Çetin, 2018, p.15). In the same period, almost half of Maraş burned down as a result of a large fire that spread rapidly in the city, and while some neighborhoods were completely destroyed, a few neighborhoods such as Çukuroba were heavily damaged (Çetin, 2018, p.18). In the first half of the 20th century, Çukuroba Mosque, which was heavily damaged twice, was reconstructed in 1940 (Özkarcı, 2007, p.11).

Built in the 17th century, the inscription of the Çukuroba Mosque states that its minaret was built in 1720. In addition, there is a two-storey dergah (sufi lodge) building in the courtyard of the mosque, and it is learned from the inscription that it was built in 1897 as an annex. During the February 6 earthquakes, the minaret of the mosque was destroyed up to its pedestal, while the minaret stones fell on the courtyard walls, causing part of the wall to collapse (Fig. 2).

Fig. 2. Damage to the minaret of Çukuroba Mosque, before (Z.Aytemiz) and after (F.Al) earthquake

3.1.3. Sheikh Mosque

The construction date of the mosque, also popularly known as Şıh Mosque, Şeyh Müslim, Şeyh Hüseyin or Şeyh Turan Mosque, is not known for certain since its foundation and inscription have not survived to the present day, but architectural influences of the 16th century are observed in accordance with the general Dulkadiroğlu region (Özkan et al., 2024, p.79). The Sheikh Mosque (Başkan, 2006, p.86), which is estimated to have suffered a fire in the 1930s, was built on the same level as the original harim level, and it is estimated that the door and arch details belong to the original structure (Özkan et al., 2024, p.88). The dome of the building was brick, the body walls were stone masonry, and the roof of the portico, which originally had wooden beams, was covered with concrete in a repair work (Özkarcı, 2012, p.110).

One of the buildings in Kahramanmaraş that was completely destroyed in the February 6 earthquake is the Sheikh Mosque. Since the roofing system, body walls and minaret of the mosque were completely destroyed, the boundaries of the Sheikh Mosque were determined from the lead dome coverings and the realm. Interestingly, no vertical structural elements were found standing in the ruins of the mosque (Fig. 3).

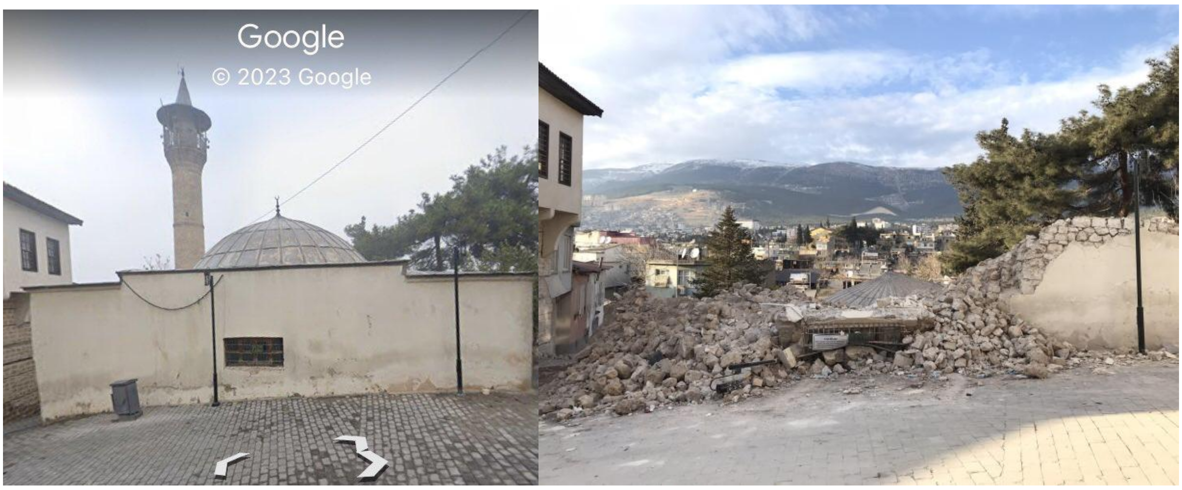

Fig. 3. Damage of the Sheikh Mosque, before (Google) and after (F.Al) earthquake

3.1.4. Şekerli Mosque

Şekerli Mosque, one of the original examples of local architecture, was built between 1695-1696. In this building, also known as Yukarı Oba Mosque or Ahmet Paşa Mosque, stone masonry was preferred for the body walls in accordance with the structural material preference of the region, while brick was used in the roofing system (Özkarcı, 2012, p.117). Settled on sloping terrain, the portico and the minaret, half of which is flat and half twisted, are the unique elements that distinguish the Şekerli Mosque from other works. Repaired in 1856, the mosque was rebuilt in 1888 and repaired again in 1937 (Özbey, 2020, p.214). The mosque also had a madrasah that has not survived (Özkarcı, 2012, p.117). On February 6, Şekerli Mosque was severely destroyed, and only the wall with the main gate and the portico survived, but the arches of the portico were heavily damaged (Fig. 4.).

Fig. 4. Şekerli Mosque, before (Google) and after (F.Al) earthquake

4. Conclusion

Throughout history, wars, epidemics and disasters have been the main cause of mass casualties. Since the 12th century, Kahramanmaraş has been a region where disasters and wars have been experienced many times, sometimes the city was completely destroyed by earthquakes, while others were deliberately destroyed in wars. Cultural heritage plays a key role in the continuity of urban memory, even after multiple destructions.

Although Kahramanmaraş, which has been shaped around the Grand Mosque and its surroundings since the Dulkadiroğlu period, has destroyed many times, the city center has not changed. This situation, which shows the impact of cultural assets on urban memory, is an important reference point for restoration and conservation works.

In the February 6 earthquakes, some of the historical buildings in Maraş were destroyed. While some of the hundreds of years old buildings were severely damaged, others were completely destroyed. Preserving the original characteristics of the cultural heritage, which is one of the main principles of restoration, is an issue that needs to be studied for buildings in the earthquake zone and restoration and reconstruction works should be designed by considering the weak points of the original structural system. The destruction of almost all historical buildings in the February 6 earthquakes highlights the vulnerability of cultural assets in the region.

[2] Gazi University, Department of Architecture, 06570 Ankara, Türkiye

Abstract. Turkey is a geography distinguished by its rich cultural heritage and mixed heritage sites that encompass overlapping designations such as historical-archaeological, urban-natural, and urban-archaeological-natural. While legislation and principles for the protection of heritage sites have been developed, the challenges arising in areas where multiple site statuses intersect remain inadequately addressed within national regulations. These challenges often involve ambiguities in authority-responsibility allocation, conservation, and usage conditions, as well as prioritization dilemmas regarding which value should be emphasized in interventions.
This study examines the current issues related to the protection of mixed heritage sites, focusing on the examples of Akdamar Island and Church (archaeological and natural values) in Van and Side Ancient City (urban and archaeological values). Through literature review and field studies, the conservation problems experienced in these areas are analyzed.

The findings underscore the importance of accurately defining and classifying mixed heritage sites. Such an approach can clarify authority-responsibility sharing and foster the development of integrated strategies for protection, leading to a more effective and comprehensive conservation process.

Keywords: Mixed Heritage; Cultural Heritage; Akdamar Island; Side Ancient City; Conservation Strategies

1. Introduction

The Cultural heritage sites, which carry the traces of the past into the present, are of great importance for societies to understand and preserve their historical and cultural identities. Among these areas, conservation sites (sit areas) stand out as regions that require special protection due to their unique values and holistic structures. The preservation of conservation sites requires an understanding that encompasses not only individual structures but also the natural, historical, and urban environment in which these structures are located.

Internationally, the first regulations for the protection of heritage sites began with the Athens Charter in 1931, followed by a more comprehensive approach to the concept of conservation introduced by the Venice Charter published in 1964 (Ahunbay, 2017, pp. 8-20). Especially the Venice Charter, by adopting a conservation approach ranging from the scale of individual buildings to the scale of the environment, formed the basis for the national legislations of many countries. In 1975, the Amsterdam Declaration introduced the concept of "integrated conservation" and emphasized the sustainability of historical and cultural values. The necessity of protecting not only urban areas but also rural areas was addressed (Jokilehto, 1999), (Perrault , 1993) ,(Viollet-le-Duc, 1990).

In Turkey, the official conservation process began with the *Âsâr-ı Atîka Regulation* of 1869, and modern conservation approaches were adopted with the Antiquities Law enacted in 1973. This law enabled the definition of concepts such as "historical site," "archaeological site," and "natural site," and with the enactment of Law No. 2863 on the Conservation of Cultural and Natural Properties in 1983, a more comprehensive understanding of conservation was developed. However, these legal regulations remain inadequate in providing clear definitions and strategies for mixed site areas where different types of sites converge (KTVKK, 1983), Âsâr-ı Atîka Nizâmnâmeleri (1869, 1874, 1884, 1906).

Mixed site areas, especially in regions where natural, archaeological, historical, and urban values geographically overlap, bring about numerous issues such as the sharing of authority and responsibility, conservation priorities, and conditions of use. In Turkey, the transfer of authority over natural site areas from the Ministry of Culture and Tourism to the Ministry of Environment and Urbanization has further complicated the management of mixed site areas. The ambiguities in defining overlapping areas make it difficult to adopt a holistic approach in conservation practices.

https://doi.org/10.31462/icearc2025_a_car_409

In this study, the current issues related to the conservation of mixed site areas are addressed, and the conservation problems encountered in these areas are examined through the examples of Akdamar Island and Church in Van and the Ancient City of Side. Based on data obtained through literature review and field studies, the necessity of accurately defining and classifying mixed site areas for a more qualified conservation process is emphasized.

2. Site Statuses And Conservation Approaches In Turkey

In the processes of protecting cultural and natural assets, two different concepts emerge: conservation at the individual scale and conservation of values that form a whole and create a texture at the area scale. Concepts related to area-scale conservation include various types of conservation sites and archaeological sites. In the Convention Concerning the Protection of the World Cultural and Natural Heritage, the protection of cultural and natural assets is addressed under three main headings: individual scale, group protection of structures, and area-scale conservation.

In Turkey, the individual-scale conservation approach is implemented through the registration of cultural and natural assets and the independent protection of the registered assets. In area-scale conservation approaches, it is aimed to protect immovable cultural and natural assets within a designated area as a whole (Çolak N. İ., 2015, p. 164). For regions where area-scale conservation is decided, the site is declared as a conservation area, resulting in a legal status change for the area to be protected. Before the declaration of the site, the assets and qualities within the area that are deemed worthy of protection are identified, and the conservation boundaries of the area are determined. Based on the evaluations, an appropriate type of conservation site is designated for the area, depending on the nature of the values present. The types and numbers of conservation sites in Turkey are summarized in the table.

Table 1. Types of Conservation Sites and Their Numbers in Türkiye, (Republic of Turkey Ministry of Culture and Tourism (T.C. Kültür ve Turizm Bakanlığı))

Conservation Sites Across Türkiye	
Type of Sıte	Number
Archaeological Site	25.353
Urban Conservation Site	365
Historical Site	242
Urban Archaeological Site	36
Mixed Site	132
Natural Site	2.572
Total	**28.700**

Depending on the values and priorities that conservation sites carry within themselves, different site statuses are defined as archaeological, urban, historical, urban archaeological, and natural conservation sites (Table 1). The definitions of these conservation sites, along with their conditions of conservation and use, are determined in laws, regulations, and principle decisions. However, although 132 conservation sites were designated as Mixed Conservation Sites by the Ministry of Culture and Tourism as of the end of 2023, there is no definition regarding mixed conservation sites in the current legislation; and no section was identified in principle decisions or regulations in which the term “mixed conservation site” is explicitly mentioned.

The concept of mixed conservation sites, which is not clearly defined in the legislation, is occasionally addressed in the literature by experts in the field. For example, Ahunbay (2017) uses the term “complex site” for mixed areas and defines them as “areas with at least two conservation site characteristics” (Ahunbay, 2017, p. 27). Similarly, Madran and Özgönül (2005) define areas that contain more than one type of conservation site as complex sites, emphasizing the coexistence of natural, archaeological, and urban values in such areas in Turkey (Madran & Özgönül, 2005, p. 18). Mixed Conservation Sites have been classified and quantified by the Ministry of Culture and Tourism based on their distinctive characteristics (Table 2).

Table 2. Mixed Conservation Sites Across Türkiye **(**(Republic of Turkey Ministry of Culture and Tourism)

Mixed Conservation Sites Across Türkiye	
Type of Mixed Site	**Number**
Archaeological and Urban Conservation Site	73
Archaeological and Historical Site	18
Archaeological, Historical, and Urban Site	7
Historical and Urban Conservation Site	34
Total	**132**

As can be seen from the table, the "site areas statistics by provinces" available on the official website of the Ministry of Culture and Tourism categorize Mixed Conservation Sites under four separate categories: Archaeological and Urban Conservation Site; Archaeological and Historical Site; Archaeological, Historical, and Urban Site; and Historical and Urban Conservation Site, including only cultural aspects. The coexistence of these areas with natural conservation sites is not addressed, and such areas have not been evaluated or quantified.

In the legislation, the spatial coexistence of natural and cultural conservation sites is defined as "overlapping areas" as follows: "…Areas where natural sites and immovable natural assets coexist and overlap with cultural sites (urban, archaeological, historical, urban-archaeological) and registered immovable cultural properties…" (Protocol, 2012) [1].

Although the spatial coexistence of cultural and natural conservation sites has not yet been defined as mixed sites in Turkey, UNESCO defines the coexistence of natural and cultural values as mixed sites for areas to be included in the World Heritage List and requires the preparation of conservation and management plans accordingly. In Turkey, only two sites have succeeded in being inscribed on the UNESCO World Heritage List as mixed properties: "Göreme National Park and the Rock Sites of Cappadocia (Nevşehir) 1985" and "Hierapolis-Pamukkale (Denizli) 1988."

In Turkey, the conditions for the conservation and use of mixed conservation sites are not clearly and explicitly defined in the legislation. The lack of appropriate legal regulations leads to various issues in the conservation of mixed sites and in the processes of authority sharing, management, use, and protection within these areas. This situation results in delays in planned activities, ineffective conservation, and the deterioration of the original values of the sites(Turkish National Commission for UNESCO).

In this study, the problems experienced in mixed conservation areas are addressed through concrete examples. The Akdamar Island in Van (archaeological and natural conservation site) and the Ancient City of Side in Antalya (urban and archaeological conservation site) were examined to identify the conservation issues encountered in these areas, and solution proposals were developed.

2.1. Van Akdamar Mixed Cultural and Natural Site

2.1.1. Akdamar Island: A Brief Historical Background

Akdamar Island, situated in the middle of Lake Van, represents a multilayered cultural heritage site distinguished by its natural landscape, the Akdamar Church a monument of significant importance to Armenian culture and the surrounding archaeological assets. Owing to these unique characteristics, the island was inscribed on the UNESCO Tentative World Heritage List in 2015 under the title "Akdamar Memorial Museum (Church)." Combining multiple cultural and natural values, Akdamar Island is recognized at both national and international levels as an important mixed site that requires preservation(Fig. 1).

Fig. 1. Van Akdamar Island

The Akdamar Church (Church of the Holy Cross) is located on Akdamar Island, within the boundaries of the Gevaş District in Van Province, situated in the Eastern Anatolia Region of Turkey, on Lake Van. As the largest lake in Turkey, Lake Van plays a significant role in shaping the natural and cultural identity of the region. Akdamar Island, historically referred to as Aghtamar, Akhtamar, or Ahtamar, is the second largest of the four islands located

[1] https://teftis.ktb.gov.tr/Eklenti/507 9,en-son-protokol-metni- 2982012.doc?0

within Lake Van. The island covers an area of approximately 700,000 m² and lies about three kilometers from the mainland (Van Akdamar Church).

The church was constructed between AD 915 and 921 under the supervision of Architect Bishop Manuel, commissioned by King Gagik I Artsruni, an Armenian monarch who ruled as a vassal to the Abbasid Caliphate during the period of the Kingdom of Vaspurakan. Akdamar Church reflects the flourishing cultural and artistic achievements of the Vaspurakan Armenian Kingdom during its peak period (Öney, 1989, pp. 1–2). The church fully embodies the cultural diversity and religious interactions characteristic of the Vaspurakan Kingdom in the 10th century, particularly through the dense relief decorations that adorn its façades. The richly ornamented exterior walls, featuring depictions of significant religious symbols and numerous historical events, contribute to the building's distinctive and authentic character (Öney, 1989, p. 11), (Fig. 2).

Fig. 2. The stone reliefs located on the eastern façade of the church (Ornamentation of Van Akdamar Church)

With the end of the Kingdom of Vaspurakan in the early 11th century, its territories were ceded to the Byzantine Empire. The structures on Akdamar Island were converted into a monastery in 1113 (Bachman, 1913). By 1882, a catholicos residence, a seminary, cells, a laundry area, a kitchen, and a cistern within the courtyard were added around the church courtyard (Fig. 3).

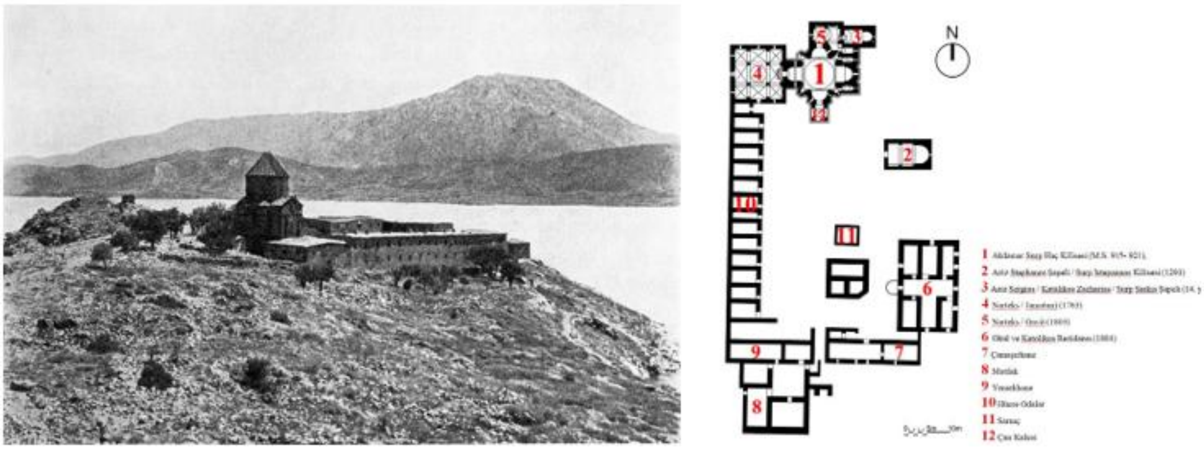

Fig. 3. According to Bachmann, the monastery plan

Until 1895, the Armenian Patriarch continued to serve alongside the structures surrounding the church. Due to political issues in the country between the 17th and 19th centuries, in 1918, the Armenian population living on the island was forced to migrate. After the island was abandoned, the site remained unused until 2005, leading to neglect and damage to the structures and their surroundings (Öztürk, 2019, p. 863). In 2003, the Ministry of Culture and Tourism initiated a restoration project to preserve the complex, with excavations starting in 2006. The site was opened to visitors as a memorial museum in 2007 (Öztürk, Biber, Çavuşoğlu, & Karaca, 2007, pp. 60, 61).
Beyond its cultural significance, Akdamar Island also holds remarkable natural value. The island is vital for species whose populations and habitats are diminishing. Its topography and vegetation provide a habitat for numerous bird species. The Akdamar Church and its surrounding natural environment form an inseparable, integrated whole.

Both natural and human-made values contribute to the island's identity and silhouette. Therefore, it is essential to approach the island as a unified site, preserving both its rich flora, fauna, and cultural heritage (Fig. 4).

Fig. 4. The Akdamar Church and Island, integrated with its nature (Akdamar church)

2.1.2. The Conservation Process of Van Akdamar Island

Akdamar Island became deserted due to the migration from the island in 1918 and remained unused for a long time. The structures, left empty for an extended period, became vulnerable to natural conditions, accelerating the deterioration process. By the 21st century, the issue of preserving the island and taking necessary steps toward it gained significant attention, and the first steps toward physically preserving the island were taken.

- In 1979, the High Council of Antiquities and Monuments declared the region an archaeological area, initiating the conservation process.
- In 1990, Akdamar Island was declared a first-degree archaeological site.
- In 2003, the Van Governorship and the Ministry of Culture and Tourism initiated survey, restitution, and restoration works to protect the cultural assets on the island (Öztürk, 2021, p. 235).
- In 2004, the projects prepared were reviewed and approved by the Diyarbakır Regional Directorate of the Protection of Cultural and Natural Heritage (Öztürk, 2019, p. 863).
- In 2005, the restoration process of the church and the chapels located on the east and northeast of the church began (Öztürk, Biber, Çavuşoğlu, & Karaca, 2007, p. 60).
- In 2006, excavation work began to uncover the complementary parts of the main structures located to the south of the church.
- The opening of Akdamar Church took place on July 31, 2006. In 2007, it began to accept visitors as a memorial museum. A religious service is held once a year at the church.
- In 2007, the Environmental Design Project was initiated to ensure access to the island, open the church for visitation, allow exploration of the building sections, and facilitate the connection with recreational areas (Öztürk, 2019, p. 871).
- The project includes ticket booths, pedestrian pathways, security rooms, indoor and outdoor seating areas, a cafeteria, souvenir shops, piers, observation terraces, disabled access, and beach arrangements (changing-dressing rooms).
- In 2010, the Eastern Anatolia Development Agency placed solar panels on the southwest of the island to meet the electricity needs of the structures on Akdamar Island (Öztürk, 2019, p. 871).
- A Landscape Design Project, covering Akdamar Island and all the structures on it, was prepared by the Ministry of Culture and Tourism. The project was reviewed and approved by the Van Regional Board for the Protection of Cultural Heritage with Decision No. 661 on July 15, 2010 (Van Regional Council for the Conservation of Cultural Heritage).
- In 2015, considering its values, Akdamar Church was included in the UNESCO Tentative World Heritage List.
- Considering the natural values of Akdamar Island, a large portion of the island was registered as a "Natural Site - Qualified Natural Conservation Area" with Decision No. 112213 on May 3, 2019 (Akdamar Island Natural Site Registration Announcement.).
- To ensure more sensitive protection of the natural values on the island, areas outside the previously designated qualified natural conservation areas were declared as "Strictly Protected Sensitive Area" in the Official Gazette No. 30822, published on July 4, 2019 (Fig. 5).

Fig. 5. Qualified Natural Conservation Area (left), Boundaries of the Natural and Archaeological Site (right), (Akdamar Island Natural Site Registration Announcement)

2.1.3. Problems Related to Preservation on the Island

Until 2011, the Ministry of Culture and Tourism was responsible for all site areas; however, following a regulation in the same year, authority and responsibility for natural site areas were transferred to the Ministry of Environment and Urban Planning. After this transfer, the publication of the "Regulation on the Procedures and Principles for the Determination, Registration, and Approval of Protected Areas" in 2012 led to significant changes in the classification of natural site areas. Areas previously classified as first, second, and third-degree natural sites were reclassified into three categories: Strictly Protected Sensitive Areas, Qualified Natural Conservation Areas, and Sustainable Protection and Controlled Use Areas.

- After the transfer of authority in 2011, coordination issues and power-sharing deficiencies became apparent in mixed site areas. Since Akdamar Island holds both natural and cultural values, these issues have been more pronounced. Inconsistent decisions due to overlapping authority hinder the protection and management processes.
- The island, which was previously registered as a first-degree natural and archaeological site, was re-evaluated in accordance with the regulation published in 2012 and registered as a Qualified Natural Conservation Area on May 3, 2019. The decision of January 5, 2017 (Decision No. 99) regarding Natural Site Protection and Use Conditions, which allowed the construction of bungalows and campsites in Qualified Natural Conservation Areas, was welcomed by the tourism sector. However, it raised concerns about the preservation of Akdamar Island's cultural and natural values. As a result, the regulation was amended on October 16, 2019, in the Official Gazette (Decision No. 30971), prohibiting the construction of bungalows in Qualified Natural Conservation Areas.
- The opening of Akdamar Island to visitors and the intensification of tourist activities have put significant pressure on the island's natural and cultural resources. Issues such as increased physical wear, environmental pollution, and degradation of the natural landscape make long-term preservation more difficult.
- Akdamar Island, with its natural and cultural heritage, is an important site. However, the insufficient steps taken for its preservation, along with the lack of regulations on the protection of mixed site areas in the legislation, result in the natural and cultural elements being evaluated separately, ignoring their interrelationship. This lack of a holistic approach to the protection of mixed sites has led to challenges in balancing the preservation of the island's natural and cultural elements.
- Akdamar Island faces significant challenges in the UNESCO nomination process. The inclusion of Akdamar Monument Museum (Church) in the UNESCO Tentative World Heritage List in 2015 is a crucial step, but it may lead to a perception that the island's natural values are less important than its cultural heritage. If the natural values are not adequately integrated with the cultural heritage, it could result in insufficient protection of the island's ecosystem and natural beauty. A focus on cultural heritage over natural values could undermine the development of sustainable protection strategies, emphasizing the need for a holistic approach to preserving Akdamar Island's diverse values.

2.2. Side Mixed Site Area

Located in the Manavgat district of Antalya, one of the important cities on Turkey's Mediterranean coast (80 meters to the east), Side is situated on a peninsula that is 400 meters wide. Due to its geography, location, climate, and fertile lands, it has attracted interest and been conquered by many civilizations. With its multi-layered historical texture, it is an important archaeological resource. In addition to its archaeological values, Side is one of the significant settlements that deserves preservation, as it combines both archaeological and urban values along with the unique cultural values of the Selimiye settlement. The Antalya Culture and Natural Heritage Conservation Board has designated this area as both an Urban and Archaeological Site.

Fig. 6. The ancient city of Side and the Selimiye settlement (Büyüksural, Karamağaralı, & Sağıroğlu Demirci, 2022)

2.2.1. An Outline of Side’s Historical Background

Side is one of the prominent coastal cities of ancient Pamphylia, a region located between Cilicia, Lycia, and Pisidia along the Mediterranean coast. Geographically, Pamphylia corresponds to the area between the Mediterranean Gulf and the Taurus Mountains in modern-day Antalya (Strabo, 2000, p. 249). The remains of columns, stones, and structures in Side indicate it was once a densely populated and prosperous city, largely due to its significant port and thriving trade network. The well-preserved ancient theater of Side, one of the finest examples surviving today, further reflects the city's importance (Corancez, 1816, pp. 375–378).

Side became a settlement in the 7th century BCE, came under Lydian rule in the 6th century BCE, and later passed to the Persians after Lydia’s fall. In 334 BCE, it opened its gates to Alexander the Great, becoming a center for coin minting during the Hellenistic period. After several shifts in power, Side was incorporated into the Pergamon Kingdom and later annexed by Rome following attacks by pirates in 78 BCE (Side Ancient City).

In the 20th century, Cretan immigrants founded the Selimiye settlement on the peninsula, merging with the ancient city. Today, Side preserves this integrated cultural landscape. The city features key elements typical of Pamphylian urbanism, including a monumental gate, colonnaded street, ancient theater, and harbor (Fig. 7, Side Ancient City)

Fig. 7. Side Ancient City

2.2.2. Conservation Process of the Ancient City of Side

Throughout its history, Side lost its significance as a major port city due to wars and external factors, leading to a long period of abandonment. During the reign of Sultan Abdulhamid II, Cretan immigrants were resettled in the area, establishing the Selimiye village between the ancient theater and the coast, which initiated the site's reoccupation (Soykal Alanyalı, 2016, p. 18). This multi-layered settlement, containing Hellenistic, Roman, Byzantine, and Ottoman cultural layers, introduced new challenges in terms of heritage conservation.

- Until the 1960s, no comprehensive conservation measures were implemented. The first planned efforts began in 1969 when the Ministry of Tourism initiated the "Side and Environs Tourism Planning International Competition," aiming to protect the archaeological remains while promoting tourism development (Çubuk, Güner & Gürsel, 1971, p. 30). The competition emphasized the conservation of major features such as the theater, harbor, and colonnaded street, while proposing controlled integration of new structures into the historic fabric.
- Following the competition, the 1/5000 scale Master Plan for Side and its surroundings was approved in 1971. Subsequently, in 1975, the Higher Council for Immovable Antiquities designated 98 civil architectural structures for protection, launching formal listing and planning processes (Boyacıoğlu, 2011, p. 8).
- From the 1970s to the 1990s, a series of plans and revisions were made to balance conservation with increasing pressures from tourism and local development. These included the designation of archaeological zones, restrictions on construction within the necropolis, and updates to conservation master plans, although implementation often faced resistance from local inhabitants and municipal authorities.
- Despite regulatory frameworks, unauthorized construction within the old village persisted. In 2012, in an attempt to better manage the area, part of the Köyiçi district was reclassified as an Urban and Third Degree Archaeological Site (Official Gazette, 2012). In 2019, after new evaluations, revisions were made to the boundaries of the protected zones, with some areas downgraded from First to Third Degree Archaeological Site status due to extensive modern development(Fig. 8).
- Today, Side remains a unique cultural landscape where ancient ruins and a living settlement coexist, requiring ongoing and adaptive conservation strategies.

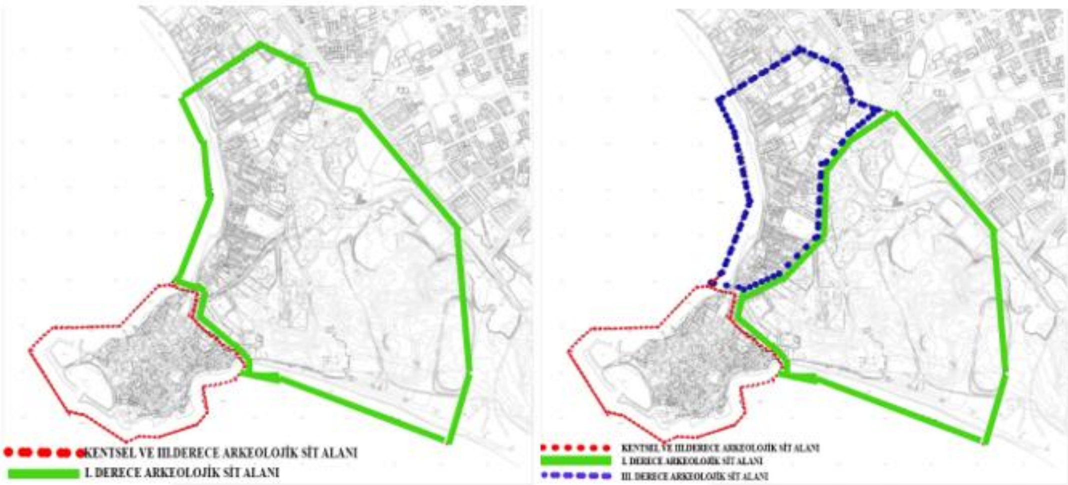

Fig. 8. 2012 Boundaries of the Ancient City of Side Archaeological Site (Left), Current Site Boundaries (Right)

2.2.3. Conservation Problems Experienced in the Mixed-Use Site Area of Side

In the 1960s, efforts were initiated to promote tourism along Turkey's Mediterranean coast, and governmental ministries developed policies to attract foreign tourists. In 1969, an international competition was organized for the planning of Side and its surroundings. As a result, Side became a major attraction, particularly during the 1980s. Rapid urban development driven by tourism, however, led to unplanned impacts on cultural heritage. The economic benefits of tourism began to outweigh the preservation of cultural values, resulting in uncontrolled construction.

- One major issue was the lack of timely intervention to protect cultural assets and the failure to implement conservation plans. This was largely due to the lack of institutional cooperation and each authority attempting to implement its own plans. For instance, in 1993, the conservation work proposed by the Side Municipality was rejected by the Antalya Conservation Board, and in 1995, the Side Municipality rejected the Antalya Board's revision of the Conservation Master Plan. Consequently, interventions to protect the ancient city were delayed, and the rate of damage increased.
- The conservation studies failed to address the needs and challenges of contemporary life, reducing their effectiveness. Uncontrolled tourism growth, combined with inadequate planning, significantly harmed natural and cultural assets (Sağıroğlu, 2016, pp. 555–560). Tourism development efforts (1969) began earlier and received more attention than conservation initiatives (1982), leaving the ancient city vulnerable. Tourism projects attracted investors, leading to the purchase of properties from local residents (Yıldırım, 2013, p. 158).
- In 1976, the Real Estate Antiquities and Monuments Board created conservation zones for Side. In 1982, the area was divided into the village center and the necropolis zone, allowing for new constructions compatible

with the traditional texture in the village center. However, this permission led to increased construction within the ancient city, conflicting with conservation principles (Büyüksural & Sağıoğlu Demirci, 2023).

- Although later conservation master plans initiated legal actions against unauthorized structures, inconsistent decisions weakened enforcement. For example, within a single parcel, construction was permitted on one part but prohibited on another, leading to court cases and further legal uncertainty (Boyacıoğlu, 2011).
- The 1998 Side Conservation Master Plan Revision allowed construction close to and even above archaeological remains (Fig. 9).

Fig. 9. New structures built within the archaeological site

- In 1999, the Antalya High Conservation Council prohibited interventions in first-degree archaeological sites, except for scientific research, but earlier construction permissions created conflicts.
- Traditional Side houses, typically one or two stories high, were affected by 1999 planning changes that increased the building height from 6.5 meters to 9.5 meters, promoting the transformation of residential areas into tourism facilities (Alparslan & Ortaçeşme, 2009, p. 170). As a result, taller structures emerged, disrupting the traditional silhouette.
- Economic shifts led locals, traditionally engaged in agriculture, livestock, fishing, and olive cultivation, to adapt their buildings for tourism, causing the loss of architectural authenticity. Adaptive reuse efforts often neglected the original character of structures, impeding cultural sustainability. Additionally, high-volume events held near ancient temples ignored potential structural impacts.
- Due to urbanization pressures, the ancient city could not be preserved as a whole, and monumental structures became isolated (Büyüksural, Karamağaralı, & Sağıoğlu Demirci, 2022).

Although the 2014 Conservation Master Plan marked significant steps toward preservation, it struggled to address how to balance the protection of archaeological values with ongoing contemporary life. In multi-layered urban fabrics like Side, prioritizing certain values over others has weakened the overall integrity. Side embodies both the traditional settlement developed by Cretan immigrants in the 20th century and Roman urban planning, requiring a holistic conservation approach that considers all layers and values. Conservation strategies must be comprehensive and carefully analyze the impacts of tourism.

3. Evaluation and Conclusion

Table 3. Problem Definition and Evaluation

Problem Identification	Evaluation
Akdamar Mixed Site Area	
The island, registered as a 1st-degree natural and archaeological site, was re-evaluated under the regulation published in 2012 and reclassified as a Qualified Natural Conservation Area on May 3, 2019. Although the island retained its characteristics, its classification was downgraded from 1st degree to 2nd degree under the new law.	In cases where site areas of different statuses overlap, all natural, historical, archaeological, and urban values of the area must be thoroughly examined, and a holistic approach must be adopted to ensure the protection of each value.

Table 3.continued

Problem Identification	Evaluation
After the authority and responsibility for natural site areas were transferred to the Ministry of Environment and Urbanization in 2011, deficiencies in authority sharing and coordination in mixed site areas became evident. As Akdamar Island contains both natural and cultural values, these deficiencies have been more strongly felt in the area. Due to overlapping jurisdictions, inconsistencies in decision-making have disrupted conservation and management processes.	In cases where different protection areas overlap, protocols should be prepared to ensure inter-institutional cooperation and to reduce management and authority-related issues between institutions.
The opening of Akdamar Island to visitors and the intensification of tourism activities have placed significant pressure on the natural and cultural resources of the area. Issues such as increased physical wear, environmental pollution, and the deterioration of the natural landscape caused by high visitor density make long-term conservation of the site more difficult.	A comprehensive planning and visitor management strategy must be developed to regulate tourism use.
The absence of a regulation in the current legislation for the protection of mixed site areas leads to the separate evaluation of site types. This situation results in the lack of a holistic approach in the conservation of mixed site areas. When personal opinions take precedence and this is combined with a lack of interdisciplinary cooperation in developing conservation strategies, a balance between the natural and cultural elements of Akdamar Island cannot be achieved.	In order to effectively protect the natural and cultural values of Akdamar Island, the current legislation must be reviewed, and mixed site areas must be evaluated through a holistic approach. In this context, an interdisciplinary conservation strategy must be adopted.
As part of Akdamar Island's UNESCO nomination process, the island was included in the UNESCO Tentative World Heritage List in 2015 following a submission that highlighted only its cultural heritage features under the title "Akdamar Memorial Museum (Church)."	This imbalance experienced during Akdamar Island's UNESCO process necessitates the development of integrated strategies that ensure equal protection of both natural and cultural values. In this context, submitting the site as a mixed property would provide a more comprehensive framework for conservation.
Side Mixed Site Area	
The failure to protect the cultural values of the rapidly developing city due to the lack of timely intervention and the inability to implement the prepared conservation plans. The reason for the failure to implement these plans is the lack of inter-institutional cooperation and the desire of each institution to implement its own plan.	In mixed site areas, practices should be developed to ensure inter-institutional cooperation and enable institutions to produce plans on a common ground.
Due to the mismanagement of uncontrolled tourism-driven development, areas without conservation plans have been significantly affected, leading to damage to natural and cultural values before they could be protected.	To protect, manage, and ensure planned development in regions with high tourism potential, site-specific policies should be developed.
In 1982, Side was evaluated in two zones: the village center and the necropolis area. In this study, permission was granted for new constructions in the village center that were compatible with the historical fabric. However, inadequately prepared conservation efforts led to irreversible impacts.	Conservation efforts must be prepared with sensitivity to site-specific conditions, ensuring that they do not allow practices that could pose problems within the regulatory framework.

Table 3.continued

The local population, whose livelihood depended on agriculture, livestock, fishing, olive cultivation, etc., began to alter their traditional buildings to benefit from tourism potential, leading to the loss of architectural and structural authenticity.	Approaches appropriate to the site's potential should be adopted, and planning should include considerations that do not overlook social life.
As buildings began to transform with tourism, their original conditions were disregarded during adaptive reuse, hindering the cultural sustainability of the structures.	When restoring buildings, the new functions assigned should be original or closely related to the original. Functions that would significantly alter the building's layout or façade should not be permitted.

Mixed heritage sites, which encompass multiple types of heritage simultaneously, require that conservation efforts address all values in a holistic manner rather than focusing on individual heritage types. However, it has been observed that this holistic conservation approach is not fully achieved in the current practices in Turkey. For example, in the Side Ancient Settlement, archaeological values are overlooked in areas designated as urban heritage sites, while in Van Akdamar Island, natural values are inadequately protected during the prioritization of cultural values. This situation reveals that a balance between the values that constitute the different layers of the site has not been established, and therefore, holistic conservation has not been effectively implemented.

In Turkey, the overlap of heritage sites with different qualities is quite common. However, there is a lack of a clear definition of mixed heritage sites in the legislation, and the protection and usage conditions for these sites are not well defined. This deficiency makes it difficult to establish protection policies in cases where heritage sites of different types overlap. In mixed heritage sites, the values associated with each heritage type should be addressed separately, and a protection strategy should be developed that covers all layers and characteristics of the site. This approach will ensure the protection of archaeological, cultural, natural, and urban values while also facilitating the harmonious transmission of these values together.

The legislation should be revised to explicitly and clearly express protection approaches for mixed heritage sites. Additionally, detailed regulations should be developed to prevent uncertainties during the implementation processes, and these regulations must be strictly enforced to prevent irreversible damage. Otherwise, serious consequences may arise, such as the destruction or complete loss of one heritage site while protecting another. In order to ensure the sustainable protection of mixed heritage sites, planning should be conducted using a holistic approach, which is critical for transmitting the site's multifaceted values to future generations.

Abstract. Climate change has begun to show its effects in various fields both globally and in our country in recent years. The impacts of climate change pose serious threats to our cultural heritage, especially in buildings constructed with stone materials. Environmental factors such as temperature fluctuations, freeze-thaw cycles, and increased humidity directly affect the physical and chemical structure of stone materials, leading to various forms of deterioration in these buildings. Deterioration, such as cracking, surface wear, color changes, and general structural weakening, not only threatens the aesthetic value of these buildings but also weakens their structural stability. If necessary precautions are not taken, this can result in irreversible damage. In this context, Erzurum, known for its harsh and cold climate, creates significant effects on historical structures, especially when combined with the region's continental conditions. A striking example of this is the Yakutiye Medrese, which is constantly exposed to these challenging climatic conditions. In light of scientific studies and analyses conducted on the city's climate and climatic variables, the aim of this study is to assess the effects of environmental threats arising from climate change on historical buildings, with a particular focus on the Yakutiye Medrese in Erzurum. The archival research to be carried out in this context is expected to play a critical role in tracking cultural continuity and in developing preventive measures and conservation strategies to mitigate the effects of climate change. These efforts are of vital importance in ensuring the long-term preservation of cultural heritage.

Keywords: Climate change; Stone structures; Erzurum; Yakutiye Medrese; Conservation strategies

1. Introduction

Changes occurring in nature have influenced societies for centuries. The historical processes, economies, population statuses, and migration movements of cities have been shaped as a reflection of what nature provides us. At the forefront of these factors is 'climate' (Gürsul & Yeler, 2022). Climate is the most fundamental factor determining the living spaces and characteristics of living beings and is a source that meets all of humanity's needs. Climate change emerges as a global issue that could lead to serious environmental and socio-economic consequences. Considering Turkey's geographical location, it is evident that our country is among the regions at risk for the potential impacts of climate change (Davarcıoğlu & Lelik, 2018).

The impact of climate on urban memory and morphology has become more pronounced since the 20th century. In addition to natural factors, human activities and industrialization, which increased with the Industrial Revolution, led to a rise in carbon emissions and the amount of greenhouse gases released into the atmosphere. This has brought the concept of 'climate change' to the forefront of global issues that require urgent solutions (Gürsul & Yeler, 2022). The Intergovernmental Panel on Climate Change (IPCC), established in 1988 (URL-1, 2025), emphasizes in its 2022 report "Climate Change: Impacts, Adaptation, and Vulnerability" (Türkeş, 2022) that without necessary measures, the impacts of climate change could result in irreversible consequences (URL-2).

The threat of climate change, which manifests in social, economic, and ecological fields, also has a profound impact on historical structures and their surroundings, which play an important role in preserving cultural continuity. Many international conservation organizations, such as the International Council on Monuments and Sites (ICOMOS) and the UNESCO World Heritage Centre (WHC), are examining the effects of climate change on cultural heritage and working on measures to mitigate these impacts. However, the threat that climate change poses to cultural heritage was acknowledged at the 29th General Assembly of WHC held in 2005 (Colette, 2007; Gürsul & Yeler, 2022).

https://doi.org/10.31462/icearc2025_a_car_449

The increasingly evident threat of climate change on our cultural heritage requires us to reshape our approaches in conservation and develop solution-oriented strategies. This study examines the effects of climate change in the Erzurum province and its surroundings on the Yakutiye Medrese, and proposes various measures to mitigate these impacts, along with solutions for the preservation of the historical structure.

2. Materials and Methods

2.1. Materials

The research area of this study, which aims to examine more thoroughly the effects of climate change on stone structures, consists of the province of Erzurum and the historical Yakutiye Medrese located within its boundaries. As research materials, the study will utilize climatic data specific to Erzurum, meteorological reports, scientific studies on long-term climate change, archival documents obtained from the Erzurum Regional Board for the Conservation of Cultural Heritage (EKVKBKM) regarding the Yakutiye Madrasa, and other scholarly research conducted on the structure.

2.1.1. Location and History of Erzurum and the Medrese

Erzurum is located in the northeastern part of the Eastern Anatolia Region, in the Erzurum-Kars section. The province is bordered by Kars and Ağrı to the east, Rize and Artvin to the north, Gümüşhane and Erzincan to the west, and Bingöl and Muş to the south. In terms of topography, the land is mainly covered with mountains, plateaus, and plains (URL-3, 2025). With its favorable natural conditions and geographic location (URL-4, 2025), Erzurum has been home to various civilizations throughout history (Demlikoğlu, 2013), and is one of the most rooted cities in Anatolia due to its strategic and cultural significance (Kutlu, 2016; Demlikoğlu, 2018) (Fig.1.).

This city, notable for the advantages of its location and the valuable heritage brought by the civilizations it hosted, has become an important stop for tourism. The cultural heritage that reflects the history of the city continuously enhances its significance in the field of cultural tourism. One of these heritage sites is the historical 'Yakutiye Medrese,' located in the city center and currently used as a museum (Temur & Açıcı, 2022).

The Yakutiye Medrese was built during the reign of the Ilkhanid ruler Olcaytu Hüdabende in the 14th century (1310-1311) by Emir Cemaleddin Yakut, on behalf of Gazan Khan and Bolugan Hatun. It is located in the city center of Erzurum, on Cumhuriyet Avenue, to the west of Lala Paşa Mosque (Fig.1.). The inscription on the main gate of the medrese contains information about the construction date and those who ordered the building. According to the Arabic inscription's translation, it says: "This medrese was built in the year 716 H. (1316 M.), during the reign of Ulcayto Sultan, 'May Allah make His kingdom eternal,' according to the noble and beautiful beliefs of Sultan Gazan and Bolugan Hatun, 'May Allah illuminate their proofs.' It was built with the income (money) by Cemaleddin Hoca Yakut-i Gâzâni." The Yakutiye Medrese, one of the largest closed-courtyard madrasas in Anatolia, is one of Erzurum's most impressive buildings with its architectural plan, balanced structure, and large decorative motifs. It is currently used as the Turkish-Islamic Art and Ethnography Museum (Erzurum Provincial Socio-Economic Profile, 2018; Temur & Açıcı, 2022).

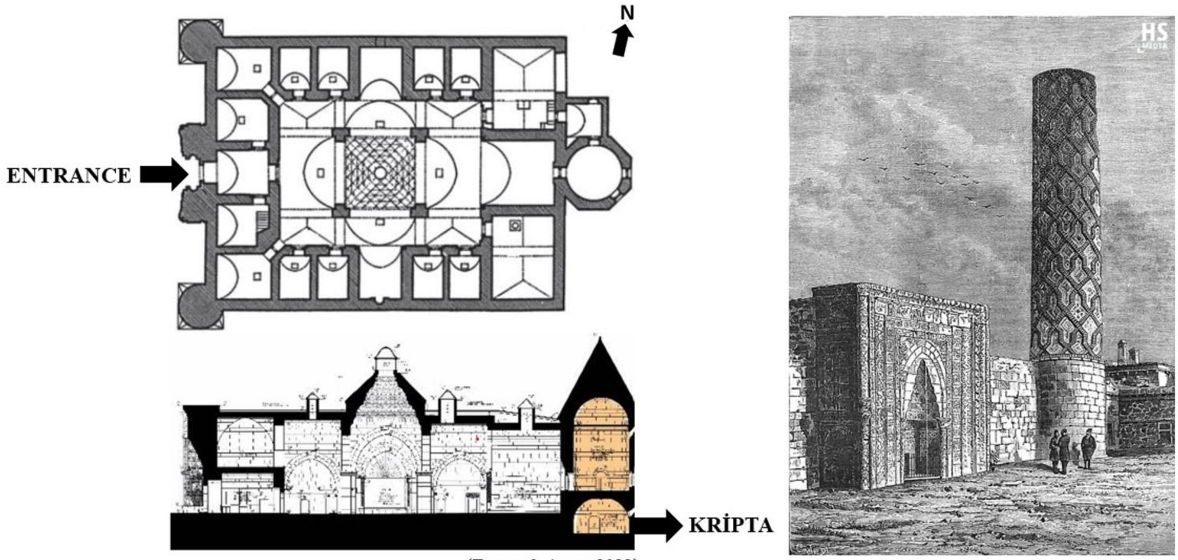
Fig. 1. The Location of the Study Area on the Map of Turkey

2.1.2. Architectural and Material Features of Yakutiye Medrese

The Yakutiye Medrese is rectangular in shape, measuring 33.4 m x 24.4 m, with a large courtyard in the center. The medrese, which has a closed courtyard, is a one-story building with three iwans, arcades, and a large structure. However, a second floor is present only in the entrance iwan (Fig.2.). The main entrance of the building is on the western façade. From the entrance gate of the medrese, a vaulted corridor leads to an inner area, which is higher and connects with another vaulted area. There are columns in the corners of the structure. The building is constructed with a central dome resting on four columns, surrounded by half domes and large arched roofs in the east-west direction. The main dome is built on a square area measuring 7.75 m, with a height of 12.9 m. There are two minarets at the northwest and southwest corners of the medrese, standing at heights of 21.2 m and 8.25 m, respectively. In the iwan on the eastern façade of the medrese, a tomb stands on a square pedestal, topped with a twelve-sided conical dome. Stairs in this area lead to the crypt (cenazelik) below (Fig.2.) (Kocaman et al., 2018; Temur & Açıcı, 2022).

The thickness of the main walls of the medrese is approximately 130 cm, and the walls rise to 7.6 m on all sides. The walls, which bear the weight of the domes, were built using a filler wall system, called "three-leafed," with bonding materials between cut stones (Kocaman et al., 2018; Temur & Açıcı, 2022). Except for the minaret's body, stone materials were used throughout the structure. The exterior of the building, including the supporting and roofing elements (arcade columns and arches, iwan walls and vaults, domes, door arches, and frames of the rooms), is covered with neatly cut stones. The interior walls and vaults of the rooms are made of rubble stone, which has been plastered later. The conical dome of the tomb is covered with red volcanic stone (andesite), locally known as "Kamber stone," which is a regional material seen in other tomb structures in Erzurum (Eskici et al., 2006) (Fig.2.).

This structure, which was used as a foundry during the Ottoman period, is known to have been used as a military depot from the late 19th century to the early years of the Republic. The building has been restored three times by the Directorate General of Foundations (1964-1973) and the Ministry of Culture (1991) during the Republic period (Kocaman et al., 2018; Temur & Açıcı, 2022).



(Temur & Açıcı, 2022) (URL-5, 2025)

Fig. 2. Yakutiye Medresesi (Temur & Açıcı, 2022; URL-5, 2025)

2.1.3. Climate Change in Erzurum

Global warming leads to temperature increases worldwide, causing climate change. Climate change is generally defined as long-term and gradually evolving changes that create large-scale and locally significant impacts on weather conditions. One of the most noticeable effects of these changes is the irregularity in precipitation patterns; the rise in temperatures increases evaporation, promoting droughts and irregular rainfall. Rising temperatures also reduce snowfall. The decrease or complete disappearance of snowfall will have significant consequences for hydrological cycles (Karaman & Gökalp, 2010). It is, of course, impossible to limit the effects of climate change to just primary parameters such as temperature and precipitation. As global temperatures rise, this directly affects wind systems as well. Particularly with the warming of oceans and land surfaces, temperature differences in the atmosphere change, which can affect the intensity, direction, and speed of winds. These changes can lead to significant shifts in local and global climate models (Gürsul & Yeler, 2022).

Erzurum, located in the northeast of the Eastern Anatolia Region, has a unique and characteristic climate due to its morphological features and geographical location. With very cold and snowy winters, and hot and dry summers, Erzurum has a continental climate (Erzurum Province 2023 Environmental Status Report, 2024), and climate deviations have occurred over time. According to Meteoblue data, a noticeable increase in air temperatures has been observed in Erzurum between 1980 and 2024. The average temperature in 1980 was 5.9°C, while it reached 7.7°C in 2024 (Fig.3.). Additionally, the annual precipitation amount has decreased from 629.6 mm in 1980 to 608.3 mm in 2024, clearly indicating that rainfall has decreased and become more irregular (Fig.4.). Erzurum's climate is not immune to global climate change, and like many regions around the world, it is facing fluctuations and reductions in rainfall (URL-6, 2025). These changes leave deep and lasting marks on Erzurum's ecosystem, negatively affecting snow quality and the duration of snow cover on the ground. On average, the ground in Erzurum is covered with snow for 107 days, but between 1931 and 2018, this period decreased by 21 days (Fig.5.). During this time, the snow height also decreased by 17% (Fig.6.). These dramatic changes significantly affect the region's climate balance and natural life, leading to a transformation in Erzurum's ecological structure.

Limiting the effects of climate change to basic parameters such as temperature and precipitation is insufficient to fully comprehend the depth of this global phenomenon. In regions like Erzurum, the increase in high temperatures has visibly raised evaporation rates, leading to serious disruptions in the moisture balance. As a result of these changes, there have been noticeable shifts in wind patterns and intensity, with atmospheric movements taking a different direction. Erzurum's 88 years of climate data reveal a significant increase in annual average wind speed. The data show a 6.7% upward trend in the long term, with the annual average wind speed rising from 8.8 km/h (Fig.7.). This is a clear indication that wind movements, as well as temperature and precipitation, are evolving as a reflection of climate change (Toy & Türkeş, 2022).

Moreover, the effects of air pollution form another significant aspect of this process. Over time, polluted air causes severe deterioration and permanent stains on building facades, accelerating the corrosion process of construction materials. Pollutants such as sulfur dioxide (SO_2) increase the concentration of acidic compounds in the atmosphere, posing a serious threat to the durability of structures. The effect of these pollutants accelerates the corrosion of materials like metal and stone, shortening the lifespan of buildings. On the other hand, the decrease in rainfall, which functions as a natural air pollution cleanser, exacerbates the situation. While rainfall helps to reduce harmful components in the air by bringing pollutants to the ground, the weakening of this natural cleaning process leads to further deterioration of air quality and an increase in the negative environmental impacts (Karaca et al., 2013).

2.2. Methods

This study, aimed at examining the effects of climate change on Yakutiye Medrese, consists of three different stages:

- Archive Research and Visual-Structural Examination: In the first stage, a comprehensive archive research was conducted on the medrese, followed by a visual and structural examination of the building.
- Analysis of Climate Data: To better understand the impact of climate change on stone structures in Erzurum, long-term climate data (temperature, humidity, precipitation, and freeze-thaw cycles) for Erzurum province were analyzed. Special focus was given to the climate changes over the last 30 years.
- Evaluation of the Relationship Between Climate and Deterioration Processes: In the final stage, the relationship between climate data and the deterioration processes of stone structures was examined in detail, highlighting the connection between these two factors.

3. Findings and Discussion

Climate change, particularly in the form of drought, has a profound impact on climatic variables, leading to significant negative effects. These impacts manifest both directly and indirectly, making the problems caused by climate change more complex. On an international level, the risks associated with climate change are generally assessed from environmental, societal, biophysical, and economic perspectives. However, historical structures and their surroundings, which play a crucial role in preserving cultural heritage, should not be excluded from this scope. This is because the effects of climate change can indirectly impact these elements, which are vital for ensuring cultural continuity (Gürsul & Yeler, 2022). In this context, international efforts in the field of conservation are based on the 2004 International Scientific Committee meeting organized by the International Council on Monuments and Sites (ICOMOS), followed by the 29th General Assembly of the UNESCO World Heritage Centre (DMM) in 2005. Since then, international organizations in this field have created various working groups to understand the threats of climate change to cultural heritage and develop solutions. Through the reports they published, they have tried to raise public awareness about the preservation of cultural heritage. Changes in temperature, rainfall, atmospheric humidity, wind intensity, as well as the interaction between sea level rise (SLR), desertification, climate change, and air pollution have been defined by the United Nations Educational, Scientific and Cultural Organization (UNESCO) as threats to cultural heritage (Sesana et al., 2021). In 2019, the ICOMOS Climate Action Working Group published an important report titled "The Future of Our Past: The Role of Cultural Heritage in Climate Action." This report deeply explored the impacts of climate change on archaeological sites, collections, historical buildings, cultural landscapes, traditional communities, and intangible cultural heritage, aiming to evaluate the vulnerability of heritage in the face of these impacts and to develop new methods and tools for its preservation. Additionally, the report argued for the establishment of a stronger connection between climate change and the preservation of cultural heritage, asserting that a bridge should be built between these two areas (Gençer, 2022).

Considering that these two areas complement and influence each other, the challenges faced by historic stone structures due to climate change pose serious threats not only to their structural integrity but also to their aesthetic values. Due to the effects of climatic changes, the material components, external surfaces, and overall durability of historical stone buildings may weaken over time, leading to greater damage. The city of Gubbio in Italy, built on a hill, has historically experienced the effects of more frequent and intense rainfall on its stone walls. The city's walls have been damaged by landslides, and the erosion of the mortar between the stones has led to the stones falling off. Gubbio is also famous for its Palazzo dei Consoli, built in the 14th century, which is the city's most iconic building and hosts art and archaeological exhibitions. However, more frequent and intense rainfall has caused cracks in the stone walls of the building, raising concerns. Similarly, the walls of Koules Castle, located in Crete and built by the Genoese in the 16th century on the seafront, are constantly eroding due to the waves that hit them (URL-7, 2025). This clearly illustrates the negative impact of climate change on stone structures, affecting wind direction and wave intensity. In this context, to deeply understand the negative effects of climate change on cultural heritage, it is crucial to be informed about the damaging factors in the literature and the consequences of these damages. The table presented below will further clarify which factors contribute to these negative effects and how they threaten our cultural heritage (Table 1.).

The examined scientific studies reveal that the primary effect of climate change observed in the Erzurum province is the rise in temperature, which has led to significant deterioration, particularly on stone structures. One of the most affected buildings is the Yakutiye Medrese, which is among the important historical structures of Erzurum. The stone materials used in the medrese have been subjected to thermal stress due to the increasing temperatures. As a result, pressure stresses have occurred on the stone surfaces of the medrese during extreme heat, while tensile stresses have emerged during cold weather. The constantly changing temperature fluctuations have weakened the integrity of the stones, leading to deep cracks, fracures, and even loss of pieces on the surface (Fig. 9-10).

Another impact of climate change is the fluctuations in precipitation. These fluctuations in both rainfall and temperature have negatively affected the quality and duration of snow cover in Erzurum. The snow melts earlier than expected, and the insufficient drainage system in the area causes more water to penetrate and accumulate in the stone material. Specifically, water accumulation within the internal structure of the stone material has led to wear, and the movement of water within the stone material has caused salt deposits to form on the surface. Additionally, with the rapid melting of snow, vegetation has started to grow on the stones (Fig. 11).

In addition, with the landscaping adjustments made in 2008, the large trees in front of the Yakutiye Medrese were removed (Fig. 12-13). The absence of the trees has increased the effect of stronger winds, which have intensified due to climate change, impacting the Yakutiye Medrese. This has caused the joints between the stone materials of the medrese to erode, leading to gaps over time. Furthermore, due to decreasing rainfall and increasing drought in recent years, dust and dirt carried by the wind have settled on the stone surfaces of the building. These dust particles have left traces on the texture of the stones, leading to their gradual deterioration (Fig. 14).

As a result of the impacts of climate change, the deteriorations observed in the stone materials of the Yakutiye Madrasa have been examined in detail. The specific parts of the structure where these deteriorations have occurred were systematically classified and numbered on technical drawings. Each type of deterioration was documented based on on-site observations and presented with supporting visual materials (Fig. 8).

Table 1. Causes and Results of Damage Caused by Climate Change

Cause of Damage	Result of Damage
Sudden fluctuations in temperature and humidity	Expansion and contraction in building materials; cracks, breakages, and loss of pieces on surfaces.
Drought	Landslides and settlement in the foundation soil; damage to building materials due to disrupted moisture balance.
Excessive rainfall and flooding	Flooding of buildings; mold and mildew formation on walls and facades due to increased moisture.
Storms and hurricanes	Damage to structural elements of buildings; collapse or detachment of roofs and facades.
Sea level rise	Submersion of historical buildings on the coast; damage to building materials from salty water.
Air pollution	Pollution on the stone surfaces of historical buildings and deterioration of materials over time due to corrosive (wearing) effects, color change (Sesana et al., 2021).

4. Conclusions and Recommendations

Climate change, which has had profound effects on the geographies and societies around the world for centuries, has gained increasing global importance, particularly since the 20th century. With the unconscious increase in human activities, this impact has also begun to strongly manifest itself in our country. In light of scientific research conducted in the Erzurum province, the traces and effects of climate change in this region are clearly observable. Studies and analyses on urban climate and climatic variables highlight rising temperatures, irregular rainfall, changes in wind speed, a decrease in snow cover duration, drought, and air pollution in the city. These effects of climate change are also negatively impacting Erzurum's historical texture. The Yakutiye Medrese in Erzurum serves as an example of this adverse impact. One of the most important historical structures in Erzurum, this medrese has been exposed to both human-induced destruction and changing natural conditions. Cracks, breakages, splits, piece losses, and joint gaps observed in the building and its façades are significant risks that threaten the structural integrity of the building. Furthermore, deterioration such as salting, vegetation growth, and surface wear is gradually causing damage to the physical structure of the medrese. Frescoes, decorations, and inscribed stones in both the interior and exterior have experienced damage, including pollution, flaking, and detachment. A comprehensive and scientific approach is required for the preservation of the Yakutiye Medrese and to prevent these damages. The first steps in this process should include identifying the risks within the building, evaluating their impacts, and determining effective conservation methods. The damages observed in the medrese, such as cracks, material and surface losses, and joint gaps, indicate that conservation efforts should be prioritized to prevent the loss of this important cultural heritage. To protect the building, the material structure and chemical properties of the stone should be thoroughly examined. Specifically, the darkening observed on the stone material requires sensitive intervention. In this regard, modern and careful techniques such as laser cleaning could be applied. Additionally, for vegetation growth and potential pests in the building, mechanical methods could be suggested rather than chemical interventions. Chemical substances could damage the historic materials and further jeopardize the structural integrity of the building. Arrangements around the Yakutiye Medrese are also of great importance.

Based on the old sources and documents, replanting the area surrounding the building with trees that are historically appropriate and restoring the natural vegetation will create an environment that aligns with the medrese's historical texture. After this restoration process, the effects of climate change on the building should be scientifically determined, and adaptation strategies should be developed accordingly. Periodic control and maintenance processes must be meticulously implemented. Long-term conservation efforts should not be limited to physical restoration. Additionally, adaptation strategies, shaped by scientific data, should be created to mitigate the effects of climate change in the region. The preservation of historical buildings in Erzurum is not only a local responsibility but also crucial for ensuring the continuity of global cultural heritage. National and international conservation principles will have a positive impact on transferring the preservation of such structures to future generations and ensuring that they protect this cultural heritage.

4th International Civil Engineering & Architecture Conference
17-19 May 2025, Trabzon, Türkiye

Fire risk assessment methods for historical buildings

Tayfur Emre Yavru*[1], Sibel Maçka Kalfa[1]

[1] *Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye*

Abstract. Historical buildings refer to buildings located within conservation areas designated by local and international institutions or within traditional contexts, possessing significant architectural or historical value. These buildings represent the cultural and architectural heritage of humanity and serve as key symbols shaping the identities of societies. However, these valuable assets are exposed to both natural and human-induced threats. Among these, fires stand out as one of the most devastating events capable of destroying such buildings. Fires often cause not only significant material losses but also the loss of cultural heritage.The impact of fires on historical buildings is not limited to material losses. These buildings are often living witnesses of history, art, and culture. The destruction of historical buildings in fires harms the shared heritage of societies and humanity. Analyzing past fire incidents involving historical buildings reveals that these buildings, due to the lack of widespread fire engineering and inspection practices during their construction periods, are particularly vulnerable to fire because of their construction systems and material choices. Various Fire Risk Assessment (FRA) methods are used to evaluate the fire resistance of these buildings in their current state. However, historical buildings require a distinct assessment method due to their unique characteristics. In this context, the study analyzes existing FRA methods, discusses the factors that should be considered for risk assessment specific to historical buildings, and highlights the strengths and/or shortcomings of these methods in comparison to one another.

Keywords: Historical buildings; Fire; Risk analysis; Assessment method; Fire risk assessment.

1. Introduction

Fire can be simply defined as the rapid oxidation of a substance involving heat and light. In general, oxidation is the chemical combination of any substance with oxygen. Heat is also produced from this combination, but it is very difficult to measure because it is so small. Fire can usually only occur when three things are present: oxygen in some form, fuel (material) that will combine with the oxygen, and sufficient heat to sustain combustion. Removing any one of these three factors will result in the extinguishing of the fire. The classic "fire triangle" is a graphical symbolization of the known elements involved in the combustion process (Fig. 1). Opening the triangle by removing one factor will extinguish a growing fire, and preventing any one factor from joining the other two will prevent the fire from starting.

Some studies in the literature show that this chemical reaction cannot consist of only these three factors. According to Haessler (1974), a fourth factor, the "reaction chain", was determined and it is stated that this factor starts from the moment the combustion starts and even accelerates during the combustion. The reaction chain is formed by the disintegration and recombination of the molecules that make up a flammable material with the oxygen of the atmosphere. The investigation of this concept has led to the discovery of many extinguishing agents that are more effective than those that managed to open the triangle. Due to this discovery, the fire triangle can be turned into a three-dimensional pyramid known as the "fire tetrahedron" (Hasofer, Beck, & Bennetts, 2006) (Fig. 1). This difference in the literature does not eliminate all the old procedures that can be used in preventing fires, but it provides additional tools with which fires can be prevented or extinguished. This difference in the literature does not eliminate all old procedures that can be used to prevent fires, but it provides additional tools to prevent or extinguish fires. When disasters that occurred in buildings throughout history are examined, fire has always been one of the greatest threats to life (Hurley, et al., 2016). In the oldest times, fires occurred in the natural environment of forests and meadows, while today the greatest fire risk in the historical fabric is fires that occur on flammable materials in the built environment. The most important reason for this can be shown as the lack of architectural/engineering services required for fire safety of historical buildings as they are today and the lack of sufficient information about fire by users (the formation of fires and what can be done to prevent it, as explained above).

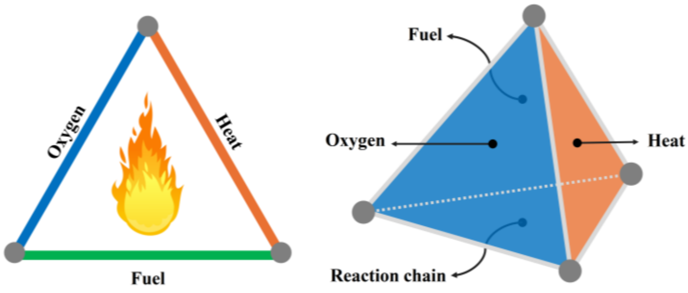

Fig. 1. Fire triangle and fire tetrahedron (Adapted from Hasofer et al. (2006))

In the first settlements built throughout history, buildings were generally small and single-story. This provided the residents with the opportunity to escape to a safe place. Since they were simple structures, lost property could be replaced relatively quickly. As civilizations became more organized and complex, settlements became larger. Buildings began to have upper floors, fires broke out, especially from the appliances used in kitchens and living rooms, and candles and gas lamps used for lighting purposes added to the fire risks, increasing the overall fire risk of the building. Throughout history, disasters such as the Great Fire of London in 1666 have caused great loss of property and life in such communities (Kıdd, 1995).

The best response to such disasters has been to learn from them. Some of the lessons learned over time include; development of building codes, consideration of compartment size (in terms of volume) in terms of fire resistance, awareness of the need for a consistent fire precaution package, importance of occupant response to fire and human behavior in a fire, etc. However, increased fire precautions in buildings have not ensured safety and fire disasters continue to occur even in seemingly safe buildings. Therefore, the way to deal with the stochastic (or random) nature of fire is probabilistic fire risk assessment (Ramachandran & Charters, 2011).

Historical buildings are vulnerable to fire due to the limited architectural/engineering services they receive and the inadequacy of the materials used in terms of fire resistance when the year of construction and the conditions of that year are taken into account. In this sense, conducting fire risk assessment on historical buildings is very important in transferring these buildings, which have symbolic value for society and are an important element of cultural sustainability, to future generations. The study focused on Fire Risk Assessment (FRA) methods accepted in the literature due to the sensitivity of historical buildings to fire.

1.1. Methodology

Within the scope of the study, the general classifications of FRA methods in the literature, the reasons for the emergence of these classifications and FRA methods specific to historical structures were investigated. As a result of these studies, the selected FRA methods were analyzed over the determined analysis headings. As a result of these analyses, evaluations and some inferences were made specifically for historical structures (Fig. 2).

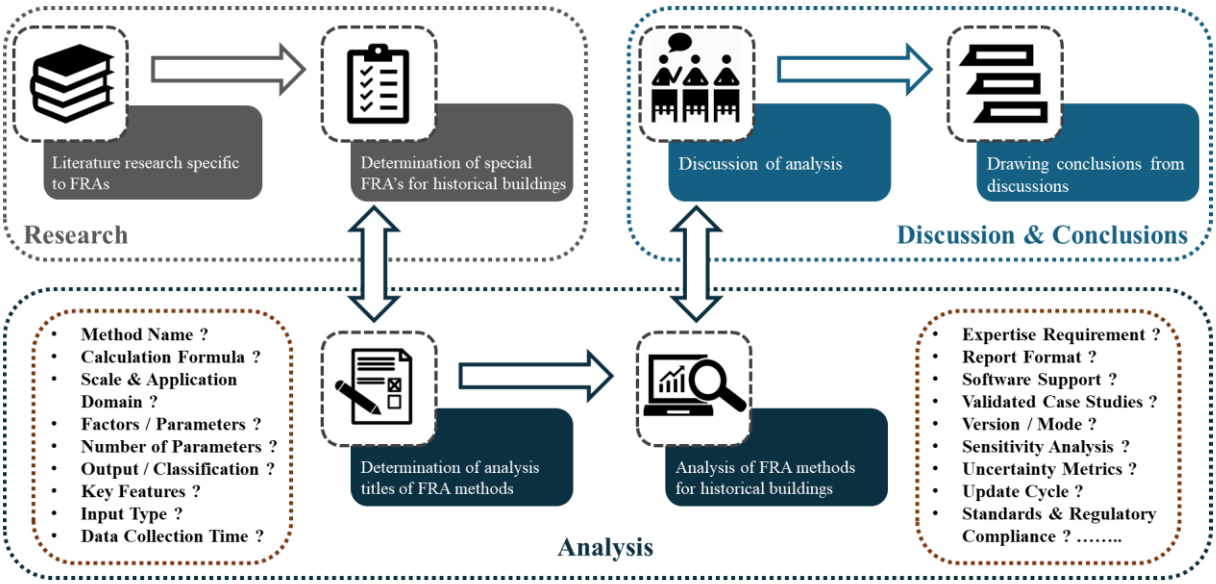

Fig. 2. Schematic description of the methodology of the study

2. Fire Risk Assessment (FRA) methods

Fire Risk Assessment (FRA) methods are a preventive tool for architects and engineers to evaluate fire risk, its possible consequences and the necessary safety measures. Risk prevention methods are the most practical tools in minimizing the consequences of fire, as they include some unpredictable factors such as human behavior and the response time of rescue services. Guerrazzi (2023)'s SFPE Fire Risk Assessment Guide defines Risk Assessment as "the process of generating information about acceptable risk levels and/or risk levels for an individual, group, society or the environment." As can be understood from their definitions, FRAs have a complex structure due to the fact that different factors serve a common purpose together. For this reason, there are many different classifications in the literature. These classifications are summarized below.

2.1. Classification of FRA methods

According to different sources, FRA methods can be classified in more than one way depending on the criteria chosen (Fig. 3). These classifications are not mutually exclusive, but they form a complex network where the same method can belong to several categories according to the criteria chosen (Iglesias, 2018). Not all methods can be classified into one of the above categories, and all categories are interrelated. In addition, sometimes the name of the category is a method itself (as in the case of checklists or indexing methods).

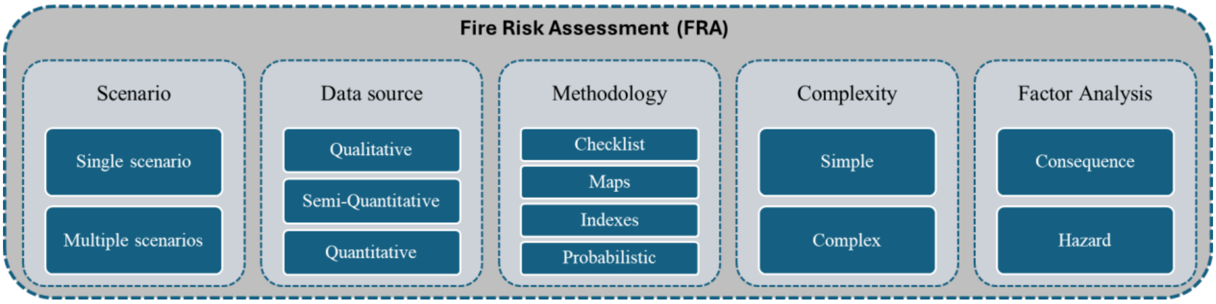

Fig. 3. Different types of classification of fire risk assessment methods (Adapted from Iglesias (2018)).

Among all the methods mentioned above, the most preferred classification is the one made through “Data source”. Within this classification, there are various different methods under the headings “Qualitative, Semi-Quantitative and Quantitative” (Fig. 4).

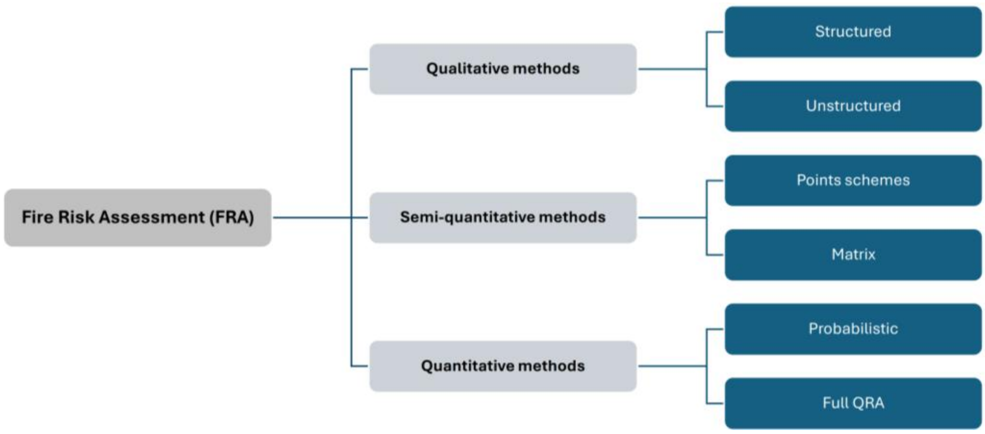

Fig. 4. Widely preferred classification of FRA methods (Adapted from Ramachandran & Charters (2011)).

Qualitative fire risk assessment is based on a subjective judgment not only of the probability of a fire hazard or fire scenario occurring, but also of the outcome of such a fire hazard or fire scenario. Qualitative fire risk assessment is often used to obtain a rapid assessment of potential fire risks in a building and to consider various fire protection measures to minimise these risks (Yung, 2008). Qualitative methods are based on identifying the factors that affect risk. These factors can be factors that affect the level of danger, such as the level of fire precautions aimed at reducing the hazard, such as flammable materials or fire detection. All of these factors are assessed against a set of benchmark values and a judgement is made as to whether the factor is higher, lower or about the same as the benchmark. All factors are then examined to assess how the assessed area compares to the benchmark values. Assessments under fire regulations for existing buildings usually fall into this category (Ramachandran & Charters, 2011).

Semi-Quantitative fire risk assessment methods give a numerical value to the risk level; however, this numerical value does not represent an exact risk value (Ramachandran & Charters, 2011).

The term quantitative fire risk assessment refers to an assessment that includes numerical quantities not only of the probability of a fire hazard or fire scenario occurring, but also of the consequences of that fire hazard or fire scenario. The numerical values of probability and consequence are multiplied to give each fire scenario a numerical fire risk value. By adding the risk values from all possible fire scenarios together, we can obtain an overall fire risk value. The overall fire risk value can be used to make comparisons with alternative or code-compliant fire safety designs (Yung, 2008).

3. Historical buildings and FRA

Historical buildings around the world are exempt from local and/or international building codes, relying on the experience of designated authorities to determine what is safe or what is an acceptable equivalent to a specific code requirement. In this sense, historic buildings suffer under codes that either completely ignore historical significance or impose strict safety requirements with minimal regard for culturally significant areas and materials. As a result, the historic character of a building can be damaged by the strict application of fire safety codes. At the same time, the current international perspective on fire safety objectives includes, in particular, the protection and preservation of life, property, mission, environment and cultural heritage (Watts Jr. & Kaplan, 2001).

Historic buildings present unique challenges for fire protection. Unlike most public and commercial buildings, a historic building exists as a work of architectural or historical significance or as a visual record. If the building is demolished, this function is eliminated. Creative solutions must be developed that meet fire and life safety objectives without compromising the historic building’s historical or architectural significance. However, no statistics are available to determine the fire vulnerability of historic buildings (Watts Jr., 1996).

It is not known exactly how much of the world's cultural heritage has been lost to fire. Fire loss data is collected only on factors related to the cause and origin of the fire. There is no fire loss data by historical significance or building age. The vulnerability of historic buildings to loss or damage from fire increases with each major fire that destroys a historic building and its contents. Historic buildings are not buildings that can be replaced, but rather irreplaceable artifacts whose value cannot be recovered through insurance payments (Watts Jr. & Kaplan, 2001).

The use of existing and abandoned historical buildings by changing their functions or preserving their existing functions is quite common today. In the face of this situation, some administrations have attempted to prepare regulations specific to these historical buildings. However, although some of the emerging approaches are more progressive than others, most of them contain incommensurable terms such as "minimum", "acceptable", "sufficient" and "reasonable". This uncertainty puts the designer, the property owner or user and the inspecting institution in a difficult position (Watts Jr. & Kaplan, 2001). As can be understood from all these uncertainties, it is very difficult to determine the behavior of historical buildings during fire through regulations.

Therefore, it is necessary to develop methods to assess the fire safety of built cultural heritage assets, taking into account their specific characteristics and focusing on the protection of heritage values. However, for most countries, conducting multi-hazard risk analysis for a large number of cultural heritage assets often requires unachievable efforts and budgets. Therefore, assessing risks for a large number of assets with limited resources is only possible when based on simple methodologies (Romão, Paupério, & Pereira, 2016). The development of risk assessment methods for historic buildings should also take into account the possibility of their application to a large number of historic buildings (e.g. in a region or across the country) without requiring excessive manpower and economic resources. Furthermore, given that historic buildings with different characteristics are likely to have different fire vulnerability factors, the specified methods should be able to account for these differences. Therefore, these methods need to be simple, yet reliable and versatile.

3.1. FRA methods for historical buildings

Fire assessment of historical structures can be applied at the scale of a single structure or at the scale of urban and/or rural settlements. Historical structures are generally located within old settlement areas and many old and new settlements are observed within these areas. In this sense, it is not possible to evaluate them independently from their surroundings in terms of risk assessment. In this sense, the complex structures of qualitative methods can be partly difficult to apply in large areas. Indicator-based methods (also called risk indexing methods) have been widely preferred in the literature in order to provide a simple and reliable way to determine the fire risk level of existing structures over large areas. Fire risk indexing systems are intuitive models of fire safety. They constitute the processes of analyzing and scoring hazards and other system features to produce a fast and simple estimate of relative fire risk. They are also known as rating tables, score schemes, ranking, numerical rating and scoring. Using professional judgment and past experience, fire risk indexing assigns values to selected variables representing both positive and negative fire safety features. The selected variables and assigned values are then processed through a combination of arithmetic functions to arrive at a single value, which is then compared to other similar assessments or a standard (Watts, 2016).

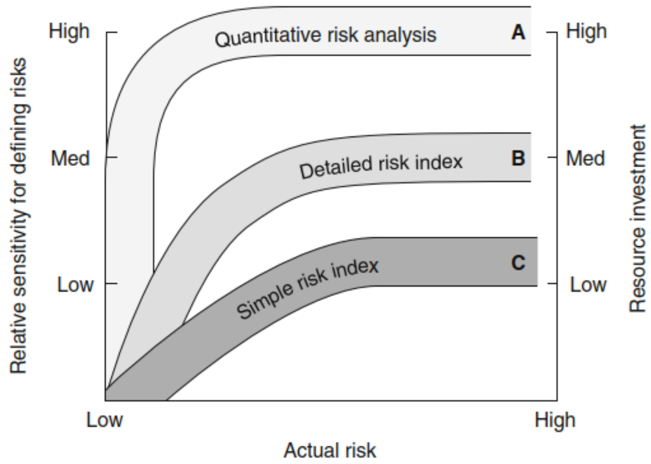

Fig. 5. Relative sensitivity for defining actual risk (Rosenblum & Lapp, 1989; Watts, 2016)).

Indexing methods are shown under the titles of "Semi-Quantitative methods" according to some sources and "Quantitative methods" according to some sources. This classification varies according to how FRAs are classified. However, the simplest explanation of this classification can be given through the graphic in Fig. 5 below. Even if the details of indexing methods are examined, they cannot provide results as sensitive as quantitative risk methods. For this reason, it is more possible to associate indexing methods with semi-quantitative methods (since they give a numerical value to the risk level, but this numerical value does not represent a definite risk value).

Within the scope of the study, the methods used in FRA research of historical structures in the literature are given below. As mentioned above, these methods are evaluated as "Semi-Quantitative" in some sources and "Quantitative" in some sources. The sources in question are presented under the titles of method name, year, place of origin, target structure (structure class) based on the study conducted by Salazar et al. (2021).

Table 1. FRA methods for historical buildings (Adapted from Salazar et al. (2021)).

Method / Year	**Origin**	**Target constructions**
GRETENER /1961-1968	Switzerland	Industrial buildings, but also used in other buildings
PURT – EURALARM /1972	Serbia	New and existing buildings
TRVB /1975-1987	Austria	New and existing buildings
ERIC /1977	France	Industrial and office buildings, dwellings
FSES /1978	USA	New and existing buildings
BOCA /1990-1996	USA	Existing buildings
ILHR/1995	USA	Historic buildings except nursing homes, hospitals and residential facilities
ARICA /1997-2000/2010	Portugal	Old urban centres
MESERI /1998	Spain	Low risk industrial buildings, but also used in other buildings
HFRI /1998-2001	UK	Historic house museums
FRIM-MAB /2000	Sweden	Multi-storey apartment buildings
SEPC /2002	Wales	Churches
FRACM /2002	Canada	Collections in museums considering the building characteristics

Table 1. continued

RAGER /2002	France	Movable objects in churches considering the building characteristics
FRAME / 2008	Belgium	New and existing buildings
MARIU /2011	Portugal	Existing buildings in old urban centres for fire risk mapping
FETAM /2013	Taiwan	Monuments and historic buildings
FRIM-HB /2014	Italy	Historic buildings
CHICHORRO /2016	Portugal	Existing buildings

When the risk definitions of the methods listed above are examined in detail, it is seen that some methods have similar formulations. This shows that the methods are developed over each other. In this sense, for example, although the FRIM-MAB and FRIM-HB methods are almost completely similar, the change in formulation is seen in the case of historical buildings. Due to such similarities, all these methods are grouped under three main headings according to Salazar et al. (2021):

a) Methods developed for ordinary structures and applied to cultural heritage assets or taking into account factors/criteria that are important for cultural heritage assets.
b) Methods developed for historical or older structures based on existing methodologies (Methods colored gray in Table 1).
c) Methods developed specifically for cultural heritage and historical structures.

The methods included in category "a" are; GRETENER, EUROALARM-PURT, TRVB, ERIC, FSES, BOCA, MESERI, FRIM-MAB and FRAME, respectively.

The methods included in category "b" are; ARICA, MARIU, CHICHORRO, ILHR and FRIM-HB, respectively. While ARICA, MARIU and CHICHORRO focus on old city centers, ILHR and FRIM-HB are created specifically for individual buildings. In addition, HFRI is partially accepted in this category because it focuses on historical museums.

The methods included in category "c" are; SEPC, FETAM, FRACM and RAGER, respectively. While SEPC and FETAM focus on historical structures, FRACM and RAGER are more focused on portable cultural assets.

4. Analysis of FRA methods for historical buildings

In light of the information provided above; the target structures for fire risk assessment in historical buildings are the "b" category, which is determined as the scope of the study. The study focused on the "b" category because the main target of the "a" category is not directly historical buildings, and the "c" category focuses on more symbolic structures and portable cultural assets compared to other historical buildings.

The methods in this category will first be analyzed based on the items specified in heading 4.1 below, and various inferences will be made from this analysis data..

4.1. Determination of analysis titles of FRA methods

When the methods in Table 1 are examined, different formulations and risk definitions are seen in each of them. This situation is due to the complexity of the general operation of the risk analysis, where different factors can coexist.

The ideal theoretical environment for conducting a risk analysis requires the probabilistic quantification of hazard, vulnerability and resilience. Both sufficient/reliable data and adequate analytical/numerical procedures are required to create probabilistic representations of these components. However, in many cases, especially in the risk analysis of cultural heritage assets, defining these components in a reliable probabilistic context becomes very complex (Romão, Paupério, & Pereira, 2016).

Probabilistic representation of risk is generally carried out on data obtained from past events. Probabilistic risk definition can be made for natural events such as earthquakes, floods, landslides or volcanic movements (Romão, Paupério, & Pereira, 2016). However, it is quite difficult and complicated to make a clear definition on fires, especially in historical buildings, due to the lack of data definition (Kincaid, 2022). When working on cultural heritage assets, the multidimensional nature of the asset's value and the complexity of its assessment are major conceptual hurdles.

To create a comprehensive risk assessment procedure and implement a framework within which the results can be regularly updated over time, the following key issues should be integrated:

a) Reliable and sufficient data for the development of appropriate hazard models.
b) Sufficient and reliable data regarding the assets at risk.

c) Appropriate procedures for modeling vulnerability.
d) Adequate models to predict the multidimensional consequences of the hazardous event.
e) Having sufficient human, time and economic resources(Romão, Paupério, & Pereira, 2016).

In the context of a risk assessment procedure for cultural heritage assets, the most difficult issue to address, regardless of the hazard in question, has been "d". Furthermore, in order to successfully address "a, b and c", issue "e" must be provided as a priority. All these fundamental issues will define the scope and comprehensiveness of the risk analysis and will be the basis for the successful regular updating and monitoring of the risk assessment results over time (Romão, Paupério, & Pereira, 2016). For this reason, it is important to have a simple methodology that can be used to determine risk reduction priorities or to identify assets that require more detailed data, especially in methods where many structures are included in the analysis and located in old settlements such as historical buildings.

In this context, the following analysis headings were determined to discuss the above outlined characteristics through the selected FRA methods (ARICA, MARIU, CHICHORRO, ILHR, HFRI and FRIM-HB):

Scale & Application Domain, Factors / Parameters, Number of Parameters, Output / Classification, Key Features, Input Type, Data Collection Time, Expertise Requirement, Report Format, Software Support, Validated Case Studies, Version / Mode, Sensitivity Analysis, Uncertainty Metrics, Update Cycle, Standards & Regulatory Compliance, Advantages and Disadvantages.

4.2. Analysis of FRA methods for historical buildings

For the comparative analysis of FRA methods, the headings determined above will be applied. First of all, the general definition of ARICA, MARIU, CHICHORRO, ILHR, HFRI and FRIM-HB methods and the sources used are given in Table 2 below. Table 3 includes a detailed comparison of the FRA methods with previously determined analysis headings.

Table 2. Calculation formulas for FRA methods

Method	Calculation Formula	Reference
ARICA	$FR_I = \frac{(1.20 \times SF_I + 1.10 \times SF_P + SF_E + SF_C)/4}{FR_R}$ *FR_I = fire risk assessment* *SF_I = ignition phase factor* *SF_P = propagation phase factor* *SF_E = evacuation phase factor* *SF_C = fire combat factor* *FR_R = reference risk factor*	- (Vicente, Silva, Varum, & Costa, 2010), - (Granda & Ferreira, 2019), - (da Mota, 2014), - (Almeida, 2013), - (Muculo, 2013), - (Santos, et al., 2011).
MARIU	$RL = E\sum_{i=1}^{11} WC_i \cdot SL_i$ *RL = risk level* *E = equalisation factor* *WC_i = weight of factor i* *SL_i = severity factor i*	- (Lopes, Coelho, & Rodrigues, 2011), - (Lopes, Coelho, & Rodrigues, 2012).
CHICHORRO	$RI = P \times G$ *RI = fire risk* *P = probability of fire ocurrence* *G = severity of fire consequences*	- (Gonçalves & Correia, 2016), - (Soares, 2021), - (Coutinho, 2017).
ILHR	$S = \sum_{i=1}^{17} w_i r_i$ *S = evaluation score* *w_i = weight of factor i* *r_i = normalized rating of factor i*	- (Rasbash, Ramachandran, Kandola, Watts, & Law, 2004), - (Kaplan & Watts, 1999).
HFRI	$(A \times B) = \sum_{i=1}^{11} A_i \times B_i$ *A × B = fire safety score* *A_i = value of factor i* *B_i = weight of factor i*	- (Kaplan & Watts, 1999), - (Watts Jr. & Kaplan, 2001).
FRIM-HB	$RI = 5.00 - S = 5.00 - \sum_{i}^{23} w_i x_i$ *RI = risk index* *S = safety score of the building* *x_i = score of factor i* *w_i = weight of factor i*	- (Arborea, Mossa, & Cucurachi, 2015).

Table 3. Comparative analysis of FRA methods for historical buildings

Feature	ARICA	MARIU	CHICHORRO	ILHR	HFRI	FRIM-HB
Scale & Application Domain	Historic urban fabric: streets, blocks, individual buildings	Urban building stock; mid-level technical expertise	Building-level, general purpose	Commercial historic buildings ≤1,115 m²	Historic house museums	Historic buildings; integrated with Carta del Rischio
Factors / Parameters	4 global (FGII, FGDPI, FGEE, FGCI); ~15 partial	11 SL × CP; E coefficient	4 global: POI (12), CTI (3), DPI (5), ESCI (7)	17 parameters (A × B)	11 parameters; w_i (%), r_i (0–5 Likert)	17 P + 6 N hierarchical
Number of Parameters	≈15	11	27	17	11	23
Output / Classification	Risk >1 → action needed; risk map; rapid screening	GR ∈ [38–1200]; 5 risk levels	Grades A++…F ("Very Low"–"Immediate")	Score; additional measures per code	Grades A++…F ("Very Low"–"Immediate Intervention")	RI [0–5]; lower RI = higher safety
Key Features	GIS integration; simplified & detailed versions	Rapid matrix; geographic mapping	Holistic optimization; simplified input mode	Heritage fabric conservation; flexible scoring	Performance-based; collection preservation focus	Policy & strategy oriented; heritage preservation
Input Type	Quantitative	Quantitative	Quantitative	Quantitative/Qualitative	Quantitative	Quantitative
Data Collection Time	Medium (1–2 days)	Low–Medium (1 day)	High (2+ days)	Medium (1–2 days)	Medium (1 day)	Medium (1–2 days)
Expertise Requirement	High	Medium	High	Medium	Medium	Medium–High
Report Format	Risk maps & tables	Matrix tables	Summary tables & score charts	Compliance reports	Score tables	Risk report format
Software Support	ArcGIS, QGIS integration	Microsoft Excel; ArcGIS; QGIS	Custom scripts (Python, R)	None	Microsoft Excel	Carta del Rischio GIS; ArcGIS
Validated Case Studies	Paranhos, Seixal, Viseu	City-wide applications	Amarante pilot	Wisconsin historic buildings	House museum pilot	Rome public office
Version / Mode	Simplified version available	None	Simplified mode available	None	None	None
Sensitivity Analysis	Available	No	Available (parameter ranges)	No	No	No
Uncertainty Metrics	None	None	Yes	None	None	None
Update Cycle	Periodic reviews	Periodic updates	Project-based	Code revision-based	Regular form updates	Continuous updates
Standards & Regulatory Compliance	Compliant with local codes	Aligned with general risk standards	Independent methodology	Direct code compliance	Museum standards	Italian risk mapping standards
Advantages	Detailed analysis; geographic integration	Fast; user-friendly	Holistic & optimizable	Heritage focus	Collection preservation	Integration; policy focus
Disadvantages	High expertise; time-consuming	Limited risk detail	Complex; tool dependencies	Limited to small buildings	Narrow scope	Complex hierarchy

5. Discussion

The differences between the scope, purpose and application features of ARICA, MARIU, CHICHORRO, ILHR, HFRI and FRIM-HB methods reveal the strengths and weaknesses of each method in terms of target scale, data requirement, interpretation style and legislative compliance.

When we look at the scale and purpose compatibility, ARICA and MARIU are approaches designed to perform risk mapping at the urban fabric level, providing rapid scanning opportunities at the block and street scale. While ARICA provides detailed spatial analysis with a data collection period of 1–2 days thanks to the integration with geographic information systems; MARIU offers a practical solution using a simple Excel-based matrix completed in just one day. In contrast, CHICHORRO and FRIM-HB simultaneously evaluate both the probability of fire occurrence and the severity of its consequences with building-based holistic optimization principles; however, comprehensive parameter sets and special automation scripts increase the application time and the level of expertise required.

In terms of speed and user-friendliness, MARIU has the highest ease of use and speed advantage among all methods, while ARICA balances the advantages of moderate complexity and rapid geographic analysis. While CHICHORRO and FRIM-HB require detailed modeling, ILHR and HFRI offer direct regulation or form-based scoring, providing relatively less automation in the field, but a more limited scale and scope of objectives

In terms of Expertise Requirement and Automation, ARICA, MARIU and FRIM-HB offer integration with common geographic or spreadsheet software (ArcGIS, QGIS, Excel) to support data processing and mapping automation; whereas CHICHORRO's Python/R scripts provide in-depth analysis but require initial development. ILHR and HFRI operate via manual form updates and score tables, thus offering limited automation possibilities but offering the advantage of direct compliance with legislation or museum standards.

In terms of uncertainty and sensitivity analysis, ARICA and CHICHORRO allow sensitivity control with parameter ranges against the variability of conditions. Since most of the other methods do not include uncertainty metrics or formal sensitivity analyses, additional Monte Carlo or probabilistic calculations can be suggested to increase the reliability of these models.

Regarding standard and regulatory compliance, ILHR and HFRI fully serve the relevant code and museum standards, while ARICA and MARIU provide a more flexible compliance, while FRIM-HB is directly integrated into the Italian "Carta del Rischio" framework.

Consequently, considering the scale, time constraints, data access possibilities and regulatory requirements required by the institution or project:

- MARIU for rapid, city-wide screening,
- ARICA for geographically detailed analysis,
- CHICHORRO or FRIM-HB for comprehensive optimization at the building scale,
- ILHR or HFRI should be preferred for situations requiring official approval and regulatory compliance.

6. Conclusions

In this study, six different fire risk assessment methods ARICA, MARIU, CHICHORRO, ILHR, HFRI and FRIM-HB were compared in terms of scale, data requirement, automation level and regulatory compliance. Among the examined methods, there is a clear distinction between rapid urban scale scanning (MARIU), block and street level analysis supported by geographic information systems (ARICA), building-based holistic optimization (CHICHORRO, FRIM-HB) and regulation-based scoring (ILHR, HFRI). This differentiation reveals that each method requires a multi-dimensional set of selection criteria, from the number of parameters to uncertainty and sensitivity analysis, from software integration to field implementation time. Therefore, not only speed or detail but also automation capability, level of expertise and regulatory compliance should be equally taken into consideration in risk assessment processes.

A holistic and sustainable fire risk management in historical building groups can only be achieved by consistently matching the technical capacity of the selected method with the application context. In this context; the size and depth of coverage of the parameter set, the level of automation and the presence of uncertainty analysis tools; whether the risk model will be applied at the city scale or on a single structure basis; data access, data quality and timeliness; and the harmonious construction of stakeholder participation dynamics (interaction mechanisms between fire departments, conservation experts, local governments and property owners) are of critical importance. In the selection of the method, not only the quantity and quality of the available data, but also how the model outputs will be interpreted by decision makers and the ways of integration into response planning should be taken into account. Furthermore, the systematic inclusion of continuous monitoring and update cycles in the methodology; for example, automatically updating the findings obtained through periodic field inspections via digital platforms, will both maintain the real-time validity of risk scores and allow for flexible revision of long-term response strategies. This approach will also support different scenario analyses, ensuring that resource allocation, emergency training and policy development are carried out within an integrated framework, thus paving the way for the dynamic improvement of fire safety standards specific to the historical texture.

Revitalizing cultural heritage: The transformative power of circular adaptive reuse in Istanbul ferry boat stations

Yasmine Tira*[1]

[1] Istanbul Gedik University, Interior Architecture and Environmental Design, 34876 Istanbul, Türkiye

Abstract. Adaptive Reuse (AR) of cultural heritage is a systemic process playing a critical role in the debate towards a more sustainable future in cities. AR stands as a crucial strategy for preserving heritage values while adapting them for future uses. However, while repurposing built heritage can be considered as a reliable strategy for reaching a better social and economic future in cities, the cultural values of heritage assets can be underscored. This paper focuses on the importance of the circular AR of cultural heritage suggesting that assigning new functions to the historical buildings contributes to the circularity-based sustainability in cities. The following research aims to reveal the transformative power of circular AR of built heritage adopting the revitalization of ferry boat stations in Istanbul as a case study. From this aim arises one main objective, i.e., revealing the social, economic and cultural value of circularity-based AR of historical ferry boat stations. Therefore, ferry boat stations in Istanbul transcend the fact of being just transportation hubs; they are a witness to the city's rich cultural heritage. Preserving their authenticity, integrity and significance while adapting them to present needs is fundamental for maintaining the Bosphorus's legacy of linking various regions with unique heritage. Examining the broader implications of circular economy (CE)-based cultural regeneration, the findings showed that circular AR have a role to play in both the socio-economic and cultural revitalization, namely the heritage tourism promotion, the local business enhancement, and the local civic pride conservation. Ultimately, this paper suggests that Istanbul's ferry boat stations play a role model for other cities aiming at setting a balance between heritage conservation and the demands of the circular city development.

Keywords: Circular adaptive reuse; Revitalization; Built heritage; Ferry stations

1. Introduction

Many definitions are given to the circular economy (CE) concept resulting in some confusions. Although, it emerged as an industrial ecology concept and was applied as a symbiosis tool for managing wastes, the popularity of CE spread out to include many other disciplines (Dąbrowski, M., Williams, J., van den Berghe, K., & van Bueren, E. 2024). Therefore, in the current concern for more livable cities, CE holds a premium role by enhancing both environmental quality and economic prosperity, while putting forward social equity for future generations (Dąbrowski, et al., 2024).

Since construction and building sector are topping in the nonrenewable energy conception, they started to intensively make use of the CE's regenerative power (Mariarosaria, et al., 2023). According to the 2020 European Commission's (EC) report on Energy efficiency in building, the building sector accounts for 36% of global greenhouse gas emissions (EC, 2020, February 17). Thus, to prevent the resultant current resource depletion and environmental impact, and to reach the EU's 2050 aim for 0 gas emission, the CE principles were applied to the building sector including built heritage.

Therefore, the contribution of CE application in the heritage conservation process is evident mostly from its role in AR projects (Gravagnuolo et al. 2021 a, b; ICLEI, 2020). Consequently, in the ongoing debate around achieving a more sustainable future for cities, cultural heritage became increasingly recognized as both an active driver and a viable accelerator. Being both an economic and a cultural asset, cultural heritage contributes to economic enhancement, plays a role in upgrading urban quality and environmental compliance (Buglione, F. *et al.* 2025). Thus, relying on the transformative power of circularity-based cultural heritage AR, it became possible to increase the lifespan of buildings, reduce waste, prevent resources depletion and promote innovative design strategies for heritage buildings while preserving their cultural value (Chiacchiera & Mondaini, 2023; Nasrullah, 2024). However, while circular AR is playing a significant role in building the way to more sustainable futures, it

*Corresponding author, E-mail: yasmine.tira@gedil.edu.tr

https://doi.org/10.31462/icearc2025_a_car_553

still reflects challenges particularly in balancing preservation prerequisites with modernization needs. Its challenges lie also in managing regulatory frameworks that enhance cultural heritage protection.

The present study discusses circularity-based heritage revitalization initiatives, questioning the transformative power of adaptive reuse of cultural heritage (ARCH) as a driver for CE implementation in heritage conservation strategies. In this perspective, the rich shore-built heritage of Istanbul city has been taken as an example. Based on onsite observation and the theoretical model building method, the following study aimed at revealing the social, economic and cultural value of circularity-based AR of historical ferry boat stations.

The following section illustrates the conceptual framework defined from the literature review and defines the main indicators for circular AR of heritage buildings regardless of the heritage context.

2. Theoretical framework: Adaptive reuse strategies for heritage buildings

As opined by Williams (2019), despite periodic technological upgrades, core infrastructure systems in many countries have remained fundamentally unchanged for decades making built heritage needing rehabilitation or replacement. Building on the potential of ARCH to activate circularity-based sustainability in cities/regions, and the crucial role AR can play in extending the lifespan of heritage buildings, the following section outlines key aspects of the relationship between ARCH and circularity-based sustainability. In the present study, empirical research based on the 'theoretical model building' (Onwuegbuzie, et al., 2012) has been applied to select, synthesize, and systematize the indicators for the circular ARCH.

2.1. Adaptive reuse of cultural heritage and circularity-based sustainability

ARCH plays a fundamental role in promoting circularity-based sustainability by revitalizing underused or discarded sites while preserving cultural identity. This approach not only improves urban resilience but also nurtures social cohesion and economic enhancement (Gravagnuolo et al., 2021).

Several studies call attention to the connectedness between the sustainable CE concept and the heritage sector (Girard, 2020). Yet, while the input of CE implementation in the heritage conservation process is definite from its role in AR projects (Gravagnuolo et al. 2021; ICLEI, 2020), few studies have examined it from a more comprehensive viewpoint. Girard and Nocca (2019) reviewed the possibility of implementing the CE at an urban scale by focusing on a cultural landscape-based approach assuming that there are interdependence relations between specific landscapes and CE/city models. Hence, in the circular approach, resources are re-used, recovered, regenerated, and shared, extending use values. Among resources, CH that has historical, artistic, and cultural values can play a significant role in the implementation of the "circular city", oriented towards implementing the "human-centered city" (Christian, 2020).

Therefore, according to Bandarin and Van Oers (2012), 'Circular City' initiatives are appropriate for ARCH because the cultural uniqueness of cities is related to features of the urban landscape including buildings (Bandarin and Van Oers 2012). It is also believed that the spatial aspect of CE for implementing the circular city approach is ARCH (Girard, 2020). Within this framework ARCH has the potential to activate the different factors of circularity-based sustainability. ARCH is conceptualized as a strategic approach to advancing a more sustainable, resilient, inclusive, and aesthetically meaningful future (Girard & Gravagnuolo, 2025: 16). As illustrated in Table 1, ARCH encompasses an overlap between the social, economic, cultural, and environmental considerations.

The socio-cultural aspect of AR projects lies in its potential to enhance community engagement (Gravagnuolo et al., 2021). AR increasingly emphasizes putting forward the community's well-being by enhancing social value (Padilla-Rivera, et al., 2020; Lundgren, 2023; Andreucci & Karagözler, 2025). Involving local stakeholders in decision-making processes enhances civic responsibility and strengthens community bonds, as demonstrated in the example of Salerno, Italy (Gravagnuolo et al., 2021). In another research, Maha Shree, et.al, (2025) elucidated the diverse methodologies employed in adapting historical structures for contemporary uses while safeguarding their intrinsic cultural value.

Table 1. Indicators for the adaptive reuse of cultural heritage (Source: the author)

Embedded indicators	Sub-indicators
Socio-economic indicators	Heritage tourism promotion, community revitalization (Maha Shree, et.al, 2025; Padilla-Rivera, et al., 2020; Lundgren, 2023; Andreucci & Karagözler, 2025)
Economic indicators	Investment and Funding, job creation, tourism-based investments (Gravagnuolo et al., 2021; Rudan, 2023)
Social-cultural indicators	Community well-being, cultural identity, civic pride enhancement, community engagement (Gravagnuolo et al., 2021)
Environmental indicators	Minimizing waste and reducing the consumption of new resources (Foster, 2020; Bosone et al., 2021).

The study helped investigate the socio-economic advantages of AR initiatives that are including, but not limited to heritage tourism promotion, community revitalization, and sustainable development. Moreover, the same research addressed the ethical considerations and conservation principles guiding AR practices to ensure that sustainable heritage management, be the potential actor to preserve authenticity, integrity and significance of cultural heritage assets. It, however, underscores the imperative of AR as a vibrant tool for safeguarding cultural heritage for future generations.

Economically wise, revitalizing cultural heritage sites through AR practices has the potential to stimulate local economies through job creation and increased tourism, as seen in several tourism destinations (Rudan, 2023). However, this contribution remains questioned especially when it comes to repurposing existing buildings for retail use (Maha Shree, et.al, 2025). Therefore, from this perspective, managing old buildings is a difficult undertaking. Retail-reuse projects typically involve many stakeholders having different interests, i.e., heritage conservation actors like governmental agencies that focus mostly on preserving the historical significance of heritage buildings, and investors who opt for economic profit.

Environmentally wise, applied materials and methods for the conservation and restoration of cultural heritage have the potential to be energy consuming, not environmentally friendly and sometimes even damaging for the health of executors. Therefore, many of the applied materials and technics prove to be neither durable nor sustainable, often leading to recurring and expensive heritage solutions (Angrisano et al., 2025: 117-118). However, aligning with CE principles ARCH has the potential to help minimize waste and reduce the consumption of new resources when revitalizing degraded heritage buildings (Foster, 2020; Bosone et al., 2021). The transformative power of circularity-based ARCH does not encompass the environmental aspect only. Inscribed in a holistic urban governance approach, circular ARCH has the gage to stimulate growth, sustainable development, social regeneration, welfare, jobs, income and livability cities/regions (Tira & Türkoğlu, 2023; Fusco Girard & Gravagnuolo, 2025).

2.2. The transformative power of the circular adaptive reuse of cultural heritage

Each city has unique characteristics and its own social and economic structure. Thus, to implement the circularity approach to its different assets, each city needs to assess the appropriate starting point. Based on the Sustainable Development Goals (SDGs) and the EU's 2050 target of 0% emissions, the EU launched the Green Deal strategy (EC, 2019) based on CE principles. The initiative showed that the circular concept can go beyond the economic circle and that cities can also adopt it to reach a long-lasting sustainable future (EC, December 11, 2019).

Putting culture at the heart of the Green Deal was meant to adopt cultural heritage as the starting point to reach Europe's 2050 goal (EC, 11 December 2019). Historic city regeneration and renewal approaches are seen as an effective entry point for the implementation of a circularity-based sustainable future (Nocca et al. 2021). However, as claimed by Nocca et al. (2021), regardless of the growing interest in CE implementation, the debate around it remains more on a theoretical level. Knowledge about how to implement the circular approach to heritage assets is still confusing.

Pioneers in adopting the circularity approach in ARCH to attend self-sustainability, are the Regeneration and Optimization of Cultural Heritage in Creative and Knowledge Cities (ROCK) (ROCK, 2019) and the Circular Models Leveraging Investments in the Cultural Heritage Adaptive Reuse (CLIC) project (ICLEI, 2020).

These studies are based on the idea that CH is used as a tool to experiment with collaborative models of urban development (Garzillo et al. 2018; ROCK, 2019). Both examples applied CE principles to CH regeneration through AR, achieving environmental, social, cultural, and economic sustainable urban development. Therefore, the objective of the CLIC initiative is to provide strategic guidance to a diverse range of stakeholders—including municipalities, public authorities, financial entities, private sector actors, civil society organizations, and cultural institutions—in the implementation of local development strategies. These strategies are principally based on harnessing the 'transformative potential' of ARCH (Fusco Girard & Gravagnuolo, 2025: 16).

One example of pilot projects led in the ROCK initiative is the case of the historic city of Bologna which is a replicator city of the ROCK project. In this example, the policy of the project is based on coordinating the collaboration between the different urban stakeholders and actors, including the community, for the regeneration of urban heritage.

In this circularity-based ARCH ore focus is given to developing inclusive and accessible public spaces in the city center and the university area of Bologna. This was achieved by enhancing pedestrianization and slow mobility through planning cultural roots, and the green mobility concept. Following a circular policy for ARCH, the historic city of Bologna could also preserve the architectural features that the porticoes are carrying (UrL-1). Therefore, the collaboration between the community and the city for the regeneration of urban commons in Bologna has been evaluated as a good governance model worth sharing with other cities (ROCK, 2020).

The example of ARCH based ROCK principles is Skopje North Macedonia. The chosen ROCK project area in Skopje city is comprised of a protected area of CH of high significance (a city fortress, the Old Bazaar, and many buildings and monuments, a vibrant open-air green market, a residential area, a commercial area, a mixed-use cultural center, four universities and finally several museums in the former Jewish district in Skopje). This multi-functional trait of the historic city contributed to attracting a large number of visitors.

However, the central area witnessed some neglect. Thus, within the ROCK initiative, and based on a collaborative co-planning principle, Skopje municipality tried to focus on the social, economic, and cultural production of space mainly through the introduction of contemporary "crafts" by ICT incubators and the collaborative workspaces for new creative industries. Consequently, the process of the project concluded in transforming the old center of Skopje into a knowledge culture technology-driven hub where heritage-based regeneration and sustainable urban development are playing a crucial role (ROCK, 2020).

Similarly, the historic center of the Netherlands had also gone a circularity-based ARCH. In Eindhoven's role model city, Living Lab applications helped implement a data infrastructure that has the potential to improve the community's quality of life in the demonstration area. The area defined for the ROCK project in Eindhoven, the NRE site, is including industrial heritage buildings, old commercial buildings, homes, and even old trees. A "*collectively supported plan*" has been implemented by the municipality for the repurposing of the former industrial regeneration area, i.e. the center of Brainport Region, Eindhoven. Under the arch of the developed 'Strijp-S' Living Lab, and collaboratively with the community, the end result was defined by the users. This made it more liveable, dynamic, and at the same time industrious than it was in old times (Eindhoven Municipality, 2019).

Assessment of the achieved and ongoing ARCH projects under the arch of the Horizon 2020 funded two projects showed that the circular ARCH boosts investment and funding. However, evaluating the financial viability of AR projects, including initial investments and potential returns, is crucial. Besides its economic viability, circular AR has a role to play in local employment as it contributes to job creation (Bosone et al., 2021).

3. Materials and methods

The methodology applied in this study is based on the review of literature sources, and an onsite discovery of AR cases with reference to historic ferry boat stations. Literature sources include scientific references, and international organization reports selected giving priority to the most recent (years 2019–2025). The sources were selected according to the main topic addressed, focusing on the regenerative role of CE in the ARCH buildings.

Through the analysis of existing literature, key criteria are identified for the circular AR in the revitalization of the existing built heritage. Special focus was given to the AR of historic ferry boat stations since they present greater challenges like the need to preserve authenticity and integrity in cities where ferries play a vital role in the transit system.

3.1. Exploration of the case studies' context: adaptive reuse of ferry boat stations in Istanbul

Located on the crossroad between Asia, Europe, and Africa, Istanbul lies at the heart of a dense movement network holding an international significance in terms of maritime transport. At the same time, Istanbul city carries an influence on the local importance of urban movement patterns and character. The morphological structure of the city's shores and the attachment of the residents to the sea enhance the role of sea-based transportation.

In the 1840s, urban maritime transportation was mainly focused on the Golden Horn. In the following years, ferry routes, expanding towards the Anatolian side, became an important element in the city's historical and social development (Çınar, 2023, March 28). This implies that the increasing importance given to maritime transportation in Istanbul resulted in defining the movement patterns and the urban design interventions of the shores. Therefore, sea rotes transportation in Istanbul dates to 1851, an era where the city was still under the Ottoman ruling system. To facilitate the transport in the city of three lands and three waters, the "beneficial company", *Şirket-i Hayriye* was established. The purpose was to respond to the growing transportation needs between Istanbul and the Bosphorus in the mid-19th century and to get by the unsafety of traditional methods that could no longer respond to the needs in terms of comfort and capacity (Şehirhatlari.istanbul, n.d). The launching of the ferry lines accelerated the incorporation of the Bosporus to the city's functional organization making the maritime transportation emerge as the defining figure and be the visionary of Istanbul's skyline.

Currently, sea routes in Istanbul are managed by three different companies, i.e. Dentur, Turyol and Şehir hatları. The ferry piers are distributed along the scenic coastlines of the Bosphorus and the Golden Horn (Fig. 1).

Istanbul ferry boat stations play a crucial role in valorizing the city's rich cultural heritage. Preserving their authenticity, integrity and significance while adapting them to present needs is fundamental for maintaining the Bosphorus's legacy of linking various regions with unique heritage. Currently, some of the ferry stations in Istanbul have additional functions, including cafes, libraries, and sightseeing points alongside their transportation functions, contributing to the reinforcement of social interaction (Yasar & Heinz, 2024).

Several examples of historical ferry boat stations went through AR interventions in Istanbul. A few of them were chosen as case studies for this research. The criteria for the choice of cases are mainly based on the accessibility, the physical condition of the current heritage building, current function of the ferry boat station, the scale of possible degradation after a new function is added to the building, the contribution of the added functions to the local business enhancement, and the involvement in the conservation of the local civic pride.

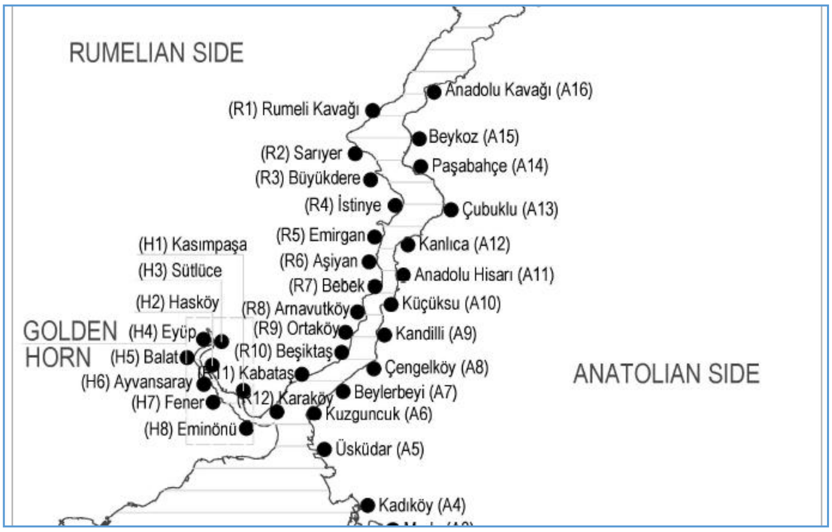

Fig. 1. City line map (Source: Yasar & Heinz, 2024)

The onsite observations were mainly based on the discovery of the architectural features and the building typologies of post-revitalization interventions. Threin, roof features, floor number, functions, structural systems, plan typology and façades features were observed in 2 different pier buildings in Kadiköy on the Anatolian coast of Istanbul, i.e., Moda ferry boat station, Kadiköy station for city lines.

3.2. Moda ferry boat station

Moda Pier was designed by architect Vedat Tek, one of the pioneers of the First National Architectural Movement, during the reign of the 35th Ottoman Sultan, Mehmed Reşad (1844–1918). The inscription on the building, adorned with floral motifs on both sides, bears the Ottoman Turkish phrase "Moda 1335," suggesting that it was built between 1916 and 1919. Moda Pier features a simpler neoclassical style (Fig. 2). With its rectangular plan, pitched roof, unique design reflected on all four facades, and elegant tiles decorating its window pediments, the pier has left a lasting cultural memory (Demirtaş, 2022).

Just at the beginning of the post-pandemic, the Transportation Coordination Directorate in coordination with the Istanbul Metropolitan Municipality (İBB) took the decision to launch an AR project for the pier. The historic *Moda* ferry boat station, which has been closed to sea transportation for many years, was reopened to service on the 1st of November 2022. From that date, the station started operating around 10 trips a day between Bostancı, Moda, Kadiköy and Kabataş lines, which are different ferry stations located between the two continents (Demirtaş, 2022).

The architectural design of the *Moda* Pier exhibits the defining characteristics of the Neoclassical style, which gained prominence in the late Ottoman period and was notably influenced by Western architectural movements (Fig.2). The building's facades are articulated with wide arched windows that not only enhance their aesthetic appeal but also allow natural light to the interior space, creating a bright and airy atmosphere (Fig.3).

The symmetrical layout refined ornamental detailing (Fig. 4), and distinctive architectural elements collectively underscore the building's alignment with the design principles of its era (Table 2). However, in interior space, simple yet expressive materials such as wood, brass, and ceramic tiles are used to complement both the architectural atmosphere created by Vedat Tek and the building's existing structural character (Çınar, 2023, March 28). Furthermore, the use of timber in the interior space reflects a contemporary interpretation of traditional Turkish architectural practices, thereby bridging historical motifs with modern sensibilities.

Table 2. The architectural features of Moda pier after renovation (Source: the author)

Roof features	Type: Hipped roof Cover: clay red tiles Wide overhangs
Floor number	Two story
Function	Ferry building, book/café, library
Structural system	Frame system
Plan typology	Rectangle and having a symmetrical layout
Façade features	Bridging historical motifs with modern sensibilities

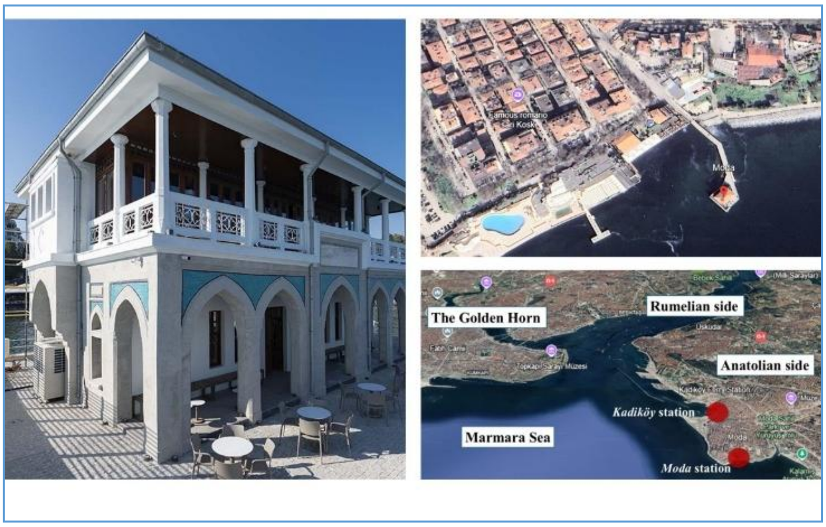

Fig. 2. Moda Ferryboat station

Fig. 3. Front view of Moda pier after the revitalization (Demirtaş, 2022)

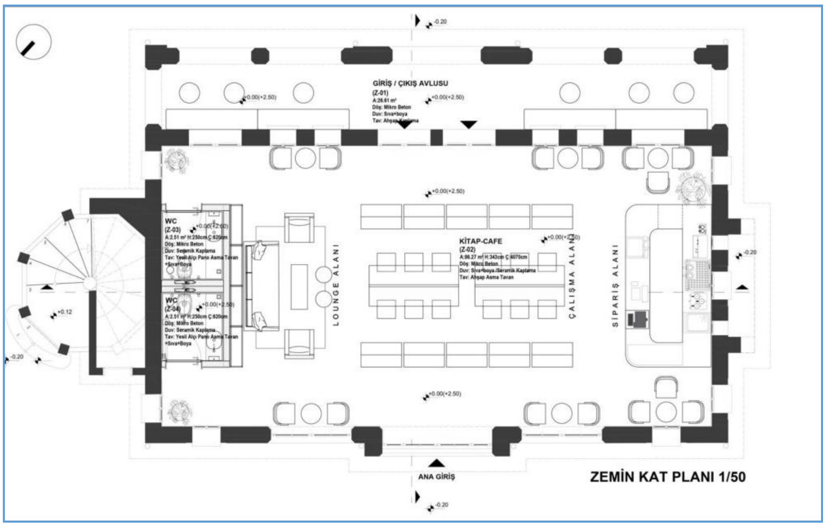

Fig. 4. The ground floor plan of Moda pier after the revitalization (*Source:* Çınar, 2023)

Table 3. The transformation of *Moda* pier after the adaptive reuse project

The starting point		
-Extending the lifecycle of the building so that it becomes stabilized, and ready to accommodate new technologies -Reduce the negative impact of the dilapidated building - Requirement for multifunctionality - Reviving the terminal building dead heritage		
Circular Economy-based actions taken		
Environmental indicators	Socio-cultural indicators	Economic indicators
- Emphasis on taking advantage of the windows' structure for a more energy efficient space. - Focusing on using local materials and techniques like	- Creation of additional functions and contemporary services in line with conservation ethics. - Repurposing while preserving the original building structure. - Re-using the building and its pier in a way that revives the nostalgia to the past and enhances the sense of identity and attachment to the collective memory.	- Transforming the space into a multipurpose area reflecting a closed-loop system where many small businesses are completing each other, i.e., the book/café space of the terminal and its relationship to the surrounding retails
Effects		
- Revitalization of the historic architectural character - The transformation of the station to a multifunctional area - Preservation of the ferry building functions and adding supplementary functions, i.e., socio-cultural functions (book café and library), tourist and recreational functions (sightseeing areas and a flexible interior) - Development of the creative sector activities		

The ground floor of the station was planned to serve as a book café and a workspace. The overall spatial layout is designed to allow the book café to function as a performance space on certain days and at specific times. By removing added walls, an open-plan layout is created. Wet areas and a service counter are positioned at the two short ends of the symmetrically planned space. The café and workspace are in the central area. Movable bookshelves and tables are introduced, making the space multifunctional and flexible. Thanks to the adaptable furniture, the layout can be easily adjusted to meet the needs of the moment—transforming the pier into both a waiting area for passengers and a potential stage for artists, as well as a sightseeing spot for visitors.

Situated on the upper level, the spacious terrace offers visitors a panoramic view of the sea, reinforcing the structure's relationship with its maritime context. keeping the historical architectural landmarks of the past when renovating the façade helped reflect the lasting impact of the city's collective memory. Therefore, only cleaning and minor repairs have been carried out (Table 3).

3.3. *Kadiköy* ferry boat station for city lines

Kadiköy ferry boat station is one of the earliest architectural interventions on the main Kadiköy public square, established on a large land reclamation from the Marmara Sea. Its structure is presently known as the Old Pier or Beşiktaş Pier (Fig. 5). Based on the inscription located on the edifice, the two-story structure was completed in 1926, during a period in which maritime transportation constituted the sole means of access between Kadiköy and the historical peninsula of Istanbul.

The building exhibits decorative facade, featuring period-specific Kütahya tiles, and for its two prominent onion domes which represent elements underscoring both the eclectic stylistic tendencies of the era and the building's symbolic prominence (Table. 4). Despite its historical and architectural significance, the pier has undergone multiple phases of restoration resulting in the loss of certain original design elements and ornamental features (Fig. 6).

Table 4. The architectural features of Kadiköy pier after renovation

Roof features	Type: Hipped roof and two onion domes Cover: clay red tiles Wide overhangs
Floor number	Two story
Function	Ferry building, book/café, library
Structural system	Frame system
Plan typology	Rectangular
Façade features	Decorative facade, featuring period-specific Kütahya tiles

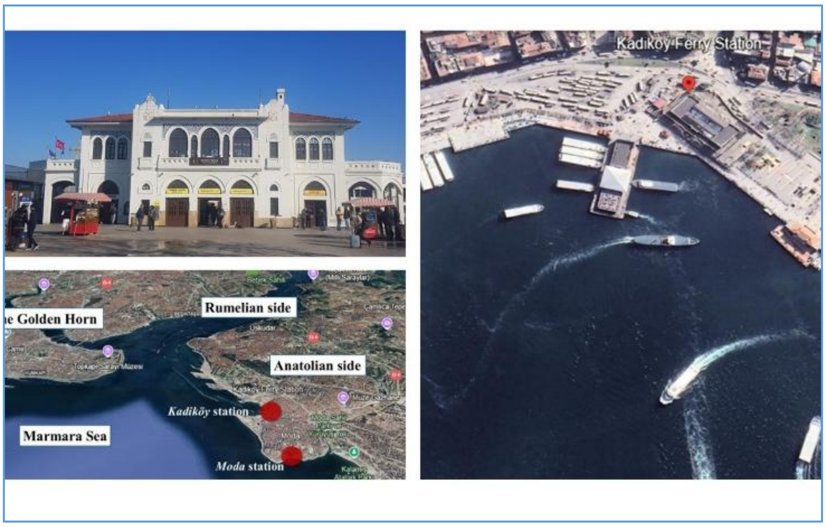

Fig. 5. Kadiköy ferry boat station or Beşiktaş pier

Fig. 6. Kadiköy ferry terminal library (UrL-2)

Modern technologies and advancements in transportation have brought significant changes to the area surrounding the pier. The development of transportation networks has increased accessibility to Kadiköy and, consequently, to the ferry terminal, resulting in a great increase in the number of visitors. With the introduction of numerous new ferry and sea-bus routes, the pier remains a vibrant and active node, continuing to serve as a preferred mode of access to Istanbul's historical landmarks. This ongoing activity contributes not only to Kadıköy's urban growth but also to the formation of a dynamic and socially vibrant environment.

Today, Kadiköy Ferry Terminal has evolved beyond its original function as a mere transportation hub. After the revitalization it went through, it has become a popular meeting point that attracts both local residents and international visitors. Neighboring many cafés, restaurants, and shops surrounding, the terminal gained a vibrant atmosphere attracting visitors. Besides, the terminal stands out as an iconic symbol closely associated with the dynamism and liveliness of Kadiköy district. As a result, Kadiköy has emerged not only as a key node in urban mobility but also as a central space for social interaction and public life (Table 5.).

Kadiköy Ferry Terminal has become a symbol of Istanbul's cultural richness through its unique fusion of historical character and contemporary urban life. For both local and international visitors, it serves not only as a historical site but also as an active space within the modern city. The ferry station continues to function as a significant architectural and cultural landmark that bridges Istanbul's past, present, and future.

Table 5. The transformation of Kadiköy ferry building after the adaptive reuse project

The starting point		
- Increasing the existing building lifecycle - Reducing the negative impact of the damaged building - Requirement for multiuse - Reviving the surroundings of the terminal's-built heritage		
Circular Economy-based actions taken		
Environmental indicators	Socio-cultural indicators	Economic indicators
Emphasis on recyclability of materials.	Creation of additional spaces and contemporary services in line with conservation ethics. Reconstruction while preserving the original building structure Reusing the building in a way that attracts more visitors, locals and tourists. Enhancing space branding by mix-use, i.e., café, library, ferry building and terrace for sightseeing	Attracting smaller businesses to the surroundings to make the area self-sufficient
Effects		
- Revitalization of the historic architectural character. - The transformation of the station to a multifunctional area - Preservation of the ferry building functions and adding supplementary functions, i.e., socio-cultural functions (book café and library), tourist and recreational functions - Supporting small businesses and generating local economic activity surrounding the ferry terminal like mobile food trucks and kiosks - The development of the creative sector activities like life music performances - Reflecting a balanced staging and branding of the historic terminal building by mixing the historical touch to the modern adequate building technologies - Enhancement of the civic pride and the sense of attachment by reviving the use of the dead-built heritage		

4. Findings and discussion

The onsite observations and the empirical research investigating the transformative power of the circular ARCH led to show that circularity-based revitalization of ferry terminals in Istanbul exhibited a creation of a closed-loop process expressed through the area's economic enhancement, creation of jobs, the equitable appropriation of heritage assets, and the increase of urban safety and security. Particularly in the case of Moda ferry terminal, the pier area presented a shift from being a leftover area to a vibrant cultural Hub and a spot for leveraging investments through CE-based AR.

The socio-economic dimensions of the circular AR of ferry boat stations in Istanbul revealed the potential of CE-driven heritage revitalization. The study showed that adopting a circular approach to AR of ferry terminals not only enhanced the historic architectural identity but also transformed these stations into multifunctional spaces. Moreover, circular ARCH enabled the preservation of the buildings' original functions while incorporating additional ones—such as socio-cultural (e.g., book cafés and libraries), tourism, and recreational uses—which contributed to increased tourist activity.

Supporting small businesses and generating local economic activity surrounding the ferry terminal like mobile food trucks and kiosks and the development of the creative sector activities like life music performances had a role to play in reflecting a balanced staging and branding of the historic terminal building by mixing the historical touch to the modern adequate building technologies. Hence, these combined factors strengthened civic pride and fostered a deeper sense of connection to local heritage. However, while AR of ferry terminals in Istanbul offers considerable potential for urban revitalization, it remains crucial to balance commercial interests with community needs to prevent adverse social outcomes.

The metamorphic cultural influence brought about by circular AR in the Istanbul case demonstrated that historical ferry stations largely retained their original identities and spatial continuity, despite undergoing multiple renovations over time due to various forms of damage. These stations, emblematic of Istanbul's rich maritime heritage, continue to serve as vital components of urban memory and significantly contribute to the preservation of the city's cultural identity.

In the arena of historic buildings revitalization through AR processes, there is no "one single standardized" solution that can fit all heritage contexts, as all built heritage sites are different and have unique features, however the results of this study may serve as a valuable resource for heritage professionals and policymakers, supporting more proactive and sustainable AR strategies that align with circular economy principles.

5. Conclusions

The foregoing research contributed to illustrating the lessons and recommendations learned from balanced circular AR of built heritage from the perspective of ferry boat terminals. Based on the observed heritage revitalization cases, AR of ferry buildings and their transformation into multifunctional areas where many small businesses are supporting the preservation of the original functions and adding supplementary ones contributed to animating the social, economic and cultural sphere of the buildings' surroundings. Therefore, interwoven socio-cultural functions (book café and library), touristic and recreational functions (sightseeing areas and a flexible interior that can be modified to receive more users) helped not only the animation of the community's sense of pride and attachment to the past, but also enhanced the attraction of tourists and non-local visitors. Thus, the main lessons learned from the present study can be resumed as follows:

- Circular AR has a role to play in both socio-economic and cultural revitalization, namely the heritage tourism promotion, the local business enhancement, and the local civic pride conservation and enhancement.
- Following a zero-waste conservation policy based on renewable energy use is an entry point to include adequate environmental impact indicators based on the circularity strategy. To bridge the existing gap, heritage conservation needs to be inscribed in an overall conservation strategy integrated into a holistic development approach.
- Istanbul's ferry boat stations have the potential to play role models for other cities aiming at setting a balance between heritage conservation and the demands of circularity-based sustainable development.

This study examined circularity-based AR indicators in two examples of two-story ferry terminals on the Anatolian coast of Istanbul highlighting their significance in terms of preservation and the circular approaches to sustainability. The case studies exploration helped show how appropriate material interventions and added functions for the reuse of ferry boat stations are key to guaranteeing a balance between the cultural values of heritage assets and the modern needs. However, the challenges that arise from the extensive use of ferry boat stations for purposes else than commuting drive the built heritage of shores to "touristification" trends. Balancing built heritage conservation with modern requirements demands careful planning and community involvement to ensure that projects meet contemporary needs while respecting historical contexts. Future research could enrich the architectural and urban development discourse by conducting comparative analyses between these piers and other coastal structures across the city. Additionally, integrating more quantitative data and analytical methods may offer deeper insights into the role of pier buildings in shaping urban development.

Rize architectural historiography: What archive sources tell us

Adem Kaçıran[1]*, Fulya Üstün Demirkaya[2]

[1] *Master Architect*
[2] *Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye*

The isolation of Rize throughout history from the Anatolian and Caucasian regions has resulted in limited references to the city in historical sources. Undoubtedly, for a study on the history of Rize, maximum benefit must be drawn from the limited data obtained from these sources. This study aims to identify and compile primary source groups that can shed light on Rize's urban history and explain how these sources can be utilized.
The study explains which historical sources can shed light on which topics. In this context, the historical sources are examined within three different time periods: the pre-Ottoman era, the Ottoman era, and the Republican era. The data have been analysed in the context of the historical information they contain, the findings obtained from these sources have been evaluated, and the periods in Rize's history where continuity or disruption occurred have been identified.
Contrary to common belief, the study reveals that Rize has origins in the Ancient Period. Early sources largely consist of Greek travel books, while Medieval sources are scarce. Post-Ottoman conquest records provide more information, and in the Republican era, visual documents allow a more concrete observation of Rize's physical environment.
Throughout the study process, all kinds of data that could provide clues about the past of the city of Rize have been carefully analysed, and any primary sources that could provide information about Rize from its foundation to the present day have been identified. The study explains what each of these sources provides information on.

Keywords: Architectural historiography; Rize city history; Archive sources; Primary sources; Secondary sources

1. Introduction

Rize is a coastal city located in the eastern Black Sea region. Characterized by a rugged, mountainous topography and heavy rainfall, the city features dense forests and limited flat land confined to a narrow coastal strip. Due to the high mountains stretching east-west to its south, Rize historically remained isolated from Anatolia. This isolation fostered a unique and independent cultural identity, while resulting in a scarcity of written and visual historical sources. Consequently, Rize has rarely been a focus of scholarly research.

The city's geography has also shaped its urban development. The limited flat areas led to concentrated construction along the coast, particularly toward the north, as expansion southward was restricted. As a result, much of the historical building stock was demolished to make way for larger, modern structures meeting the needs of a growing population. This has left very few historical buildings standing today. The lack of surviving structures and limited written sources has contributed to the misconception that Rize has a shallow historical background. Many locals and some researchers perceive the city as historically insignificant, a view frequently encountered in studies on Rize's past. This perception has further diminished interest in preserving the city's historical heritage, accelerating the destruction of remaining historical structures.

Current evidence, however, indicates that settlement in Rize dates back to the 2nd century AD. Its sheltered bay made it an attractive site for early settlers. During the Byzantine and Ottoman periods, Rize's strategic position near the imperial borders enhanced its significance, particularly in terms of security and maritime activity. The ongoing uncertainty regarding Rize's settlement history largely stems from the underutilization of available data and the lack of comprehensive studies. Throughout history, Rize has been part of major civilizations including the Eastern Roman Empire, the Empire of Trebizond, the Ottoman Empire, and the Republic of Turkey, shaping a multilayered urban memory. Although gaps remain, limited but meaningful historical data from the Ancient Period to the present exists. When assessed these sources (travel books, archival documents, and existing literature) hold considerable potential for filling major gaps in the historiography of Rize.

Accordingly, this study aims to analyse archival records that could contribute to the writing of Rize's urban history and to highlight their historiographical potential. Within this scope, archival materials are examined across

* Corresponding author, E-mail: ademkcrn@gmail.com

https://doi.org/10.31462/icearc2025_a_car_560

three periods: the Pre-Ottoman Era, the Ottoman Era, and the Republican Era. Documents are analysed with a focus on settlement patterns, construction activities, and the dynamics of building and demolition, all crucial for illuminating Rize's architectural history.

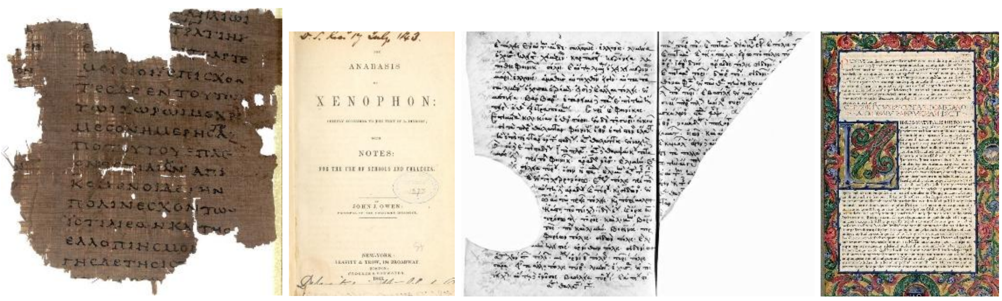
2. Primary Sources from the Pre-Ottoman Period

The absence of archaeological excavations in the city center has resulted in extremely limited concrete evidence regarding Rize's ancient settlement. Today, the only surviving structure from this period is Rize Castle, located in the city center. Although limited, the castle constitutes an important historical trace, offering insights into the city's early settlement pattern. Moreover, much of the existing knowledge about Rize's pre-Ottoman history relies on ancient Greek sources and traveler narratives contained within these texts. These accounts provide valuable information about the region's ancient existence and historical topography. In addition, Rize Castle holds significance for understanding the early history of the city.

2.1. Travel Books:

The most significant written sources that shed light on Rize's early history are undoubtedly travel accounts. Due to Rize's location at the center of the coastal line of the Colchis and Pontus regions, where maritime activities were crucial in Antiquity, it became a notable stop for many travelers. These accounts, mostly written in Ancient Greek, describe voyages undertaken by sea. Although ancient Greek texts are among the few sources that illuminate Rize's early history, it cannot be said that ancient authors provided detailed or comprehensive information specifically about the city. The references to Rize in these texts are generally limited and indirect. The name of Rize first appears in Arrianus's work dated to AD 131 (Arrianus, 2025). Prior to this, although Herodotus, Xenophon, Scylax (Pseudo-Scylax), Strabo, and Pliny do not refer directly to Rize as a settlement, their accounts offer insights into the political conditions and general characteristics of the region. In later periods, works by Arrianus, Ptolemaeus, and Procopius begin to mention Rize more explicitly. These travel accounts cover a timeline from the 6th century BC to the 4th century AD. The medieval period, however, remains obscure for the city's history, as no primary written sources concerning Rize from this era have been discovered.

Herodotus's *Histories*, written in the 5th century BC, provides comprehensive information about the political structures, social life, and major wars in the Black Sea and Anatolian regions (Herodotus, 1973). Although Herodotus does not mention Rize directly, his references to the ancient Colchis region and its ethnic groups offer valuable insights into the socio-cultural structure of the area during Antiquity (Herodotus, 1973). He describes the migration of the Scythians into the Colchis region from the north and their subsequent dispersal across Asia following their defeat by the Medes. While Herodotus's historical framework provides a general perspective on the early history of the region, more direct references to Rize emerge only with Arrianus's *Periplus of the Euxine Sea* written in AD 131. While the historical framework provided by Herodotus offers a general perspective on the early period of the region, the accounts of travelers up until Arrianus's *Periplus of the Euxine Sea* (AD 131) do not directly address the city of Rize. Works such as Xenophon's *Anabasis* (4th century BC), the *Periplous* attributed to Pseudo-Skylax, Strabo's *Geographica* (Strabo, 2025), and Pliny the Elder's *Naturalis Historia* (Pliny, 2025) provide an indirect historical foundation by describing the geography, climate, early population movements, and interactions between Colchis and neighbouring civilizations. These texts are significant sources that can be considered indirect references for the historiography of Rize and its surroundings in Antiquity (
Fig. 1).



(a) (b) (c) (e)

Fig. 1. Ancient Greek travel books's ancient manuscripts (a) A fragment from Herodotus's *Histories*, located in the Papyrology Room of the Sackler Library, (b) Xenophon's Anabasis, published in New York by Leavitt & Trow in 1843, (c) Ancient Greek Periplus of Scylax National Library of France, Department of Manuscripts, (d) First page of the Pliny's "Historia Naturalis" printed by Johann of Speyer

The earliest written source providing direct information about Rize is Arrianus's *Periplus of the Euxine Sea*, written in AD 131. This work is of great importance as it is the first reference to the name Rize in ancient literature.

Arrianus's observations of the region include not only geographical and strategic information about the Black Sea coast but also local settlement names, marking Rize's first documented appearance in history. Based on the mention of the Rhizius River, and considering the distances and place names given by Arrianus, it is understood that the river passes through what is now the city center of Rize. This is significant as it suggests that the city of Rize is named after a river and provides insight into the region where the city was first established (Arrianus, 2005).

Ptolemaeus, in his *Geography* written in the 2nd century AD, mapped the known world of his time and discussed major settlement areas. In his work, he mentions the Rizous Harbor along with important Black Sea ports, recording settlements and the distances between them (Ptolemaeus, 2025). His reference to Rizous Harbor is important both in showing the existence of this region in antiquity and in establishing Rize as a port city by AD 150. This information helps us understand the continuity of settlement in the region and places Rize within the economic and commercial network of the Black Sea region (

Fig. 2).

Procopius's *History of the Wars* and *On Buildings*, written in the 6th century AD, are also key written sources for information about Rize during the early Byzantine (Eastern Roman) period. *History of the Wars* is important for its detailed description of the boundaries of the Roman city of Rhizeum, while *On Buildings* is significant for its account of the urban development activities in Rize during the reign of Emperor Justinian.

(a) (b)

Fig. 2. Greek texts that directly mention Rize City (a) Start page of Periplus of the Euxine Sea (Arrianus, 1533), (b) Ptolemaeus's Geographia map showing the region of Colchis

In a region with limited archaeological and written data from the pre-Ottoman period, it is necessary to address the Rize Castle, which sheds light on the area's historical past. Although it does not serve as a written document, the physical presence of the castle -its architectural features, location, and construction techniques- provides the opportunity to draw inferences about the city's settlement history and physical fabric during the pre-Ottoman period (

Fig. *3*). In Procopius's "On Buildings," the newly constructed defensive structure he mentions is likely the Rize Castle that still stands today, and it is understood to be located in the area where the city was originally founded. In this regard, architectural structures, in addition to written documents, can be considered valuable sources that complement the limited information provided by early period travel books.

Fig. 3. 2024 Year Rize Castle (Author Archive)

3. Primary Sources from the Ottoman Period

After Sultan Mehmed the Conqueror's (Mehmed II) conquest of Trabzon in 1461, the districts of Atina (Pazar), Hemşin, and Arhavi in the Rize region were incorporated into the Ottoman Empire shortly thereafter. According to historical sources, it is known that the conquest of Rize occurred approximately one month after the capture of Trabzon (Ak, 2000; Aksu, 1968; Bostan, 2002).

After the Ottoman conquest, the city's historical topography can be traced in greater detail compared to the previous period, thanks to the existence of primary sources and a significant amount of literature. Early Ottoman documents are an important source group for the city of Rize, where data from the Ancient and Medieval periods are scarce. Inscriptions, waqf records, Tahrir Registers (cadastral records), Şer'iyye Registers (court records), travel books, annuals, maps, and visual materials, which provide a rich source of information about Rize and its surroundings, are the primary sources for the city's architectural and art history. In addition to these documents, which nearly continuously reveal the physical development of the city between the 15th and 20th centuries, military and administrative documents containing information about Rize's defence organization, castles, and military units sent to the region also hold valuable data and clues. Together, these sources contribute to the development of a comprehensive perspective on the city's historical continuity, physical fabric, and social dynamics.

3.1. Tahrir Registers (Cadastral Records):

The oldest Tahrir Registers that provides information about Rize's demographic structure after the conquest is the 1486 Tahrir Register.(Bostan, 2002). The Tahrir Registers from 1515 to 1583, compiled after 1486, are also important documents that illuminate 16th-century Rize (Bostan, 2002; Ak, 2000).

The registers kept during this period of Ottoman rule over Rize were created to document provincial administration and to systematically manage the taxation system. They contain detailed data on population, property, and production relations. Particularly, Hanefi Bostan's 2002 work, “XV-XVI. Asırlarda Trabzon Sancağında Sosyal ve İktisadî Hayat”, offers significant evaluations regarding the changing demographic structure of the city following the Ottoman conquest, the neighbourhoods inhabited by Muslim and non-Muslim communities, and the likely locations of these neighbourhoods, based on these registers (Bostan, 2002).

The names of districts, neighborhoods, and villages in the tahrir registers provide important clues for understanding the changes in the boundaries of the regions that encompass the center of Rize (Nefs-i Rize), the western part of the city (Akrotil), and the eastern part of the city (Emare) during the Ottoman period, as well as the subsequent subdivision of these areas into smaller neighbourhoods. These documents not only offer indirect information on the locations of neighbourhoods within the city but also contain detailed data on population, household numbers, religious affiliations, and economic activities, shedding light on the social structure. Additionally, the records provide insight into the development activities and include information about waqf (vakıf) properties. The tahrir registers meticulously recorded the assets and income sources of waqfs belonging to religious and educational institutions such as mosques, madrasas, and tekkes established in Rize. Through these records, traces of the history of some buildings that still exist today can be traced, and it is also possible to identify structures that no longer exist or those that were demolished and rebuilt over time. All these data allow for a chronological and comparative evaluation of the physical and institutional development of Rize, offering an indispensable reference source for urban historiography.

3.2. Salnames (annuals) of the Trabzon Province

The Salnames of the Trabzon Province are an important group of sources providing information about the Black Sea region during the 19th-century Ottoman period. In the Salnames of the Trabzon, Rize is mentioned as a district governed from the center of the Trabzon Sanjak (district) between 1869 and 1876. After the Ottoman Empire ceded Batum to the Russians in 1877, Rize was separated from the Trabzon Sanjak and became the center of the Lazistan Sanjak. Consequently, in the Salnames (annuals) of the Trabzon Province from 1877 to 1904, Rize was elevated from a district status to a sanjak (subprovince) within the Lazistan Sanjak (1877 Salname of the Trabzon Province)

The Salnames of the Trabzon Province, covering the period from 1869 to 1904 and containing information about Rize, were translated into Turkish by Kudret Emiroğlu and published in Latin script by the Trabzon Foundation between 1993 and 2009. In these salnames, it is possible to find a wealth of information about the city's history, as well as detailed records of structures such as medreses, mosques, hammams, fountains, and inns, along with population data for the entire sanjak, distance tables, and annual production statistics. Additionally, some sections of the salnameler, titled “Malumat (information) about Rize,” contain specific explanations about the city’s history or current events. Expressions like "Hamam-ı Cedid," "Medrese-i Atik," and "Atik Han" provide valuable insights into the structures that existed in the city during the Ottoman period.

3.3. Rize Şer-iyye Registers:

Another important source group that provides highly interesting and original information for the writing of urban history is the "Qadi registers" or "court records." These sources, covering the period from the classical era to the Republic, shed light on the multifaceted relationships between individuals and society, as well as individuals and the state (İpşirli, 1991). As registers that document all information under the knowledge of women, such as legal disputes, construction, exploration, and repair decisions, they serve as memory sources containing any matters related to urban life.

It is known that the earliest Rize Şer-iyye register was kept in 1854. The Rize Şer-iyye Registers, maintained until the early 20th century, explicitly state the names of the parties involved in a lawsuit, the neighborhoods where the parties resided, and the names of the administrative units the neighborhoods were part of. This information is crucial for understanding the formation of the city during that period. Furthermore, although no information may be found about the physical structure of a building mentioned in the records, whether related to social events, foundations, repairs, or property sales, the mention of its name and location still helps identify the city's layout during that period. Additionally, references to philanthropists's contributions to the construction of mosques and madrasas, as well as the income from their foundations, enable the identification of historical buildings that once existed in the city or provide insights into the old names of such structures.

For example, in the 1495 Rize Şer-iyye Registers, the entry stating that a baby was found in the courtyard of the "Orta Cami-i Şerîf" reads "…kasaba-i mezkûre derûnunda kâin Orta Câmi'-i Şerîf havlusunda bulunmağla iltikāt olunub ebeveyni ma'lûm olmayub malı dahî olmadığı hâlde liecli'l-irdâ' ve't-tebennî…" This statement indicates that the Orta Camii was standing between 1869 and 1871, as recorded in the Shari'a register, and that it was referred to by the same name used today (Rize Şer'iyye Register No. 1495).

3.4.Travel Books

Travel Books, like in the Ancient Period, are important in the Ottoman Period as well for understanding the general structure of the city. Rize became a city that attracted the attention of various travelers and observers during the Ottoman period; these individuals documented their impressions of the city. Some of the main figures who provided information about Ottoman Rize include Defterdar Sarı Mehmed Paşa, Per Minas Bijişkyan, Victor Fontanier, James Brant, Karl Koch, and Şâkir Şevket. These works provide information about Rize's physical and natural environment, maritime and port activities, commercial movements, and agricultural production.

Defterdar Sarı Mehmed Paşa's "Zübde-i Vekayiât," written between 1656 and 1704, is an important source for Ottoman historiography of its period. Having served in the state's finances, Sarı Mehmed Paşa provides detailed information about financial policies and the provincial organization. In this context, he mentions the active use of Rize Port, located at a strategic point near the border during the Ottoman-Russian wars, for military supplies and ship docking (Defterdar Sarı Mehmed Paşa, 1995).

Per Minas Bijişkyan, who carried out observations along the northern and southern coasts of the Black Sea between 1817 and 1819 due to his role (as a vicar-priest) in the region, offers detailed insights into the port cities he visited in his work "Karadeniz Kıyıları Tarih ve Coğrafyası." In the Rize section of his work, Bijişkyan provides information about the city's location, its neighborhoods, the agricultural products grown in the region, and important buildings constructed in the city (Bijişkyan, 1969). He also offers interesting insights into the origin of Rize's former name, Rhizius (İrizios).

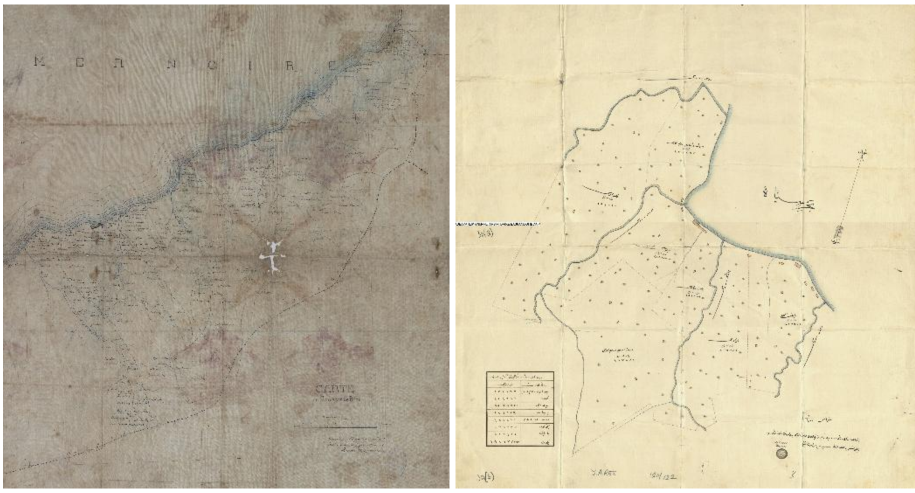
Among the city's visitors were political officials, soldiers, consuls, natural scientists collecting plants and insects, archaeologists, historians, geographers, and geologists. Victor Fontanier, a French consul, wrote "Notice sur la côte de la Mer Noire, appelée Lazistan" (Notes on the Black Sea Coast, Known as Lazistan), a unique and significant source containing travel observations about the eastern Black Sea coast of the Ottoman Empire in the 19th century (Yılmaz, 2014). In 1831, during his visit to Lazistan (Rize), Fontanier thoroughly explored the region. His work describes the city's built environment and geography in detail. Fontanier discusses the appearance of houses built by the local people, the state of Rize Castle, the location of the marketplace, and the natural environment. Similarly, James Brant, another consul stationed in the region, wrote "Journey Through A Part of Armenia and Asia Minor," a travel book containing detailed observations of his travels in Ottoman lands in the first half of the 19th century. Brant, during his tenure as England's consul in Trabzon, documented his travels in the eastern Anatolian region and Black Sea coasts, providing insights into Rize as well (Brant, 1836). He mentions Rize's fertile land, the agricultural products grown there, the renowned linen fabric produced, and the large marketplace on the city's coastal area.

Karl Koch, a German botanist and naturalist, wrote about his observations in Ottoman lands during his travels in 1843–1844 in his book "Wanderungen im Oriente während der Jahre 1843 und 1844" (Prof. Dr. Karl Koch's 1843-1844 Journey in the Eastern Black Sea Mountains and Northeastern Anatolia). His travel book provides detailed descriptions of 19th-century Rize, documenting the city's physical appearance, natural environment, agricultural production potential, and daily life practices of the people. Koch observed Rize's relationship with the sea, its settlement pattern, and the people's main livelihoods. The book includes information on Rize's history and the state of Rize Castle during that period. Koch's accounts not only shed light on the physical environment but also on the simple lifestyle, clothing, and cultural traditions of the local people, contributing to the understanding of the region's historical and social fabric. The work is significant for offering insights into how Rize was perceived in Europe during the mid-19th century and how scientific circles evaluated the region.

Observations about the region were not limited to foreign travelers; local historians also provided valuable information about Rize and its surroundings. One such historian, Şâkir Şevket, did not travel to Trabzon like the other travelers but wrote about the region with the local knowledge acquired from being born and raised in Trabzon. Born in 1847 in the Ortahisar district of Trabzon, Şâkir Şevket sheds light on the history of various settlements along the eastern Black Sea coast, including Rize, in his 19th-century work “Trabzon Tarihi.” Şâkir Şevket discusses Rize's historical, geographical, and commercial aspects and mentions an old building in the city, possibly Rize Castle, along with Bijişkyan’s views about the city's name.

3.5. Maps and Sketches:
The desire to observe urban space and to depict these observations has existed since the earliest periods of history. Maps are a product of humanity’s efforts to better understand and familiarize itself with its surroundings. Most maps are found either in private archives or scattered across various thematic studies.

The earliest surviving map produced for Rize, based on modern cartographic knowledge, dates to 1894, and in this map, only the place names within the city are indicated. In later maps and sketches, it is possible to observe that structures began to be depicted as well. Such maps serve as important sources that help explain the city's spatial changes and transformations. By superimposing maps prepared for different periods, it becomes possible to evaluate aspects such as the building stock, transportation networks, and other urban potentials (
Fig. 4,
Fig. 5).



(a) (b)

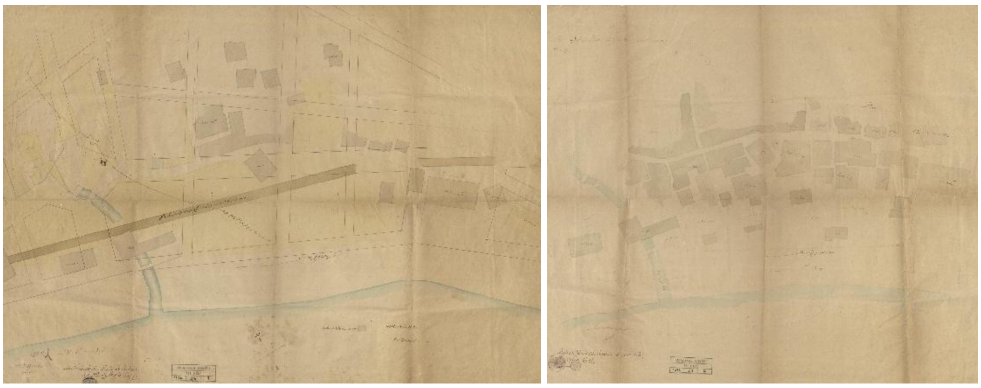

Fig. 5. The 1918 Map Depicting the Structures in the City of Rize (BOA, ML.EEM. 1336-39)

3.6. Photographs:
Visual documents that offer a glimpse into the past serve as realistic and objective evidence for historians, making them significant sources in historical research. Photographs are among the most tangible visual materials that enable the physical perception of a city. The earliest known photograph of the city of Rize appeared in the Servet-i Fünûn Journal in 1896 (Fig. 6).

In addition, the images included in Sultan Abdülhamid II's photographic album are among the oldest visual records of the city of Rize. Their direct depiction of historical structures makes them particularly significant for the architectural history of the city (Fig. 7).

Apart from these documents, it is believed that the first civilian photograph of the city was taken in 1907 (Fig. 8).

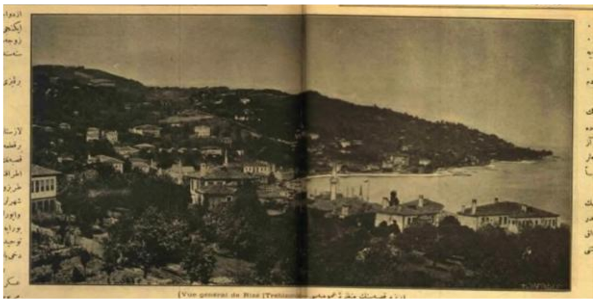

Fig. 6. The general view of the city of Rize in 1896 (Servet-i Fünûn Journal, 1896)

Fig. 7. The photographs of Rize featured in the album of Sultan Abdulhamid II (URL-1)

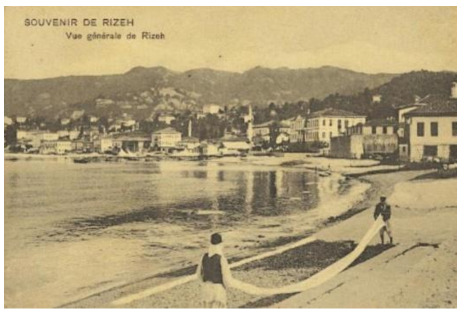

Fig. 8. The first civil photograph thought to have been taken in the city of Rize (Recep Koyuncu Archive)

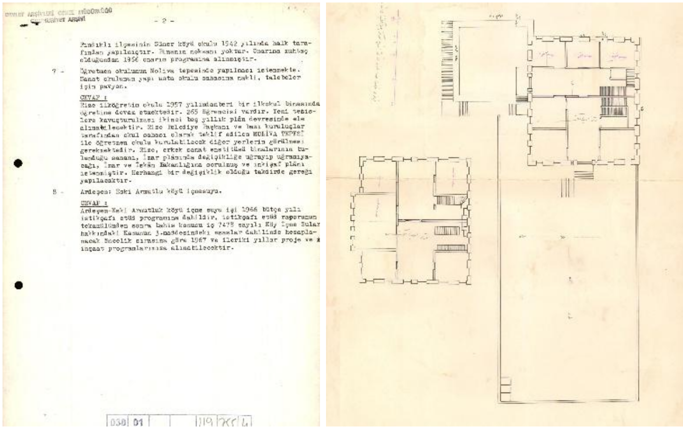
Rize photographs, as visual documents of the era, provide crucial data to be analysed alongside other written and visual sources. They not only trace the visual traces of documented structures but also help identify unknown buildings through maps and written sources in their environmental context. Ottoman-era photographs offer visual data on Rize's social structure and daily life. These images allow a more concrete evaluation of the clothing, agricultural activities, social events, and daily tasks of Rize's people.

4. Primary Sources from the Republican Era

Until the Republican era, Rize was known as the Lazistan Sanjak; it became a province one year after the declaration of the Republic (Aksu, 1968). In 1933, Rize was merged with the Artvin province to form a single administrative region, but by 1936, the provinces were separated again, and the city regained its original name, Rize (Rize Gazetesi, May 25, 1933; Rize Gazetesi, January 25, 1936).

After Rize became a province, significant urban development activities began. The development of tea cultivation, which was tested in the 1920s and became widespread in the 1940s, strengthened Rize economically. After 1960, significant advances were made in urbanization. Urban development, agricultural transformation, and urbanization during this period can be traced through primary sources such as official correspondence, municipal reports, local newspapers, maps, and photographs.

4.1. Administrative and Bureaucratic Documents:
The Presidential Republican Archive is key to understanding Rize's development, its relationship with central administration, regional responses, and the impact of government policies. The archive contains documents on the state's administrative plans, local government relations, and public investments. Reports, correspondence, and budget decisions from civil administrators in Rize provide important data on the city’s economic and social transformation. It also includes visual materials like photographs, drawings, and plans of the city's buildings. (Fig. 9).



(a) (b)

Fig. 9. Administrative Documents from the Republican Era (a) Correspondence Identifying the Needs of Rize Province in 1966 (BCA, 30-1-0-0. 119-755-4), (b) Plans of the Rize Secondary School Building from 1928 (BCA, 180-9-0-0. 97-473-7)

4.2. Municipal and Provincial Yearbooks:
Municipal and provincial yearbooks are official publications prepared periodically, documenting the urban development activities in Rize, as well as the city’s agricultural activities, socio-economic structure, and social change. These yearbooks include information on infrastructure projects within municipal services, as well as services in areas such as education, health, sanitation, and transportation, along with population data, budget information, and aspects of social life in the city (Fig. 10, Fig. 11).

Yearbooks, published in 1967, 1973, and 2002, are important reference sources for tracking the physical and institutional changes/transformation of Rize during the Republican era. The statistical tables, city maps, and visual materials such as photographs included in the yearbooks provide detailed information about the city's physical fabric.

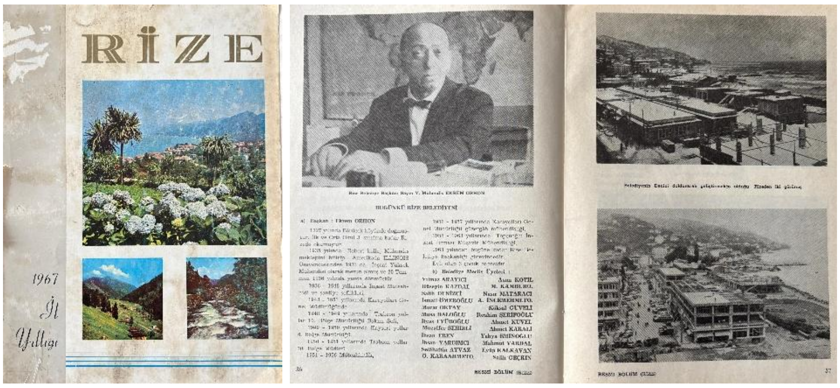


Fig. 10. 1967 Rize Provincial Yearbook

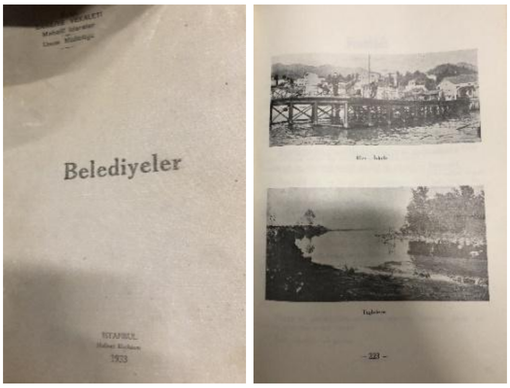

Fig. 11. 1933 Municipal Yearbook

4.3. Newspapers and Journals:

The written press holds significant importance in historical research as it directly reflects the events, debates, and public sentiment of a period. Local newspapers and journals in Rize during the Republican era form a live archive of local history by documenting the city's agenda, issues, developments, and expectations, while reflecting the political, social, and cultural structure of the time. From these newspapers, it is possible to trace the development of urban activities, as well as the destruction, construction, and restoration of important buildings. The Rize Gazette, the city's first newspaper, was published in 1931 and continued until 1942. As the only newspaper in Rize during the early Republican period, it contains valuable information about the city’s urbanization process. After the 1950s, important local newspapers such as Rize'nin Sesi, Rize, Zümrüt Rize, Şirin Rize, and Memleket Gazetesi emerged. Additionally, major national newspapers such as Akşam, Cumhuriyet, Son Posta, Hakimiyet-i Milliye, and Ulus, which provided significant information about Rize, were also notable during this period (
Fig. 12).

Rize

Fig. 12. Local and national newspapers providing information about Rize: (a) Rize Gazetesi, dated August 6, 1931, (b) Akşam Gazetesi, dated October 9, 1938.

4.4. Travel Books:

In the early years of the Republic, memoirs and travel writings by authors who travelled to Rize provide valuable insights into the city's social fabric and daily life. These texts detail Rize’s natural environment, architecture, street life, the clothing of its people, hospitality, and economic activities. Notable travel writings about Rize from the Republican era include Mirza Gökgöl's " Doğu Karadeniz Bölgesinde Bir Araştırma Gezisi" (1937), Selahattin Çoruh’s "Ankara’dan Rize’ye" (Çoruh, 1948), and Abdullah Taymas's "Yeşil Rize ve İli Province" (Taymas, 1950) (
Fig. 13). Also, "The Byzantine Monuments and Topography of The Pontos" (Bryer & Winfield, 2020), a two-volume work prepared by Anthony Bryer and David Winfield in 1985, although not a direct travel books, provides significant information about the city's settlement history. It identifies existing and lost structures, offering valuable insights into their condition during the relevant period.

Fig. 13. The travel account *Ankara’dan Rize’ye*, authored by Selahattin Çoruh

4.5. Maps and Urban Plans:
Maps, plans, drafts, and sketches have become crucial sources for local history, particularly for the 19th and 20th centuries. In this context, the development of modern cartography during the Republican era and the presence of urban planning maps are highly significant. These documents help us understand the urban planning perspective of the time and the development of urban and rural areas in the city.

According to the Municipal Law enacted in 1930, which assigned municipalities the responsibility of preparing city plans, urban planning efforts in Rize began in the 1930s. French urban planner Lambert, Governor Mehmet Hurşit, and other municipal leaders played key roles in these efforts (Bay, 2023). Based on available data, it was decided in 1939 to prepare a cadastral map of Rize’s 300-hectare residential and non-residential area (Ulus, May 26, 1939). In June 1939, the contract for preparing this cadastral map was awarded to engineer İbrahim Rahmi Arı. However, while the cadastral map was completed, the urban plan was not prepared until 1946. Arı’s cadastral map has not survived to the present day. In 1946, the urban plan for Rize was prepared and approved by Nezihe and Pertev Taner. The plan was published in the Arkitekt magazine in 1947. The map is valuable not only for representing the period but also for explaining the urban planning policies that aligned with the era’s political context (Kaçıran, 2024) (Fig. 14,

Fig. 15,

Fig. 16,

Fig. 17).

4.6. Photographs:
Photographs from the Republican period offer a relatively rich visual archive compared to earlier eras and can be categorized into themes such as individual buildings, panoramic city views, and scenes from social life. The increase in photographs of the city during this period makes those taken from the early years of the Republic essential sources for studies on Rize’s urbanization, architectural development, infrastructure investments, and daily life practices (
Fig. 18). Images of public ceremonies, mass events, and natural disasters illuminate the city's social structure, while panoramic views provide information on street texture, the location of extant or lost structures, and architectural features. Advances in photography, allowing images from similar angles or aerial views across time, enable analysis of the city's physical transformation. By capturing space, time, and people within a single frame, these images serve as essential visual sources for tracing the layers that shape the city's identity.

5. Conclusions
The archival documents are indispensable sources for historians in addressing the issue of finding “sufficient” and “accurate information” in the historical analysis of cities. These documents allow the tracing of events that

occurred centuries ago, from their causes to their consequences. Not only can these documents provide valuable information about the architectural history of cities, but they also offer insights into their economic, social, and political conditions. Particularly, the primary sources discussed here, along with studies on social, political, and economic history, provide essential information for architectural history researchers, especially those involving direct transcription works.

Rize city has experienced a unique development process in many aspects throughout history due to the natural isolation caused by its geographical structure. This isolation has led to limited written and visual sources related to the city's history, which, in turn, has contributed to the perception that Rize has no significant history and that the city's origins are not very ancient. However, the primary sources available today reveal that Rize has been a settlement area since the Ancient Period and has maintained its existence under the influence of various civilizations throughout history. Therefore, despite the scarcity of historical data, although the past of Rize city remains dark and filled with uncertainties, the city possesses an undiscovered heritage waiting to be explored.

After the first mention of Rize in historical sources in 131 ADS, the city is referenced in various ancient Greek travel books until the 6th century. Due to the lack of sufficient data from the Middle Ages, the city's history during this period appears obscure, but after the Ottoman conquest at the end of the 15th century, records about the city have survived to the present day. The first photograph of Rize, which provides an idea about its physical structure and building stock during the Ottoman period, emerged at the end of the 19th century, and with the increase in visual documents since then, it has become possible to gain concrete insights into the city's physical structure. The Republican Era represents a period when abundant data about Rize became available, and the physical environment of the city began to be fully illuminated. The transformation process in the city's physical structure occurred over an extended time frame, from the initial settlement period to the present day, within a social, economic, and administrative framework that involved many societal dynamics. The archival documents in question make it possible to analyse the dynamic historical topography of the city—monuments, residences, streets, squares, ports, etc.-and its changes/transformation.

This study presents a comprehensive evaluation of documents mostly found in personal archives or scattered in various thematic works. However, it cannot be said to be exhaustive. It is highly probable that there are still undiscovered documents in foreign archives. The existing and awaiting documents are undoubtedly unique in clearly revealing the physical transformation of the city of Rize, which we know has undergone significant interventions.

Acknowledgments
This study is based on the Adem Kaçıran's master thesis completed under the supervision of Assoc. Prof. Dr. Fulya Üstün Demirkaya in 2024. However, in the course of preparing the paper, the references, as well as the data and information, have been updated to the extent possible.

Customized Kutahya pozzolan and metakaolin-based geopolymers for stone conservation: Initial findings on mechanical properties

Zeynep Sena Karkaş*[1], Seden Acun Özgünler[1], Elif Tuba Alhan[1]

[1] İstanbul Technical University, Faculty of Architecture, İstanbul, Türkiye

Abstract. Geopolymers are inorganic materials utilized primarily as alternatives to cement, owing to their workability, customizability, non-toxicity, and high strength characteristics. These properties offer innovative alternatives to existing stone repair materials, which are usually cement-based mortars that do not adapt to the original stone material and cause many serious damages. Therefore, this study aims to produce tailor-made geopolymer binders for repairing historical stone structures and initially investigate the mechanical properties. In this context, firstly, the geopolymer binder mixtures were prepared at different ratios of metakaolin and Kutahya volcanic pozzolan while keeping the SiO_2/Al_2O_3, Na_2O/Al_2O_3, Na_2O/SiO_2 and H_2O/Na_2O proportions constant and the mechanical properties (compressive and flexural strength) of the geopolymer binders were evaluated. Secondly, based on the results, geopolymer mortar mixtures with a binder/aggregate ratio of 1:1 and 1:2 was prepared using natural limestone (Kufeki) powder as an aggregate, and their mechanical properties were evaluated. Moreover, since the future use of geopolymer in the restoration sector is significant, laboratory temperature was used for curing conditions (20±2 °C and 50±5 % relative humidity) in this study to simulate outdoor conditions. The compressive and flexural strength results are promising when compared to the technical specifications of certain ready-mixed stone repair mortars utilized in significant historical stone buildings abroad. This study indicates that metakaolin-natural volcanic pozzolan based geopolymer may be explored as a viable environmentally friendly alternative binder for stone repair mortars in future applications.

Keywords: Stone repair mortar, Geopolymer, Metakaolin, Natural volcanic pozzolan, Cultural Heritage

1. Introduction

Different types of natural stones have been used as traditional materials in historic monuments worldwide. Even though natural stones are known for their durability and longevity, they are susceptible to chemical weathering, physical degradation, and biological factors which mean that they cannot be classified as a truly inert material. Over time, this deterioration process especially affects architectural details exposed to external factors, causing cracks, surface loss and fragmentation of stone elements. Plastic repair techniques are used in conservation practices to eliminate such material losses and restore both the structural integrity and aesthetic value of historical stone monuments. This method is also known by various terms such as stone repair mortar, stone patch, surface fill and stone imitation (Válek et al., 2019; Isebaertet al., 2014;Ashurst & Ashurst, 1988). This method utilizes specially formulated mortars compatible with the original stone, that enable the reconstruction of missing or damaged areas and ensure the preservation of the monument's authenticity and durability (Válek et al., 2019).

Nowadays, two primary approaches are used in the design of plastic repair mortars for natural stones. The first approach is based on ready-mixed stone repair mortars, which are preferred for their ease of application and consistent quality. However, these products show significant limitations when selecting by users, such as lack of transparency regarding performance data, mortar composition information and non-standardized testing, as well as the inability to adapt to project-specific requirements (López-Arce et al., 2016; Lubelli et al., 2021; Török & Szemerey-Kiss, 2019).

Furthermore, differences in the manufacturing processes of products can cause significant performance differences between batches. As a result of this, concerns about the durability and consistency of repairs over time (Válek et al., 2019). A recent study on commercial repair mortars revealed different chemical and mechanical properties for each mortar compared to different substrates (Lubelli et al., 2021).

* Corresponding author, E-mail: karkas17@itu.edu.tr

https://doi.org/10.31462/icearc2025_a_car_568

The second approach involves designing custom stone repair mortars based on the characteristics of natural stones in order to create a composition that matches the original stone substrate as closely as possible (Isebaert et al., 2019). White cement is the most commonly used binder in many restoration projects for reconstructing missing stone parts due to its desirable color and relatively low sulphate and alkali contents (Papayianni, 2022; Papayianni et al., 2015; Stefanidou et al., 2015). Although cement-based mortars have good mechanical strength properties, their low deformability under large thermal cycles may be dangerous. This is because their high density and low porosity, coupled with high coefficients of thermal expansion, can impact natural stones (Quist et al., 2018; van Hees et al., 2002). Given the drawbacks of white cement, various environmentally friendly materials, such as geopolymers, have recently been investigated as binders in the preparation of repair mortars (Clausi et al., 2016; Van Roosmale et al., 2023). There are different types of geopolymers, which are inorganic, each with unique properties that can be modified by the accessible raw materials, aggregates and alkaline materials used (Cong & Cheng, 2021).

Initial studies on producing of geopolymers in heritage conservation have generally used metakaolin as a precursor (Clausi et al., 2016; Pagnotta et al., 2020; Ricciotti et al., 2017; Van Roosmale et al., 2023). In these studies, curing conditions at room temperature have been adopted to simulate outdoor environments during the development of geopolymer binders for stone repair in historical buildings because of its applicability (Clausi et al., 2016; Van Roosmale et al., 2023) However, many studies have investigated the possibility of the use of natural pozzolans to obtain geopolymers as an alternative to traditional cement (Bondar et al., 2010, 2011a, 2011b; Robayo-Salazar et al., 2016; Tchakoute et al., 2013).

On the other hand, their semi-crystalline nature constrains their effectiveness as the main precursor, particularly at room temperature (Robayo-Salazar et al., 2016; Tchakoute et al., 2013). For this reason, metakaolin is generally added to facilitate geopolymer formation and enhance reactivity under ambient conditions (Djobo et al., 2014; Robayo-Salazar et al., 2016; Tchakoute Kouamo et al., 2012).

Currently, there has been little or no research which focus on the combined the use of natural pozzolan and metakaolin materials in the field of stone conservation. Recognizing this gap, the aim of this study was to investigate whether such a combination could offer a viable solution for use in plastic repair of natural stone materials. In addition to this, the literature review highlights that the ratios of SiO_2/Al_2O_3, Na_2O/Al_2O_3, Na_2O/SiO_2, and H_2O/Na_2O, depending on the type of alkali activators used, significantly influence the mechanical properties of geopolymer binders (Davidovits, 1999; Ekiz Barış, 2022; Firdous et al., 2018; Palomo et al., 1999; Shi et al., 2006).

Therefore, firstly, these ratios were kept constant in geopolymer mixtures prepared with metakaolin and Kutahya volcanic pozzolan. The effect of varying metakaolin content on the compressive and flexural strength of the geopolymer binder system was examined under laboratory conditions (20 ± 2 °C and 50 ± 5% relative humidity) after both 7 and 28 days of curing. Based on the findings, secondly, geopolymer mortar mixes were produced using natural limestone (Kufeki) powder as aggregate, with binder-to-aggregate ratios of 1:1 and 1:2, and their mechanical properties were evaluated accordingly. Finally, the compressive and flexural strength results were compared with the technical specifications of certain commercial stone repair mortars commonly used in significant historic stone structures abroad.

2. Materials and methods

2.1. Materials

Kutahya volcanic pozzolan (NP) was first dried in a Memmert ventilated oven at 70 °C in order to remove its inherent moisture. Following this, the material was subjected to a series of grinding steps: initially in a RETSCH jaw crusher, then in a toothed mill to achieve particles below 1 mm, and finally in a ball mill for further refinement. Since particle fineness directly influences alkali activation reactivity, it contributes to improved mechanical strength (Firdous et al., 2018), appropriate sieving was performed. A review of the literature reveals that various studies on alkali-activated materials have employed different maximum particle sizes, including 90 μm (Ekiz Barış, 2022), 150 μm (Beghoura & Castro-Gomes, 2019), 200 μm (Tekin, 2016), and even up to 400 μm (Lemougna et al., 2011). In line with these findings, ground Kutahya volcanic pozzolan was sieved through a 150 μm mesh and subsequently stored in PE-coated containers to maintain its condition.

The metakaolin (MK) used as an artificial pozzolan in the mixtures was supplied by Kaolin Endüstriyel Mineralleri San. ve Tic. AŞ, located in Istanbul. The specific gravity of the metakaolin is 2.52 g/cm³. The combined content of silicon oxide (SiO_2), aluminium oxide (Al_2O_3), and iron oxide (Fe_2O_3) accounts for 97.18%, indicating a high pozzolanic activity. The chemical compositions of Kutahya volcanic pozzolan and metakaolin are presented in Table 1.

Table 1. Chemical composition of Kutahya Tuff and Metakaolin (%)

Material	SiO_2	Al_2O_3	Fe_2O	TiO_2	CaO	MgO	K_2O	Na_2O	Others	LOI
Kutahya tuff	72.57	11.67	1.39	0.06	1.07	1.07	5.92	1.03	0.27	4.95
Metakaolin	56.10	40.23	0.85	0.19	0.16	0.51	0.24	0.07	0.07	1.10

Sodium hydroxide (NaOH) was supplied by Kimyalab, while sodium silicate (Na_2SiO_3) was taken from ZAG Kimya LTD. The sodium hydroxide was provided in prill form with 99% purity, and potassium hydroxide was supplied in flake form with 90% purity. The Mod III sodium silicate solution, delivered in liquid form with 99% purity, had a molar ratio (SiO_2/Na_2O) of 2.74

Prior to the preparation of the solution mixtures, the NaOH was dissolved in deionized water and allowed to rest for 24 hours to ensure it was ready for use. In addition, natural limestone (Kufeki) powder sourced from Çatalca, Istanbul, was utilized as aggregate.

2.2 Mixture design

2.2.1 Geopolymer binders

For the synthesis of geopolymer binders, distilled water was added to the sodium silicate solution, which was then conditioned at 20 ± 2 °C and 50 ± 5% relative humidity for 24 hours. Following this period, solid sodium hydroxide was dissolved into the solution to modify its composition. Kutahya pozzolan was added to the prepared solution and mixed using a mortar mixer. The mixing process was carried out at a low speed (140 ± 5 rpm) for 60 seconds. Following this, water was incorporated and mixing continued at the same speed for an additional 60 seconds. The mixture was finally stirred at high speed (285 ± 10 rpm) for 180 seconds. After the mechanical mixing was completed, the remaining unmixed material manually mixed to the sides of the mixer was manually integrated so as to ensure homogeneity.

The fresh mortar was placed into molds (40 × 40 × 160 mm) and compacted by means of mechanical vibration for 60 seconds to eliminate trapped air bubbles. For each geopolymer binder formulation, three samples were prepared to ensure consistency and reliability in the tests. The fresh mixes were placed in molds that were covered with polyethylene (PE) sheets to prevent moisture loss and kept at 20 ± 2 °C and 50 ± 5% relative humidity for 2 days. After this initial period, the specimens were removed from the molds and allowed to cure under the same environmental conditions. The sample labels used for the synthesis, along with the constant ratios and corresponding water/solid ratios, are presented in Table 2. Furthermore, the production stages of the geopolymer binders are shown in Fig. 1 and the condition of the binder samples at the 7th day of curing is shown in Fig. 2.

Table 2. Details of geopolymer binders

Sample Code	NP (%)	MK (%)	SiO_2/Al_2O_3 (M)	Na_2O/Al_2O_3 (M)	Na_2O/SiO_2 (M)	H_2O/Na_2O (M)	Water/Solid Ratio
GP1	60	40	6.0	0.72	0.12	12	0.33
GP2	65	35	6.0	0.72	0.12	12	0.35
GP3	70	30	6.0	0.72	0.12	12	0.47

Fig. 1. Production stages of geopolymer binders

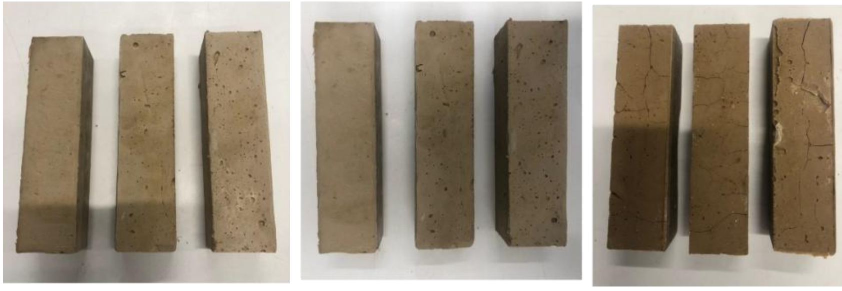

Fig. 2. The appearance of geopolymer binder samples on the 7th day of curing
(from left to right: GP1, GP2, GP3).

2.2.2 Geopolymer-based mortars

Geopolymer mortars with binder/aggregate ratios of 1:1 and 1:2 was prepared using geopolymer binders, respectively. Initially, the dry mixture of Kutahya pozzolan (sieved through 150 µm sieve diameter), metakaolin and aggregate was mixed for 5 minutes. This was followed by a gradual mixing process using a mortar mixer: the mixture was mixed at low speed (140 ± 5 rpm) for 60 seconds, then the activator solution was added and mixed at the same speed for another 60 seconds. Finally, the mixture was mixed at high speed (285 ± 10 rpm) for 180 seconds so as to ensure a homogeneous structure. This was followed by an additional 5 minutes of mixing with a mechanical hand mixer to further homogenize the mixture.

The fresh mortar was placed in molds (40 × 40 × 160 mm) and compacted by mechanical vibration for 60 seconds to remove trapped air bubbles. Three samples were prepared for each geopolymer binder formulation. To prevent moisture loss, the molds were covered with polyethylene (PE) sheeting and kept at 20 ± 2 °C and 50 ± 5% relative humidity for 2 days. After this period, the specimens were removed from the mold and left to cure under the same environmental conditions. The sample labels and proportions used for the synthesized geopolymer-based mortars are presented in Table 3, while the demolding and curing process of the NP+MK geopolymer mortar mixtures is illustrated in Fig. 3.

Table 3. Details of geopolymer-based mortars

Sample Code	NP (%)	MK (%)	Binder/Aggregate ratio	Water/Solid ratio
GP1-1	60	40	1/1	0.40
GP1-2	60	40	1/2	0.40
GP2-1	65	35	1/1	0.49
GP2-2	65	35	1/2	0.49
GP3-1	70	30	1/1	0.47
GP3-2	70	30	1/2	0.47

Fig. 3. Demolding and curing of NP+MK geopolymer mortar mixtures
(from left to right: GP1-1, GP2-1, GP3-1).

2.3 Test methods

Flexural tensile strength for each hardened geopolymer binder and mortar mixture was evaluated by means of three prismatic samples tested under the third-point loading method, in accordance with TS EN 1015-11. On the other hand, compressive strength was measured using six fragments obtained from the broken halves of these prisms after flexural testing (TS EN 1015-11, 2000). The reported values represent the average of three specimens for flexural strength and the average of six fragments for compressive strength.

3. Result and discussion

This study examined the compressive and flexural strength behavior of geopolymer binders and mortars which are formulated with different proportions of natural pozzolan (NP) and metakaolin (MK). Tests conducted at 7 and 28 days highlighted that, in addition to binder composition, the water-to-solid (W/S) ratio and binder-to-aggregate (B/A) ratio also had a meaningful impact on mechanical properties. Furthermore, in order to isolate the component effects on the mechanical properties, the SiO_2/Al_2O_3, Na_2O/Al_2O_3, Na_2O/SiO_2 and H_2O/Na_2O ratios were kept constant in all samples.

When examining the compressive strength data obtained from the GP1, GP2, and GP3 series samples (Fig. 4), it was observed that the highest compressive strength was achieved in the GP1-1 sample (Fig. 5), which contained 40% MK and had a water-to-solid (W/S) ratio of 0.40 (9.00 MPa at 28 days). This outcome can be attributed to the high soluble Al_2O_3 content of MK, which promotes the presence of a large amount of amorphous aluminosilicates within the system. As previously reported in the literature (Tchakoute Kouamo et al., 2012, 2013), the addition of MK creates a more favorable environment for geopolymerization, unlike NP, which has a semi-crystalline structure. Having a better understand about these kinds of microstructural developments will be possible via a comprehensive examination of the geopolymer binder's microstructure.

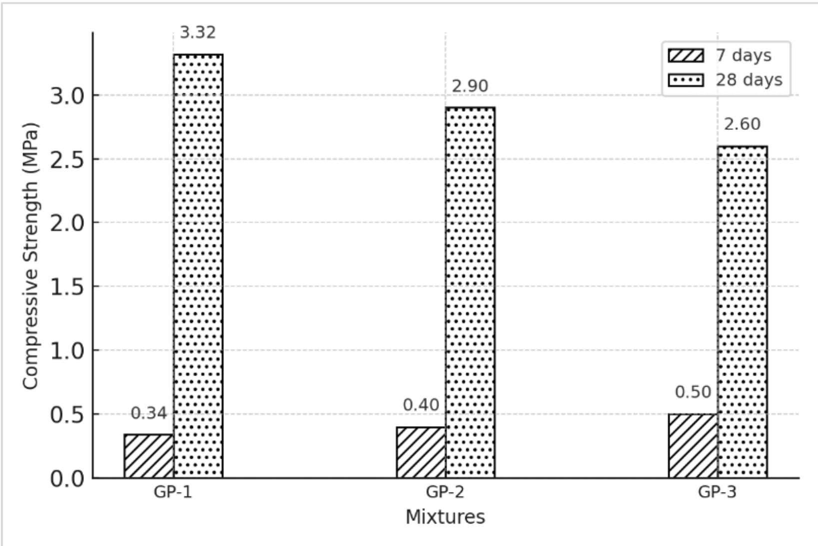

Fig. 4. Compressive strength of geopolymer binder mixtures

Fig. 5. The appearance of geopolymer mortar samples on the 28th day of curing (from left to right: GP1-1, GP2-1, GP3-1).

In the GP1-2 and GP2-2 samples, in which the binder-to-aggregate ratio was increased to 1/2, a significant decrease in compressive strength was recorded (Fig. 6). In particular, the 28-day strength of the GP2-2 and GP3-

2 samples (Fig. 7) were measured at 4.77 MPa and 2.05 MPa, respectively. This reduction can be explained by the lower amount of binder and the decreased water retention capacity within the matrix. Furthermore, efflorescence observed in the GP3-2 sample (Fig. 7) — formed by the crystallization of excess sodium ions through carbonation on the surface— negatively affected the strength (Vickers et al., 2015).

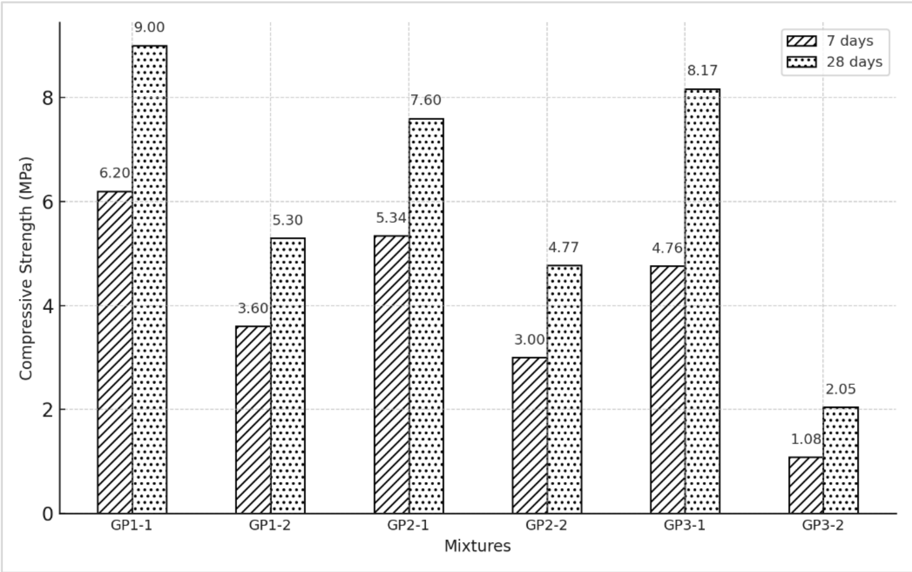

Fig. 6. Compressive strength of geopolymer mortar mixtures

Fig. 7. The appearance of geopolymer mortar samples on the 28th day of curing
(from left to right: GP1-2, GP2-2, GP3-2).

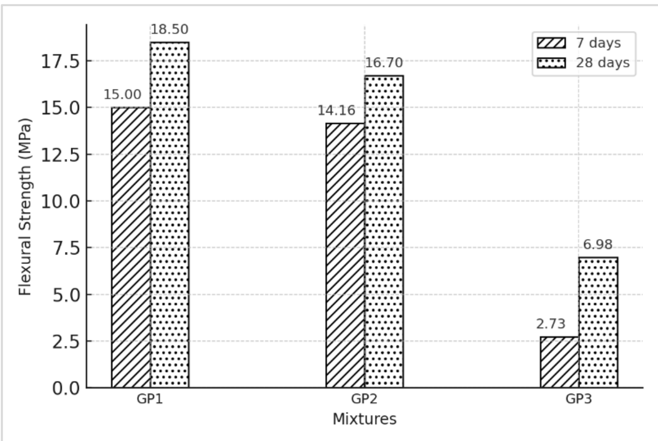

Fig. 8. Flexural strength of geopolymer binder mixtures

Flexural strength results followed a similar trend (Fig. 8 and Fig. 9). GP1-1 led with a value of 4.00 MPa at 28 days, reinforcing the benefits of high MK content and a lower water ratio (Fig. 9). A tightly bonded matrix may helps resist microcracking and enhances flexural performance.

On the other hand, the GP3-2 mixture, which had the lowest MK content (30%) and the highest water content (0.47), showed a compressive strength of just 1.29 Mpa (Fig. 9). The excessive amount of water likely interfered with gel formation, inducing a more porous and fragile structure (Clausi et al., 2016).

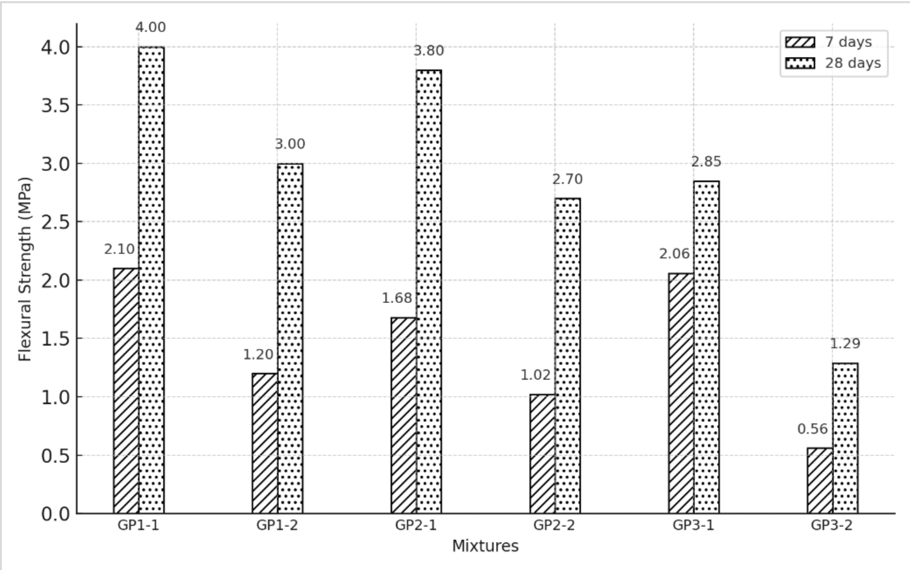

Fig. 9. Flexural strength of geopolymer mortar mixtures

The curing conditions used in the experiments to simulate ambient environmental conditions were set at 20 ± 2 °C and 50 ± 5% relative humidity (RH). However, this represents a lower humidity environment compared to the reported some values in the literature, such as 90% RH. This may have reduced the mechanical strength by means of slowing down the formation of aluminosilicate gel (Clausi et al., 2016; Robayo-Salazar et al., 2016). Moreover, the use of higher water content in some mixtures may have further intensified this effect and limited the strength development.

The mechanical performance of the developed geopolymer mortars was compared with that of several widely used commercial stone repair products, as summarized in Table 4. Among all tested mixtures, GP1-1 stood out with a compressive strength of 9.00 MPa and a flexural strength of 4.00 MPa at 28 days, outperforming all commercial references in terms of flexural behavior. Similarly, GP3-1 achieved strength values to some products, such as Jahn M70 and Bridevaux mortars.

It is important to note that these strength levels were reached under ambient curing conditions with relatively low humidity, without the need for heat condition or specialized environments. This highlights the potential of pozzolan and metakaolin-based binders according to their ratios as a sustainable and practical alternative to traditional cement-based restoration mortars.

Table 4. Compressive and Flexural Strength Comparison with Composition

Sample Code	Compressive Strength (28d) [MPa]	Flexural Strength (28d) [MPa]	Composition
GP1-1	9.00	4.00	NP 60% + MK 40%
GP1-2	5.30	3.00	NP 60% + MK 40%
GP2-1	7.60	3.80	NP 65% + MK 35%
GP2-2	4.77	2.70	NP 65% + MK 35%
GP3-1	8.17	2.85	NP 70% + MK 30%
GP3-2	2.05	1.29	NP 70% + MK 30%

Table 4 continued

Jahn M70	17.0-22.0	3.7-4.2	Mineral-based (URL-1)
Lithomex	7	-	Natural hydraulic lime, aggregates (URL-2)
Restoration Mortar ZF (Remmers)	8	5	Mineral-based (URL-3)
Artar Pierre	13	2.7	quartz aggregate, hydraulic binders, admixtures, and mineral pigments (URL-4)
Artopierre TF	2.4	1.3	Air lime + hydraulic lime, siliceous sands, organic additives, mineral pigments (URL-5)
Bridevaux	8.0-11.0	2.1-4.0	Mineral-based; lime, trass, white cement, additives (URL-6)

4. Conclusion

This research investigated how variations in NP/MK content, binder/aggregate ratio, and water/solid ratio affect the mechanical properties of geopolymer binders and mortars. Based on the experimental findings, the following conclusions can be drawn:

- Increasing the metakaolin content to 40% and lowering the water/solid ratio to 0.40 had a positive effect on both compressive and flexural strength.
- The 1:1 binder/aggregate ratio provided more consistent strength improvement than 1:2 mixes.
- The GP1-1 formulation offered the highest performance across all evaluated parameters due to its balanced design.
- The visible efflorescence showed that the importance of appropriate alkali ratio in order to provide mechanical stability and surface quality.
- The curing conditions used in this study were enough for comparative purposes, but likely limited for maximizing strength potential especially in NP-rich systems.

Moreover, when compared to many commercial stone repair mortars, the GP1-1 and GP3-1 formulations achieved compressive and flexural strength values within a competitive range. In particular, GP1-1 exceeded the flexural performance of all reviewed commercial products, which demonstrates its potential for use in restoration applications where crack resistance and cohesion are critical.

Overall, geopolymer mortars designed with high ratio of MK, lower water content and improved curing conditions represent a promising alternative to conventional cementitious binders. These systems demostrate strong potential for sustainable construction applications and may offer certain advantages in restoration or conservation works which durability and environmental compatibility are important.

Investigation of windows of traditional houses in Duzce-Prusias region

Onur Çelik*[1], Alper Bideci *[1]

[1] *Duzce University, Faculty of Art, Design and Arhitecture, Department of Architecture, 81000 Düzce, Türkiye*

Abstract. Turkey's rich cultural past has hosted many different civilizations throughout history, and this has shaped the country's rich cultural heritage. This diversity is not limited only to art, literature and music, but also makes itself felt strongly in the architecture of traditional Turkish houses. Traditional Turkish houses have a unique architectural structure shaped in line with local climatic conditions, social structure and cultural climates. Building elements also bear important traces in this original architecture.

This study involves examining the windows of traditional Turkish houses in the Prusias region of Düzce province. In the study, as a result of the analyzes made on three different buildings selected from the historical neighborhoods in the Prusias region, the condition of the windows of these buildings was discussed in detail. Through the studies carried out on traditional buildings, the functional features of the windows, their dimensions, wing opening directions, material properties, number of horizontal and vertical partitions, ornamentation and decoration details were examined. Window models were created by taking window surveys of each building and these window models were documented by taking photographs. As a result of the research, the unique structural and aesthetic features of the windows of traditional houses in the Prusias region were revealed; It was concluded that the windows should be repaired and protected. In this way, the window designs and aesthetic features of our traditional buildings have been left as a legacy to future generations.

Keywords: Düzce-Prusias Region, Traditional Turkish House, Window.

1. Introduction:

Turkey's cultural past is clearly evident in the unique architectural features of traditional Turkish houses. The Turkish house is an important type in world architecture literature, the most striking basic elements in the facade designs of these houses are the unique arrangements in the window rows and the distinct proportions on the facade surface. This rhythmic order that forms the facade offers a flexible analysis based on traditional measurements and proportions. Especially the window spaces and arrangements on the wall surfaces are not only a formal approach, but also a form of expression that bears the traces of a cultural and social lifestyle. In this context, the facade design of the Turkish house is seen as the architectural features of a traditional philosophy of life and cultural identity (Yüksek, 2004) .

For centuries, the purpose of benefiting from daylight has become an important factor in building design (Yener, 2008). Window joinery serves the function of illuminating and ventilating the interior of spaces in traditional Turkish houses. Openable and closed window sashes provide coolness in the summer months and contribute to the preservation of interior heat in the winter months. The layout and features of the equipment elements are planned according to ergonomic principles such as efficiency of use, order of use and storage. Fixed equipment in Turkish houses are the basic elements that provide functional shaping of the space. External factors in traditional Turkish houses, factors such as land structure, street and landscape relationship play a role in the distribution pattern. Similarly, the opening directions, proportions and dimensions of the windows are also affected by these factors. It is observed that especially the dimensions on the facades facing the landscape or the garden are larger and windows are used more frequently (Sakal & Kahraman, 2020). .

Traditional Turkish houses in different regions of Türkiye have their own unique structural features. In the architectural design of these houses, the window joinery among the façade elements also has a distinct originality. The preservation of the window joinery is important in terms of transferring these cultural formations to future generations.

1.1. Purpose:
The history of Düzce province, located in the Western Black Sea Region, dates back to the Hittite civilization that reigned between 1390-800 BC. In the historical process, Düzce has been under the influence of various tribes and states and today, people with different cultural identities live together (Kaya, 2023). Within the borders of Düzce province, there are important archaeological and architectural remains such as the Prusias region ancient theater, aqueducts, city walls and examples of traditional civil architecture. Düzce was separated from Bolu province and became a province on December 9, 1999.

The aim of this study is to examine the window joineries with unique architectural and structural features of traditional Turkish houses located in different regions of Anatolia in the Prusias region of Düzce province and to evaluate the usage characteristics, material properties and geometric appearances of the window models specific to the region.

1.2. Method:
For the purpose of this study: Traditional Turkish houses in the Prusias region within the borders of Düzce province were selected as the study area. These houses were divided into regions on the map and each was named and the window elements were examined in detail. The dimensions of the window elements were measured and damaged and divided sections were identified. The functional properties of the window models, the construction materials used and the usage details of these materials were investigated in detail and the work process was documented by taking photographs of the windows. Drawings of the window models were taken and drawings were produced in digital environments using the survey drawings and window models were extracted.

2. Information About Traditional Turkish House Windows:
Space comes into existence thanks to light. Light is among the important parts of structures surrounded by walls. Humans have opened gaps at certain intervals in order to provide light and air access to the space part that is limited by walls by separating it from its natural environment, protecting it and covering it. Windows are the most obvious example of these interventions and gaps (Uluengin,1982). Windows are elements located on the outer shells or inner walls of structures and undertake important functions. While these elements fulfill basic tasks such as air circulation, establishing visual relations and creating connections between spaces; they also undertake functions such as lighting, security and control (Bulut, 2001). The use of window elements at different intervals and periods creates an important effect on people who are deeply attached to geometric and numerical data. Along with the rhythmic effect of the gap order, the surrounding, decoration and ornamentation of this space, the material, color and texture of the building surface and structural elements offer endless variety in this area. From the beginning of the void to the present day, every civilization has handled and processed these elements in a unique manner, reflecting its cultural identity (Uluengin,1982).

2.1. Traditional Turkish House Window Types:

2.1.1. Vertical Sliding Windows (Guillotine):
The guillotine window is a type of window commonly used in Ottoman and Turkish architecture. There are different types of this window, single-wing and double-wing (one fixed, the others movable or both wings movable), and these types are the most frequently used models (Demirkan, 2023). Guillotine windows contain two glass panels. These panels move between the slats located on the sides. They generally move up and down. This design allows the panels of the window to move independently (Fig. 1).

Fig. 1. Guillotine Window Example

2.1.2. Double Casement Window:
Double-winged window systems are generally a type of window consisting of two sashes, each of which can be opened separately. This system allows for more efficient air performance. The ability to open the sashes independently enables effective ventilation of the space. Double-winged windows usually have large glass panel surfaces, which allows more light to enter the interior (Fig. 2) (Sakal & Kahraman, 2020).

Fig. 2. Double Casement Window

2.1.3. Skylights:
Skylights are types of windows that are opened to the dome drums and skirts of domes, especially in Anatolian Turkish Architecture, in order to allow natural light into interior spaces, and are closed with fixed plaster workmanship (Sağiroğlu Arslan, 2014) . This window placement is designed to provide maximum light and ventilation and is usually located in high positions. Although the form dimensions of skylights are rectangular or square, they can also be created in different geometric structures depending on the local architectural structure and design preferences. They are usually made fixed because they are at a height that people cannot reach and do not need to be opened (Sakal & Kahraman, 2020). .

2.1.4. Concentric Window:
A type of window created in the 19th century by designing two windows in a row to provide heat and sound insulation. It was usually made in rectangular and elliptical shapes. The construction material used was wood (Çelik, 2025a) .

2.2. Traditional Turkish House Window Elements:

2.2.1. Lintel:
Small stone, concrete or wooden beams placed on the upper part of these forms and sitting on the side walls in order to carry the wall loads on the window edges are also called "lintels". Lintels are fastening elements placed on the upper part of the jambs or window openings and transmit the loads coming from the top to the side walls, allowing for wide window options (Sağiroğlu Arslan, 2014) .

2.2.2. Jamb:
Jambs are vertical frame elements placed on both sides of window and door openings. They are made of stone or wooden materials. They are placed on both sides of the door and window frame as a post element. Jambs consist of sections such as the post post (window post), the post sill and the post stone (Sağiroğlu Arslan, 2014) .

2.2.3. Telaro:
Telaro is the fixed section that connects the window to the wall. In openable windows, the window sash is mounted to the telaro by means of a hinge. The hinge is a metal support element used to ensure the movement of the sash and to transfer load to the telaro separated from the sash. The mounting method of the hinge determines the opening direction of the sash (Bulut, 2001).

2.2.4. Sill:
The sill is a structural element used to cover the junction of the window sill with the wall plaster. It is located on both sides and the upper part of the window. In double-skinned windows, this element, which forms a slot for the sash together with the frame during the transportation of the inner sash, is also used to ensure the aesthetic integrity of the interior space (Bulut, 2001).

2.2.5. Wing:
The movable carrier connected to the telaro by a hinge is defined as 'wing'. In window joinery, the telaro-wing joint is designed in the joint area between the sash and the telaro to prevent the passage of unwanted elements such as air, water, and dust into the interior. When the sash is closed, the recess (lamb) and protrusion (tenon) connection elements that are compatible and have complementary features on the sash and telaro surfaces in order to ensure the sealing of the joint between them are called 'bini' (Bulut, 2001).

3. Field Study:

3.1 Düzce Prusias Region:
Prusias region of Düzce province in the Western Black Sea Region is a settlement area located at an altitude of approximately 200 meters in the northeast of Düzce Plain. Prusias region borders Zonguldak and Bolu provinces to the east and Sakarya province to the west. Düzce province is bordered by the Black Sea to the north (Fig. 3) (Sabuncu, 2022).

Fig. 3. Duzce Province Map (Çelik, 2025b)

The location of Düzce, especially its proximity to major metropolitan cities such as Ankara and Istanbul, directly affects the economic situation of the province. This easily accessible location provides the opportunity for Düzce to become an important trade and industrial center thanks to its easy access to economic activities. In this context, in the sectoral evaluations made, it is observed that Düzce has a rapidly developing structure in the industrial field (Besli, 2019).

The study area is a Bithynian city known as Prusias ad Hypium, located 8 km north of Düzce province, in the middle of Ankara and Istanbul. The settlement was built on a hill in the middle of the Little Melen Stream (Hypios). This hill stands out as a part of the mountain range (Bilir, 2013). The city, which remained under the sovereignty of the city of Herakleia Pontica for a long time since its foundation, was added to the borders of the Kingdom of Bithynia together with the city of Tios by the King of Bithynia Prusias I. It was named Prusias ad Hypium, meaning Prusias near the Hypios (today's Melen) River. The city, which has been inhabited continuously since its foundation, was included in the Ottoman lands by Prusias Gazi, one of the margraves of Osman Bey, in 1323. Its name in the Ottoman Period was Üskübü. It was later named Prusias and has remained with this name to the present day (Okan, Bilir & Çalişkan, 2022). The settlement was divided into I, II and III degree archaeological sites by the Kocaeli Cultural Heritage Preservation Board with the decision numbered 894 dated 20.03.2013. Houses, city walls, Roman bridges, aqueducts and theatre were registered as sites (Naldan, 2019).

3.2 Characteristics of Traditional Houses in Prusias Region:
The traditional building culture seen in the Prusias Region is the wood frame (infilled with bricks in between) system. It forms the carrier system of a skeleton structure consisting of columns and beams. The wood frame skeleton system used in traditional local houses is built on stone foundation walls. The spaces between this wood frame skeleton system are filled with stone, adobe, wood or brick. This system is generally called 'hımı'. These walls are then plastered and the system is completed. In some houses, the walls are left without plastering. Thus, a structure as light as possible is obtained. The ground floor of the Prusias traditional house, which is generally designed as 1 or 2 floors and rarely as 3 floors, is mostly allocated for uses such as barn, hayloft, service units and kitchen, while the main living floor of the house has always been the first floor. The roofs, which also have a sloping wooden system, are generally covered with Marseille tiles and rarely with Turkish style tiles. The historical housing texture in the region is mostly composed of wooden frame houses with brick fillings connected with lime mortar (Fig. 4) (Tanriverdi Kaya, Demir & Ayengin, 2017).

Fig. 4. Housing Texture Example

One of the most important visual effects in the façade arrangement is the windows. The size and width of the windows vary according to the façade of the house; there are fewer windows on the lower floors and more on the upper floors. The width and height measurements of the windows are made in various sizes and dimensions in order to maintain the rectangular form. At this point, it is observed that guillotine and casement type wooden joinery windows are preferred (Naldan, 2019).

4. Results and Discussion:

In this study, the models, functions, horizontal and vertical axis positions, dimensions, material types and connection details of the windows in three different structures selected from the Düzce-Prusias region were determined. The structures were categorized as İşler Evi, Terzialiler Evi and Kaleler Evi according to their locations.

4.1 İşler House Windows:

The building is located on Çarşıiçi Street and is within the second degree archaeological site. The three-storey building consists of a ground floor, first floor and second floor. The ground floor is used for commercial purposes and there is a shop here. The door and window elements of the building are damaged and some are completely dysfunctional. All door and window joinery is made of wood. The floor of the building is built with solid rubble stones and the upper floors have a wooden cracked brick wall system. In this system, the building loads are transferred to the ground via wooden studs and beams positioned within the wall. The section dimensions of the wooden upright elements used in this structure with a traditional wooden system were selected as 10 cm on average. The ground floor consists of two rooms and an entrance hall. The floor plans of the structure are designed in accordance with the interior sofa plan type. There are uprights called "shoulders" on the edges of the windows on the first and second floors. In addition, there is a large fixed window on the upper part of the entrance door, and thanks to this window, the entrance hall and the staircase section are illuminated with natural light (Fig. 5).

Fig. 5. İŞLER House Facade Photos

Six types of windows have been determined in İşler House according to their sizes. These windows İH-W1 (126x115 cm), İH-W2 [151x118 cm), İH-W3 (89x145 cm), İH-W4 (167x130 cm), İH-W5 (127x130 cm) ve İH-W6 (137x131 cm)'dir. The appearance of the windows is given in Fig. 6.

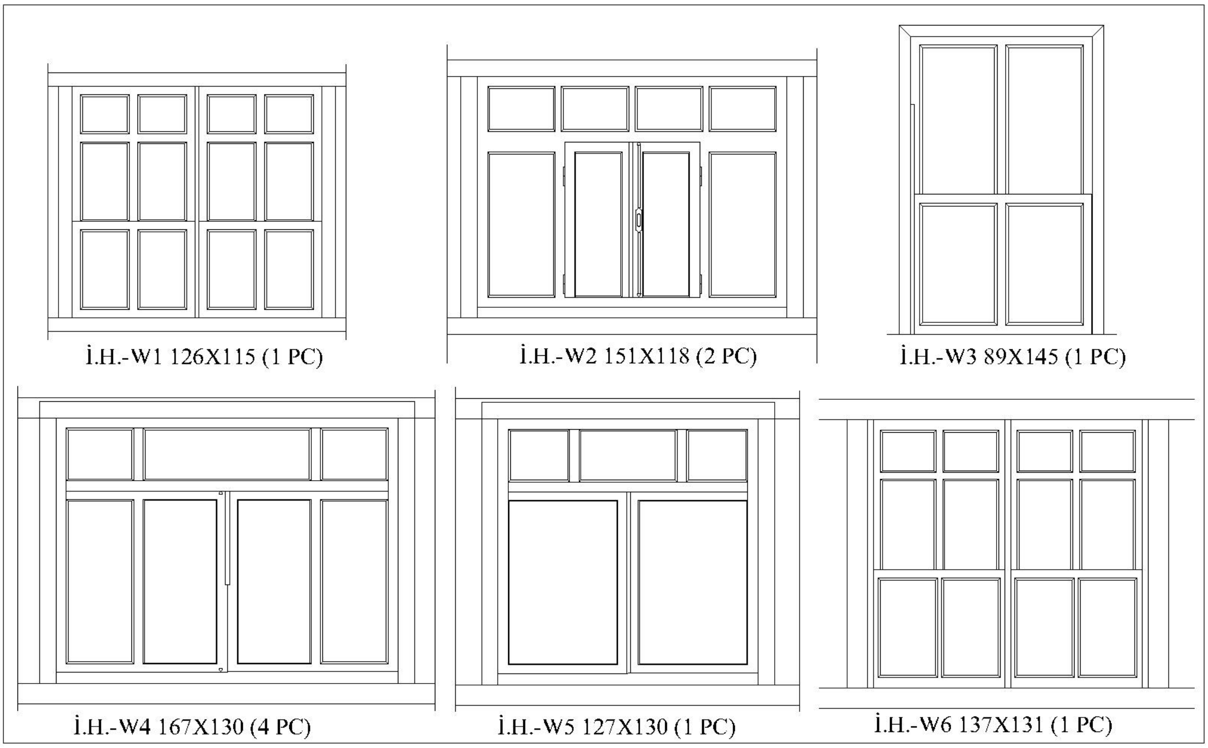

Fig. 6. İŞLER House Window Views

4.1.1. İ.H.-W1(126 x 115 cm):

The P1 opening window in İşler Evi is a two-pane guillotine type model and is located on the second floor of the building. The window is placed on the inside of the wooden frame wall. The frame-wing and wing-wing joints are designed in a flat manner. In order to ensure the stability of the fixed wing, the lower part is supported with slats. The openable wings are supported from the inside with fixed wings and a flat slat on the top and from the outside with a slat fixed to the sill. The openable wings move up and down between these slats. The connection of the window frame to the wall is provided by connecting to fixed wooden studs. The window wings have a sliding system that moves vertically. The dimensions of the window are 126 cm x 115 cm. The window joinery is divided into three rows horizontally and four rows vertically (Fig. 7 and Fig. 8).

Fig. 7. İ.H.-W1 Window View

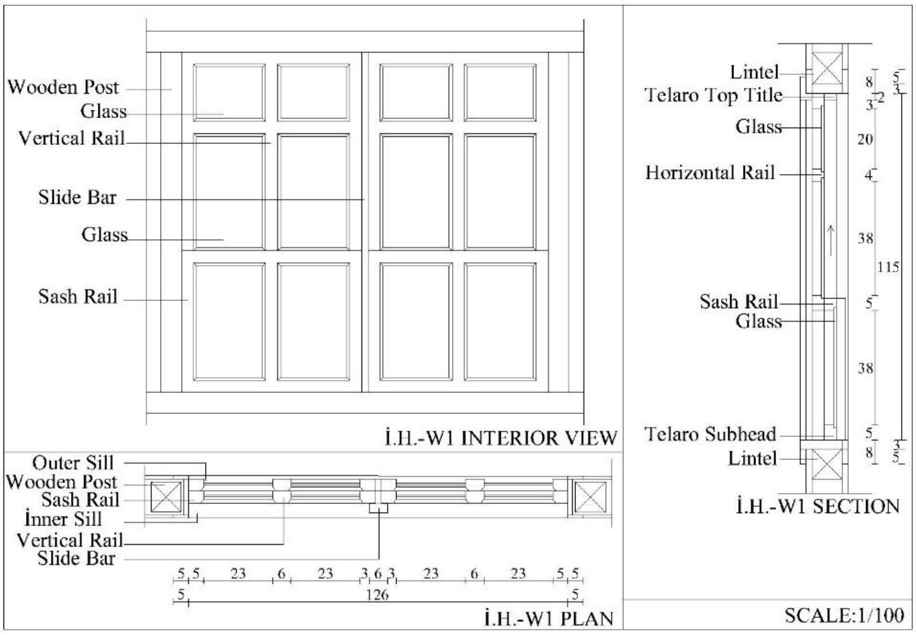

Fig. 8. İ.H.-W1 Detail Drawing

4.1.2. İ.H.-W2 (151 x 115 cm):

The window on the inside of the wooden frame wall, the frame-wing and wing-wing joints are designed according to the lamp detail. The upper part of the window is fixed and divided into four equal sections with vertical cuts. There are two openable wing windows positioned at the bottom, and there are two fixed windows on the sides. The joinery is painted in white. The internal locking of the windows is designed according to the period and integrated on the wing. The locking system of the window, The locking system moves up and down by working with the metal arm on the wing, this metal bar enters the slots inside the openings on the upper and lower parts and provides locking opportunity. There is no metal railing on the window in question. The window is designed to open horizontally and rotatably towards the interior. Since the wings can be opened inwards, the hinges are mounted on the inside of the window. The dimensions of the windows are 151 cm x 115 cm, and the divisions are designed to be three sections horizontally and four sections vertically (Fig. 9 and Fig. 10).

Fig. 9. İ.H.-W2 Window View

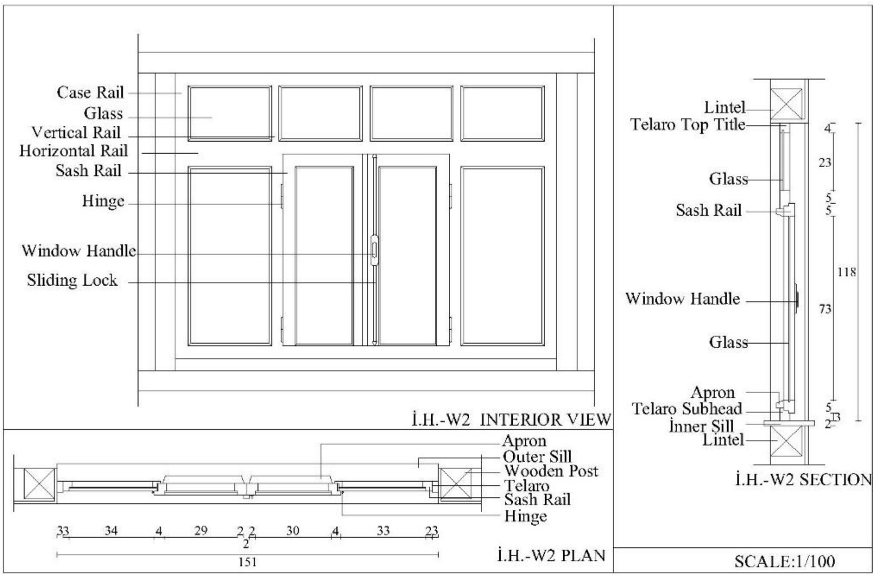

Fig. 10. İ.H.-W2 Detail Drawing

4.2 Terzialiler House Windows:

Terzialiler House is located next to the historical Roman Bridge. The three-story structure is designed as a basement, ground floor and first floor. The construction technique is based on the principle of wooden material placed inside with frames. The outer walls are covered with Baghdadi plaster, while the inner walls are covered with plaster selected as "malis" and made of water, soil and straw. The foundation of the building is built of rubble stones. In addition, wooden beams are placed between the rubble stone walls to ensure their integrity. All of the doors and windows in the structure are made of wood. In terms of spatial organization, the rooms are built to be on the sides of the sofa. The windows on the ground floor are wooden with wings, and on the first floor there are two and three-pane guillotine type windows. On both sides of the door entrance, sliding guillotine windows were placed to provide light to the hall. Vertical and horizontal lines were used around the room windows. On the first floor, a bay window was made to project outwards from the hall. There are two guillotine type windows on the front facade of the bay window and one on each side facade. The bay window in question added movement to the facade design. Some doors and windows in the building were deformed (Fig. 11).

Fig. 11. TERZİALİLER House Facade Photo

Five types of windows were determined in the Terzialiler house according to their sizes. These windows are TH-W1 (68x140 cm), TH-W2 (46x99 cm), TH-W3 (47x87 cm), TH-W4 (157x128 cm) and TH-W5 (210x130 cm). The appearances of the windows are given in Fig. 12.

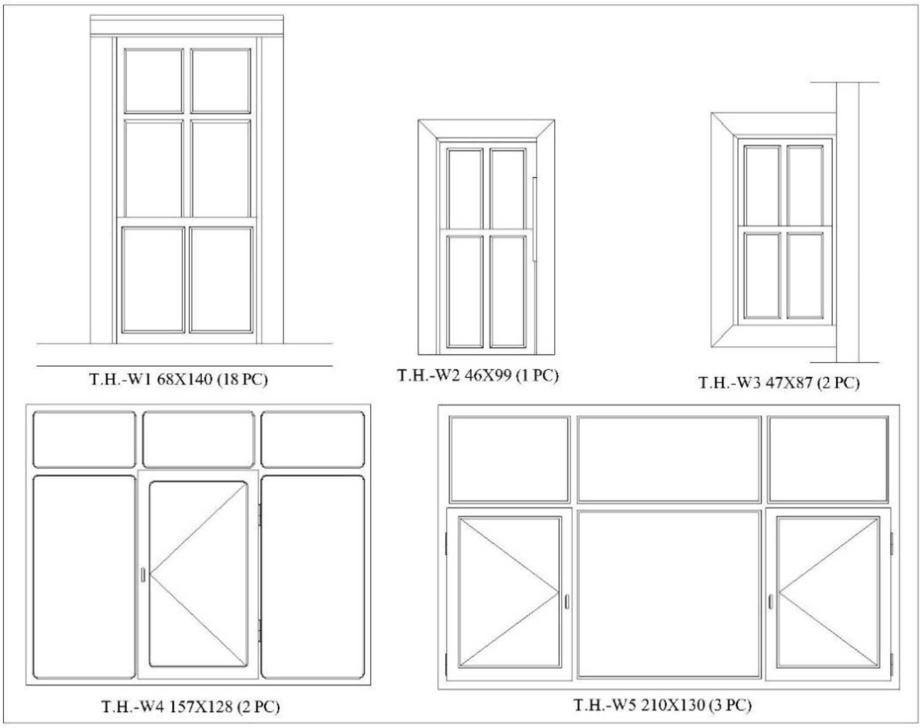

Fig. 12. TERZİALİLER House Window Views

4.2.1. T.H.-W1 (68 x 140 cm):
The windows located on the ground and first floors of the building have a single-pane guillotine type window model and are placed on the inside of the wooden frame wall. The windows in question are placed on horizontal joists, and the frame-wing and wing-wing joints are designed in a flat form. The opening wings are supported from the inside with fixed wings on top, a flat lath on the bottom, and a lath fixed on the joist from the outside. Thanks to this mechanism, the opening wings can move up and down so that they remain between the laths. When the windows are placed directly on the joists, no sill is made on the window. There is no locking system or railing in the parts of the structure. The window opening wings are vertical sliding. There is a fixed wing in the upper section and a movable wing in the lower row. The dimensions of the windows are 68 cm wide and 140 cm long. There are a total of 18 windows of the same series in the structure. The window joinery is designed to have three sections horizontally and two sections vertically (Fig. 13).

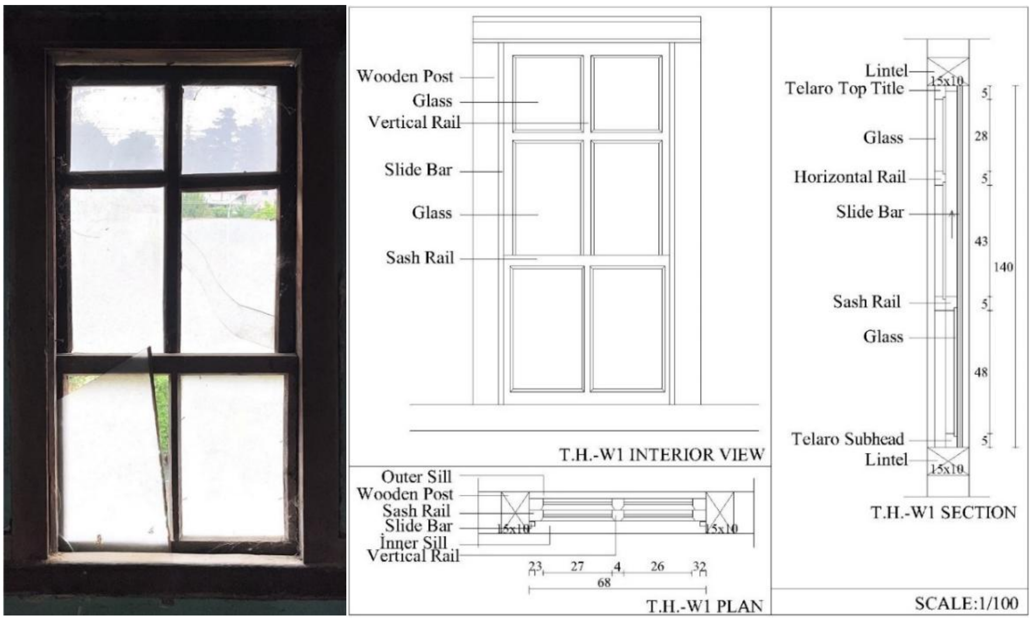

Fig. 13. TH-W1 View And Detail Drawing

4.2.2. T.H.-W4 (157 x 128 cm):

The window, positioned on the inside of the wooden frame wall, has the details of a frame-wing with lamp and a wing-wing with lamp. The upper section of the window is fixed and divided into three sections with vertical slats. In the lower section, there are two fixed windows on the edges and an openable wing window in the middle. The joints at the junction points of the window frame with the wall are covered with plaster on the inner and outer surfaces and painted. There is a locking system in the interior of the windows. The window is locked by turning the tongue of the metal window handle. No metal railing is used in the window design. The window is designed to rotate towards the interior. Since the window wings open inwards, the hinges are arranged to be located in the interior. The window dimensions are 157 cm x 128 cm. The divisions in the window joinery consist of two sections horizontally and three sections vertically (Fig. 14 and Fig. 15).

Fig. 14. TH-W4 Window View

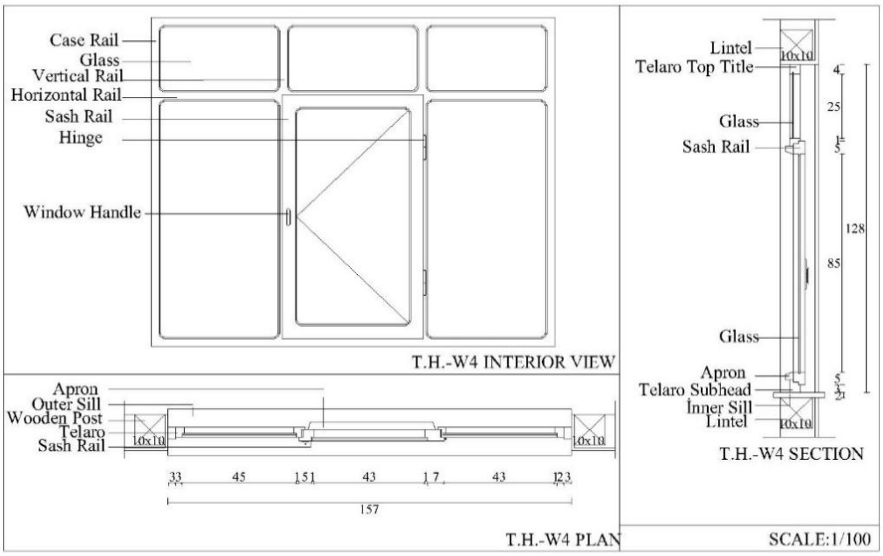

Fig. 15. TH-W4 Detail Drawing

4.3 Kaleler House Windows

Kaleler Evi is located right next to the ancient theater. The building has three floors: basement, ground floor and first floor. The construction system of the house consists of brick material filled into a wooden frame. The exterior and interior walls of the building are covered with traditional Baghdadi plaster and painted. The foundation of the building is made of rubble stones. All doors and windows of the building are built using wood. The rooms are designed to be on the sides of the sofa. Guillotine type windows were preferred as the window model. Both vertical and horizontal girders were used on the edges of the room windows. Some windows in the building are deformed (Fig. 16).

Fig. 16. KALELER House Facade Photo

Three types of windows were determined in the Kaleler house according to their sizes. These windows are KH-W1 (68x140 cm), KH-W2 (46x99 cm) and KH-W3 (47x87 cm). The appearances of the windows are given in Fig. 17.

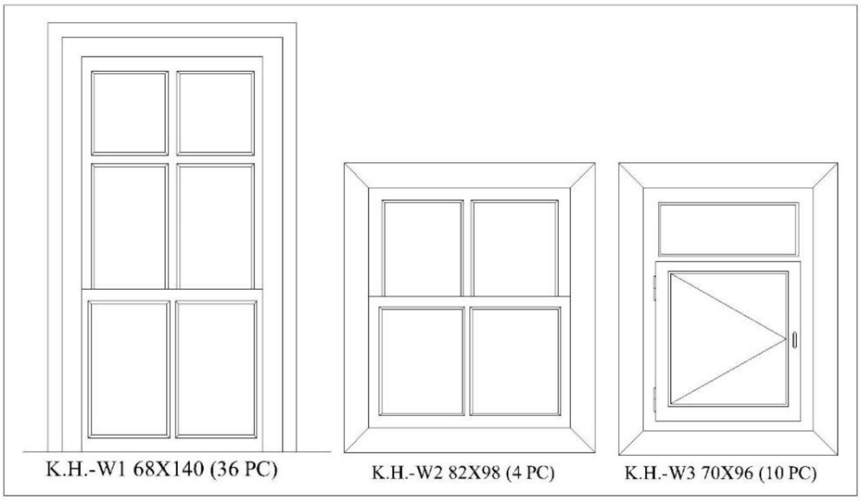

Fig. 17. KALELER House Window Views

4.3.1. K.H.-W1 (68 x 140 cm):

The window is located on the inside of the wooden frame wall and has a single-pane guillotine type window model. This window is located on the ground and first floors of the building. The windows in the building are placed on horizontal joists and supported by joists around them. The frame-wing and sash-wing combination is designed in a flat manner. The opening wings operate with a vertical sliding movement. While there is a fixed wing in the upper section, there is a movable wing that opens upwards in the lower row. The opening wings are supported by a fixed wing and a flat lath on the top and are strengthened with a lath fixed to the upper level of the sill on the outside. The wings can move up and down by remaining between the slats. The window is surrounded by sills on the outer and inner surfaces. The window, which is painted in brown tones, does not have any locking system or railing. The window dimensions are 68 cm x 140 cm and there are a total of 36 identical model windows in the structure. The sections in the window joinery form three horizontal and two vertical series (Fig. 18).

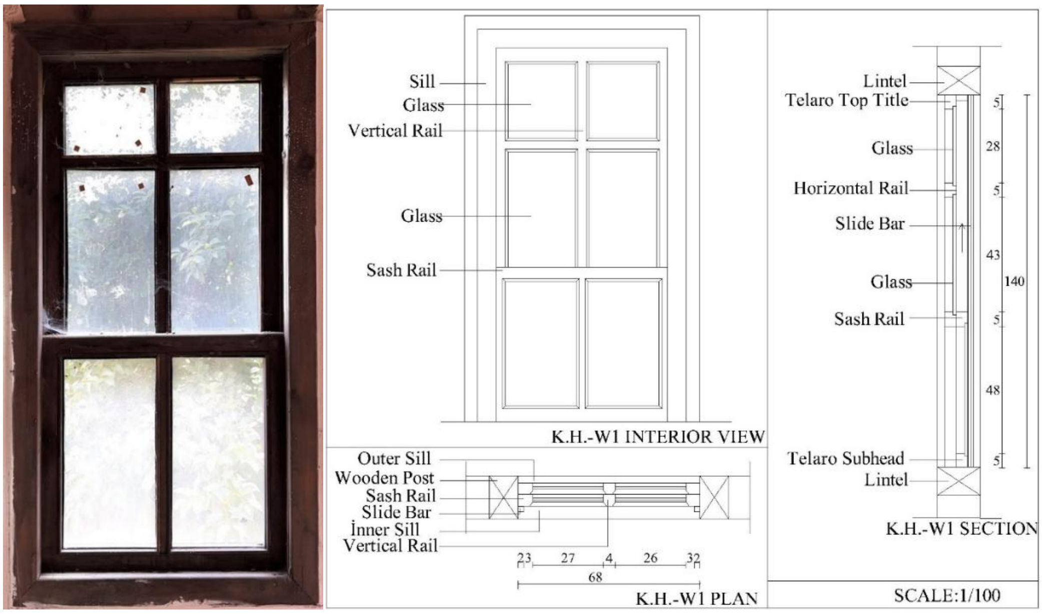

Fig. 18. KH-W1 View And Detail Drawing

4.3.2. K.H.-W2 (83 x 98 cm):
The window is located on the inside of the wooden frame wall and is designed in a single-pane guillotine type model. The frame and sash combination and the sash-sash combination are made in a flat manner. The opening wings move vertically, there is a fixed sash on the top, and there are upward-moving wings on the bottom. The opening wings are supported by the fixed wings on the inside, and the upper part of the sill is supported by a fixed slat on the outside. The opening wings can move up and down between the slats. The window is coated with brown paint. The window dimensions are 83 x 98 cm, and there are two horizontal and two vertical series of panes. There are a total of 4 identical model windows in the structure (Fig. 19).

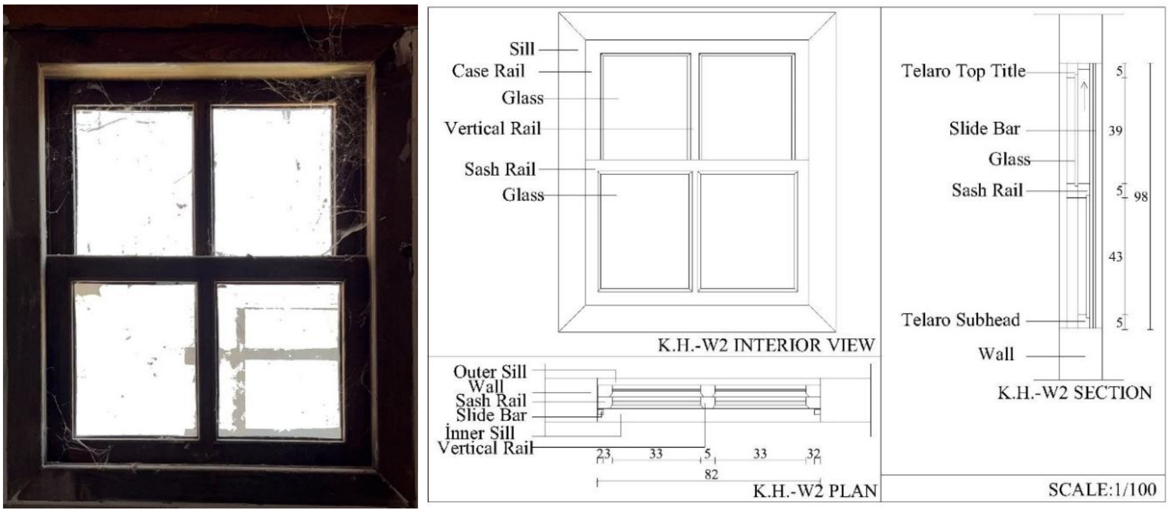

Fig. 19. KH-W2 View And Detail Drawing

5. Conclusions
Analyses conducted on traditional houses in Düzce reveal that some houses have begun to lose their original characteristics. This situation necessitates taking various protection measures in order to prevent the disruption of the continuity of these structures with historical value. The carrier systems of the houses generally consist of wooden frame material, but various materials have been used as fillings between the wooden frames. These materials are generally observed as brick, adobe filling or wooden slats.

The window frames are made entirely of wood, considering the intense climate conditions and abundant forest areas. The frames are placed on the inside of the wall, the inner frame is placed in accordance with the depth of the wall with wooden cladding and supported with wooden frame material from the outside. These frames form the window frame together with the wooden sill located at the bottom. The wings and sometimes the drips on the frames are designed with horizontal records. There is no fixed strut between the wings. The window sections successfully reflect the square record and rectangular texture samples frequently seen in traditional Turkish houses. The wings are divided by elegant slats and contain different outdoor perspectives. The case and records are generally made in similar dimensions. In addition, the wall junction of the case is covered with wooden cladding or slats to protect against leaks. In double-winged windows, special locking gaps are designed with a remarkable system by being integrated into the lower or upper sash. Some double-winged windows open by turning sideways outwards, so the hinges are made on the outside. This system is different from today's.

Various regions of our country have a rich history with unique architectural structures. However, due to the conditions in our country, there are some deficiencies in the preservation of these architectural heritages. This research aims to contribute to the transfer of this information to future generations by examining the construction and technical features of the windows in our traditional buildings.

Acknowledgments
This research received no external funding.

Seismic assessment and effectiveness of structural retrofitting techniques: A case study of industrial chimneys at Khosravi Leather Factory in Tabriz

Safiyeh Nami[*1], Farhad Akhoundi[1a], Sepehr Amer[1b]

[1] *Tabriz Islamic Art University, Faculty of Architecture and Urbanism, Tabriz, Iran*

Abstract. The Khosravi Leather Factory in Tabriz is historically significant as a key example of Iran's early industrial era. Following its renovation and transformation into part of the Islamic Art University of Tabriz, the factory building has become an essential component of the university campus. This study focuses on the dynamic behavior of the industrial chimneys within this complex, which are tall and slender structures that are vulnerable to seismic forces.
The previously implemented seismic retrofitting technique involved installing metal rings around the chimneys, and this technique is thoroughly examined in this study. Output-only dynamic testing was conducted to investigate the behavior and effectiveness of the retrofitting method. The tests were performed twice: first with the rings in place and then after their removal to eliminate any residual pressure effects.
The test results, along with the observed changes in frequency, demonstrate that this retrofitting technique did not achieve the intended improvement in structural performance. This article provides valuable insights into the seismic assessment of industrial chimneys and critically evaluates the effectiveness of retrofitting techniques, using the Khosravi Leather Factory as a key case study.

Keywords: Seismic assessment; Structural retrofitting techniques; Industrial chimneys; Khosravi Leather Factory; Dynamic testing.

1. Introduction

The preservation and enhancement of seismic performance in historical and industrial structures have gained significant attention in the fields of engineering and architectural restoration. Ensuring the structural integrity of these buildings while aligning them with modern safety standards poses unique challenges, often necessitating innovative retrofitting techniques. In this context, the present study offers a comprehensive investigation focused on the dynamic response and numerical analysis of an industrial historical chimney subjected to a specific retrofitting method.

The primary objective of this research is to assess the effectiveness of the employed retrofitting technique, which involves strategically placing metal rings to enhance the chimney's resistance against seismic forces.
Historical structures, such as the chimney under examination, frequently lack comprehensive original design information. Consequently, the research adopts a methodology that combines dynamic experimental testing, advanced numerical modeling, and seismic analysis to provide valuable insights into the behavior of the structure and the impact of the retrofitting approach.

Given the absence of fundamental structural information, all parameters utilized in the study are derived from practical experiments, ensuring an appropriate and accurate assessment. The experimental phase involves ambient vibration testing conducted in two stages, offering a precise understanding of the chimney's response to seismic excitation. Furthermore, the empirical findings validate the numerical modelling, enabling the simulation of structural behaviour under various conditions, both before and after retrofitting implementation.

The subsequent sections of this paper deals with specific methodologies employed, presenting the dynamic structural study, experimental procedures, and numerical analysis in detail. The obtained results are critically analyzed and discussed to reveal the extent of the retrofitting technique's influence on structural response. Through

[*]Corresponding author, E-mail: s.nami@tabriziau.ac.ir

https://doi.org/10.31462/icearc2025_a_car_736

this comprehensive exploration, the study aims to contribute to a broader understanding of retrofitting strategies for historical and complex structures, providing valuable insights into their enhanced seismic performance.

2. Case study: Description of a Historical Chimney

The focus of this research is a chimney situated in the city of Tabriz, erected during the first Pahlavi period. This chimney is an integral component of the former Khosravi Leather Factory complex, which has been meticulously renovated and repurposed as part of the Tabriz Islamic Art University. Its construction is attributed to the year 1931 AD. However, no architectural blueprints or construction particulars are available. Consequently, all requisite information vital for this study—encompassing structural geometry and material properties—was acquired on-site and through diverse tests.(Nami, 2022, 3)

Due to the scarcity of substantial data and architectural blueprints, the comprehensive geometry of the industrial chimney was ascertained using laser scanning technology. Post the quantification of the structure's geometry, the architectural dimensions of the industrial chimney were determined. It takes the form of an incomplete hollow cone, standing at a height of 25.85 meters, with an octagonal base reaching to a height of 6.01 meters. At the base level, the outer diameter spans 4.7 meters, tapering to 1.9 meters at the summit. The wall thickness exhibits uniform variation, transitioning from 1 meter at the base to 0.40 meters at the uppermost point. (Nami, 2022, 3)

In recent years, this structure has undergone a retrofitting process involving the installation of 11 metal rings at approximately one-meter intervals encircling the chimney. Fig. 1-a presents a photographic portrayal of the chimney, while Fig. 1-b depicts documentation and intricacies of the structure subsequent to the measurement procedure.

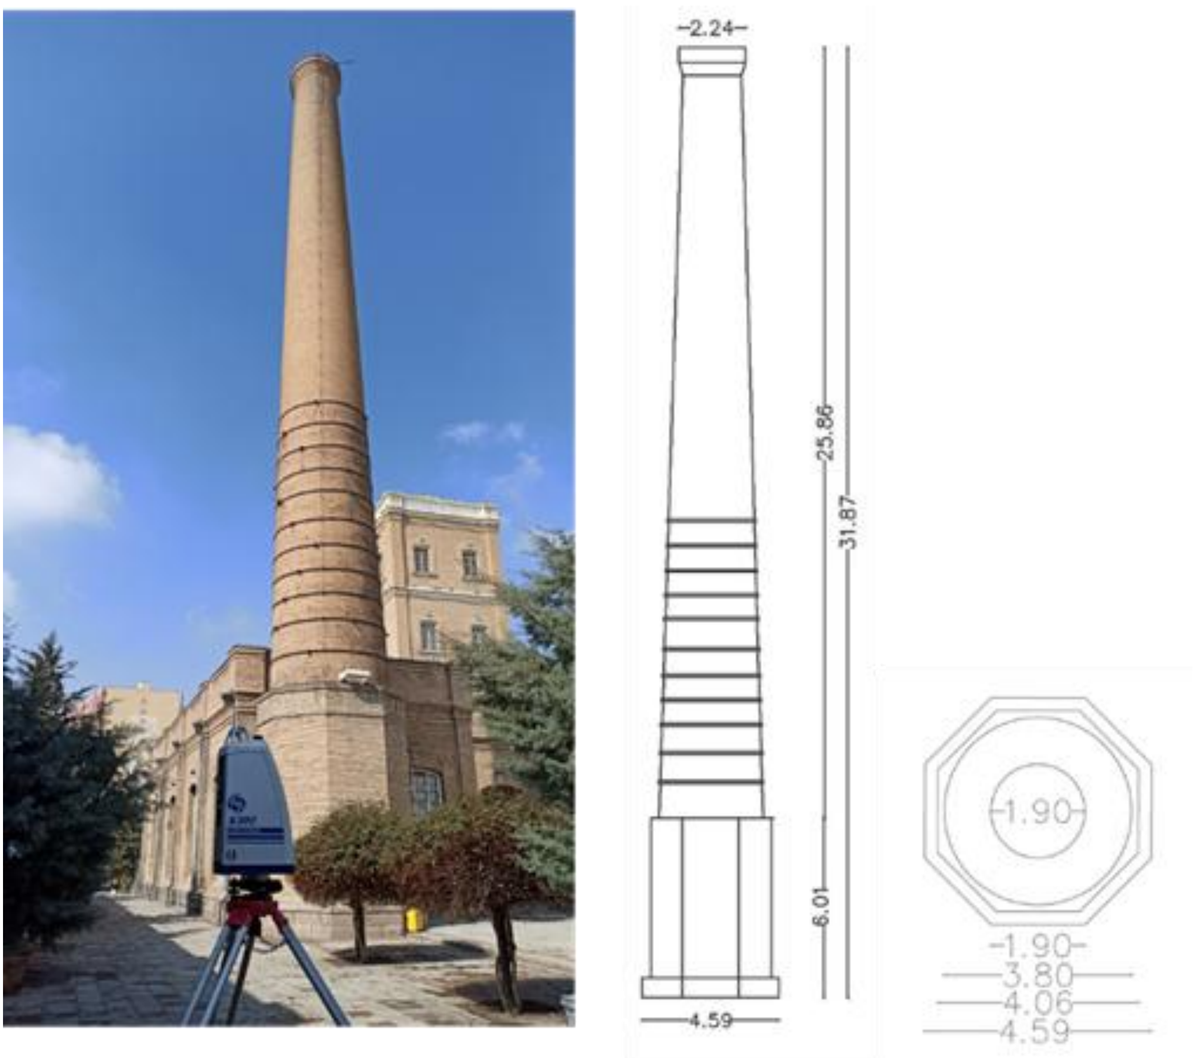

Fig.1. a:photo of chimney b: Geometric Specifications of masonry Chimney

2. Modal Testing

The identification of dynamic characteristics in structures holds paramount importance across diverse industrial domains, including automotive, aerospace, robotics, and civil engineering, among others.

Extensive research has been dedicated to both numerical and experimental techniques for identification of dynamic behavior of structures. Modal analysis, a laboratory-based method, stands as a suitable approach for characterizing dynamic parameters within structures and constructing a mathematical or modal model (Ghalishooyan, 2015). In civil structures, experimental modal parameter identification involves the extraction of modal parameters—comprising frequencies, damping ratios, and mode shapes—from dynamic measurements. These parameters serve multitude of purposes, including refining finite element models, detecting and pinpointing potential structural damages, conducting prolonged structural health assessments, and evaluating structural integrity subsequent to intense loading scenarios like earthquakes.

Nevertheless, numerous real-world structures pose challenges to the application of experimental modal analysis for acquiring modal parameters. Consider large-scale structures, where effectively stimulating the structure and measuring applied forces to the structure may be unfeasible. Many structures experience excitation due to forces stemming from their operational behavior, rendering the measurement of these forces impractical. Consequently, focus has shifted toward methods that obviate the necessity for direct excitation and force measurement in modal parameter identification. These methods are known as Operational Modal Analysis (OMA) or Ambient Modal Analysis, relying solely on recording structural responses to naturally occurring forces during routine operating conditions (Salehi, 2018, 55).

2.1. Experimental Procedure:

Ambient vibration tests were conducted by to determine modal parameters under two distinct conditions: prior to retrofitting and post-retrofitting (comprising natural frequencies and mode shapes).

The main objective of these tests was to update the numerical model of the chimney. The operational modal test was executed in a two phases. The initial phase encompassed subjecting the structure to testing under its existing state, including the presence of metal rings intended for retrofitting. In the subsequent stage, the metal rings, previously affixed to the structure for retrofitting purposes, were systematically removed to nullify their impact on the structure's behavior. In both stages, operational modal testing was conducted utilizing 12 cable-mounted accelerometers strategically positioned at 2.5-meter intervals. (Nami, 2022, 5)

The operational modal test is done as follows:

1. Placement of accelerometers at 2.5-meter intervals along the chimney's height.
2. Activation and interconnection of accelerometers with the data logger.
3. Capture and recording of data transmitted by the accelerometers through the data logger.
4. Formulation and extraction of relerant information and data for subsequent analysis.

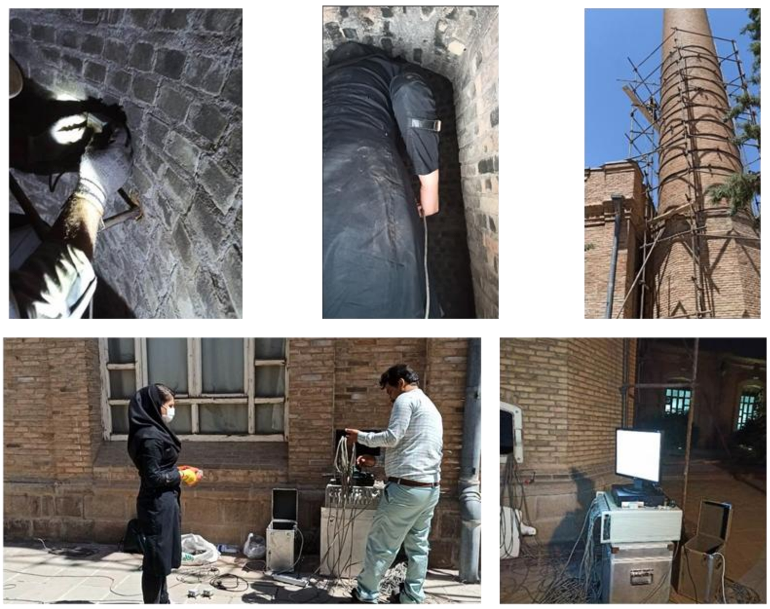

Fig.2. Stages of Operational Modal Testing

3.Numerical Modeling:

Numerical modelling and analyses encompass a scaled simulation of the investigated structure. The correctness of results increases as the simulation accuracy and detail improve, yet this progress necessitates a balance between computational requirements and time investments. Thus, the choice of modelling approach must be guided by project prerequisites. This study employed a macro-level modelling approach to streamline the numerical model and enhance computational efficiency.

Utilizing the information gleaned from the structure, as elaborated upon in preceding sections, a meticulous numerical model was constructed to execute the required analyses with the utmost precision. The finite element model utilized in this study adhered to a macro-level modelling methodology, focusing on simplification to conserve time and computational resources. The geometry of the chimney model is illustrated in Fig.1. The abridged structural representation encompasses a conical section measuring 25.85 meters in height with an average thickness of 0.7 meters, accompanied by an octagonal base section extending to a height of 6.01 meters. All elements within this model were treated as regular curved shells. The entire model comprised 7,907 elements and 7,945 nodes. The structural supports and foundation were also simplified, with all degrees of freedom constrained.

The material properties in this study are presented in table 1.

The compressive strength and elastic modulus were extrapolated from biaxial flat-jack tests, while the tensile strength was considered as 0.1 times the compressive strength.

4. Pushover Analysis:

Nonlinear pushover analysis constitutes a static approach for assessing the seismic performance of structures. The fundamental premise lies in the assumption that the structure under scrutiny can be simplified into a single-degree-of-freedom system in accordance with its seismic response. Inertial forces resulting from ground motion are approximated onto the structure through a lateral load distribution. A pushover analysis is a procedure in which the magnitude of the lateral load excited in a structure is increased monotonically until failure. The lateral load is applied in a predefined load pattern. Central to the Nonlinear Pushover (NLPO) method is the construction of a capacity curve. This curve delineates the correlation between base shear and node displacement, functioning as a pivotal parameter (Nortman, 2019, p. 32). Such a relationship characterizes structural capacity concerning peak force, deformation, and the capacity for deformation alteration.

In this study, a pushover analysis was conducted on the modelled structure to explore its seismic behaviour. The outcomes of the principal structure analysis, sans rings, were juxtaposed with the retrofitted state, incorporating metal rings. Fig. 3 depicts the capacity curve obtained from the pushover analysis of the structure before strengthening.

Table 1. Optimized values of the materials used in chimney model

Material	Elastic Modulus MPa	Specific mass Kg/m3	Poisson's coefficient	f_c MPa	f_t MPa
Masonry material	2340	1900	0.25	1.001	0.1001

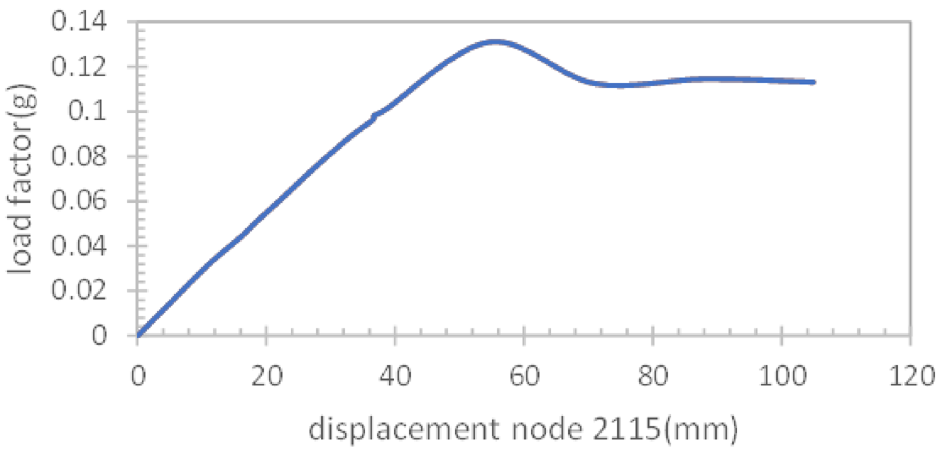

Fig.3. Pushover analysis

5. Structure After Retrofitting

Retrofitting a structure entails deploying techniques and strategies to bolster its performance against imposed loads. Within this study, the focus centers primarily on seismic forces, recognizing their significance, particularly in Tabriz city.

Fundamentally, all retrofitting strategies adhere to one of two principles: either mitigating seismic demand through these techniques or enhancing structural capacity against external forces. Consequently, a range of retrofitting options exists, with the optimal choice contingent upon factors like structural conditions, economic considerations, resource accessibility, requisite expertise, and more.

Within this project's framework and considering prevailing conditions, the application of metal rings emerged as the retrofitting technique for the analyzed structure. This research is centered on assessing the precise influence of this retrofitting approach. Accordingly, diverse implementations of this approach were executed on the modeled structure, each followed by pushover analysis using mass-proportional loading. Comparing the resultant capacity curves facilitates the assessment of structural resistance alterations post-retrofitting. These rings were linearly modeled as Beam Class III elements (Fig. 4).

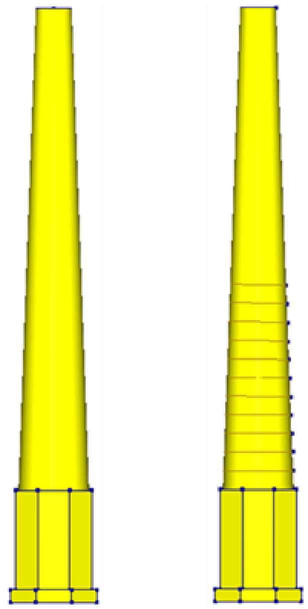

Fig.4. Model of chimney a: without rings b:after strengthening with rings

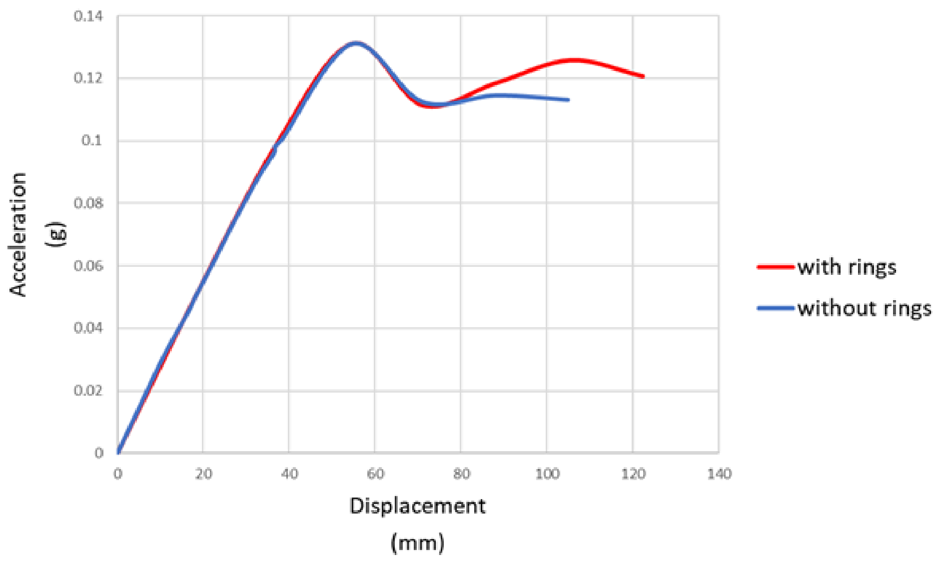

Fig.5. Comparison of pushover analysis before and after strengthening with rings

After several iterations of analyses and placing rings at different heights, the most optimal configuration was achieved at one-third of the chimney's height. (Fig. 6).

Based on the curves depicted in Fig.7, under the most optimal utilization of metal rings in this structure, the structural resistance observed a rise of approximately 9.16% compared to its pre-retrofitting state. However, this percentage increase does not meet the criteria for satisfactory structural retrofitting.

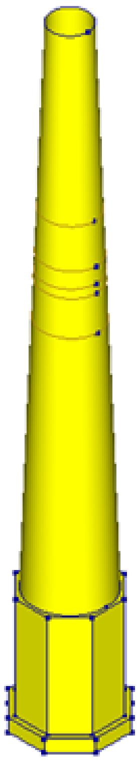

Fig.6. Model of chimney after strengthening with rings at one-third of the chimney's height from the top

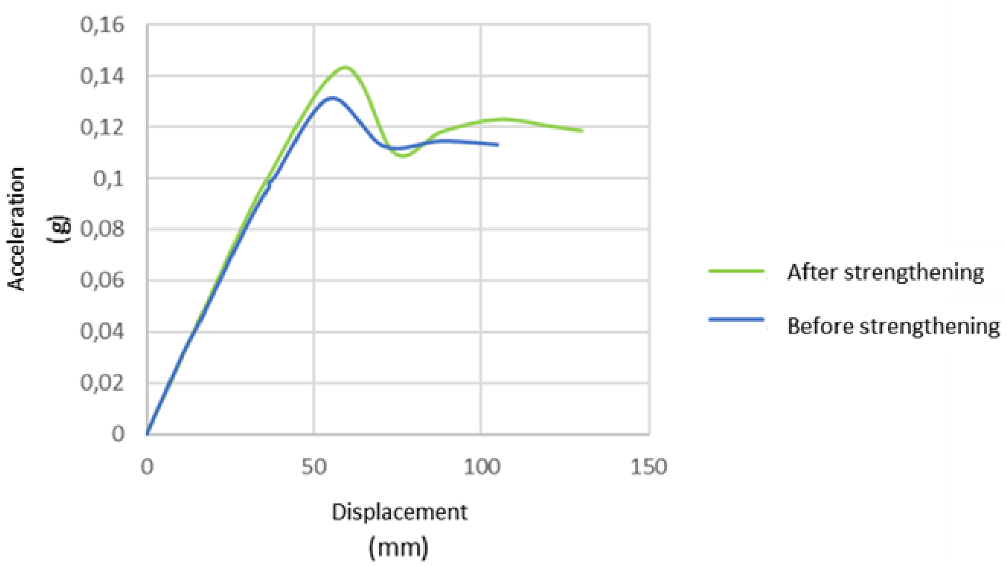

Fig.7. Comparison of pushover analysis before and after strengthening with rings at one-third of the chimney's height from the top

6. Conclusion

In light of the findings, it is evident that the chosen retrofitting method involving the placement of metal rings had a limited impact on overall structural integrity enhancement. Comprehensive numerical modeling and seismic analysis revealed that the retrofitting approach resulted in only an 11.5% increase in structural resistance when the metal rings were optimally positioned one-third from the top of the chimney. Placing the rings under current conditions had no effect on strengthening the structure. This modest improvement falls short of meeting the necessary strengthening requirements for the subject structure.

In conclusion, while the investigation provided valuable insights into the behavior of the industrial historical chimney under the retrofitting technique, the results highlight the limitations of this approach in significantly enhancing structural robustness. The study underscores the importance of considering alternative or supplementary retrofitting strategies to achieve the desired level of structural improvement, particularly in the context of historical and complex structures, where achieving substantial gains in resistance may require more advanced interventions.

Vulnerability assessment of Holy Mary Historical Church in East Azerbaijan, Iran according to Italian Guidelines

Samira Gharehayaghi*[1], Farhad Akhoundi[1]

[1] *Tabriz Islamic Art University, Faculty of Architecture and Urbanism, Tabriz, Iran*

Abstract. Iran, renowned for its rich architectural heritage, is located in an earthquake-prone region, which necessitates the preservation of historical monuments. The East Azerbaijan province, in the northwest region of the country, houses numerous significant heritage sites, notably several historical churches. However, research indicates that only 13 out of 49 churches within the province remain standing, with many having been either destroyed or left in disrepair. A particularly noteworthy example is the Church of Holy Mary, an important architectural heritage site that features distinctive elements of Armenian ecclesiastical architecture. This church was constructed in AD 1518 in the town of Jolfa, along the banks of the Aras River. This study's primary objective was to conduct a comprehensive assessment of the seismic safety of the Holy Mary Church utilizing qualitative methods. This was accomplished through field surveys and extensive library research to ensure a thorough understanding of the church's historical context as well as its architectural and structural features. Following this, the qualitative approach was adopted based on Italian guidelines for evaluating and mitigating seismic risks to cultural heritage to assess the church's seismic vulnerability. The findings revealed a seismic safety index of less than 1, which indicates that the church does not have sufficient safety measures to withstand potential seismic events. This study underscores the critical need to integrate qualitative assessments for the preliminary evaluation of historical buildings' seismic safety, as it is an effective method for quickly estimating a building's safety status before any interventions.

Keywords: architectural heritage; seismic assessment; historical church; Italian guideline; East Azerbaijan Iran

1. Introduction

Religious heritage is culturally and spiritually significant. It embodies a community's history, art, and traditions, while serving as a spiritual center and home for believers. Christian buildings in Iran hold a significant role in representing the country's multiculturalism. These stunning structures, built with grandeur and unique architectural techniques, serve as a testament to the Christian community's rich history in this region, despite their dwindling numbers due to migration. In the meantime, Armenian churches in Iran, especially in East Azerbaijan province, are clear examples of various cultural, social, and religious interactions that indicate the cultural diversity of this region. Historical Armenian churches are a symbol of Armenian culture and architecture from the distant past to the present, as well as a sign of coexistence and ethnic interactions in Iran's history. These buildings showcase the creativity and vitality throughout this multi-millennial geographical space where civilizations have intersected. However, research data reveals that only 13 of the 49 churches in East Azerbaijan province remain standing, with many having been destroyed or fallen into disrepair. (Malekmian, 2001) Therefore, preservation of these historical monuments is crucial, especially in regions prone to earthquakes. Located on the Alpine-Himalayan earthquake belt, Iran is one of the seismically active regions of the world (Abdollahzadeh et al., 2014), and the East Azerbaijan region in North-western Iran is one of the most seismic regions of the country, having experienced many seismic events during its long history (Standard No. 2800, 2014)

As a result, there is an urgent need for structural and seismic evaluation of these buildings to assess their vulnerability and prevent potential destruction. Evaluating the seismic performance of historical monuments is essential for protecting architectural heritage and creating effective preservation strategies. Understanding the structural behavior of these buildings is a crucial first step in this process.In this regard, the Italian guideline "Guidelines for evaluation and mitigation of seismic risk to cultural heritage" (DPCM, 2005) is proposed as a reliable source of guidance that can be employed for the vulnerability assessment of heritage buildings under seismic loads.(Torelli et al., 2020).

*Corresponding author, E-mail: samira.gare1995@gmail.com

https://doi.org/10.31462/icearc2025_a_car_757

These guidelines can be used as a scientific and practical basis for the protection of cultural heritage, especially the Armenian churches of East Azerbaijan. This guideline introduces qualitative methods for assessing the vulnerability of various historical monuments. These include villas and buildings with bearing walls and horizontal diaphragms, religious structures and large halls without intermediate diaphragms, as well as towers and bell towers, other slender structures. Additionally, it covers masonry bridges, triumphal arches, and other arch-based structures.

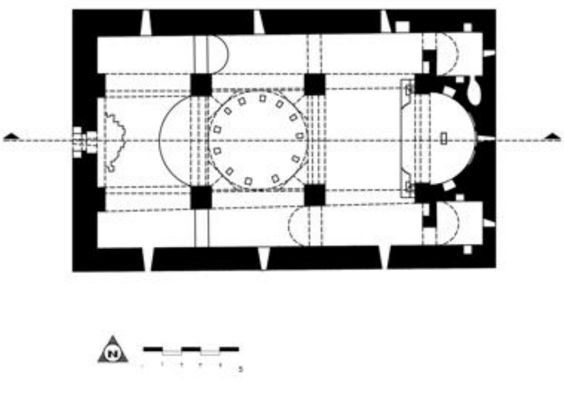
In 2023, a seismic vulnerability assessment of Ali Monsieur House in Tabriz, Iran, was conducted using Italian guidelines, applying a qualitative analysis method suited to buildings with bearing walls and horizontal diaphragms (Gholami & Akhoundi, 2023). This article aims to focus on the vulnerability assessment of the Holy Mary Church in East Azerbaijan, Iran, employing the qualitative method designed for religious structures with large halls. With a rich history dating back to AD 1518, the Holy Mary Church, belonging to the Armenian Gregorian sect, stands as one of the most significant and oldest Armenian churches in East Azerbaijan. This church presents a unique opportunity for assessing seismic vulnerability and developing conservation solutions. In addition to exploring the architectural features and historical context of the Holy Mary Church, this article will provide a qualitative assessment of its current condition based on the established Italian guidelines.

2. Case study: Holy Mary church

The Church of the Holy Mary, demonstrated in Fig. 1, was built in AD 1518 on the scenic slopes of the Sham Valley, overlooking the Aras River. (Karang, 1351). This historical site reflects the architectural style of its era and serves as an important cultural landmark for the local community.

The Church of the Holy Mary of Jolfa is designed as a three-nave basilica. The interior showcases vaulted ceilings, and the exterior features a gable roof. A magnificent high dome is prominent at the center of the Holy Mary church, visible from both the inside and outside of the church. The walls and vaults are constructed from stone, while the dome is made of brick.

Fig. 1. Eastern facade of Holy Mary church (Left: Archives of the Cultural Heritage Organization, East Azerbaijan Province) (Right: Author)



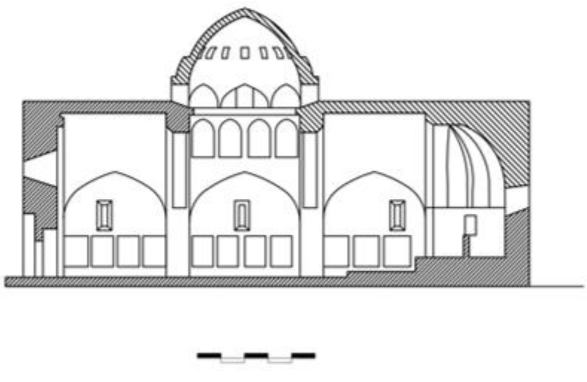


Fig. 2. Left: Plan (Hoviyan, 2003), Right: Section of the Holy Mary church (Hoviyan, 2003),

The church measures twenty-two meters and thirty centimeters in length and thirteen meters and fifty centimeters in width. The dimensions of the apse are four meters and eighty centimeters by three meters and twenty centimeters. The apse stands eighty centimeters higher than the church ground level, and there are two rows of stairs on both the northern and southern sides of the apse, providing access to it. Inside the church, four columns are arranged in two rows. Each column has a square cross-section with each side measuring one meter. The distance between the columns is four meters and eighty centimeters, and they are connected by a truss arch (Hoviyan, 2003). Plan and cross-section of the church are presented in Fig.2.

The spaces between the arches are filled with rubble stone and mud mortar. The dome, featuring twelve skylights, is supported by brick pendentives constructed in the spaces created by the arches.(Fig. 3) The layout of the streets surrounding the church, along with the remnants of villagers' houses (Fig. 4), indicates that many homes once existed in proximity to the church. (Hoviyan, 2003)

Fig. 3. Dome, pendantives and skylights (Left: Archives of the Cultural Heritage Organization, East Azerbaijan Province, Right: Author)

Fig. 4. Holy Mary church and the ruins of the ancient village of Darreh Sham (Archives of the Cultural Heritage Organization, East Azerbaijan Province)

3. Materials and methods

This study utilized qualitative methods to investigate the seismic behavior of the Church of the Holy Mary. To this end, a comprehensive examination of historical documents, maps, and old photographs was conducted to gain insight into the church's history, structure, and previous damage. By understanding the architectural style and historical significance of the church, a more thorough assessment of its vulnerabilities can be achieved. Additionally, a field visit was conducted to assess the condition of the building, focusing on structural damage, cracks, signs of deterioration, and the surrounding environmental conditions. Photographs and videos were captured from various angles of the church for accurate documentation, allowing for a detailed visual record of its current state. Moreover, a qualitative evaluation of the building was performed using the Italian conservation guidelines based on the data gathered. This comprehensive approach not only enhances the understanding of the church's seismic vulnerability but also aids in planning future restoration efforts.

3.1. Qualitative analysis

The qualitative assessment in this study follows the method outlined in the "Guidelines for Evaluation and Mitigation of Seismic Risk to Cultural Heritage". These guidelines, established since 2005, are designed to align with Italy's technical standards for reducing seismic risk and protecting historical buildings. The primary objectives of these guidelines are to provide a method for identifying buildings, assessing their seismic safety, and designing retrofitting interventions all while considering the historical characteristics of each structure. The guidelines provide specific assessment methods designed for the different geometries of buildings. In particular, they introduce a qualitative assessment approach for structures featuring large halls without intermediate diaphragms. For example, the seismic behavior of buildings like churches is analyzed by separating it into macro-elements, which can include façades, halls, apses, bell towers, vaults, and triumphal arches. Each of these components behaves independently in relation to the entire structure of the church.

This methodology thoroughly examines 28 damage mechanisms all of which are outlined in Table 1. Each mechanism is associated with various macro-elements typically found in religious buildings, helping to clarify the specific vulnerabilities or measures each structure may face. By utilizing the correct form, it is possible to establish a vulnerability index (1).

$$i_v = \frac{1}{6}\frac{\sum_{K=1}^{28}\rho_k(V_{ki}-V_{kp})}{\sum_{K=1}^{28}\rho_k} + \frac{1}{2} \quad (1)$$

The next step after calculation of the vulnerability index is to calculate the accelerations corresponding to limit state of damage and ultimate limit state based on 5.16 and 5.17 equations on DPCM (2005) and thereby the seismic safety index of the church (2) (DPCM, 2005).

$$I_S = \frac{a_{SLU}}{\gamma_i S\, a_g} \quad (2)$$

The importance factor of the building, referred to as γ_i is determined based on DPCM (2005) - Table 2.1. The coefficient related to the soil and foundation layers is represented by S and is determined according to NTC18 (Code, I. B., 2018). The design basis acceleration, ag, is established in accordance with the Iranian Seismic Code (Standard 2800). In this context, if the value obtained for I_S is greater than one, the building is resistant to seismic events, and if this value is less than one, the building does not have the expected safety.

3.1.1. Reference limits for cultural heritage

For historic architectural structures, ensuring safety and protection against seismic risks involves two key objectives. First, there is a focus on safeguarding occupants from potential dangers during rare, high-intensity earthquakes, known as the Ultimate Limit State (SLU). Second, it aims to reduce economic and functional damages that may occur during more common, low-intensity earthquakes, referred to as the Limit State of Damage (SLD). The specified limit states are as follows:

•The Ultimate Limit State (SLU) pertains to a building's condition during earthquakes with a 10% probability of occurrence in 50 years.

•The Limit State of Damage (SLD) evaluates the condition during earthquakes with a 50% probability over the same period (DPCM, 2005).

Table 1. 28 damage mechanisms in the churches (DPCM, 2005)

Mechanisms			
4- Nartex	3- Shear mechanisms in the facade	2- Damage at the top of facade	1- Overturning of the facade
			8- Vaults of the nave	7- Longitudinal Response of the colonnade	6- Shear mechanisms in the side walls	5- Transversal vibration of the nave
			12- Vaults of the transept	11- Shear mechanisms in the transept walls	10- Overturning of the transept facade	9- Vaults of the aisles

*Grade of effectiveness in vulnerability indicators
**Grade of effectiveness in aseismic measures

Through a comprehensive field visit and inspection focused on macro-elements and the associated damage mechanisms, as well as an assessment of vulnerability indicators and the aseismic measures relevant to these mechanisms, a scoring table has been derived, which is presented in Table 2. Additionally, the detailed descriptive form of Table 4 is expanded in Table 3, where it incorporates aseismic measures alongside vulnerability indicators. This detailed analysis is particularly relevant for the active mechanisms observed in the Holy Mary Church.

Table 3. Asiesmic measures and Vulneability indicators in active mechanisms of Holy Mary church

Active Mechanisms	**Aseismic measures**	**Vulnerability Indicators**
Overturning of the facade	-	✓ Presence of thrusting elements (vaults)
Damage at the top of facade	-	-
Shear mechanisms in the facade	-	-
Transversal vibration of the nave	-	✓ Presence of vaults and arches
Shear mechanisms in the side walls	-	-
Longitudinal Response of the colonnade	-	✓ Presence of heavy vaults in the central nave
Vaults of the nave	-	-
Vaults of the aisles	-	-
Triumphal arches	✓ Adequate arch thickness	✓ Presence of Dome, Drum and Tiburio
Dome, Drum and Tiburio	-	✓ Presence of large openings in the drum
Overturning of the apse	-	✓ Presence of thrusting vaults
Shear mechanisms in the presbytery and the apse	-	✓ Heavy roof coverings
Vaults in the presbytery and the apse	-	-
Roof mechanisms: side walls of nave and aisles	-	✓ Presence of static thrusts in the roof ✓ Heavy roof coverings

4. Results and discussion

The qualitative assessment of the Holy Mary Church's structural integrity, based on calculations stemming from relations 1 and 2, as well as equations 5.16 and 5.17 outlined in the DPCM (2005), has yielded notable findings, which are presented in Table 6. The safety index of the Church was evaluated under two distinct conditions: the ultimate limit state (SLU) and the limit state of damage (SLD). The analysis reveals safety indices of 0.250 and 0.235, respectively, both of which are less than 1. This indicates a concerning vulnerability of the structure to seismic events with a 10% and 50% probability of occurrence within a 50-year period. Furthermore, as displayed in Table 6, the vulnerability index for the Church of St. Mary is quantified at 0.648. It is essential to note that this vulnerability index systematically excludes the seismic characteristics of the site and the local soil conditions; these elements are integrated within the safety index calculations. Consequently, the results highlight the multifaceted nature of structural vulnerability in relation to seismic risks.

Table 4. Results of the qualitative assessment

	Inspector analysis	Sensitivity analysis
Vulnerability index	0.648	0.583 $<i_v<$0.690
Acceleration corresponding to limit state of damage (a_{SLD})	0.033g	0.038g$>a_{SLD}>$ 0.031g
Acceleration corresponding to ultimate limit state (a_{SLU})	0.135g	0.154g$>a_{SLU}>$ 0.124g
Safety index (a_{SLD})	0.235	0.268$>I_s>$ 0.216
Safety index (a_{SLU})	0.250	0.285$>I_s>$ 0.229

The results of the sensitivity analysis indicate that the vulnerability index of the assessed structure ranges from 0.583 to 0.690. This finding highlights a concerning level of vulnerability when subjected to potential seismic activities. Furthermore, the analysis of the safety index reveals that, under the limit state of damage, the values fluctuate between 0.216 and 0.268, and for the ultimate limit state, the range extends from 0.229 to 0.285. These results suggest that the seismic safety index of the building, based on both the researcher's evaluations and the sensitivity analysis, is below the critical value of 1. This indicates that the structure may not be sufficiently strong to withstand seismic forces. By incorporating sensitivity analysis into the assessment process, we enhance the reliability of the findings and reduce the chances of personal bias affecting the evaluation. This approach leads to a more objective understanding of the building's safety status and highlights the need for further improvements to meet necessary safety standards against seismic risks.

5. Conclusions

The first step in preserving historical monuments is to assess their seismic performance, which is crucial for both their conservation and safety. These historic structures are often vulnerable during seismic events due to a combination of factors, including material degradation, structural settlement, excessive weight, and inadequate maintenance. Therefore, evaluating these buildings is extremely important. One of the primary methods for assessing seismic performance is the qualitative method. This study presents a qualitative evaluation of the historic Church of St. Mary, based on Italian conservation standards. St. Mary is recognized as one of the oldest Armenian churches in Iran, with a history dating back to 1518. Given its location in a seismically active region and its status as the sole remaining testament to a once-thriving historical village, the need for a seismic assessment of this building is significantly underscored. This article not only examines the architectural and historical features of St. Mary but also provides a qualitative evaluation of its condition using Italian guidelines.

The results of the safety index derived from the qualitative assessment conducted by the inspector revealed values of 0.250 for the ultimate limit state and 0.235 for the limit state of damage. Furthermore, the sensitivity analysis indicated that the safety index for the ultimate limit state ranged from 0.229 to 0.285, while the limit state of damage yielded a range between 0.216 and 0.268. These findings suggest that the seismic safety index of the building, as assessed through both the researcher's evaluation and the sensitivity analysis, is below 1, indicating that the structure does not adequately withstand seismic events. It is important to note that integrating sensitivity analysis into the qualitative evaluation the impact of subjective interpretations by the researcher has been minimized, resulting in enhancing the reliability of the assessment of the building's safety status.

All these results highlight the vulnerability of the Holy Mary Church structure to potential seismic events in the region. A review of the safety indices for the limit state of damage and the ultimate limit state suggests that this church is at risk from both rare, high-intensity earthquakes and more frequent, lower-intensity seismic events. The qualitative assessment method is an effective and widely recognized tool in the seismic evaluation of buildings, enabling a prompt estimation of safety prior to any interventions and facilitating the development of effective conservation strategies.

Recognizing the consequences of neglecting seismic safety in historic churches such as the Holy Mary is particularly important, especially in earthquake-prone regions like northwestern Iran, where many churches have been destroyed or fallen into disrepair. This study highlights the urgent need for increased awareness and specialized efforts concerning the preservation of Armenian churches in Iran. These structures represent more than just relics of the past; they are living embodiments of a rich cultural heritage and vital connections to the region's multicultural history, deserving preservation for future generations.

Abstract. Ankara, which was declared as the capital of the Republic, has hosted the designs of famous and valuable architects with its rapid development activities. These valuable examples are concentrated in the Ulus and Yenişehir axes that form the old city center. Anafartalar Street is an approximately 1.5 km long street that starts from Ulus Square, turns in front of the old municipality, and ends in Samanpazarı. All of the structures bordering the street were built during the republican period; some of them have been preserved until today in the form they were built in the early republican period. However, these structures, which experience problems such as development activities in the region, rent, infrastructure and superstructure problems, unqualified functional changes, and neglect, are losing their original characteristics and becoming obsolete. Within the scope of this paper, the original architectural examples that have survived to the present day on Anafartalar Street have been typologically analyzed and detailed according to their periods and architectural features. The problems of the street, along with buildings changes and deteriorations, have been identified and examined under headings. The original structures identified have been evaluated within the scope of protecting modern architectural heritage within the context of DOCOMOMO, UNESCO, and the European Council regulations and recommendations. The data obtained have shown that there are unique examples built by pioneer architects in different architectural periods in the study area, but despite the fact that the structures are registered, changes and transformations, especially those originating from unqualified commercial functions and infrastructure/superstructure problems have hindered protection.

Keywords: Early Republican Architecture; Modern Architectural Heritage; Conservation; DOCOMOMO, Restoration

1. The Importance and Formation of Anafartalar Street

Ankara was founded in a mountainous region around the Hatip Stream on fertile lands fed by numerous streams south of the Çubuk plain. The data shows that the first settlement in Ankara began in the Phrygian period. The Lydians and Persians then ruled the city in turn. The city, which was taken by Alexander the Great, was captured by the Galatians in the 3rd century BC. The Tectosags, the raiding tribe of the Galatians, chose Ankara as their capital. After being captured by the Roman Emperor Augustus, the city continued as a large garrison. The temple, large - small baths, and gladiator graves that have survived from this period to the present day are in a way that tells us of the importance of the city. The city, which came under Seljuk rule in 1073 after the Roman period, was especially developed with mosques, madrasahs, and defensive structures during the reign of Alaaddin Keykubat. The Alaaddin Mosque, Ahi Şerafeddin Mosque, Ahi Evran Mosque, Akkale, and Akköprü are among the structures that have survived from this period. The city, which was under Mongol rule for a period and then under Eretnaoğulları rule, joined the Ottoman principality in 1354 and remained under the Ottoman Empire's protection until the republic's declaration.

In the second half of the 19th century, the reflection of the centralized management approach in the provincial cities on the space is seen in Ankara as the equivalent of the administrative structures built in the northwestern perimeter of the traditional city, in the area near the Hacı Bayram Mosque (Avcı, 2017). The arrival of the railway to the city in the early 1890s turned the new center, connected to the station street, into a focal point. Municipal services in Ankara, dating back to the 1860s, are carried out in the building designed in 1883, located on the branch of today's Anafartalar Street, formerly called Balıkpazarı Street, near the new center (Kolay, 2018:238-239) (Fig. 1)

Fig. 1. Old Ankara Municipality Building (İ.Ü. Nadir Eserler Kutuphanesi, 90431-36)

Just before the declaration of the Republic, Ankara was declared the capital on October 13, 1923. With the declaration of the capital, a rapid population increase occurred, and the state made significant investments in the development of Ankara, whose population increased after it became the capital. The first studies that were initiated within this scope were zoning plans. However, in order to solve the housing problem of the population, which was 20,000 in the 1920s and reached 75,000 in 1927, and to accelerate zoning studies, Ankara Municipality was established by the law dated February 16, 1924, instead of Ankara Municipality, which had insufficient powers from the Ottoman period (Duru, 2012: 3; Çapa, 2020: 78).

The 1924 Ankara Municipality Map, which included the first planning decisions of the Ankara Republic, was prepared by a military commission (Cengizkan, 2004:19). The commission, established under the chairmanship of the Minister of Public Works at the beginning of 1924, prepared a city plan consisting of 4 sheets and submitted it to the Municipality. In the article written in the Hakimiyet-i Milliye newspaper dated 15 Kanunsani (January) 1924, it is stated that the first sheet of this plan covers the area around the Grand National Assembly, the neighborhoods around Bent Creek, and the vicinity of the Municipality Office. In the 1924 plan, it is seen that an axis with a linear line called Balıkpazarı Street starting in front of the Old Municipality Building was defined (Fig. 2). Upon determining that this plan was inadequate to meet the needs of the new capital, the Municipality commissioned Carl Lörcher to prepare a new plan. In the Lörcher plan, Anafartalar Street is located as a linear street starting from the front of the Municipality and connecting to the traditional center via Çıkrıkçılar hill (Cenzgizkan, 1927: 59).

Fig. 2. Balıkpazarı Street and the Municipality Building on the 1924 Ankara Municipality Map (Salt Archive: APLMMV06). (https://archives.saltresearch.org/handle/123456789/102344) (Adapted by the authors)

The importance of Anafartalar Street, which is currently formed by the combination of Karaoğlan Street, Balıkpazarı Street, and Cocuk Sarayı Streets, was realized with the acceleration of construction works in the 1920s. The area between Işıklar Street, Konya Street, and Anafartalar Street, which was destroyed by the fire of 1916, is one of the areas that was primarily planned and built (Tunçer, 2014; 27). The four buildings built by the public on Anafartalar Street are of great importance in Turkish Architecture with their period's successful and exemplary projects. Gazi and Latife Schools (1924) Courthouse (1925-26), Child Protection Agency General Directorate Building (1927, Arif Hikmet Koyunoğlu) (Aslanoğlu, İ, 2001) constitute the earliest important examples built on the street (Fig. 3). The importance of the structures is also understood from the fact that the street was known as Cocuk Sarayı Street during this period (Tuncer,2014;27). In addition to public structures parallel to the apartment development in Yenişehir, shops, inns, and passages continued to be built on the street along with the first apartment buildings of Ankara. During this period, Anafartalar Street became a center where all civil servants living in the Ulus district and its surroundings shopped. In the bazaar, where all daily needs could be met, many commercial activities such as luxury products such as furs, hats, carpets, jewelers, tailors, hairdressers, barbers, and photographers were carried out. This street, which was very important for Ankara, attracted attention with its apartment buildings, clean and wide sidewalks, and shops with awnings (Bilgen, 1985; 20).

Fig. 3. The newly constructed patronage (Himaye-i Etfal) building in Ankara (Servet-i Fünun, 14 April 1927)

However, the fact that the growth of the capital was confined within the historical city center caused different searches to emerge quickly; Anafartalar Street relatively lost its importance in its early years. In this context, the suggestion that Ankara should grow in the south direction is included in the Lörcher plan (Cengizkan, 2004) and is also reflected in the writings of intellectuals of the period. From Hamdullah Suphi Bey's article titled "Şehremini Haydar Bey" in the Hakimiyet-i Milliye newspaper dated June 11, 1924: *"It is a waste twice to stir up and move old Ankara too much; the result will be weak and inadequate. Secondly, we will spend more on fixing the old than making the new. The city should gradually move towards the southern ridges."* With the planning decisions taken in the Lörcher plan and the subsequent Jansen plan, Yenişehir was determined as the city center, and sub-centers such as Çankaya and Maltepe Kurtuluş emerged. Starting from the 1930's, public institutions were also moved to the Bakanlıklar area on the axis of the new center. For this reason, there was a change in the socio-cultural user profile on Anafartalar Street, and the houses on the street were generally re-functioned within a commercial context. Over time, with the involvement of unqualified trade, it became a region preferred by the middle and low-income groups; for this reason, some qualified buildings were demolished, and some changed and deteriorated.

The study conducted within the scope of this report focuses on the current state of Anafartalar Street due to its importance. It aims to identify the problems and present suggestions as a result of the analyses made with various field studies and observations of the street between 2022-2025.

2. Documented problems on Anafartalar Street

It has been determined that 106 buildings on Anafartalar Street are in both directions. 30 of these structures are registered. 11 of the registered structures are public structures. Structures with different functions built on the street starting from the 1940s are lined up on both sides of the street.
The problems detected in the field examination were evaluated in two categories: area- and structure-based.

2.1. Area-Based Problems Detected

In the examination carried out in the area, it was determined that traffic is one of the most important elements that damage the texture and structures. Anafartalar Street is the main artery connecting Ulus Center to Kurtuluş and Cebeci. The street constitutes the main artery providing access to important public or private health, education, culture, and administrative structures. For this reason, it constitutes a primary transportation axis and is used intensively. Although the street is primarily used one-way, it forms the route of more than 100 buses. In addition, the beginning of Çıkrıkçılar Street is the departure point of minibusses on the street, which is also a route for many others. In addition to public vehicles, the street is also used by private cars, freight vehicles of various sizes, taxis, and motorcycles.

One of the most important problems caused by this situation is the discharges on the ground due to vibration, cracks, and similar structural deteriorations in cultural assets. Vibration on the ground can be easily felt, especially when materials brought to wholesale businesses are transported by heavy tonnage vehicles. Another problem caused by heavy vehicle traffic is the discoloration and crusting problems caused by the condensation of carbon monoxide gas from vehicle exhausts on the building surfaces. This gas also forms carbonic acid when it falls to the ground with precipitation, damaging the surfaces.

Another problem caused by heavy vehicle traffic is the cars parked on the road or wherever considered appropriate. Since these vehicles park in several rows, pedestrian safety problems occur, and elderly, children, and disabled users cannot safely exit the sidewalk. It has been determined that parking is also done on the sidewalk, at the pedestrian crossing, at the door and garage entrance, and at the shop front on the street; and due to this situation, pedestrian safety cannot be provided even on the sidewalk. Although it has been observed that methods such as constantly having more than one traffic police officer in the area, warning with various warning signs, installing obstacles to prevent access to the sidewalk, and removing vehicles with tow trucks have been applied, it has also been determined that they have not been successful.

Fig. 4. Unplanned parking lots (a,b) ;Traffic jam and heavy vehicles on street (c,d)

Another problem related to heavy traffic is the unplanned use of every vacant building plot or every garden accessible from the street as a parking lot. This use affects the continuity of traffic due to the entrance and exit from the street; it also causes damage to the structures due to parking in the spaces between the structures. It has also been observed that vehicle and pedestrian safety cannot be ensured due to unplanned parking lots.

One of the problems detected in the area is the decrease in security, especially at night. During the fieldwork, it was determined that the trade and storage functions supporting this function were very intense. It is seen that the trade function is largely concentrated on businesses doing wholesale; there are very few businesses doing retail sales. Apart from the trade function, there are public institutions and organizations and very few small-scale restaurants in the area and the immediate vicinity.

The research conducted by Çıtır (2023) reveals a significant change in original functions. Within the scope of the literature data obtained, it was determined that the original function of most 106 structures was commercial, followed by housing, public administrative buildings, mosques, and school buildings. However, the situation in 2022 shows that the commercial function increased from 61% to 84%; functions such as education and health decreased; and the shelter function disappeared (Çıtır, 2023:54; 54; Koç et al. 2022).

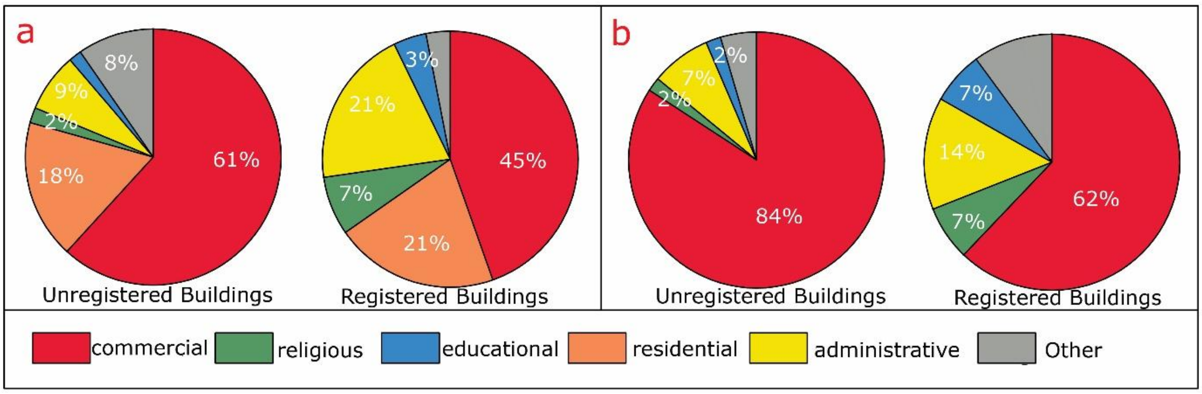

Fig. 5. Original function (a) and Current function (b) distribution graph of the buildings on Anafartalar Street (edited from Çıtır, 2023:54).

The increase in commercial use causes the area to be used intensively during the day but not at all in the evening, thus decreasing night security. The street becomes a place used by unwanted crime-prone groups at night; this causes qualified functions to move away from the area or not be located in this area.

It is seen that the original texture of the street has also been lost over time. After the demolition of the original structures, the unqualified and high-rise buildings built in their place prevent the visibility and perception of original and registered structures. It is seen that the height of the floors has increased over the years, and in this context, there has been a decrease in qualified structures. In the examination carried out in the area by Çıtır (2023), it was determined that there were 9 1-storey, 13 2-storey, 8 3-storey, 29 4-storey, 19 5-storey, 21 6-storey and three buildings higher than 6 (Çıtır, 2023:58).

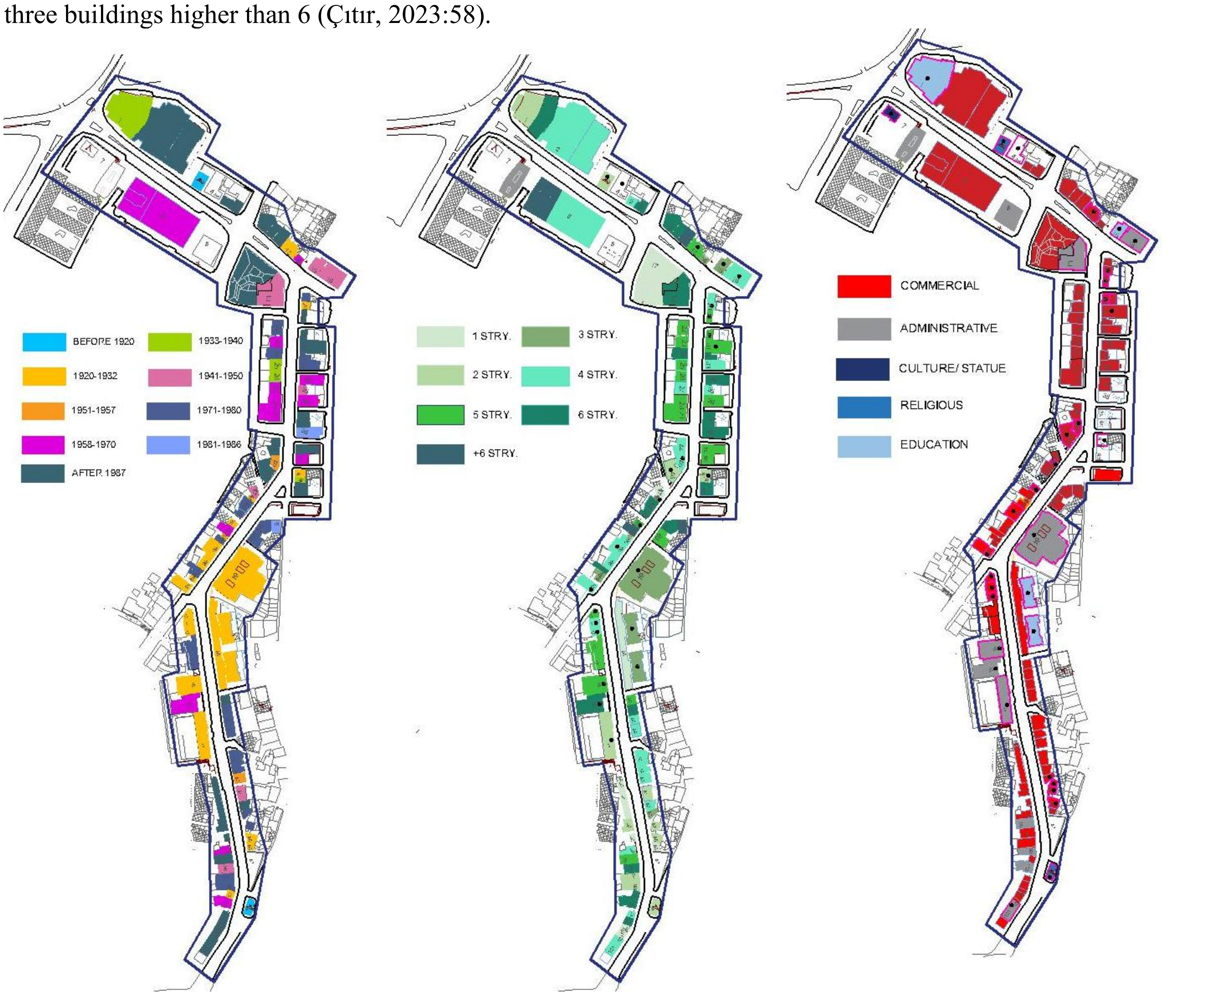

Fig. 6. Analysis of the construction date (A) (Çıtır, 2023:61). number of floors (B) (Çıtır, 2023:58) and Current function distribution graph (C) (Çıtır, 2023:54) of the buildings on Anafartalar Street

The study conducted by Çıtır (2023) determined that of the structures in the area, 25 structures, 19 of which are registered, were built between 1920-1930; 4 structures, 1 of which is registered, were built between 1930-1940; 6 structures, 3 of which are registered, were built between 1940-1950; 16 structures, 1 of which is registered, were built between 1950-1970; and 22 structures, 1 of which is registered, were built after 1970 (Çıtır; 2023:80). When the analysis of floor height and construction year is superimposed, it is seen that the floor height increases in the late-era structures.

2.2. Problems Identified Based on Structures
In the examination conducted in the field, it was determined that structure-based problems are generally related to function changes. Function changes are observed in most registered or unregistered qualified structures. This change is present in all residential structures; It is also seen in some commercial structures due to the change in the goods sold.

Fig.7. An apartment building example of inappropriate transformations (Kaya, 2023:65)

It is seen that the ground floors of the structures used as residences are especially transformed into commercial functions, and the upper floors are transformed into warehouses of these commercial enterprises. The biggest problem this transformation has caused is the conscious interventions such as transforming elements such as doors and stairs and breaking the walls to allow the space to take more materials since the structures were not built as warehouses. These interventions destroyed original elements; because of this, unqualified additions were made in their places. In the field examination, it can be seen that the upper floors continue to be used as warehouses. In the study conducted by Kaya in 2023; what was destroyed with the transformation of an apartment building adjacent to the street is revealed. This structure was built as a residence but transformed into a commercial function over time. It has been determined that the original elements of the structure were destroyed in order to easily stack the materials in the rooms within the scope of the transformation (Kaya, 2023:72). Another negative aspect of these transformations is the deterioration that occurs as a result of the lack of necessary cleaning and maintenance due to storage use. In addition to various accumulations, moisture, biological problems, and structural problems due to excessive load, such as plaster and paint peeling, breakage, etc., can also be seen during the transportation of the material.

Within the scope of functional transformations of buildings, there have been many examples of opening different entrances, especially to rent out commercial spaces on the lower floors by increasing them. In order to access these entrances from outside the building, unqualified staircases and similar additions have been made on different facades from different levels; the facade character and originality have been damaged. It is seen that some of these additions, which are generally preferred as metal, have also suffered severe deterioration and affected the facade. These interventions, which have been made on many different levels, also prevent the facade from being understood and read.

Unqualified additions to the side facades have also caused small commercial streets to form in front of these facades. In order to prevent the products exhibited in these streets to be shown to the customers from being affected by atmospheric conditions and to ensure that they can be walked around easily, these streets have been covered with unqualified upper covers. However, it is seen that these covers have adverse effects on the facades of the building, especially moisture, in addition to bad appearance. In addition, the structure's integrity cannot be understood due to these upper covers; the facades cannot be seen.

Fig. 8. Unqualified additions and changes on the rear sides of the buildings

Another element that negatively affects the integrity of the facades in buildings is large and colorful signs incompatible with the texture and structures. These signs are kept very colorful and large to be seen from a distance; they are designed even a few stories high depending on the functions on the upper floors. Since there are many side by side and one under the other, it is impossible to understand and perceive the facades. This pollution, which is very serious, especially in unregistered buildings, also causes structural damage due to the heavy loads that are tried to be attached to the facades of the building; traces of rusting iron remain and have an adverse effect as a moisture element on the facade.

Even if the function of the buildings does not change, unqualified interventions made to make them suitable for comfort conditions also create another problem. In this context, the most frequently encountered intervention is the air conditioning units hung on the facade. Since these units are fixed to any place on the facade to spend the least amount of material, they create strange and ugly images and look ugly. However, in examples where necessary maintenance is neglected, it is frequently seen that dirty water flows from the facade to the street when they are operated. In addition to being metal, the buttress irons that are fixed to the facade are also metal, so they rust and cause pollution. Because it is an important need in hot weather, many air conditioning units hung on the facade create a serious load in total, which causes an unexpected and uncalculated load to be added to the structure structurally.

Apart from air conditioning units, iron networks, railings for security purposes, and changed architectural elements are other types of deterioration. In this context, the changes that have come to our attention are elements that make it difficult to read the original elements. In addition, there are also many examples where cables are passed through the facades, and careless interventions are made, even if they do not damage the structure.

3. Conclusions

Anafartalar Street continued as the most important trade center and prestigious (distinguished) housing area of Ankara's capital from the Early Republican Period to the 1960s. The trade areas bordering it in the immediate vicinity, Samanpazarı, Çıkrıkçılar Yokuşu, Denizciler Street, and Ulus, brought liveliness, dynamism, and prestige to the economic and social life of Anafartalar Street. There are also social and cultural urban living areas and buildings in this area and its immediate vicinity where distinguished families live. Bakeries (Istanbul, Halk, Kadıköy, Akat, Akalın, Şark Bakeries), restaurants (Boğaziçi etc.), shops in different sectors (Jewellers, Eyüp Sabri Tuncer Store, Lale (Togo) Shoe, Sebat Pharmacy, İstanbul Pharmacy, Haim Kohen Shoe Shop - Atatürk's shoemaker-, Foto Ar, Foto Spor, Foto Rıdvan etc.), coffee houses (Kızılırmak, Taflan etc.), patisseries, Melek Cinema, Şengül Bath, Libraries (Gençlik, Tarık Edip Bookstore and Libraries), Child Protection Institution (Himaye-i Etfal) and the garden and swimming pool belonging to this institution and the surrounding residential areas were urban spaces used and shared by all city dwellers. Apart from public buildings, it is known that the city's first apartment buildings were also built on the Street. There were workplaces and shops on the ground floors of these apartment buildings (such as Talas, Dökmeci, and Hamamcızadeler Apartments).

With the restructuring of the capital with the Republic, the city and administrative center was shifted to Yenişehir, Kızılay, Bakanlık, and Ulus City Center, and therefore, Anafartalar Street began to lose its importance and value. In recent years, with the changing shopping style, the increase in large shopping malls preferred on an urban scale, and online shopping, the commercial life on Anafartalar Street lost its former liveliness and dynamism and collapsed.

Although commercial activities continued on Anafartalar Street during this change process, those who adapted to the changing commercial style (such as Boğaziçi Lokantası, Ayakkabı Dünyası) opened branches in the new city center and shopping malls and developed their commercial organizations and activities. Therefore, tradespeople and the local government did not care about this Street; no maintenance or repair was done on it for approximately 30-40 years. Thus, the Street began to become dilapidated. The fact that the existing houses do not have the comfort facilities of today's new centers is shifting from the Ulus region, and the elite families have left the area, which has caused both economic and social changes on the Street negatively. The fact that the tradesmen and users do not care about the old life habits and values, that they deny the historical, cultural and social values of the environment, or that they are not sensitive about these issues (such as advertising and sign pollution, the use of the Street as a parking lot, distrust of neighbors) are among the reasons for both the loss of prestige and the physical-spatial collapse of the Street. A rehabilitation project is currently being implemented on the Street. Within this study, it is seen that the problems that fall within the scope of simple repair in the structures have been resolved; unqualified applications, such as signs and billboards that cover the facades of the structures unnecessarily, have been removed or arranged. It has been observed that the signs are made in a single type with gray text on a black background, following a particular system so as not to cover the facade; unqualified coatings are removed, and a single type of black aluminum coating is applied; the architectural elements forming the facade are renewed in the same way, and the facades are painted, thus achieving a clean and healthy quality. However, the scope of restoring the Street to its former glory should be considered from different perspectives.

In this context,

- Preparation and dissemination of environments and information programs to raise awareness and sensitivity of commercial and business owners about the historical, cultural, and physical values of this Street,
- Tradesmen's participation in the Street's recovery efforts, their in-kind and cash support must be provided,
- Preparation and implementation of promotion programs for the city and even the entire country in order to protect the original characteristics of Anafartalar Street and its immediate surroundings and ensure sustainability,
- Programming of social and cultural activities (festivals, exhibitions, concerts, etc.) with the cooperation of tradesmen
- Following fair methods in recovery efforts, not giving privileges to individuals or institutions, and creating an environment of trust in this regard
- Ensuring the interest and support of local government(s), the Ministry of Culture, and all relevant civil society organizations (such as Ankara Chamber of Commerce, Ankara Tradesmen and Craftsmen Association, Ankara Jewelers' Chamber) in the subject,
- Urgent development of solutions regarding the transportation problem of the Street as much as (or primarily) improving the structures and/or physical-spatial structure and implementation,
- Determining the needs and expectations of the tradesmen in projects to be produced with the participation of the tradesmen in solutions aimed at increasing economic gain, which is the priority of the tradesmen,

- Considering the importance of the Street (starting from Hacıbayram and covering Kale and Hamamönü) within the urban scale "cultural tourism basin", developing and urgently implementing solution proposals regarding increasing the level of accessibility,
- Considering the location of the Street in Ulus Historical City Center, solving the parking problem, especially creating parking areas that will facilitate the access of vehicles belonging to local and foreign tourists to the Street.
- Immediately ensure security on the Street and its immediate surroundings, and take the necessary measures to illuminate the area at night.

It will ensure that the value of the Street is preserved and that the necessary measures are taken to pass it on to future generations both in terms of structure and structure. In this context, the fact that the region was included in the UNESCO temporary heritage list with the name "Ankara: The Planning and Building of a Republican Modern Capital City" on 11/04/2025 is also a very positive development. With this success, an important step has been taken in the positive transformation and development of the region.

The impact of climate change on adobe structures in UNESCO World Heritage List

Oğuz Kırcı*[1]

[1] *Avrasya University, Department of Architecture, Trabzon, Türkiye*

Abstract. As the impacts of climate change increase and become more visible, understanding the vulnerability of cultural heritage values to climate change has become an integral part of conservation efforts. According to UNESCO, one in six cultural heritage sites is under threat due to climate change. To ensure the conservation of cultural heritage values, it is essential to investigate the effects of climate change on heritage sites and to develop solutions for their protection. Consequently, studies on the impact of climate change on cultural heritage have recently gained momentum.There is a growing interest in sustainable natural and traditional building materials to cope with the impacts of climate change. Due to its low energy requirements during production, recyclability, and lack of need for additional insulation, adobe has been used as an ecological and sustainable material throughout history. Structures built with adobe have been an essential part of local architecture in various cultures over the centuries. However, these structures can weaken due to climate-induced factors such as humidity, temperature fluctuations, and erosion.This study examines the deterioration of adobe materials used in structures located within UNESCO World Heritage cultural sites as a result of their exposure to climate change, as well as the conservation practices implemented or recommended to address such deterioration. By analyzing these cultural heritage assets, the study aims to create a literature resource on the conservation of adobe structures and materials.

Keywords: Climate change; Cultural heritage; Adobe; UNESCO World heritage list; Conservation and restoration

1. Introduction

Climate change is a global phenomenon that affects both tangible and intangible cultural heritage. Extreme weather events are causing damage to cultural values. These rising temperatures are accompanied by consecutive droughts and floods caused by intense rainfall. Changes in humidity levels, fluctuations in freeze-thaw cycles, and biological degradation pose further threats to historic buildings and sites (Pasikowska-Schnass, 2024). According to UNESCO, one in six cultural heritage sites is currently under threat due to climate change (Banjo, 2025). In order to preserve cultural heritage values, it is essential to understand the impacts of climate change on heritage sites and respond effectively (UNESCO Türkiye Milli Komisyonu, 2025). As the effects of climate change intensify and become more visible, understanding the vulnerability of cultural heritage to climate change is expected to become an integral part of conservation efforts (Perry & Falzon, 2025). For this reason, research on the impact of climate change on cultural heritage has gained significant momentum in recent years. Since the issue entered UNESCO's agenda, it has gained visibility through international discussions and continues to be examined in various publications.

Adobe, one of the most widely used building materials in the world, is produced by mixing earth, water, and certain additives. Due to the accessibility of its raw materials, adobe is typically produced on-site. Its characteristics—such as requiring little or no energy during production, being entirely recyclable, and not requiring additional insulation—have made adobe a preferred material in many structures throughout history (Zakar & Eyüpgiller, 2015).

2. UNESCO World Heritage List and Adobe Properties

The United Nations Educational, Scientific and Cultural Organization (UNESCO) aims to identify, protect, and preserve cultural and natural heritage around the world that is considered to be of outstanding value to humanity. This objective is articulated in the Convention Concerning the Protection of the World Cultural and Natural Heritage, adopted by UNESCO in 1972. What makes the World Heritage concept exceptional is its universal applicability. World Heritage sites, regardless of the territory on which they are located, belong to all peoples of the world (UNESCO, 2025a).

* Corresponding author, E-mail: oguzkirci@gmail.com

https://doi.org/10.31462/icearc2025_a_car_803

Although there are numerous cultural heritage properties around the world, not all of them are included in the UNESCO World Heritage List. In order for a cultural heritage property to be inscribed on the World Heritage List, it must possess Outstanding Universal Value and meet at least one of the ten selection criteria established by UNESCO. These criteria are outlined in the Operational Guidelines for the Implementation of the World Heritage Convention. To reflect the evolving concept of World Heritage, the Committee periodically reviews and revises the selection criteria. Table 1 presents the content of the selection criteria defined by UNESCO (UNESCO, 2025b).

As shown in Table 1, Criteria I–II–III–IV–V and VI are related to the selection of cultural heritage properties, while Criteria VII–VIII–IX and X pertain to the selection of natural heritage properties. Within the scope of these criteria, there are currently 1,223 properties inscribed on the UNESCO World Heritage List. A search on the official UNESCO World Heritage website using the terms “adobe,” “mud-brick,” and “mud brick” yielded 28 heritage properties constructed with adobe materials. General information about these adobe heritage sites—such as their country, date of inscription, property category, and whether they are listed as in danger—is presented in Table 2.

Table 1. UNESCO World Heritage List Selection Criteria (UNESCO, 2025b)

UNESCO World Heritage List Selection Criteria		
Cultural Criteria	**I**	to represent a masterpiece of human creative genius
	II	to exhibit an important interchange of human values, over a span of time or within a cultural area of the world, on developments in architecture or technology, monumental arts, town-planning or landscape design;
	III	to bear a unique or at least exceptional testimony to a cultural tradition or to a civilization which is living or which has disappeared
	IV	to be an outstanding example of a type of building, architectural or technological ensemble or landscape which illustrates (a) significant stage(s) in human history;
	V	to be an outstanding example of a traditional human settlement, land-use, or sea-use which is representative of a culture (or cultures), or human interaction with the environment especially when it has become vulnerable under the impact of irreversible change;
	VI	to be directly or tangibly associated with events or living traditions, with ideas, or with beliefs, with artistic and literary works of outstanding universal significance. (The Committee considers that this criterion should preferably be used in conjunction with other criteria);
Natural Criteria	**VII**	to contain superlative natural phenomena or areas of exceptional natural beauty and aesthetic importance;
	VIII	to be outstanding examples representing major stages of earth's history, including the record of life, significant on-going geological processes in the development of landforms, or significant geomorphic or physiographic features;
	IX	to be outstanding examples representing significant on-going ecological and biological processes in the evolution and development of terrestrial, fresh water, coastal and marine ecosystems and communities of plants and animals;
	X	to contain the most important and significant natural habitats for in-situ conservation of biological diversity, including those containing threatened species of outstanding universal value from the point of view of science or conservation.

Table 2. General Information on Adobe Properties in the UNESCO World Heritage List

UNESCO World Heritage List	**Country**	**Date of Inscription**	**Category of Property**	**In Danger**
Abu Mena	Egypt	1979	Cultural	Yes
Tchogha Zanbil	Iran	1979	Cultural	No
Archaeological Ruins at Moenjodaro	Pakistan	1980	Cultural	No
Old Walled City of Shibam	Yemen	1982	Cultural	Yes
Old Town of Ghadamès	Libya	1986	Cultural	Yes
Bahla Fort	Oman	1987	Cultural	No
Historic Centre of Lima	Peru	1988	Cultural	No
Old Towns of Djenné	Mali	1988	Cultural	Yes
Archaeological Sites of Bat, Al-Khutm and Al-Ayn	Oman	1988	Cultural	No
Taos Pueblo	USA	1992	Cultural	No
Coro and its Port	Venezuela	1993	Cultural	Yes

Table 2. continued

Archaeological Zone of Paquimé, Casas Grandes	Mexico	1998	Cultural	No
Tiwanakun Spiritual and Political Centre of the Tiwanaku Culture	Bolivia	2000	Cultural	No
Samarkand – Crossroad of Cultures	Uzbekistan	2001	Cultural	No
Ashur (Qal'at Sherqat)	Iraq	2003	Cultural	Yes
Cultural Landscape and Archaeological Remains of the Bamiyan Valley	Afghanistan	2003	Cultural	Yes
Bam and its Cultural Landscape	Iran	2004	Cultural	No
Pasargadae	Iran	2004	Cultural	No
Kunya-Urgench	Turkmenistan	2005	Cultural	No
At-Turaif District in ad-Dir'iyah	Saudi Arabia	2010	Cultural	No
Cultural Sites of Al Ain Hafit, Hili, Bidaa Bint Saud and Oases Areas)	United Arab Emirates	2011	Cultural	No
Historic Centre of Agadez	Niger	2011	Cultural	No
Shahr-i Sokhta	Iran	2014	Cultural	No
Aqueduct of Padre Tembleque Hydraulic System	Mexico	2015	Cultural	No
Arslantepe Mound	Türkiye	2021	Cultural	No
Sudanese style mosques in northern Côte d'Ivoire	Côte d'Ivoire	2021	Cultural	No
Dholavira: a Harappan City	India	2021	Cultural	No
Royal Court of Tiébélé	Burkina Faso	2024	Cultural	No

As seen in Table 2, the UNESCO World Heritage List includes properties from various countries around the world. The chronological range of inscriptions—beginning with Abu Mena and Tchogha Zanbil in 1979 and extending to the Royal Court of Tiébélé in 2024—demonstrates the continued acknowledgment of adobe architecture as a valuable heritage asset across various regions. Geographically, these sites are concentrated in areas characterized by historical and climatic diversity, including the Middle East, North and West Africa, South Asia, and Latin America. This distribution underlines the adaptability and cultural resonance of adobe construction techniques in response to local environmental and societal needs. A notable point of concern is that some of these sites are currently listed as World Heritage in Danger. Specifically, sites located in countries such as Yemen (Shibam), Libya (Ghadamès), Mali (Djenné), Iraq (Ashur), and Afghanistan (Bamiyan Valley) are exposed to threats stemming from armed conflict, environmental degradation, or insufficient preservation efforts. In total, 7 out of the 28 sites are in danger, which highlights the fragility of adobe architecture and the urgent need for effective, context-sensitive conservation strategies.

All of these heritage values must be preserved and transmitted to future generations by meeting UNESCO's selection criteria and by maintaining their outstanding universal value, thus helping to bridge the past and the future. The specific selection criteria met by these 28 adobe-based World Heritage properties are presented in Table 3.

Table 3. Selection Criteria of Adobe Properties on the UNESCO World Heritage List

UNESCO World Heritage List	Criterion Description
Abu Mena	**Criterion IV:** Abu Mena is an exceptional early Christian monastic and pilgrimage center in the Near East, showcasing a blend of Egyptian and Mediterranean architectural influences.
Tchogha Zanbil	**Criterion III:** The ruins of Susa and Tchogha Zanbil are the only surviving examples of architectural development from the Middle Elamite period (1400-1100 BCE). **Criterion IV:** The ziggurat at Tchogha Zanbil is the best-preserved monument of its kind and the largest outside Mesopotamia.
Archaeological Ruins at Moenjodaro	**Criterion II:** Moenjodaro represents the earliest planned city in the Indian subcontinent, significantly influencing later urban developments. **Criterion III:** Moenjodaro, the best-preserved Indus Valley urban ruin from the 3rd millennium BC, provides exceptional testimony to the Indus civilization.

Table 3. continued

Old Walled City of Shibam	**Criterion III:** Shibam's dense multi-storeyed buildings with minimal ground-level openings reflect intense family rivalries and a long-standing homogeneous society, now threatened by socio-economic change. **Criterion IV:** Shibam, encircled by a fortified wall, is a prime example of Hadrami urban planning, with its grid layout and towering mudbrick houses, reflecting the city's economic and political prominence from the 16th to 19th centuries. **Criterion V:** Shibam, nestled between mountains and a floodplain wadi, is the last surviving evidence of a society adapted to spate agriculture, yet vulnerable to floods and socio-economic shifts.
Old Town of Ghadamès	**Criterion V:** Ghadamès is an exceptional Saharan settlement with a unique built heritage adapted to the harsh climate, serving as a key trans-Saharan trade hub for 2,000 years while developing distinctive architecture and traditions.
Bahla Fort	**Criterion IV:** Bahla Fort and its oasis settlement exemplify a defensive architectural ensemble that supported tribal prosperity in Oman and the Arabian Peninsula during the late medieval period.
Historic Centre of Lima	**Criterion IV:** The Historic Centre of Lima exemplifies Spanish colonial urban and architectural development in Latin America, showcasing adaptation to local materials, climate, and earthquakes. San Francisco de Lima is a remarkable and complete convent complex from the colonial era.
Old Towns of Djenné	**Criterion III:** Djenné-Djeno and associated sites provide exceptional evidence of pre-Islamic civilizations in the inland Niger Delta, showcasing evolving dwellings, industrial techniques, and rich archaeological finds. **Criterion IV:** Djenné's architecture, influenced by Moroccan and Toucouleur styles, exemplifies a significant historic period with vertical structures, buttressed facades, and the iconic 1906-1907 Mosque reconstruction.
Archaeological Sites of Bat, Al-Khutm and Al-Ayn	**Criterion III:** The settlements, necropolises, and workshop areas of Bat, al-Khutm, and al-Ayn form the most complete and well-known archaeological complex in Eastern Arabia from the 3rd millennium BCE. Cuneiform texts indicate that Magan (Oman) was a major copper extraction center, exporting to Mesopotamia and possibly the Indus Valley. The site provides evidence of increasing social hierarchy and economic changes due to long-distance trade. **Criterion IV:** The necropolis of Bat is a unique and characteristic testimony to the evolution of funerary practices during the Early Bronze Age in Oman.
Taos Pueblo	**Criterion IV:** Taos Pueblo is an outstanding pre-Hispanic architectural ensemble that has preserved its traditional forms due to the continuous living culture of its community.
Coro and its Port	**Criterion IV:** Coro and its Port showcase unique adobe architecture uncommon on the Caribbean Coast. Traditional mud-building techniques, such as bahareque, adobe, and tapia, have been adapted to social, climatic, and environmental conditions, forming a distinctive architectural style. **Criterion V:** Coro is an exceptional example of an early Spanish colonial town on the Caribbean coast of South America. It has preserved its original layout and urban landscape, combining Spanish, Mudéjar, and indigenous styles, later influenced by Dutch architectural elements from Curaçao and Aruba.
Archaeological Zone of Paquimé, Casas Grandes	**Criterion III:** Paquimé, Casas Grandes, serves as significant evidence of North America's cultural evolution, particularly highlighting pre-Hispanic trade and cultural exchanges. **Criterion IV:** The archaeological remains of Paquimé, Casas Grandes, showcase the evolution of adobe architecture in North America, demonstrating its fusion with advanced Mesoamerican techniques.
Tiwanakun Spiritual and Political Centre of the Tiwanaku Culture	**Criterion III:** The ruins of Tiwanaku provide remarkable evidence of the empire's influence in shaping the Andean pre-Hispanic civilization. **Criterion IV:** Tiwanaku's structures are outstanding examples of ceremonial and public architecture, representing a major Andean civilization.

Table 3. continued

Samarkand – Crossroad of Cultures	**Criterion I:** Samarkand's architecture and urban design, positioned at the crossroads of ancient cultures, exemplify masterpieces of Islamic cultural creativity. **Criterion II:** Architectural ensembles like Bibi Khanum Mosque and Registan Square significantly influenced Islamic architecture from the Mediterranean to the Indian subcontinent. **Criterion IV:** Samarkand's historic townscape reflects key phases of Central Asian cultural and political history from the 13th century to today.
Ashur (Qal'at Sherqat)	**Criterion III:** Ashur, founded in the 3rd millennium BC, was the first Assyrian capital and a key religious and political center, reflecting successive civilizations from Sumerians to the Parthian revival. **Criterion IV:** Ashur's remains illustrate the evolution of building practices from the Sumerian and Akkadian periods through the Assyrian empire and Parthian revival.
Cultural Landscape and Archaeological Remains of the Bamiyan Valley	**Criterion I:** The Buddha statues and cave art in Bamiyan Valley exemplify the Gandharan school of Buddhist art in Central Asia. **Criterion II:** The artistic and architectural remains of Bamiyan Valley reflect the interchange of Indian, Hellenistic, Roman, and Sasanian influences in Gandharan art, later influenced by Islam. **Criterion III:** Bamiyan Valley bears exceptional testimony to a vanished cultural tradition in Central Asia. **Criterion IV:** Bamiyan Valley is an outstanding example of a cultural landscape that illustrates a significant period in Buddhism. **Criterion VI:** Bamiyan Valley represents the most monumental expression of Western Buddhism and was a major pilgrimage site for centuries. Its monuments, including the destroyed Buddha statues, hold strong symbolic value.
Bam and its Cultural Landscape	**Criterion II:** Bam, located at the crossroads of key trade routes on the Iranian plateau, exemplifies the interaction of diverse cultural influences. **Criterion III:** Bam and its Cultural Landscape provide exceptional evidence of the development of a trading settlement in a desert environment in Central Asia. **Criterion IV:** Bam is an outstanding example of a fortified settlement and citadel in Central Asia, utilizing the chineh (mud layer) and khesht (mud brick) techniques. **Criterion V:** Bam's cultural landscape represents human-nature interaction in a desert environment, sustained by the qanat system, which is now vulnerable to change.
Pasargadae	**Criterion I:** Pasargadae is the earliest and most outstanding example of royal Achaemenid architecture. **Criterion II:** Built by Cyrus the Great with contributions from various peoples of his empire, Pasargadae marks a key phase in the evolution of classical Persian art and architecture. **Criterion III:** Pasargadae, with its palaces, gardens, and the tomb of Cyrus the Great, is an exceptional testimony to the Achaemenid civilization in Persia. **Criterion IV:** The "Four Gardens" royal ensemble in Pasargadae became a prototype for Western Asian architecture and landscape design.
Kunya-Urgench	**Criterion II:** The architectural tradition of Kunya-Urgench influenced Iran, Afghanistan, and later the Mughal Empire in India. **Criterion III:** Kunya-Urgench is a well-preserved testament to the Islamic culture of Khorezm, despite the disappearance of its original society.

Table 3. continued

At-Turaif District in ad-Dir'iyah	**Criterion IV:** At-Turaif Citadel represents a fortified urban ensemble in an oasis, showcasing the Najdi architectural style. It exemplifies an environment-adapted building method using adobe for palatial structures with geometric decoration. **Criterion V:** At-Turaif District in Ad-Dir'iyah illustrates a key phase of settlement on the Arabian plateau. In the mid-18th century, it became the capital of an independent Arab State and an important religious center, exemplifying human adaptation to the desert. **Criterion VI:** At-Turaif was the first historic center with unifying influence in the Arabian Peninsula. It played a key role in spreading the message of Salafiyya, influenced by Sheikh Mohammad Bin Abdul Wahhab's teachings and his alliance with the Saudi Dynasty in the 18th century.
Cultural Sites of Al Ain Hafit, Hili, Bidaa Bint Saud and Oases Areas)	**Criterion III:** The Cultural Sites of Al Ain showcase the evolution of prehistoric cultures in a desert region, documenting the transition from nomadic hunter societies to sedentary oasis settlements, demonstrating sustainable human development from the Neolithic to the Iron Age. **Criterion IV:** The tombs and architectural remains of the Hafit, Hili, and Umm an-Nar cultures illustrate human development during the Bronze and Iron Ages on the Arabian Peninsula. The aflaj system, introduced in the 1st millennium BC, exemplifies ancient desert water management techniques. **Criterion V:** The oases of Al Ain demonstrate the long-standing ability of civilizations in the northeastern Arabian Peninsula, particularly in protohistoric periods, to sustainably manage water resources and develop a fertile environment within the desert.
Historic Centre of Agadez	**Criterion II:** From the 15th century, Agadez became a major trans-Saharan trade hub, reflecting cultural exchanges through its unique mudbrick architecture, blending diverse stylistic influences within the Aïr region. **Criterion III:** Agadez's historic town features exceptional mudbrick architecture, including the Grand Mosque with its towering minaret and the Sultan's Palace. For over five centuries, it has preserved its cultural, commercial, and artisanal traditions.
Shahr-i Sokhta	**Criterion II:** Shahr-i Sokhta illustrates the transition from village life to urbanization, showcasing significant cultural, social, and economic advancements from the late Chalcolithic to early Bronze Age. **Criterion III:** Shahr-i Sokhta provides exceptional testimony to a civilization engaged in trade and cultural exchange with the Indus Plain, Persian Gulf, Oman Sea, and Central Asia. **Criterion IV:** Shahr-i Sokhta is an outstanding example of early urban planning, featuring mud-brick structures, burial grounds, workshops, and distinct functional zones.
Aqueduct of Padre Tembleque Hydraulic System	**Criterion I:** The Tepeyahualco aqueduct bridge is a unique architectural masterpiece with the tallest single-level arcade built from Roman times to the 16th century. Its innovative use of adobe formwork instead of scaffolding set it apart, making it an exceptional engineering achievement. **Criterion II:** The Padre Tembleque hydraulic system showcases a fusion of Roman masonry aqueduct traditions, Arab-Andalusian hydraulic techniques, and Mesoamerican collective labor practices. It embodies Franciscan humanist ideals through its innovative construction, reflecting cultural exchange and engineering excellence. **Criterion IV:** The Padre Tembleque aqueduct is an outstanding example of hydraulic architecture, combining Roman and Renaissance engineering with Mesoamerican construction techniques. Its use of regional materials and unique methods created an innovative hydraulic system.
Arslantepe Mound	**Criterion III:** Arslantepe offers exceptional evidence of early administrative elites during the Late Chalcolithic period, showcasing their societal role and relationship with the public. The site's well-preserved architectural and archaeological remains provide a detailed and rare insight into daily life, sealed by a sudden destruction event.

Table 3. continued

Sudanese style mosques in northern Côte d'Ivoire	**Criterion II:** The Sudanese-style mosques of northern Côte d'Ivoire illustrate cultural exchanges between the Gur and Mandé regions from the 14th to 18th centuries, blending Islamic and local architectural traditions. **Criterion IV:** These mosques exemplify architecture reflecting Islamic migration southward since the 14th century, symbolizing the spread of Islam and the fusion of Islamic and local styles.
Dholavira: a Harappan City	**Criterion III:** Dholavira is an exceptional example of a proto-historic Bronze Age urban settlement of the Harappan Civilization, showcasing a multi-cultural and stratified society from 3000 BCE to its decline. **Criterion IV:** Dholavira exemplifies Harappan urban planning with its structured city layout, multi-layered fortifications, advanced water reservoirs, drainage system, and extensive use of stone.
Royal Court of Tiébélé	**Criterion III:** The Royal Court of Tiébélé exemplifies Kasena culture through its unique adobe architecture, decorative style, and social-political significance, preserving its identity over time.

An examination of Table 3 reveals that the adobe heritage sites listed on the UNESCO World Heritage List reflect the historical, architectural, technological, and socio-economic development processes of various civilizations. These values are not merely physical structures; rather, they function as dynamic entities that embody past value systems, forms of cultural interaction, and human-environment relationships. In this context, urban settlements, regionally interpreted architectural styles, spaces serving as religious and political centers, and cultural landscapes that reflect sustainable ways of living are particularly noteworthy. Moreover, monumental structures constructed using unique building techniques provide evidence of both technological advancement and the utilization of local materials. These findings indicate that heritage sites are not only witnesses to the past but also serve as significant reference points for understanding cultural continuity and diversity.

Table 4. The Authenticity of Adobe Properties on the UNESCO World Heritage List

UNESCO World Heritage List	Authenticity
Abu Mena	The authenticity of the monastery is based on the preservation of its overall design, buildings, and original construction materials. Although few structures remain completely intact, ground plans and some vertical elements have been preserved. The large basilica, churches, and industrial remains demonstrate the region's structural and technological development during the 4th century.
Tchogha Zanbil	Despite conservation efforts, the historical monuments of Tchogha Zanbil have largely retained their authenticity in terms of form, material, and location.
Archaeological Ruins at Moenjodaro	Moenjodaro, one of the earliest urban centers of the Indus civilization, has preserved its authenticity through its baked brick structures and city planning; however, it is endangered due to environmental developments.
Old Walled City of Shibam	While Shibam has maintained its authentic elements reflecting traditional lifestyles and architecture, the tendency toward concrete construction and external factors pose a threat to its authenticity.
Old Town of Ghadamès	The Old Town of Ghadamès has preserved its authentic character without interventions in the design and materials of its buildings. Although its residents no longer live there permanently, they continue to utilize the old town. The city features a unique architecture with high parapeted roofs, enclosed alleyways, and traditional construction materials. Traditional building techniques have been preserved, and water management and cultural practices have continued. Throughout history, the city has served as an important trade center and contains valuable manuscripts providing insights into its past.
Bahla Fort	Bahla Fort was included in the List of World Heritage in Danger in 1988 due to rapid deterioration but was removed from the list following restoration efforts in 2004. Although some inappropriate interventions occurred during the 1990s, since 1995, efforts have focused on preserving the original structure using mudbrick-based materials. The abandonment of traditional houses and lack of preservation of the marketplace are the main threats to the site's authenticity.

Table 4. continued

Historic Centre of Lima	The Historic Centre of Lima has largely preserved its original urban layout and historic expansion areas. Public, private, and religious structures reflect European architectural influences while also adapting to the region's natural and social conditions. The city's traditional way of life strengthens the authenticity and identity of the center. However, threats such as earthquakes, real estate speculation, and informal commerce necessitate strict regulations to preserve its authenticity.
Old Towns of Djenné	Djenné's authenticity is ensured through its well-preserved adobe construction materials and the continuation of traditional building techniques passed down through generations. The city retains its identity as a "devout city," characterized by the Great Mosque and its cultural values.
Archaeological Sites of Bat, Al-Khutm and Al-Ayn	Bat and its surroundings form an ancient site that has maintained its authenticity through monumental towers, tombs, and irrigation systems. The tombs have been reused over time, sustaining their functional significance.
Taos Pueblo	Taos Pueblo has preserved its authenticity in terms of location, design, materials, and cultural functions. The community continues to use traditional construction techniques and maintain their traditional lifestyle. Modern elements have remained limited, and electricity and water installations are prohibited within the walled area. Nevertheless, factors such as town expansion, tourism, airport expansion plans, and environmental threats pose risks to its authenticity.
Coro and its Port	The urban layout of Coro and its traditional adobe construction system have been preserved to the present day. The city maintains the irregular block pattern reflecting Spanish influence. While the spatial and structural characteristics of the buildings have been preserved, traditional building techniques continue to be employed today. This continuity reflects the historical spirit and development of the site.
Archaeological Zone of Paquimé, Casas Grandes	Paquimé is a significant archaeological site that has largely avoided large-scale changes, preserving its authenticity. Conservation efforts have been limited to applying original adobe materials as protective coatings, aiming to maintain the site's physical integrity. The region's authenticity is tied to the cultural heritage of the Grande and Colorado river peoples, and this influence is evident in architectural features such as T-shaped designs and porticoed facades.
Tiwanakun Spiritual and Political Centre of the Tiwanaku Culture	Tiwanaku is an archaeological site that has retained a high degree of authenticity. However, a detailed conservation plan is essential to sustain this authenticity.
Samarkand – Crossroad of Cultures	Although the historical fabric of Samarkand and Afrasiyab has been preserved, the construction of modern buildings and changes within private properties pose threats to their authenticity.
Ashur (Qal'at Sherqat)	Ashur has remained uninhabited since the 2nd century BCE, which has enabled the preservation of its remains' authenticity. The site's historical structure has remained largely intact, with only an Ottoman-era barracks and an excavation house constructed later. Restoration efforts carried out in the 1980s were conducted using traditional materials and techniques.
Cultural Landscape and Archaeological Remains of the Bamiyan Valley	The Bamiyan Valley retains the traces of the past through its cultural and archaeological remains. While the site has preserved its authenticity through traditional structures and land use, it is at risk due to modern developments and requires a carefully managed conservation process.
Bam and its Cultural Landscape	The site has largely maintained its authenticity thanks to restorations conducted with traditional materials and techniques. Although some modern restorations were damaged during the 2003 earthquake, original materials have remained well-preserved. The culture of adobe architecture, urban layout, and traditional craftsmanship continue. It is crucial that restorations are carried out in accordance with international principles to sustain authenticity and to ensure the continuation of historical practices.

Table 4. continued

Pasargadae	Pasargadae has been preserved in its original location and structure, remaining unaffected by modern interventions. Recent restorations have been undertaken using traditional methods, fully maintaining the historical fabric of the site.
Kunya-Urgench	The site continues to function as a religious center and pilgrimage site, thus preserving its overall authenticity. The main monuments have retained much of their original materials and possess a reasonable degree of authenticity. Some structures have been partially reconstructed to prevent complete collapse. Overall, the principal monuments have largely maintained their original character.
At-Turaif District in ad-Dir'iyah	The site's authenticity is preserved through components that have neither been altered nor reconstructed. Although the structures remain in a ruined state, a restoration program faithful to the original plans is being implemented. A careful conservation approach must be prioritized to maintain the site's authenticity.
Cultural Sites of Al Ain Hafit, Hili, Bidaa Bint Saud and Oases Areas)	The prehistoric sites of Al Ain largely retain their authenticity; however, the partial reconstruction of some circular tombs limits this authenticity. Iron Age irrigation systems, such as the Hili 15 falaj, have survived intact but have been subject to later additions. While early restorations of the oases since the 1980s focused on reconstruction, recent efforts have emphasized the importance of authenticity. Local governments and farmers are making efforts to sustain the oases, though these processes must be carefully monitored due to economic and environmental pressures.
Historic Centre of Agadez	Although the monuments and palaces generally preserve their authenticity, the use of modern materials in window and door frames negatively impacts their original character. Similarly, residential buildings face threats from the use of non-traditional materials such as cement, metal, and modern blocks, as well as from aggressive advertising in vivid colors, all of which compromise the aesthetic and historical fabric.
Shahr-i Sokhta	The desert landscape of Shahr-i Sokhta, along with its surface archaeological remains and complex architecture, strongly reflects the site's preserved authenticity.
Aqueduct of Padre Tembleque Hydraulic System	The physical components of the hydraulic system have maintained their traditional structures and thus their authenticity. A six-kilometer section in Zempoala continues to function in water transportation, while the extension toward Otumba is planned to be revitalized. This process must be supervised by heritage experts. Local communities contribute to the conservation of the system through maintenance and repairs using traditional techniques. Particularly, the glyphs on the aqueducts reveal the collaborative construction efforts between indigenous peoples and Spanish clergy.
Arslantepe Mound	At Arslantepe, the structures—particularly the palace complex—are entirely authentic, with no reconstruction efforts undertaken. The adobe walls, plasters, wall paintings, and floors have been preserved in their excavated state. Minor repairs have been made using only original materials. The roofing system has been designed not to damage the archaeological layers. The palace complex and the surrounding landscape remain unaltered, with excavation findings providing insight into the region's artistic and cultural production capacities.
Sudanese style mosques in northern Côte d'Ivoire	The eight mosques in northern Côte d'Ivoire have largely preserved their authenticity through their architectural forms, traditional building materials, and techniques. The Sudanese-style architecture is sustained with local materials and the continued presence of traditional craftsmen. Although modern mosques have been constructed, the traditional ones are still actively used for worship and social activities. However, the continued authenticity of these mosques depends on community support and the availability of local craftsmen.

Table 4. continued

Dholavira: a Harappan City	Dholavira exhibits a systematic urban layout with fortifications, gates, water systems, and workshops, all reflective of Harappan culture. Structures have been preserved in situ using scientific conservation methods to maintain their authenticity. Excavations have revealed the city's architectural features and planning, which are well preserved due to the use of stone and adobe materials.
Royal Court of Tiébélé	The Royal Court of Tiébélé has largely preserved the architectural and traditional practices distinctive to the Kasena culture. The maintenance of traditional motifs and the creation of new ones will further strengthen the cultural continuity of the site. Nevertheless, the increasing use of modern construction materials may threaten the property's authenticity.

An analysis of Table 4 reveals that the majority of adobe-based cultural heritage sites inscribed on the UNESCO World Heritage List have largely retained their authenticity in terms of construction materials, building techniques, spatial organization, and functional continuity. This preservation is primarily attributed to the continued use of traditional methods and materials, the limitation of modern interventions, and the sustained cultural practices of local communities.

3. Results and Discussion

Among the main factors contributing to the deterioration of adobe materials, which have been used as building materials throughout history, water plays a primary role. This includes rainwater, capillary rise from the ground, and faulty or insufficient drainage. In addition, temperature fluctuations (such as high humidity levels and extreme temperature changes), as well as biological and anthropogenic factors—such as vegetation, animals, and human activities—also significantly contribute to the degradation of adobe structures (Ashurst, 1990; Orbaşlı, 2008; Zakar & Eyüpgiller, 2015). These factors, whether acting independently or in combination, can lead to the disintegration of the wall mass, causing partial or complete collapse, or result in vertical misalignment and deformation of the wall plane. Common forms of deterioration observed in adobe walls include superficial and structural cracks, cavities, and perforations (Zakar & Eyüpgiller, 2015). Natural phenomena such as excessive rainfall, temperature fluctuations, and drought—arising from climate change—inevitably cause damage to heritage sites constructed with adobe materials. Table 5 presents the climatic events affecting adobe heritage sites inscribed on the UNESCO World Heritage List, the resulting forms of deterioration, and the corresponding preventive or remedial measures taken.

Table 5. Climate Change Impacts, Observed Damages, Preventive Measures, and Interventions on UNESCO World Heritage List

UNESCO World Heritage List	Climate Change	Damages	Measures
Abu Mena	Rise in groundwater levels	Structural collapses and foundation deterioration	Groundwater control and structural reinforcements
Tchogha Zanbil	Intense precipitation and drought	Erosion, subsidence, and surface abrasion	Protective roofing, drainage systems, and digital monitoring
Archaeological Ruins at Moenjodaro	Flooding and temperature fluctuations	Cracking, surface disintegration, and abrasion	Waterproofing, temporary coverings, and local conservation planning
Old Walled City of Shibam	Heavy rainfall and flooding	Structural failures, plaster detachment, and foundational decay	Structural bracing and temporary roof systems
Old Town of Ghadamès	Extreme temperature and drought	Cracks, plaster detachment, and moisture damage	Localized repairs and traditional heat-mitigation techniques
Bahla Fort	Heavy rainfall and thermal variation	Erosion, settlement, and timber decay	Structural reinforcement, adobe repair, and visitor restrictions
Historic Centre of Lima	El Niño events and heavy rainfall	Decay, plaster loss, and ground subsidence	Wall repairs, drainage implementation, and protection strategies

Table 5. continued

Old Towns of Djenné	Sudden rainfall and thermal variation	Erosion, decay, and dome deterioration	Traditional plastering rituals, monitoring, and flood protection
Archaeological Sites of Bat, Al-Khutm and Al-Ayn	Heavy rainfall	Erosion and stone displacement	Stone wall reinforcement and rainwater drainage
Taos Pueblo	Drought, sudden rainfall	Cracks and plaster flaking	Adobe restoration using traditional methods
Coro and its Port	Rainstorms	Surface abrasion and wall collapses	Drainage systems and adobe surface renewal
Archaeological Zone of Paquimé, Casas Grandes	Temperature fluctuation	Surface cracking and spalling	Restoration and application of climate-resilient materials
Tiwanakun Spiritual and Political Centre of the Tiwanaku Culture	Heavy rainfall	Ground deformation and structural shifting	Rainwater drainage and structural reinforcement
Samarkand – Crossroad of Cultures	Freeze–thaw cycles	Ceramic loss and wall cracking	Thermal insulation and ceramic restoration
Ashur (Qal'at Sherqat)	River flooding	Erosion	Dam planning and site protection measures
Cultural Landscape and Archaeological Remains of the Bamiyan Valley	Freeze–thaw action and rainfall	Surface flaking	Rock stabilization and microclimate control
Bam and its Cultural Landscape	Post-seismic climatic impacts	Subsidence and moisture damage	Reconstruction and enhanced climate resilience
Pasargadae	Extreme temperature and drought	Stone deterioration	Application of surface protective coatings
Kunya-Urgench	Increased soil moisture	Wall swelling and cracking	Ground drainage and brick repair
At-Turaif District in ad-Dir'iyah	Sandstorms and drought	Abrasion and surface loss	Restoration and sand control measure
Cultural Sites of Al Ain Hafit, Hili, Bidaa Bint Saud and Oases Areas)	Extreme temperature	Cracking	Climate-adaptive repairs
Historic Centre of Agadez	Sandstorms	Surface deterioration	Adobe restoration
Shahr-i Sokhta	Extreme temperature	Cracking and flaking	Preventive measures and roof coverings
Aqueduct of Padre Tembleque Hydraulic System	Thermal fluctuation	Stone erosion	Stone reinforcement
Arslantepe Mound	Rainfall	Erosion	Protective roofing and adobe repair
Sudanese style mosques in northern Côte d'Ivoire	Rainfall and thermal variation	Surface abrasion	Localized repairs
Dholavira: a Harappan City	Flood and drought	Stone displacement	Water management systems
Royal Court of Tiébélé	Rainfall	Paint fading and surface deterioration	Traditional painting and protective coatings

Table 5 systematically illustrates how cultural heritage sites, primarily constructed using adobe building technologies, inscribed on the UNESCO World Heritage List, are affected by climate change. The data detail the climatic threats encountered by each site, the resulting physical damages, and the implemented or proposed conservation measures. The table highlights the regional variability of climate change impacts, emphasizing the significance of each site's geographic and climatic context. It is evident that adobe materials are particularly vulnerable to moisture and thermal fluctuations, often resulting in rapid and irreversible deterioration. The conservation responses indicate the application of systematic and adaptive approaches tailored to the specific vulnerabilities of these heritage structures.

4. Conclusions

For heritage properties to be inscribed on the UNESCO World Heritage List, they must meet one or more of the selection criteria established by UNESCO. Among the adobe (adobe) heritage properties that have been inscribed on the World Heritage List by fulfilling these criteria, several have suffered damage due to climate-related changes—particularly from extreme rainfall and significant temperature fluctuations. This study investigates the types of damages observed, the conservation measures taken, and the intervention methods applied to safeguard these properties. Based on the findings, it is understood that seven of the listed adobe heritage properties are currently at risk of disappearance. Therefore, it is crucial to ensure their protection and survival, as well as to conserve other adobe heritage sites that are not yet listed but reflect the historical and cultural narratives of their respective countries.

In light of this study, the following conservation strategies and intervention techniques are proposed for adobe heritage structures affected by climatic phenomena:

- Development of drainage systems to protect against rising groundwater.
- Installation of protective roofs to guard against heavy rainfall.
- Construction of temporary shelter structures.
- Reproduction of deteriorated adobe materials using traditional construction methods.
- Structural reinforcement of weakened adobe wall systems using support elements.
- Application of surface coatings to prevent further deterioration of the adobe material following interventions.

Revitalization and integration of historic city walls and castles into the urban fabric: A comparative analysis

Murat Tutkun*[1], Elif Uğurlu[1], Merve Tutkun[1]

[1] *Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye*

Abstract. Anatolia has hosted various civilizations throughout history, making it a geographically diverse region that bears the traces of these cultural formations. The cities within this region stand out not only for their historical structures but also for the social, cultural, and economic dynamics that have evolved around them. In particular, historic city walls and castles have played significant roles as both defensive structures and cultural symbols throughout different historical periods. However, natural disasters, improper urban planning, and rapid urbanization have made the preservation of these structures and their transmission to future generations increasingly challenging. In this context, the conservation of historic city walls and castles is not only an architectural concern but also a social and cultural responsibility. This study aims to examine the preservation status, restoration efforts, and adaptive reuse strategies of historic city walls and castles surrounding the historic city centers of ten different cities in Anatolia from a comparative perspective. Through literature reviews supported by historical, architectural, and archaeological data, as well as as comparative analysis methods, the transformations of these castles over time and their integration processes into contemporary urban fabrics have been thoroughly analyzed. The research highlights the challenges encountered in preserving the architectural and cultural values of historic castles and city walls. In this context, it draws attention to core problems such as restorations and repairs carried out throughout the life cycle of these structures, improper urban planning practices and their impact on historic walls and castles, adaptive reuse cases, and the difficulties in integrating their original functions into modern life.

Keywords: Urban Conservation; Restoration; Castle and City Wall Structures; Adaptive Reuse; Cultural Heritage

1. Introduction

Anatolia has been home to many civilizations throughout history and has a rich heritage bearing the traces of the cultural formations of these civilizations. Historical fortifications and castles, one of the most important elements that determine urban identity, have functioned not only as defensive structures but also as elements that shape the cultural, architectural and social dynamics of the cities in which they are located (Algharibi, 2024). While these structures reflect the defense strategies and administrative structures of cities, they also reveal the spatial organization of settlements, their relationship with trade networks and social memory. However, natural disasters, wrong zoning practices and rapid urbanization threaten the physical integrity of these structures and lead to radical changes in urban morphology (Özkaynak, 2023).

In this transformation process, how to integrate historical fortifications and castles into the modern urban fabric has become one of the main research areas of conservation policies. These structures should be preserved and integrated into urban life not only for their physical presence but also for their historical, cultural and artistic values (Tan, 2014). However, conservation policies and practices vary across countries due to differences in legal frameworks, planning strategies and implementation processes. In Turkey, although the Law No. 2863 on the Protection of Cultural and Natural Assets constitutes the basic legal infrastructure for the protection of urban heritage, local governments need to take more effective decisions to integrate these structures into modern urban life (Bahçeci Başarmak, 2022).

International examples reveal that different models have been implemented for the conservation and re-functionalization of historic walls and castles. In cities with largely preserved fortifications, such as Italy, fortifications are integrated with pedestrian paths, cultural spaces and green areas and positioned as an active component within the city (Naiboğlu, 2019). Such examples constitute an important reference for developing sustainable conservation models for fortified cities in Anatolia.

* Corresponding author, E-mail: m_tutkun@ktu.edu.tr

https://doi.org/10.31462/icearc2025_a_car_820

In this context, this study aims to examine the conservation processes, restoration practices and integration models of the historic walls and castles surrounding the historical city centers of 10 different cities in Anatolia from a comparative perspective. Using a comprehensive comparative analysis method supported by historical, architectural and archaeological data, the study will examine in detail the transformations of these structures from past to present, their relationship with urban planning and their adaptation processes based on conservation policies. In addition, the role of local governments, the effectiveness of existing legal regulations and the impact of social awareness on these processes will be evaluated and assessments will be made in the context of sustainable conservation and integration models. The main aim of the study is to develop sustainable and integrated conservation policies for the preservation of historical fortifications in Anatolia and to propose new strategies on how these structures can be incorporated into modern urban life.

2. Materials and Methods

This study aims to provide a comprehensive assessment of the conservation and integration of historical fortifications and castles in Anatolia into the modern urban fabric. The methods used within the scope of the study are discussed under three main headings by adopting an interdisciplinary approach. Within this framework, firstly, literature research was conducted on national and international academic studies, declarations and legal regulations on the conservation, restoration processes and re-functionalization of historical buildings. In this context, the practices carried out within the framework of the Law No. 2863 on the Protection of Cultural and Natural Heritage and UNESCO's principles for sustainable conservation practices of cultural heritage were also taken into consideration. In the second stage of the research, 10 cities with historical fortifications and castles in Anatolia included in the scope of the study and the conservation, restoration and re-functioning processes carried out in these cities were analyzed comparatively. In this context, the physical conditions of historical castles and fortifications, the restorations they have undergone, their level of integration with the modern urban fabric and the conservation problems encountered were evaluated, and the success potentials of conservation practices were evaluated together with their positive and negative aspects. In the third part of the study, spatial and structural analyzes are discussed. In this framework, the basic analytical method was used to examine the spatial organization and structural conditions of the historic walls and castles, and evaluations were made through urban morphology analysis. In this context, in order to evaluate the relationship of historical buildings with the urban fabric, spatial sequence analyses were used to examine the impact of fortifications and castles on urban mobility, their transformation in the spatial context and their accessibility within the city. In line with the data obtained, sustainable strategies for the protection and integration of historical fortifications in Anatolia into urban life were evaluated. In this context; conservation of historical castles and fortifications as cultural heritage, functional transformation proposals compatible with urban planning, development of holistic management models, sustainable tourism and economic benefit creation approaches have been discussed.

3. Conservation, Urban Conservation, Restoration and Reuse

Cultural Assets, which are related to science, culture, religion and fine arts belonging to historical periods or which have been the subject of social life in prehistoric or historical periods and which have unique scientific and cultural value, vary from the scale of movable objects to the urban scale. It is important in terms of cultural, social and economic sustainability that individual buildings, cities and urban ruins, which are the products of various civilizations from prehistoric times to the present day, reflecting the social, cultural, economic, architectural and similar characteristics of the periods they lived in, are protected and transferred to future generations. The sustainability of cultural heritage can be ensured by the concepts of time, continuity, protection and co-existence with change. Conservation, which is defined as the preservation of cultural heritage in order to transfer past values to future generations, is an important responsibility of today's societies. The Concept of Conservation is defined within the scope of the Law No. 2863 on the Protection of Cultural and Natural Heritage; within the framework of conservation, maintenance, repair, restoration and function change operations of immovable cultural and natural assets. In the context of the Concept of Conservation, in accordance with the relevant Law, conservation zoning plans based on field research, including archaeological, historical, natural, architectural, demographic, cultural, socio-economic, property and construction data, are prepared in order to protect cultural and natural assets in line with the principle of sustainability, taking into account the interaction-transition area of the area. Socio-cultural and historical data, which have an important place in urban planning data, have a key importance in the formation of multi-layered historical city models. In this context, while preparing Conservation Zoning Plans, area management models are used in accordance with principles such as conservation principles and use and building restrictions, sanitization, renovation areas and projects, open space system, pedestrian circulation and vehicle transportation, design principles of facilities, densities, parcel designs, local ownership, etc. (Algharibi, 2024; Başarmak, 2022).

Reuse practices developed for the continuity of the existence of historical buildings, which have become obsolete and idle due to various reasons over time, by adapting to today's conditions, have the potential to be beneficial in many ways to the three components of sustainable development (social, environmental, economic).

It contributes to environmental balance as it reduces energy and resource use by preserving the existing building stock; to sociocultural development by maintaining cultural values through the preservation of historic buildings; and to economic development by eliminating the cost of building a new structure and increasing the asset value of the region by improving the building and its surroundings. The main challenge of reuse is to find the most appropriate new function that does not compromise the principles of conservation and the values of historic buildings, while at the same time contributing to development. The success of the new function is about balancing these opportunities and challenges. Due to the negative effects of rapid urbanization and population growth, technological and military developments, Defense Buildings, which have lost their original function despite their historical value and importance, are among the most important Cultural Assets that affect the urban scale and planning decisions in this context. Castles and fortifications used for public defense in the historical process have been replaced by underground shelters due to the mobility of modern weapons. In the historical process, defensive structures such as castles, fortifications, etc., which were built to protect cities and living spaces, including building communities, from external influences, have remained in a dysfunctional position due to the development of modern defense methods in technological and military terms and the change of war strategies. Historical walls and castles are important structures reflecting the architectural, military and cultural heritage of past civilizations. However, the protection and preservation of these structures is of great importance due to the loss of their functions over time, natural wear and man-made destruction. Historical walls and fortresses, which are considered among the most important heritage in many cultures around the world, include the Great Wall of China, known as the world's longest defensive wall; the Walls of Istanbul (Turkey), dating from the Byzantine period, such as the Walls of Theodosius and the Walls of Constantine; the Walls of Diyarbakır (Turkey), dating from the Roman period, which is on the UNESCO World Heritage ; the Walls of Carcassonne (France), known as a perfectly preserved walled city from the Middle Ages; and the Walls of Avignon (France), which stands out among the historical walls during the Papal period; Examples include the Harran Walls (Turkey), known as a historical fortification system from ancient Mesopotamia; the York City Walls (England), dating back to the Roman period and extended in the Middle Ages; the Krak des Chevaliers Walls (Syria), a castle and fortification complex from the Crusader period; the Great Zimbabwe Wall (Zimbabwe), an African fortification system of stone; and the Trojan Walls (Turkey), the legendary defensive walls of the ancient city of Troy. (Yolcu,2023; Algharibi,2024; Başarmak,2022; Naiboğlu,2019)

Today, the adaptive reuse of these important historical buildings to contemporary needs plays a critical role in terms of both the protection of cultural heritage and tourism and urban development. International restoration principles (such as the Venice Charter, Burra Charter) should be taken as a guide for the conservation of historic walls and castles. In line with these principles; the use of original materials and techniques, structural reinforcement and stabilization, archaeological and historical analysis, and the principle of minimal intervention come to the fore. In the context of the use of original materials and techniques; it is essential to preserve the original materials and use new materials with similar properties. Traditional construction techniques should be applied without disturbing the historic fabric of the building. In the context of structural strengthening and stabilization; modern engineering solutions (carbon fiber reinforcement, steel supports, etc.) should be applied to strengthen the structural systems that have weakened over time without disturbing the original fabric. Archaeological and historical analysis includes detailed documentation, archaeological excavations and historical research to understand the original form of the building before restoration. Intervening as little as possible, preserving the original elements and avoiding unnecessary additions are considered in the context of the principle of minimal intervention. When the issue is evaluated in the context of sustainable conservation principles, it is seen that the preservation of the relevant structures and their adaptation to today's comfort conditions and their transfer to future generations is only possible through reuse. In particular, defensive structures that have lost their original function, such as castles and fortifications, can be used as cultural and art centers with functions such as concert halls, exhibition areas or open-air theaters by developing functional transformation projects; as museums and historical parks by creating interactive museums or archaeoparks reflecting the military past of the structures; As education and research centers that can host history and architecture studies in cooperation with universities or cultural institutes; reuse for tourism purposes with the use of boutique hotels, luxury accommodation and gastronomy facilities that do not disrupt the historical texture are considered as functional suggestions that can ensure that the relevant buildings that have lost their original function in the literature can hold on to the vital cycle (Yolcu, 2023).

4. Historical Castles, Fortifications and Their Relationship with the City

Castle; It is defined as a defense structure built to hold a land, land, a geographical place and to ensure its security. They are structures built for defense purposes on the roads where the arrival of the enemy is expected, in cities of strategic importance, passages and bottlenecks, in a position to dominate the region in which it is located. It has entered the architectural literature as defensive structures consisting of thick and high walls with battlements, towers and fortifications built to defend a certain area. Such fortifications have been used since antiquity and served as administrative, political and economic centers in addition to their military functions. Some castles provided accommodation for the people of the palace. It defines a whole settlement in itself with service structures in which people can stay permanently and meet their daily vital . Defensive structures and settlements such as castles and fortifications are purpose-designed structures, regardless of their size. Formation and spatial organization are directly oriented towards function. It is seen that fortress structures generally consist of sections with different characteristics such as inner castle, outer castle, city hall, rabat, tower (inner / outer) / head tower, gate tower, poterna, fortification wall / curtain wall, rampart, battlements, battlements with battlements, arrow battlements, moat, etc. The inner castle is defined as the last defense located at the highest point or the center of a walled city, where the administrative level and/or the city's dignitaries are located; the şehristan is the section where the commercial and residential areas, religious and public buildings, which constitute the main part of the city, are located; and the rabat isthe functions and structures related to trade, which are mostly outside the walls and around the castle gates, are located. The castle square, on the other hand, defines the large areas in the center of the castle where soldiers gather and train. The preservation of the architectural and historical integrity of castles, city walls and surrounding settlements, which are important structures of urban identity, is only possible if the relationship between these structures and the city can be fully analyzed. For example, when castles and city walls are evaluated morphologically; it is known that castles and city walls were built as outer fortresses and adjacent to residential areas for defense purposes in ancient times. In the Greek and Hellenic periods, there were city walls surrounding the cities; in the Roman period, walled cities were replaced by single castle structures or walled castle settlements; in the Byzantine period, due to the decrease in the security environment in the settlements, walls were built for protection surrounding the city centers again, and for this reason, it is understood from the literature that Byzantine cities were depicted as castle-cities (castron). Within the scope of the study, 10 different cities (Kayseri Castle, Erzurum Castle, Amasya Castle, Van Castle, Tokat Castle, Trabzon Castle, Istanbul Rumeli Fortress, Konya Castle, Sivas Castle, Antalya Castle) located in different regions of Anatolia with historical walls and castles and the conservation, restoration and re-functioning processes carried out in these cities were evaluated comparatively.

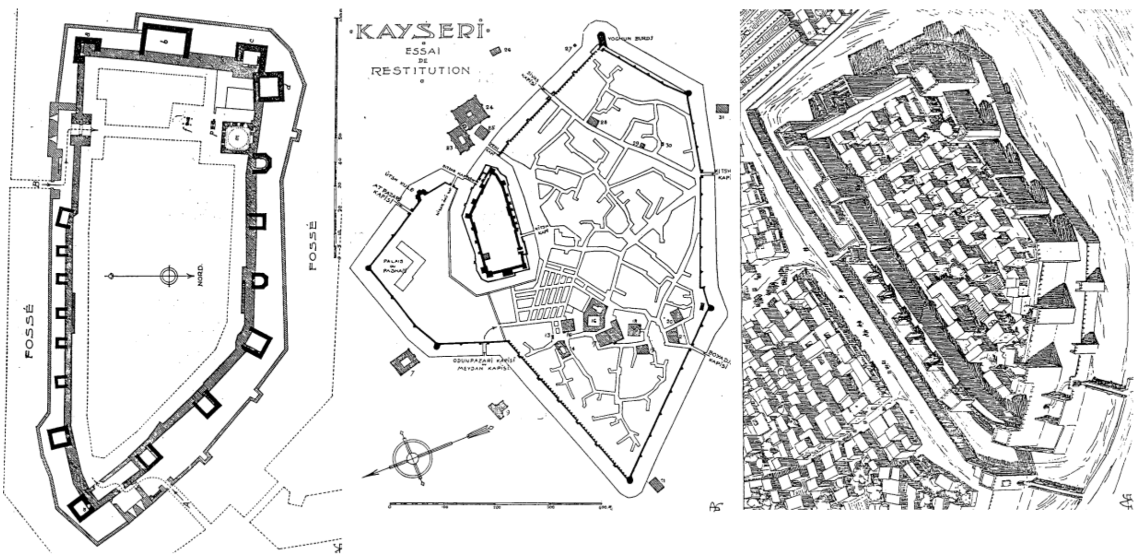

Fig. 1. Plan of Kayseri Castle (İnbaşı, 2003).

Table 1. Kayseri Castle Analysis Table

Name of Structure	Kayseri Castle
Location	Kayseri province, Melikgazi district, city center, around Cumhuriyet Square. (Akok, 1964; Güner, 2021)
Construction Date / Period	Roman Period, 238-244 AD, reign of Emperor Gordianus III. (Yolcu, 2023;İnbaşı, 2006)
Producer / Produced by	Roman Emperor Gordianus III (Passenger, 2023).
History of the Building	It was built as a military base during the Roman period and was repaired during the Byzantine and Seljuk periods. During the Ottoman period, it lost its military function and was opened to civilian settlement and trade. (İnbaşı, 2006; Yolcu2023Güner, 2021)
Architectural Features	The citadel is adefense system surrounded by bastions opening in four directions. The bastions have three to four floors. Wall roads, battlements and vaulted spaces are noteworthy. (Akok, 1964)

Table 1. continued

Materials and Construction Techniques	Cut stone, rubble stone, lime mortar, wood, reed and iron were used. These materials were also documented in Ottoman repairs (İnbaşı, 2006; Akok, 1964).
Changes Over Time	It underwent major repairs in 1507 and 1553. In the 20th century, it was used for commercial purposes, and a reinforced concrete bazaar was built in 1987. After the 2008 competition, the re-functioning process was initiated (Güner, 2021; İnbaşı, 2006).
Conservation Status and Challenges	Restoration practices have emphasized commercial and touristic use, and conservation principles have been violated from time to time (Güner, 2021).
Current Usage	Cultural activity area and commercial units. There are shops and temporary exhibition within the Inner Castle (Güner, 2021).
Potential for Reuse	The castle has the potential to be integrated into urban life while preserving its cultural heritage identity (Akok, 1964).
Place in the Urban Fabric and Integration Status	While in the 19th century it had more widespread connectivity, today its physical integration with new streets has increased (Yolcu, 2023).
Evaluation and Recommendations	Re-functionalization processes should be planned in line with conservation principles, and economic-oriented interventions should not damage cultural identity. Pedestrian connections should be strengthened (Güner, 2021; Yolcu, 2023).

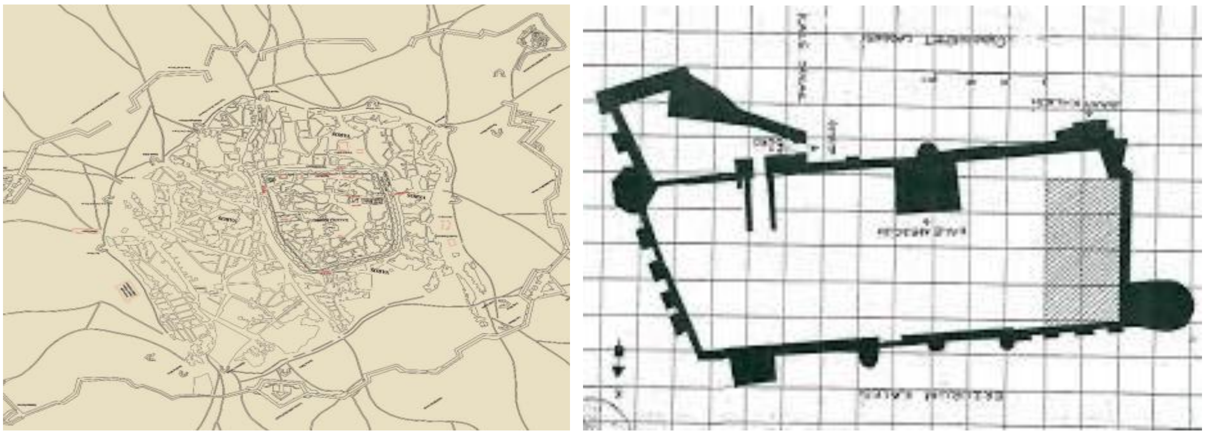

Fig. 2. Erzurum Castle, Walls, Bastions and Erzurum Castle Plan (Küçükuğurlu, 2017; URL-3).

Table 2. Erzurum Castle Analysis Table

Name of Structure	Erzurum Castle
Location	Erzurum province is located on the northern slopes of the Palandöken Mountains at the highest point of the city center (Gündoğdu, 2016).
Construction Date / Period	It was built between 415-420 AD by the Eastern Roman Emperor Theodosius II (Gündoğdu, 2016).
Producer / Produced by	Eastern Roman (Byzantine) Emperor Theodosius II (Gündoğdu, 2016).
History of the Building	First established as a military garrison, it was strengthened with various fortifications during the Byzantine, Saltuklu, Seljuk, Mongol and periods (Solmaz, 2013; Küçükuğurlu, 2010).
Architectural Features	The citadel is approximately 50x130 m, surrounded by 2-2.5 m thick walls; the bastions are square, octagonal and polygonal in plan (Gündoğdu, 2016).
Materials and Construction Techniques	Cut stone, rubble stone, brick, lime mortar, walnut and hornbeam wood, cast iron were used (Demlikoğlu, 2022).
Changes Over Time	Bastions were added in the 18th-19th century, and in the 20th century the wall stones were used in public buildings; the Outer Fortress was destroyed (Küçükuğurlu, 2010).
Conservation Status and Challenges	Although it is a 1st degree archaeological site, its surroundings have been transformed with modern buildings and 12% of the traditional texture has disappeared (Atabeyoğlu et al., 2009).
Current Usage	Within the scope of the Kültür Yolu Project, it was reorganized as an open public space and became a part of social life (Kokarca & Batuhan, 2022).

Table 2. continued

Potential for Reuse	Cultural routes have the potential to be integrated into urban memory through open-air museums and functional transformations (Kokarca & Batuhan, 2022; Demlikoğlu, 2022).
Place in the Urban Fabric and Integration Status	Historically, the development of the city was shaped around the castle and transformed into transportation axes with the Jacques Lambert Plan of 1938 (Küçükuğurlu, 2010).
Evaluation and Recommendations	Conservation should be planned on a holistic, physical, social and environmental level; public participation should be ensured and cultural memory should be preserved (Atabeyoğlu et al., 2009; Küçükuğurlu, 2010).

Table 3. Amasya Castle Analysis Table

Name of Structure	Amasya Castle (Harşena Castle)
Location	The province of Amasya is located on the northern slope of Yeşilırmak on the summit of Mount Harşena (Karabağ, 2022; TÜBA-AR, 2021; Amasya Municipality (n.d.)).
Construction Date / Period	The first structures date to the Hellenistic period (3rd century BC); they were built by the Pontic Kingdom (Karabağ, 2022; TÜBA-AR, 2021; Amasya Municipality (n.d.)).
Producer / Produced by	During the reign of Pontic King Mithradates I (301-266 BC), the castle was built as the capital (Karabağ, 2022; Amasya Municipality (n.d.)).
History of the Building	The castle was used during the Roman, Byzantine, Danishmendli, Seljuk, Eretnalı and Ottoman periods and developed with various repairs and additional structures in each period (Canıbek, 2020; Karabağ, 2022; TÜBA-AR, 2021; Amasya Municipality (n.d.)).
Architectural Features	The castle consists of three sections; Upper Castle, Kızlar Sarayı Mevkii and Lower Castle. The walls are square and rectangular in plan, in harmony with the natural topography. The King's Tombs stand out with their monumental triangular pedimented facades (TÜBA-AR, 2021; Karabağ, 2022; Amasya Municipality (n.d.)).
Materials and Construction Techniques	Cut stone, rubble stone, wood, brick; the walls were built with the overlapping method. Ancient cisterns were created with rock carving techniques (TÜBA-AR, 2021; Karabağ, 2022; Amasya Municipality (n.d.)).
Changes Over Time	The fortress was strengthened with repairs from 69 BC onwards; internal structures were added during the Ottoman period and abandoned after 1832. Since 2009, it has been revived with excavations (Canıbek, 2020; Karabağ, 2022; Amasya Municipality (n.d.)).
Conservation Status and Challenges	Most of the walls have been destroyed and only the foundations remain. However, it has gained archaeological and cultural importance thanks to excavations and conservation efforts after 2007 (Karabağ, 2022; TÜBA-AR, 2021; Amasya Municipality (n.d.)).
Current Usage	It is considered as an excavation site and cultural route. Kızlar Sarayı Mevkii has the potential to become an archaeological park (Karabağ, 2022; TÜBA-AR, 2021; Amasya Municipality (n.d.)).
Potential for Reuse	It can be re-functionalized as an open-air museum, cultural walkways and an area integrated with the integrity of the historical/cultural landscape (Canıbek, 2020; Karabağ, 2022; Amasya Municipality (n.d.)).
Place in the Urban Fabric and Integration Status	Kale is the oldest and central settlement of Amasya. During the Pontic period, a three-unit city structure was formed and the settlement spread to the plain over time. Today, the visual and physical relationship with the historical texture continues. (Karabağ, 2022; TÜBA-AR, 2021; Amasya Municipality (n.d.)).
Evaluation and Recommendations	Sustainable preservation of the multi-layered historical texture; supporting excavations; integrating the castle and its surroundings into cultural tourism are recommended. Public participation and local government cooperation are important (Karabağ, 2022; Canıbek, 2020; TÜBA-AR, 2021).

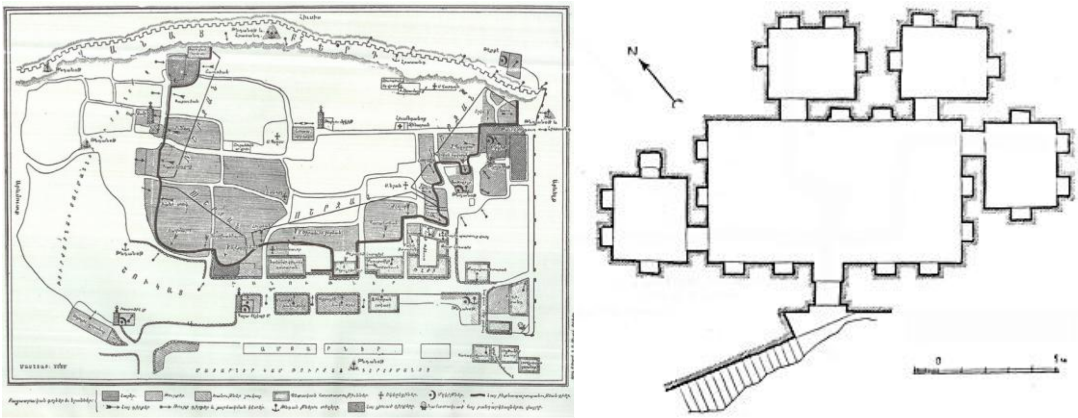

Fig. 3. Van Castle Plan (Konyar, E., Genç B. Avcı, C. & Tan, A., 2019, URL-8).

Table 4. Van Castle Analysis Table

Name of Structure	Van Castle
Location	Van province is located on a high cliff to the east of Lake Van (Tarhan & Sevin; Öztürk).
Construction Date / Period	It was built during the Urartian Kingdom (9th century BC) (Tarhan & Sevin; Ciloşoğlu & Açık; Erzen).
Producer / Produced by	It is associated with the construction process initiated by the Urartian King Sarduri I (Tarhan & Sevin; Genç & Konyar).
History of the Building	The fortress was used during the Urartian, Medieval, Seljuk and Ottoman periods and assumed military and administrative functions (Erzen; Ciloşoğlu & Açık; Tarhan & Sevin).
Architectural Features	The walls, built with massive cut stones, include a citadel, the Analıkız monument, bastions and towers from the Ottoman period (Genç & Konyar; Erzen; Tarhan & Sevin).
Materials and Construction Techniques	Horasan mortar, large cut stone, stone-filled walls; cyclopean walls and bedrock carving techniques were used (Tarhan & Sevin; Erzen; Öztürk).
Changes Over Time	From the 16th century onwards, defense systems were strengthened by the Ottomans; they became dysfunctional after the Republic (Ciloşoğlu & Açık; Erzen; Öztürk).
Conservation Status and Challenges	It was damaged in various periods; excavation and restoration works started after 1995 (Öztürk; Erzen).
Current Usage	It is considered as a cultural heritage site, archaeological excavation site and tourism destination (Öztürk; Tarhan & Sevin).
Potential for Reuse	It can be functionalized with the integration of open-air museum, cultural routes, memory space and landscape (Genç & Konyar; Öztürk).
Place in the Urban Fabric and Integration Status	It is associated with the Old Van City and is one of the focal points of urban memory and diffusion (Ciloşoğlu & Açık; Öztürk).
Evaluation and Recommendations	Preservation of its multi-layered structure, support for excavations and sustainable conservation with public participation are recommended (Erzen; Genç & Konyar; Öztürk).

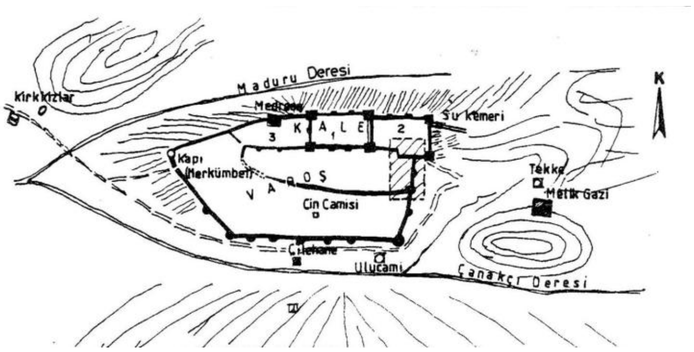

Fig. 3. Plan of Tokat Castle (URL-11).

Table 5. Tokat Castle Analysis Table

Name of Structure	Tokat Castle
Location	The province of Tokat is located on a steep hill that is an extension of the Akdağs, northwest of the city (Mesut Çıtak; 5th Tokat Symposium).
Construction Date / Period	The exact date of construction of Tokat Castle is unknown. The rock graves and the stepped water tunnel in the castle indicate a history dating back to the Pontic Kingdom period (1st century BC) (Mesut Çıtak). Some researchers suggest that the structure mayduring the Roman Empire (30 BC - 395 AD) (Kadir Çakar). The present fortress form is thought to have been strengthened during the Byzantine period, especially between the 4th-6th centuries AD.
Producer / Produced by	According to Evliya Çelebi, a person named Dok-ad from the Amelika tribe; according to other sources, it is related to the Byzantine Empress Eudoxia (5th Tokat Symposium).
History of the Building	It was used in Roman, Byzantine, Dânişmendli, Seljuk, Eretna, Kadı Burhâneddin and Ottoman periods; and assumed military, administrative and religious functions (Mesut Çıtak; Kadir Çakar; 5th Tokat Symposium).
Architectural Features	It contains walls, bastions, moats, worship areas, water cisterns, 362-step stone stairs and various structures in the inner castle (Kadir Çakar; 5th Tokat Symposium).
Materials and Construction Techniques	Cut stone, rubble stone, rock carving techniques were used; it was built in accordance with the topography (5th Tokat Symposium).
Changes Over Time	Its defense systems were strengthened during the Ottoman period; it lost its military importance in the 18th century (5th Tokat Symposium; Kadir Çakar).
Conservation Status and Challenges	It was destroyed over time; some structures were unearthed by archaeological excavations in recent years (Kadir Çakar).
Current Usage	It is considered as a cultural heritage site and tourism destination. Especially the dungeon section stands out (Kadir Çakar).
Potential for Reuse	Prison and sadness tourism can be evaluated within the scope of open-air museums and thematic cultural routes (Kadir Çakar).
Place in the Urban Fabric and Integration Status	It has enabled Tokat to become a classical fortress city; it has historical-urban integrity with the surrounding neighborhoods (Mesut Çıtak; 5th Tokat Symposium).
Evaluation and Recommendations	Preservation of the multi-layered structure, evaluation of the thematic tourism potential and sustainable conservation with public participation are recommended (Kadir Çakar; Mesut Çıtak; 5th Tokat Symposium).

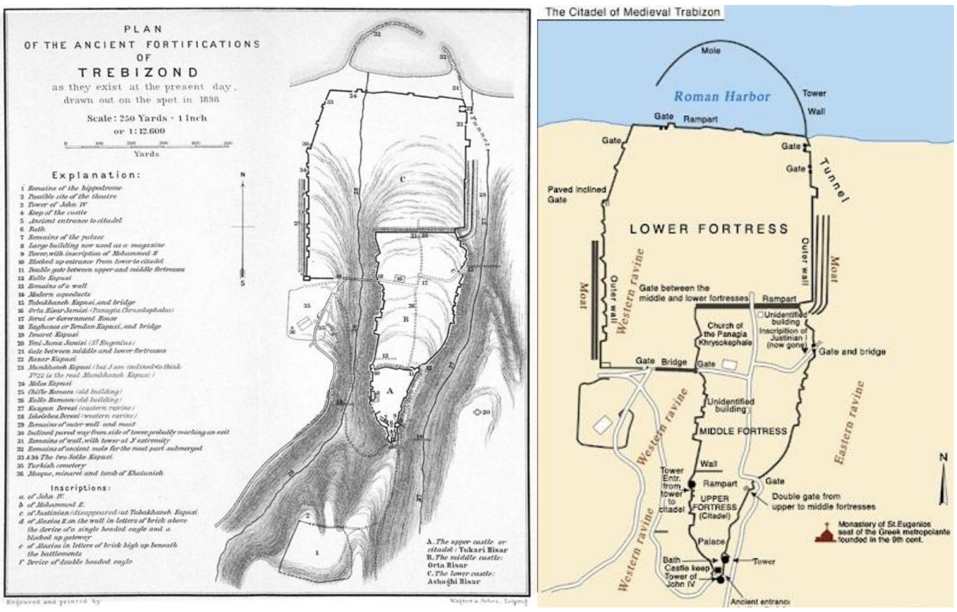

Fig. 4. Plan of Trabzon Castle (URL-13, 14).

Table 6. Trabzon Castle Analysis Table

Name of Structure	Trabzon Castle
Location	Trabzon is located between two valleys on a rocky outcrop suitable for the topography extending to the Black Sea coast. The city consists of parts: Upper Hisar (Inner Castle), Ortahisar and Lower Hisar (Fulya Üstün Demirkaya; Oğuz Kırcı).
Construction Date / Period	The first settlement dates back to the 7th century BC, the early phases of the city wall system date back to the Hellenistic period, and parts of the city walls date back to before the 3rd century AD (Trabzon History Volume ; Trabzon'da Fetih ve Şehir; Bilge Bahar).
Producer / Produced by	Although it is not certain by whom the first defense structures were built, important fortifications and a palace complex were constructed during the reign of the Komnenos of Trabzon (1204-1461) (Bilge Bahar; Trabzon'da Conquest and the City).
History of the Building	Trabzon Castle was used during the Roman, Byzantine, Komnenos, Ottoman and Republican periods and assumed military, administrative, religious and commercial functions (Bilge Bahar; Trabzon History Volume 2).
Architectural Features	The triple fortification system consisting of Upper, Middle and Lower Hisar includes towers, gates, palace buildings, baths, aqueducts, mosques and commercial buildings. The thickness of the walls exceeds 9 meters in some areas (Fulya Üstün Demirkaya; Trabzon'da Fetih ve Şehir; Bilge Bahar).
Materials and Construction Techniques	Cut stone and rubble stone were used; wall systems were built in harmony with the topography, parallel to the valleys and according to the slope (Bilge Bahar)
Changes Over Time	During the Ottoman period, the walls were fortified and new gates and bastions were added. In the 20th century, destruction occurred around the castle due to uncontrolled urbanization and transportation projects (Trabzon History Volume 2).
Conservation Status and Challenges	Although there are more than 500 registered buildings today, the integrity of the castle has been disrupted by modern construction; some parts of the city walls have become detached from today's urban fabric.
Current Usage	It is protected as a cultural heritage site and some parts are considered as tourism destinations. The palace ruins and aqueducts in the stand out (Bilge Bahar; Conquest and the City in Trabzon).
Potential for Reuse	Open-air museum, history-tourism routes, cultural activity areas for the castle and its surroundings can be planned (Conquest and the City in Trabzon).
Place in the Urban Fabric and Integration Status	It shaped Trabzon's 'kalekent' identity. The fortification systems determined the urban morphology and settlement plans (Fulya Üstün Demirkaya).
Evaluation and Recommendations	Conservation of the multi-layered historical texture, the creation of site management plans, increasing local participation and sustainable conservation strategies compatible with cultural tourism are recommended (Bilge Bahar; Conquest and the City in Trabzon).

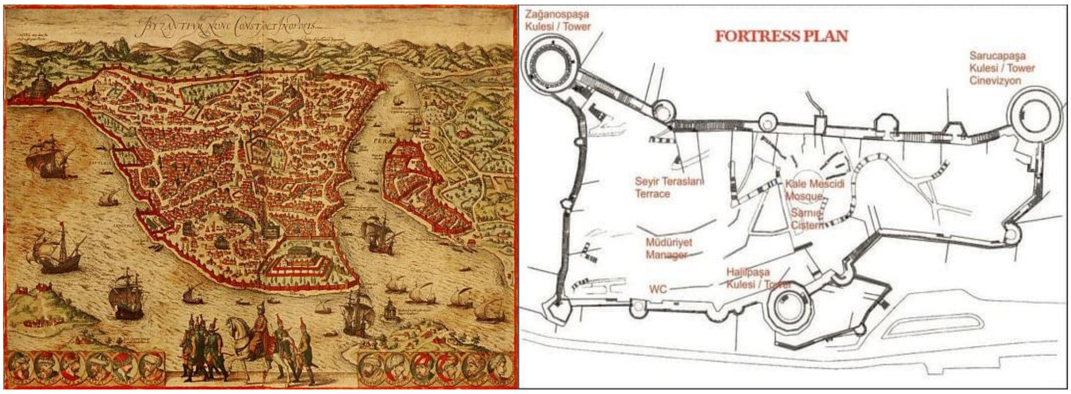

Fig. 5. Istanbul Old Map and Rumeli Hisarı Plan (URL-18, URL-19).

Table 7. Istanbul Rumeli Hisarı Analysis Table

Name of Structure	Istanbul Rumeli Hisarı
Location	The province of Istanbul is located on the European side of the Bosphorus, between Baltalimanı and Bebek, on the narrowest point of the Bosphorus. (Engin Özerler; Hülya Utkuluer)
Construction Date / Period	Built in 1452 by Mehmed II before the conquest of Istanbul (Abdullah Mehmet Avunduk; Engin Özerler)
Producer / Produced by	It was built by the Ottoman Sultan Mehmed II. (Aynur Can; Hülya Utkuluer)
History of the Building	It was built in 1452 for defense purposes, used as a prison after the conquest, and gained a historical identity over time. (Abdullah Mehmet Avunduk; Hülya Utkuluer)
Architectural Features	It consists of three large towers, thirteen small bastions and fortification walls in a plan close to rectangular. The towers are named with the letters A-B-C. (Abdullah Mehmet Avunduk)
Materials and Construction Techniques	Rubble stone, limited brick, spolia; spolia stone is used close to the coast. (Abdullah Mehmet Avunduk)
Changes Over Time	It has undergone earthquakes, fires, restorations; a comprehensive restoration in 1953 and a process that was restarted in 2021. (Hülya Utkuluer; Abdullah Mehmet Avunduk)
Conservation Status and Challenges	Additions such as the construction of a theater were criticized, and a new restoration process was initiated by IBB in 2021. (Hülya Utkuluer)
Current Usage	It is used as a cultural event space; its function as a museum and stage has diminished over time. (Aynur Can; Hülya Utkuluer)
Potential for Reuse	Open-air museum, revitalization of historical and cultural activities, strengthening ties with the local community. (Aynur Can; Hülya Utkuluer)
Place in the Urban Fabric and Integration Status	Part of the Bosphorus silhouette, it is in a neighborhood structure where different socioeconomic groups are intertwined. (Aynur Can)
Evaluation and Recommendations	In addition to physical restoration, social memory, local identity and cultural continuity need to be preserved. (Aynur Can; Hülya Utkuluer)

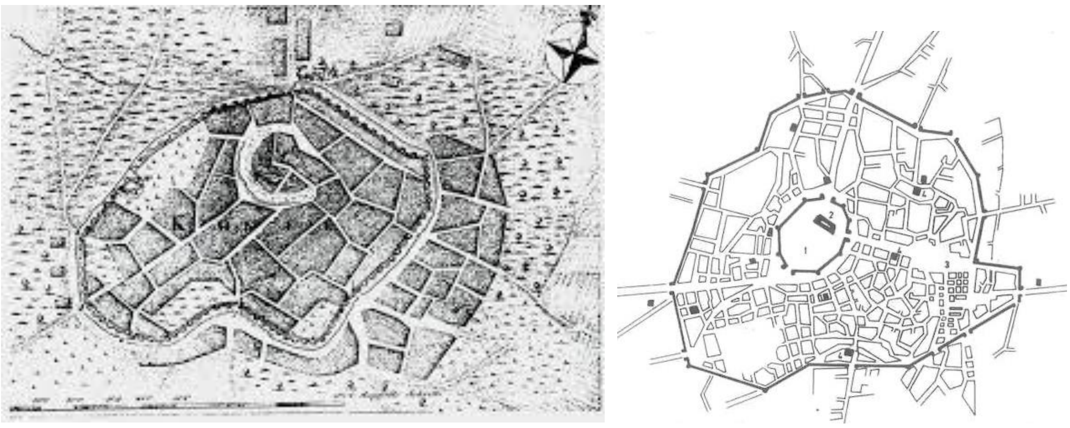

Fig. 6. Plan of Konya Castle (URL-23).

Table 8. Konya Castle Analysis Table

Name of Structure	Konya Castle
Location	Inner Castle: Alaeddin Hill; Gevale: Takkeli Dağ, 1675 m altitude; Ahmedek: West of Alaeddin Hill; Outer Castle: Surrounding Konya (Ahmet Şen; Emine Güney; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)
Construction Date / Period	It was founded during the Roman period, strengthened during the Byzantine period, and major fortifications were built during the Seljuk period during the reigns of Kılıçarslan II (1156-1192) and Alaeddin Keykubat I (1220-1237). (Mustafa Önge; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)
Producer / Produced by	Kılıçarslan II, Alaeddin Keykubat I, İzzeddin Keykâvus I (Emine Güney; Yusuf Küçükdağ et al.; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)

Table 8. continued

History of the Building	Konya Castle is a multi-layered defense structure dating from Roman to Ottoman times. Gevale Castle was used as a diplomatic center and palace; Ahmedek as a dungeon; and the Outer Castle as a structure associated with urban expansion. (Ahmet Şen; Emine Güney; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)
Architectural Features	Multi-layered defense system: İç Kale, Gevale and Ahmedek castles; fortifications with towers; moated layout; rectangular bastions (Mustafa Önge; Yusuf Küçükdağ et al.)
Materials and Construction Techniques	Cut stone, rubble stone, Sille stone; the walls were supported by rectangular bastions (Ahmet Şen; Mustafa Önge)
Changes Over Time	With the Tanzimat, the city walls were dismantled; Ahmedek became a quarry; Gevale lost its military importance (Mustafa Önge; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)
Conservation Status and Challenges	Only the foundations of Ahmedek remain; Gevale is known with limited physical remains; and most of the Castle is known with traces of(Emine Güney; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)
Current Usage	Ahmedek parking lot/art gallery; Gevale is considered an archaeological site (Emine Güney; Mustafa Önge)
Potential for Reuse	Archaeological park can be re-functionalized as a cultural route focused on urban memory (Ahmet Şen; Emine Güney)
Place in the Urban Fabric and Integration Status	Alaeddin Hill surrounds the city center; Gevale overlooks the city from a height; city wall gates influenced the spatial orientation (Konya's Defense Structures - Volume 22 Issue 3; Emine Güney)
Evaluation and Recommendations	Social memory should be preserved along with physical traces; public awareness should be supported (Ahmet Şen; Mustafa Önge; Konya'nın Savunma Yapıları-Cilt 22 Issue 3)

Table 9. Sivas Castle Analysis Table

Name of Structure	Sivas Castle
Location	It is located on a natural elevation called Topraktepe in the center of Sivas province. (Levent Keskin; Oğuz Ceylan)
Construction Date / Period	The first traces of settlement date back to the 2nd millennium BC; it was fortified during the Byzantine period and rebuilt during the Seljuk period. (Oğuz Ceylan; Levent Keskin)
Producer / Produced by	It was fortified during the reign of Byzantine Emperor Justinian and rebuilt during the reigns of Dânişmend Gazi and Anatolian Seljuk Sultan Alaeddin Keykubâd I. (Oğuz Ceylan)
History of the Building	It is a multi-layered structure witnessing the Hittite, Roman, Byzantine, Seljuk and Ottoman periods. (Levent Keskin; Hülya Kaya Hasdemir)
Architectural Features	It consists of and castle; built on a sloping terrain; and houses water cisterns, bastions, weapon depots, a mosque and a church. (Abdullah Kaya; Oğuz Ceylan)
Materials and Construction Techniques	Large cut stone, rubble stone and spolia were used. The walls reach 15-20 meters (Oğuz Ceylan)
Changes Over Time	Destroyed by Timur's attack, it was restored during the Ottoman period. After 2015, restorations were carried out. (Oğuz Ceylan; Abdullah Kaya)
Conservation Status and Challenges	Cracks, stone removal and deformations were observed on the wall surfaces. (Abdullah Kaya)
Current Usage	It is protected as part of the historic skyline, but has been largely abandoned. (Abdullah Kaya)
Potential for Reuse	It can be integrated with archaeological parks, open air museums and cultural routes. (Erdal Eser; Hülya Kaya Hasdemir)
Place in the Urban Fabric and Integration Status	Topraktepe is a strategic focal point in urban memory; it is integrated with the public spaces around it. (Levent Keskin; Hülya Kaya Hasdemir)
Evaluation and Recommendations	Revitalization of social memory, preservation of historical continuity and scientific restoration are necessary. (Hülya Kaya Hasdemir; Erdal Eser)

Fig. 7. Antalya Castle - 1957 Beyru et al. Plan (Özer, 2023).

Table 10. Antalya Castle Analysis Table

Name of Structure	Antalya Castle
Location	It is located in the Kaleiçi district of Muratpaşa district in Antalya province. It is in the old city center surrounded by walls overlooking the Mediterranean Sea. (Fatih Yilmaz)
Construction Date / Period	Founded by Attalos II in the 2nd century BC, the city was fortified with walls during the Roman period; its layered defense structure developed during the Middle Ages, and it came under Seljuk rule in 1207 and Ottoman rule in 1423. (1905-Evren Dayar)
Producer / Produced by	Roman Emperor Hadrian (Hadrian's Gate), Seljuk Sultan Alaeddin Keykubad I (Fluted Minaret), Hassa Architect Mustafa Raşid Efendi (1815 restoration). (Fatih Yılmaz; Evren Dayar)
History of the Building	Although the foundations of the urban fabric date back to the settlement of Korykos, the fortification systems were shaped by the Romans and fortified during the Byzantine and Seljuk periods. The 1905 maps show three districts bounded by the inner fortress and the outer walls. (1905-Evren Dayar)
Architectural Features	The triple fortification system (moat, curtain wall, outer wall) was supported by monumental structures such as Hıdırlık Tower, Hadrian's Gate and Fluted Minaret. (Evren Dayar; Özgen Kurt)
Materials and Construction Techniques	In addition to materials such as cut stone, spolia stone and memzûc mortar, traces of these techniques can be traced in structures such as the Baruthane Burcu and the palace baths on the 1905 maps. (1905-Evren Dayar)
Changes Over Time	After the 1895 fire, the neighborhood fabric was destroyed, and 1905 maps document fire areas, empty parcels and structural changes. (1905-Evren Dayar)
Conservation Status and Challenges	After 1905, with the modernization process, many city gates were removed and the expansion of the city led to the wall system being limited to a symbolic function. (1905-Evren Dayar)
Current Usage	Tourism, marina, cultural heritage area; some areas are used as archaeological parks and museums (Fatih Yılmaz; Özgen Kurt)
Potential for Reuse	Cultural routes, archaeological parks and open air museums can be integrated with tourism and education. (Evren Dayar; Özgen Kurt)
Place in the Urban Fabric and Integration Status	Kaleiçi is divided into three zones; these areas, bounded by the inner city walls, have assumed a central role in urban memory with the harbor and religious buildings. (1905- Evren Dayar)
Evaluation and Recommendations	Scientific restoration, interdisciplinary planning and strengthening social memory are recommended for the preservation of the historical fabric. (Evren Dayar; Özgen Kurt; Fatih Yılmaz)

4. Conclusions

Within the scope of the study, comparative analyses of 10 different castle-city examples in Anatolia have revealed findings on the conservation, re-functionalization and integration of historical walls and castles into the modern urban fabric. The analyzed examples show that similar problems were encountered periods and at urban scales, but the conservation and integration strategies applied varied. Partial conservation and reuse practices were observed in Kayseri, Erzurum and Trabzon; whereas in cities such as Konya, Sivas and Tokat, the remains of the city walls were largely destroyed and integration remained weak. In the case of Rumeli Hisarı, it was observed that the military history of the structure could be integrated with the cultural tourism potential, while archaeological excavations and cultural routes contributed to the conservation processes in the castles and walls of Van and Amasya. In the examinations and evaluations;

- Most of the historical walls and castles in Anatolia lost their military functions over time and remained under the pressure of urbanization
- In many castles, restoration practices are carried out for touristic and economic purposes rather than preserving the original values;
- Historic walls and fortresses continue to be the main elements that guide the morphological development of cities, but modern development practices have seriously damaged this integrity;
- Project-oriented approaches override holistic conservation objectives;
- When the level of public participation and social awareness is low, the integration of historic buildings into daily life is limited;

results have been reached. In this framework, it is necessary to prioritize the original identity in the protection of the original architectural, cultural and social values of historical buildings in restoration and re-functioning works; modern interventions should not harm this identity; sustainable integration models should be planned, in this context, walls and castles should be planned not only as touristic destinations but also as public spaces that are actively used in the daily life of local people; participatory conservation processes should be increased by ensuring effective cooperation between local administrations, academia and non-governmental organizations; comprehensive site management plans should be prepared especially for large-scale and multi-layered historical sites, and in this context, a balance between conservation, use and promotion should be established; innovative functionalization strategies should be determined and cultural routes, open-air museums, culture - art activity areas and sustainable tourism projects and re-functioning projects should be developed for historical walls and castles under the supervision of expert architects; the current status of the buildings should be documented in digital environment and regular follow-up of the conservation processes should be ensured. It should be kept in mind that historical fortifications and castles are not only structures bearing the traces of the past, but also living assets that shape the cultural identity, social memory and spatial continuity of cities, and therefore conservation and integration processes should not be limited to short-term projects; they should be carried out on the basis of sustainable, holistic and participatory approaches.

Preserving Algeria's architectural heritage: Balancing tradition and modern restoration practices

Meryem Kadri[1]

[1] *University of Oum El Bouagui, Department of Architecture, 04000 Oum El Bouagui, Algeria*

Abstract. Algeria's rich architectural heritage faces significant challenges in preservation and restoration, particularly in the context of aging buildings and the rapid urbanization of the country. This study examines the conservation and restoration practices of historical structures in Algeria, with a focus on preserving cultural identity while addressing modern needs. The methodology combines fieldwork involving the assessment of key historical sites, such as Ottoman and French colonial buildings, with expert interviews and archival research. The research investigates the current approaches to conservation, comparing traditional techniques with modern restoration methods that integrate advanced materials and technologies. Results show that the most successful restoration projects are those that carefully balance the original construction materials—such as stone, clay, and wood—with modern, sustainable solutions, including the use of bio-based materials and energy-efficient systems. Challenges in conservation include the lack of standardized guidelines, insufficient funding, and the risk of losing authenticity due to overzealous modernization. However, pilot projects focused on adaptive reuse, such as transforming old palaces into cultural centers, demonstrate that careful restoration can breathe new life into heritage buildings while respecting their historical value. The study concludes by proposing a comprehensive framework for improving conservation practices, emphasizing the importance of collaboration between government bodies, local communities, and conservation experts. The aim is to promote a holistic approach that combines technical expertise with cultural sensitivity to safeguard Algeria's architectural heritage for future generations.

Keywords: Conservation; Restoration; Architectural heritage; Algeria; Adaptive reuse

1. Introduction

Algeria possesses a rich and multifaceted architectural heritage that reflects centuries of historical, cultural, and geopolitical transformations. From the majestic Roman ruins of Timgad and Djemila to the intricate Islamic architecture of the Almoravid and Ottoman dynasties, and the symmetrical facades of French colonial urbanism, Algeria's built environment serves as a living archive of Mediterranean and North African civilizations (Bouchène et al., 2012). These architectural forms are not only valued for their aesthetic and historical significance but also for the intangible cultural narratives they carry—stories of identity, adaptation, and resilience (UNESCO, 2019).

However, this invaluable heritage is under increasing threat. The pressures of rapid urbanization, especially in major cities like Algiers, Oran, and Constantine, have led to the encroachment upon or even the demolition of historic quarters to make way for modern developments (Djabri & Bouchlaghem, 2021). Environmental degradation, including rising humidity, air pollution, and the effects of climate change, accelerates the deterioration of ancient building materials such as limestone, adobe, and wood (González-Zambrano et al., 2020). Moreover, insufficient conservation policies, lack of public awareness, and a shortage of skilled artisans trained in traditional techniques have exacerbated the deterioration of heritage sites (Fakhar, 2016).

While governmental and international efforts—such as the UNESCO designation of the Kasbah of Algiers—have raised awareness, many restoration projects remain inconsistent and sometimes misguided. Interventions often prioritize aesthetics over structural or historical fidelity, occasionally resulting in irreversible damage or loss of authenticity (Benamara, 2018).

* Corresponding author, E-mail: kadrimeriem33@yahoo.com

https://doi.org/10.31462/icearc2025_a_car_830

This study investigates the potential of combining traditional knowledge systems—like lime plastering, rammed earth, and wood joinery—with modern restoration tools, such as digital surveying, non-destructive testing (NDT), and sustainable building materials. The goal is to propose a culturally sensitive and technically viable approach to conserving Algeria's architectural heritage that ensures its endurance and relevance for future generations (Lourenço et al., 2019).

By analyzing field-based case studies and recent restoration experiences, the objectives of this article are to:

Evaluate the current state of heritage conservation practices in Algeria;

Examine the comparative effectiveness of traditional and modern techniques;

Identify key challenges and best practices;

Propose a hybrid restoration framework adapted to Algerian contexts.

Ultimately, this research underscores the need for an interdisciplinary and balanced approach that values historical authenticity, local knowledge, technological innovation, and environmental sustainability (Avrami et al., 2000). Preserving Algeria's architectural legacy is not merely about maintaining old buildings, but about safeguarding the collective memory and identity embedded within them.

2. Methodology

This study employs a qualitative and exploratory approach, combining field research, expert insights, and historical documentation to evaluate heritage conservation strategies in Algeria. The goal is to identify successful restoration practices that integrate traditional techniques with modern materials and technologies.

2.1. Site Selection and Contextual Analysis

Representative heritage sites were selected from key urban regions in Algeria, including Ottoman palaces in Constantine, Kasbah structures in Algiers, and French colonial facades in Oran. The selection criteria included architectural diversity, current conservation status, historical relevance, and accessibility.

2.2. Field Survey and Documentation

A comprehensive field survey was conducted at each site. This involved:

On-site observations to assess the condition of materials, structural integrity, and previous interventions.

Photographic documentation of façades, materials, details, and pathological manifestations (cracks, humidity, erosion).

Architectural assessment using sketches and measurements to analyze traditional construction systems such as stone masonry, rammed earth walls, and timber framing.

2.3. Expert Interviews

Semi-structured interviews were held with architects, heritage conservators, engineers, and local craftsmen. These interviews aimed to:

Understand the challenges faced in conservation efforts.

Document knowledge of traditional building techniques.

Evaluate the perception of modern restoration interventions.

2.4. Archival Research

Historical maps, colonial records, technical restoration reports, and UNESCO documentation were analyzed to reconstruct the architectural history of each site and understand previous preservation efforts.

2.5. Data Analysis and Synthesis

The collected data were thematically analyzed to compare:

Traditional restoration techniques (lime plaster, stone joints, earth reinforcement)

Modern restoration techniques (fiber-reinforced materials, chemical consolidants, digital scanning)

A comparative matrix was created to assess the efficiency, authenticity preservation, and sustainability of each approach.

2.6. Framework Development

Based on the results, a hybrid conservation framework was proposed. It balances technical rigor with cultural sensitivity, aiming to guide future restoration policies and on-site practices.

3. Results and Discussion

3.1. Comparative Performance of Restoration Techniques

Through extensive site documentation and expert analysis, three dominant approaches emerged in the Algerian context:

Traditional methods: such as lime plastering, wooden joinery, and stone masonry.
Modern methods: including epoxy resins, synthetic sealants, and concrete-based repairs.
Hybrid approaches: combining traditional craftsmanship with modern technologies.
The Fig. 1 provides a comparative analysis based on four criteria:
Authenticity retention: Traditional methods scored the highest (90%), while modern approaches often compromise historical integrity.
Material sustainability: Hybrid solutions outperformed others by integrating eco-friendly materials (e.g., bio-based binders).
Cost-efficiency: Hybrid solutions remain economically viable, especially in adaptive reuse projects.
Durability: Modern and hybrid solutions demonstrated superior longevity.

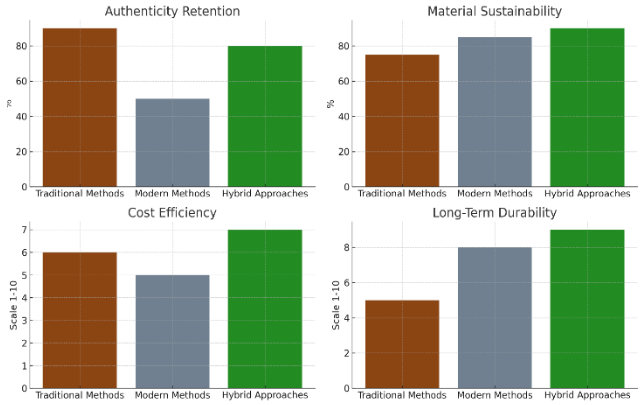

Fig. 1. Comparative performance of restoration methods in terms of authenticity, sustainability, cost, and durability

3.2. Case Studies of Successful Interventions
a) The Palace of Ahmed Bey (Constantine)
This Ottoman-era structure was restored using lime-based mortars, hand-carved cedar wood, and digital scanning for accurate measurements. The project succeeded in preserving intricate details while improving structural integrity (Fig.2).

Fig. 2. Interior view of restored wooden ceiling at Ahmed Bey Palace, Constantine

b) Casbah of Algiers
In the heart of Algiers, restoration projects were guided by UNESCO protocols. Some dwellings were rehabilitated using hybrid methods, maintaining mud-brick walls while reinforcing foundations with carbon fiber mesh (Fig.3).

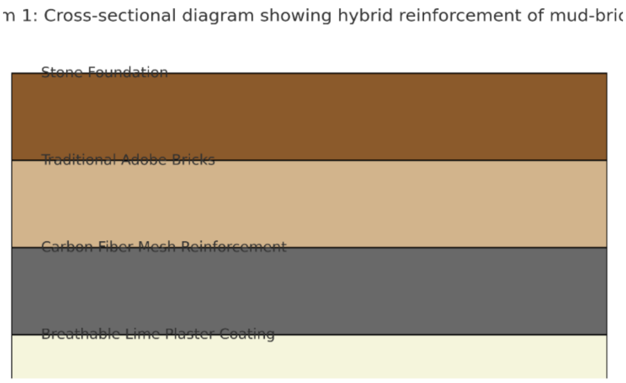

Fig. 3. Cross-sectional diagram showing hybrid reinforcement of mud-brick wall

c) Colonial Villas in Oran

These buildings faced damage due to concrete degradation and moisture. Restoration integrated breathable waterproof plasters and green roof systems to prevent water ingress and promote energy efficiency (Fig. 4).

Fig. 4. Restored facade of a colonial villa in Oran using eco-compatible materials

3.3. Obstacles and Constraints

Several systemic and technical obstacles were identified:

Lack of standardized guidelines: Practitioners often lack consistent manuals, leading to varied results.

Funding gaps: Many projects rely on international aid or temporary municipal budgets, compromising continuity.

Over-modernization: Overuse of incompatible materials (e.g., cement, PVC) alters the buildings' thermal and aesthetic qualities.

Loss of traditional skills: Many local artisans no longer practice heritage construction methods, risking permanent knowledge loss.

Table 1. Summary of challenges encountered in heritage restoration projects.

Challenge	Impact	Example
Non-compatible materials	Structural cracking, humidity issues	Kasbah cement repairs
Funding inconsistency	Project discontinuation	Oran municipal restorations
Lack of skilled artisans	Loss of craftsmanship and authenticity	Elimination of zellij patterns
Regulatory gaps	Conflicts between ministries and cities	Constantine project delays

3.4. Benefits of Adaptive Reuse

Projects that transformed heritage structures into museums, community centers, or guesthouses showed multiple benefits:

Extended building lifespan

Tourism and socio-economic gains

Stronger community engagement (Fig. 5)

Fig. 5. Former Ottoman residence converted into a cultural center in Tlemcen

4. Conclusion

The preservation of Algeria's architectural heritage stands at a critical crossroads, shaped by the tension between respecting traditional craftsmanship and embracing modern innovation. This study has shown that a hybrid approach—where modern techniques and sustainable materials are integrated with traditional restoration methods—offers the most promising path forward. Such an approach not only ensures structural durability and energy efficiency but also retains the authenticity and cultural integrity of heritage buildings.

Through comparative analysis of restoration techniques and field evaluations, the research highlights that projects which value historical context, engage local expertise, and adopt environmentally conscious strategies are more successful and socially accepted. The inclusion of community stakeholders, conservation experts, and interdisciplinary teams emerges as a fundamental pillar for effective heritage management.

However, the challenges remain significant. The absence of standardized conservation guidelines, limited funding, and the growing pressure of urban development pose ongoing threats to Algeria's historical sites. If left unaddressed, these factors could accelerate the erosion of cultural identity embodied in the built environment.

Therefore, this article advocates for a national conservation framework grounded in adaptive reuse, education, and policy reform. By encouraging local authorities, academic institutions, and civil society to collaborate in documenting, restoring, and reusing historic structures, Algeria can safeguard its architectural legacy for future generations. It is not merely about preserving old walls, but about protecting the narrative, memory, and soul of Algerian cities.

Acknowledgments

The author gratefully acknowledges the support and collaboration of the Directorate of Culture of Oum El Bouaghi for facilitating access to heritage sites and archival materials. Special thanks are extended to the local craftsmen and restoration professionals who generously shared their knowledge of traditional building techniques, as well as to the architects and engineers involved in ongoing restoration projects for their valuable insights.

The author also wishes to thank the academic advisors and colleagues from the Department of Architecture at the University of Oum El Bouaghi for their constructive feedback during the research process. Lastly, appreciation is given to the participants of the ICEAR 2025 Conference Organizing Committee for providing a platform to share this work and foster meaningful dialogue on heritage preservation.

Artificial intelligence (AI) assisted digital reconstruction of historical buildings

İzzettin Kutlu*[1], Deryanur Şimşek[1]

[1] *Mardin Artuklu University, Department of Architecture, 47100 Mardin, Türkiye*

Abstract. Historical buildings, as an essential component of cultural heritage, historical traces of the past to the present. However, they are confronted with the need for conservation and reconstruction due to the natural effects and human intervention they are exposed to over time. Artificial intelligence (AI) and digital tools provide significant contributions to the documentation and reconstruction processes of historical buildings. This study utilises digital modeling techniques to document historical structures that are critically endangered cultural heritage, while utilizing artificial intelligence-assisted methods to reconstruct destroyed or damaged sections of the building. The study aims to document damaged or partially destroyed historical buildings with digital tools and to produce AI-assisted reconstruction representations. In this context, historical buildings in Mardin that reflect the rich cultural heritage of Anatolia were discussed. The study consists of 6 stages: data collection, literature review, fieldwork, digital documentation process, AI-assisted image generation and evaluations. During the documentation process, high-accuracy 3D models of the current status of the buildings were produced, while the image generation process was conducted through an artificial intelligence using diffusion-based algorithms. This process offers an effective solution for faster prediction in the reconstruction of destroyed historical buildings. The study concluded that, with technological developments, both effective use of digital tools and AI-assisted research can contributes to the processes of preserving cultural heritage and passing on to future generations.

Keywords: Historical buildings; Artifical intelligence; AI; Digital reconstruction; Mardin

1. Introduction

Historical buildings are the most important physical landmarks that shape the collective memories of societies, build their identities, and maintain cultural continuity. Their architectural forms, use of materials, construction techniques, and spatial organisation make them more than just physical objects. Historic buildings also hold valuable information about the social, economic, political, cultural and historical characteristics of the geography in which they are constructed (Jokilehto, 2017; Feilden, 2007). In this context, these buildings are not only valuable evidence of the past but also sustainable elements of the cultural connections to be created with future generations (UNESCO, 2011). However, over time, this valuable heritage faces the risk of destruction or complete disappearance as a result of natural disasters, wars, environmental conditions, negligence and ineffective interventions (De la Torre, 2013; Avrami et al., 2019; Demas, 2002). This situation has led to an urgent need to conserve, document, and, where necessary, reconstruct historical buildings.

In the twenty-first century, more systematic, accessible and practical approaches to cultural heritage management have become possible through the integration of digital technologies with traditional conservation and restoration methods (Guidi et al., 2009; Remondino & Rizzi, 2010). Digital documentation techniques such as photogrammetry, laser scanning, heritage building information modelling (HBIM), geographic information systems (GIS), thermal imaging, and three-dimensional (3D) modelling allow for detailed analysis of the current condition of buildings while also providing supportive tools for monitoring deterioration processes and decision-making (Dore & Murphy, 2012). Using these technological tools, digital records can be generated with high accuracy, even in areas where physical access is difficult or dangerous. This enhances the sustainability of conservation and interventions (Letellier & Eppich, 2015; Spallone et al., 2017). Since the beginning of the twenty-first century, artificial intelligence (AI) has become another important element, transforming the field of cultural heritage. In particular, algorithms such as computer vision, object recognition, deep learning, and generative adversarial neural networks (GANs) can develop fast and data-driven solutions for the reconstruction of missing parts of damaged or completely destroyed structures (Wang & Xiong, 2022; Li, 2021; Zhu et al., 2025). AI-assisted systems have the potential to offer a new paradigm in reconstruction processes by supporting human expertise,

* Corresponding author, E-mail: izzettinkutlu@artuklu.edu.tr

https://doi.org/10.31462/icearc2025_a_car_860

especially in tasks such as interpolation of missing parts and recognition of similar structural patterns (Trzeciak & Brilakis, 2023; Oreni et al., 2013). These technologies not only provide fast and accuracy but also provide a scientific basis for simulating different scenarios of the reconstruction process (Mishra et al., 2024; Karimi et al., 2024).

Reconstruction is the practice of producing a representation of the building in its original state, particularly in cultural heritage buildings where the original materials and form were damaged. Today, digital reconstruction makes it possible not only to re-visualise physically lost parts but also to reconstruct these representations by verifying them with multiple data sources (photographs, drawings, archival documents, written witness accounts) (Fernández-Palacios et al., 2017; Kuroczyński et al., 2014). In this process, data generation tools supported by artificial intelligence can identify the patterns of damaged parts and generate possible reconstruction scenarios. When the literature on digital reconstruction is examined, Giovannini (2018) proposed the "Virtual Reconstruction Information Management Modelling (VRIMM)" methodology, emphasising that uncertainties and interpretations in 3D digital reconstruction processes should be documented transparently. Brumana et al. (2013), on the other hand, developed a HBIM-based approach for cultural heritage buildings, integrating scanning and survey data and demonstrating that conservation activities can be managed more effectively. Mary (2025) stated that generative AI technologies have a transformative potential in cultural heritage conservation. Marchello et al. (2023) discussed the innovative effects of Virtual Reality (VR) and Augmented Reality (AR) technologies on digital representations of cultural heritage through case studies of digital reconstruction in the context of knowledge production, narrative fiction and user participation. Arzomand et al. (2024) indicate that AI-assisted text-to-image generation processes integrate with historical data to develop a new and dynamically based approach to the reconstruction of heritage buildings. Fang et al. (2024) suggested a method that combines 3D point cloud data and diffusion-based AI techniques to create very accurate and stable digital models of historical buildings. Croce et al. (2023) proposed an AI-assisted semi-automated Scan-to-BIM approach to increase the automation of the conversion of historical buildings from point cloud data to digital reconstruction models. Chashyn et al. (2024) developed a systematic approach for the digital management of historical buildings by proposing a city intelligent modelling (CIM)-based analysis platform and supported HBIM processes with the integration of parametric modelling and advanced data analysis. These developments in the literature greatly enhance the technological dimensions of digital reconstruction processes.

Digital documentation and reconstruction of cultural heritage requires new applications that examine the possibilities offered by AI-assisted digital methods through local examples. This study focuses on the digital documentation and AI-assisted digital reconstruction of historical buildings in Mardin, an important cultural heritage site, using the possibilities offered by technology. The aim of this study is to preserve endangered cultural heritage structures through digital representations and to develop a comprehensive and reliable documentation model that enables their reconstruction using AI-assisted methods. During the six-stage research process, the data collected through field studies were converted into high-accuracy 3D digital models. In addition, using AI-assisted diffusion-based algorithms for the damaged parts of the buildings, the damaged parts were reconstructed using digital images. Digital reconstruction processes are considered in two different approaches: image completion and new image generation. From this perspective, the study fills an important gap in the literature in terms of demonstrating the potential of AI-assisted reconstruction processes and revealing the effectiveness of digital technologies in documenting cultural heritage.

2. Materials and Methods

Mardin, located in the Southeastern Anatolia Region of Turkey, has an important dataset in terms of cultural heritage, with its unique urban texture containing traces of different civilisations. Throughout history, Mardin has hosted many civilisations, such as Assyrian, Roman, Byzantine, Artuqid and Ottoman (Dursun, 2024; Aydın et al., 2024). Today, it presents a unique urban identity with its cultural heritage, which is characterised by traditional stonework, religious buildings, and government buildings reflecting the traces of these civilisations (Fig. 1). Within the scope of this study, two different scales of examples reflecting the cultural heritage characteristics of the city of Mardin were examined. Digital reconstruction applications were conducted on the civil architecture example in Midyat and the ruined fortification wall of the ancient city of Dara. In this study, involving a cross-scale analysis, traditional buildings and fortification walls were considered to evaluate the potential of digital reconstruction of damaged structures that differ in both function and scale.

Fig. 1. The heritage sites considered within the scope of the study

Advancing digital technologies significantly increases the potential for the use of new tools in conservation, restoration, and urgent intervention efforts at cultural heritage sites. In particular, it has become possible to integrate digital technologies effectively in the reconstruction of historical buildings and the development of intervention strategies, beyond documentation processes. This method provides higher accuracy, data-based analysis and multi-layered representation in conservation practices and improves the systematisation of intervention processes. In this study, a six-stage methodological approach was adopted for the digital documentation and AI-assisted reconstruction of cultural heritage buildings utilising these technologies (Fig. 2).

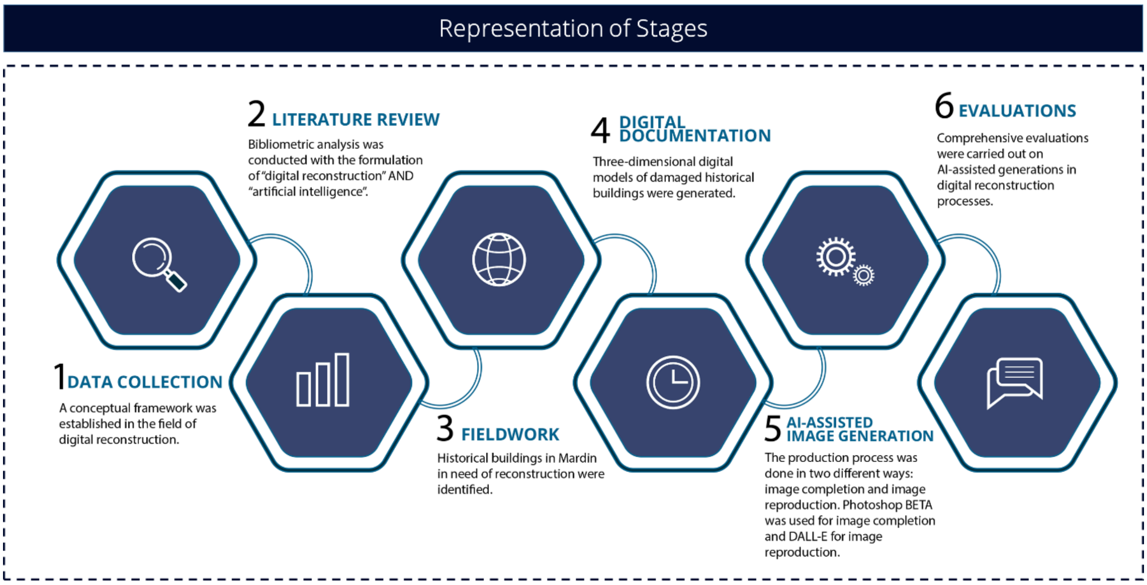

Fig. 2. Methodological flowchart of the study

The first stage of the study was the data collection process. At this stage, the conceptual framework of digital documentation techniques and reconstruction for cultural heritage buildings was defined. In the second stage, a literature review was conducted. Using the Web of Science (WoS) database, studies on digital reconstruction applications and AI-assisted methods for cultural heritage buildings were systematically analysed. Bibliometric analysis was performed through the VOSViewer software, and the main research trends and keyword correlations in the literature were visualised. Bibliometric analysis is considered an effective method for investigating knowledge production processes and identifying gaps in a particular field (Donthu et al., 2021). The third stage of the study involved fieldwork. Fieldwork was carried out in Mardin's historical heritage sites to document heavily damaged or demolished buildings on site and to record their current condition in detail. Field studies are considered an essential research method in documentation and intervention processes as they enable direct observation of the physical and spatial characteristics of cultural heritage buildings (Dimes & Ashurst, 2007). In the fourth stage, digital models of the buildings selected during the fieldwork were generated. Three-dimensional digital modelling has become a fundamental tool in cultural heritage studies in terms of documenting the current situation and providing basic data for reconstruction processes (Guidi et al., 2009). In the fifth stage, AI-assisted digital reconstruction processes were performed. This stage employed two distinct AI tools. The AI-assisted completion module of Photoshop Beta was used to complete the existing images, and the DALL-E 3 inpainting model was used to produce new images. Diffusion-based visual production technologies are gradually becoming widespread in the field of cultural heritage for the completion of incomplete data sets and the development of reconstruction alternatives (Gîrbacia, 2024; Bevilacqua et al., 2022). In the final stage, the resulting digital models and AI-assisted reconstruction outputs were comprehensively evaluated.

3. Findings

The findings section of the study presents both the current research trends in the literature and the original data obtained from field studies within the framework of a multi-layered analysis. In this context, the role of AI-assisted digital reconstruction applications in the field of cultural heritage was determined through bibliometric methods. Then, the digital models and AI-assisted reconstruction representations produced as a result of the field studies conducted in the city of Mardin were analysed. Thus, with the findings obtained, a holistic relationship was created between both the theoretical framework and the applied outputs, and the contributions of the research to the literature and field studies were revealed from different perspectives.

3.1. Bibliometric Analysis of AI-Assisted Digital Reconstruction Studies

The increasing trend towards AI-assisted digital reconstruction studies in the field of cultural heritage indicates that technology has become not only a documentary tool but also an active actor in the reproduction, completion and interpretation of cultural data. A bibliometric search of the WoS database with the formulation *"digital reconstruction" AND "artificial intelligence"* revealed that the first study in this field was conducted in 2016. The search was carried out under the heading "Topic", and all academic studies obtained as a result of the search were considered without any classification. As a result of the search, it was determined that there were a total of 10 studies as of April 2025. These studies were systematically examined, and the themes, basic field trends and methodological diversity of AI-assisted digital reconstruction studies were determined. The studies were presented in table form in chronological order as *"Authors, Publication Year, Title, Research Area, Country, Document Type"* (Table 1).

Table 1. Overview of selected studies indexed in the WoS database

Authors	Publication Year	Title	Research Area*	Country	Document Type

*Research Area: Information available in the WoS database was presented.

According to the results of the bibliometric analysis, only three studies directly focused on the theme of "heritage." Kouvoz (2020) discusses how big data analytics can be used for the conservation and management of cultural and historical heritage sites, emphasising the role of data-driven approaches in digital transformation. Ozturk et al. (2024) examined the use of innovative technologies for the digital transformation of cultural heritage and evaluated the integration of AI-based methods into digital conservation efforts. Ceccarelli et al. (2023) optimised data processing for cultural heritage structures by developing AI-assisted semantic segmentation methods in the transition from point cloud data to HBIM representation. To reveal the relationality of these studies on the study area, a keyword co-occurrence network map was generated (Fig. 3).

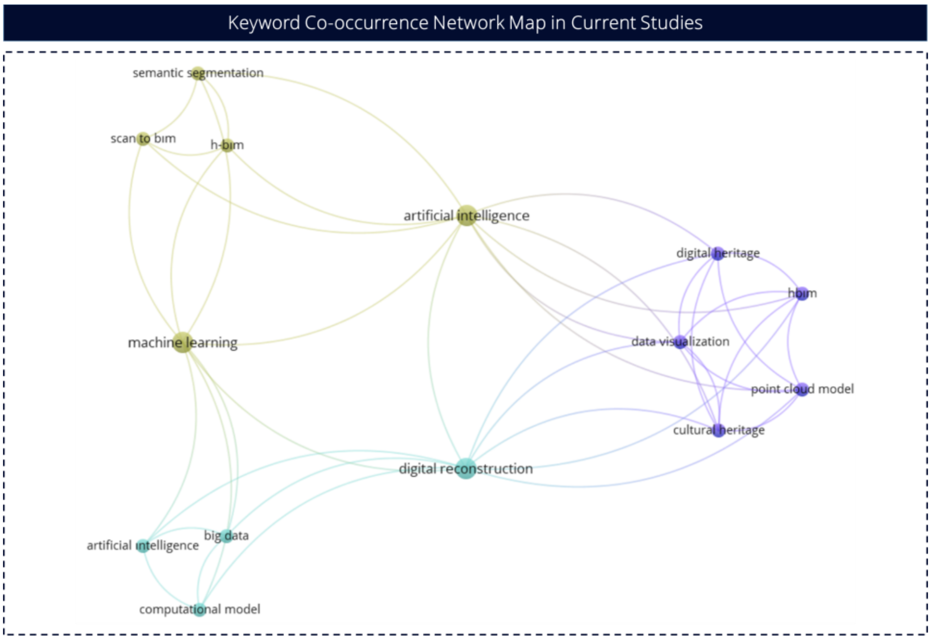

Fig. 3. Keyword co-occurrence network maps a result of bibliometric analysis

The keyword co-occurrence network map from the three studies shows the main themes and ideas related to AI-assisted digital reconstruction in cultural heritage. The study revealed a high level of interaction between the words "digital reconstruction", "artificial intelligence", and "machine learning". Notably, these central concepts relate to more technical and contextual terms like "cultural heritage", "point cloud model", and "semantic segmentation". The study demonstrates that AI-assisted modelling practices have the potential to be integrated not only at the technological level but also in the digital representation processes of cultural heritage structures. However, the limited number of studies representing the term “cultural heritage” in the network also reveals that the research intensity in the field has not yet sufficiently included cultural dimensions. These findings clearly indicate that AI technologies should be integrated into cultural heritage-related processes with more in-depth representations.

3.2. Digital Documentation and Modeling Processes in Cultural Heritage Buildings

This section of the study focuses on the digital documentation and modelling of heritage sites in two different geographic and cultural contexts in Mardin. The first is an example of traditional civil architecture in Midyat, and the other is the ancient city fortification wall of Dara, an archaeological site in the countryside. The traditional house documented in Midyat has unique characteristics in terms of the region's stone architecture, ornamentation, and materials used. The northern fortification wall in Dara, on the other hand, is significant because it belongs to the Ancient Roman period and reveals the local materials and textures of the region, as well as the architectural formation for defence. Due to the presence of heavily damaged and collapsed sections of civil architecture and the fortification wall, it has become essential to document their current condition with high-accuracy digital modelling.

The modelling process required separate fieldwork for both areas. The PhotoScan program developed by Agisoft was used in the modelling process for both areas. PhotoScan allows one to create a 3D model by aligning photographs taken from different angles with a depth-sensing algorithm. The first fieldwork involved taking 383 photographs of the traditional house from various angles. The photos were added to the Photoscan program. The program identified and aligned 379 of the added photos and created a point cloud model. After the creation of the point cloud model, a dense point cloud was created with the “build dense cloud” command, which is automatically defined in the program. With the generation of the dense point cloud, the “build mesh” command was run to build the mesh model. After the mesh model was formed, the "build texture" command was run to integrate the textures in the photographs into the model, and the textured model generation process was completed (Table 2).

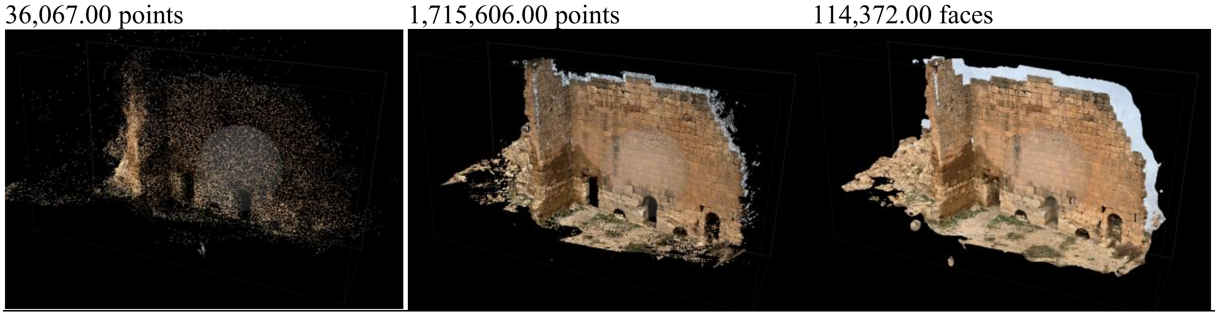
Table 2. Digital model generation process of a traditional Midyat house

Point Cloud Model	Dense Point Cloud Model	Textured Model
141,931.00 points	29,322,297.00 points	1,827,577.00 faces

The second field study involved the modelling of the fortification wall located at the end of the Agora in the northern direction in Dara. To create the model, 42 photographs were taken for the northern fortification wall, and all 42 photographs were aligned by the program to create a 3D digital model. Initially, the program generated a point cloud model, followed by a dense point cloud. Finally, a textured model was produced, and the digital documentation process was completed (Table 3).

Table 3. Digital model generation process of the Dara Fortification Wall

Point Cloud Model	Dense Point Cloud Model	Textured Model
36,067.00 points	1,715,606.00 points	114,372.00 faces



Modelling processes are not only limited to the production of visual documents but can also provide multi-layered contributions in terms of pre-reconstruction evaluation and digital archiving. The digital models produced within the scope of the study constitute a data set for the AI-assisted reconstruction process.

3.3. AI-Assisted Digital Reconstruction from 3D Representations

In this section, the process of AI-assisted visual reconstruction on digital models of cultural heritage buildings was discussed within the framework of two different AI models. The first artificial intelligence model is the DALL-E 3 Inpainting AI model that performs text-to-image generation. With this AI model, it is aimed to visualise the undestroyed and original conditions of the buildings whose digital models were created by performing a prompt engineering process. The second model is Photoshop Beta's "generative fill" AI, which can automatically fill, change, or complete missing areas with content by defining the area you select on an image with text. With this model, it is aimed to complete the demolished and damaged areas of the buildings over the existing photographs of the buildings by AI in accordance with the original structure. This process also provides an opportunity to comparatively evaluate the productivity capacity of two different AI models in terms of both data generation and verification.

With the first AI model, the images obtained from three different 3D digital models of the traditional house in Midyat and the North fortification wall of Dara were uploaded to DALL-E 3 Inpainting and production were performed by writing "prompts" that define the original state for each image. ChatGPT-4o software, an AI tool developed by OpenAI, was also used in the prompt engineering process.

- For the Midyat traditional house *"Using the uploaded photogrammetric images of a historical house, some parts of which have been demolished, taken from different angles. Reference the photogrammetric images I uploaded. Complete the missing parts of the historical building in the black background based on its original architectural style, materials and structure. Preserve the authentic stone textures, window forms and traditional building details typical of 19th-century Mardin's traditional housing architecture. Avoid adding any modern elements"* prompt was used.

- For the Dara fortification wall *"Using the uploaded photogrammetric images of a ruined city wall from multiple angles as reference, reconstruct the missing sections of the wall in accordance with its original architectural style, materials, and structural logic. This wall belongs to the ancient fortifications of Dara Ancient City, located in Southeastern Anatolia (present-day Mardin, Turkey), dating back to the Late Roman–Byzantine period. Avoid introducing any modern elements. The reconstruction should reflect authentic military architecture from late antiquity, characterised by high-quality stonemasonry and monumental proportions. Complete the wall seamlessly based on the referenced visuals, preserving historical accuracy and photorealism"* prompt was used.

At the end of this process, outputs for each building were obtained (Fig. 4). The model can analyse textual inputs and data sets together. Natural language processing and image synthesis algorithms are used in an integrated manner. In this context, DALL-E has the capacity to make sense of not only a descriptive text but also a historical-architectural context and transform it into a new visual output. Through visual comparisons, this dataset provided the opportunity to analyse the potential and limitations of generative AI in terms of the formal integrity of buildings.

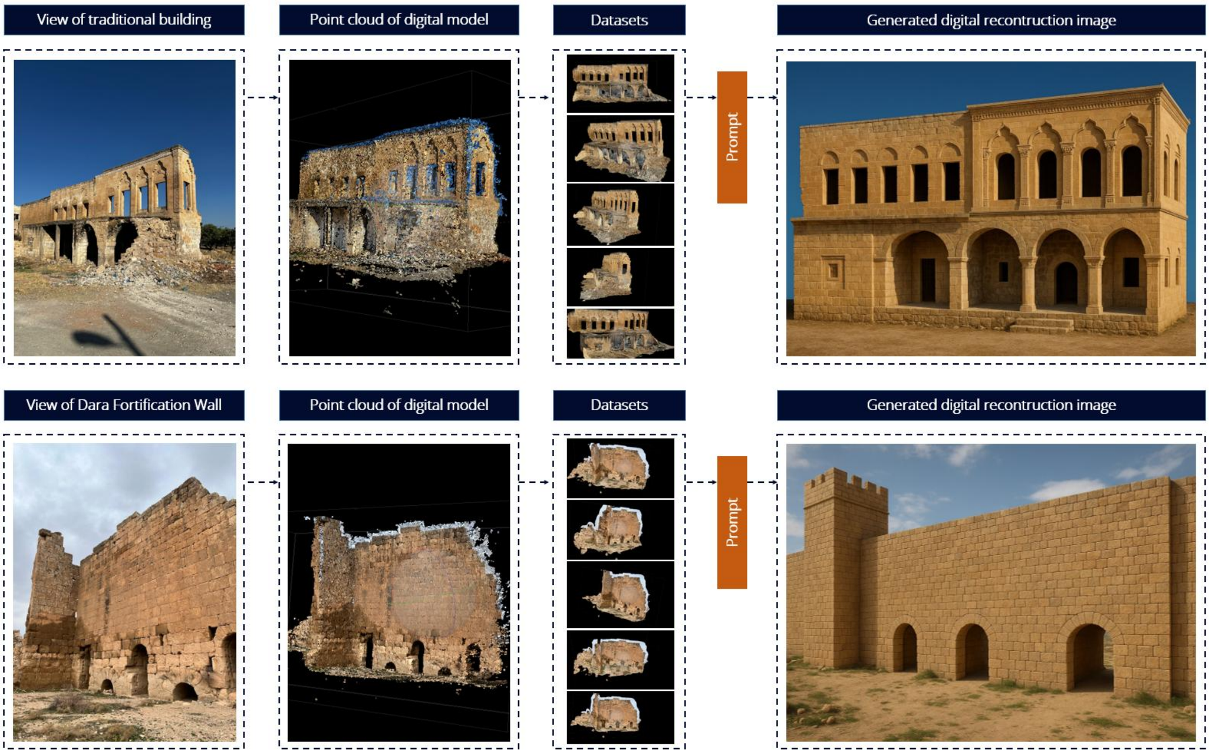


Fig. 4. Reconstruction images from digital model datasets with DALL-E 3 Inpainting

In the second AI model, the photographs of the same structures taken from the field study were imported into the Adobe Photoshop Beta program. Then, for each of them, a prompt engineering process was conducted, and AI-assisted visual completion processes were applied. ChatGPT-4o software, an AI tool developed by OpenAI, was also used in the prompt engineering process.

- For the Midyat traditional house *"Reconstruct the missing parts of the traditional Midyat stone house using limestone, windows, thick walls and roof elements. In the process, preserve the original window openings, arches and facade proportions by referencing the building remains in the image. Match the texture and structural rhythm. No modern materials. Provide 3D volume to match the original texture"* prompt was used.
- For the Dara fortification wall *"Reconstruct the missing parts of the ancient stone fortification wall using the existing architectural and structural features in the image as a reference. Use matching limestone textures, rusticated surfaces, and original fortification wall forms typical of Late Roman-Byzantine fortifications. Avoid modern elements. Complete the wall authentically and seamlessly"* prompt was used.

Photoshop Beta's generative fill feature created new textures in the damaged areas by correlating the prompt used with the visual context. During this process, AI not only analyses the texture, light-shadow distribution and perspective of the existing image but also produces realistic and holistic visual outputs by placing the prompt in an architectural context. Photoshop Beta's generative fill tool is characterised by its capacity to produce a more controlled and environmentally contextualised image, especially when completing defective or damaged areas (Fig. 5).

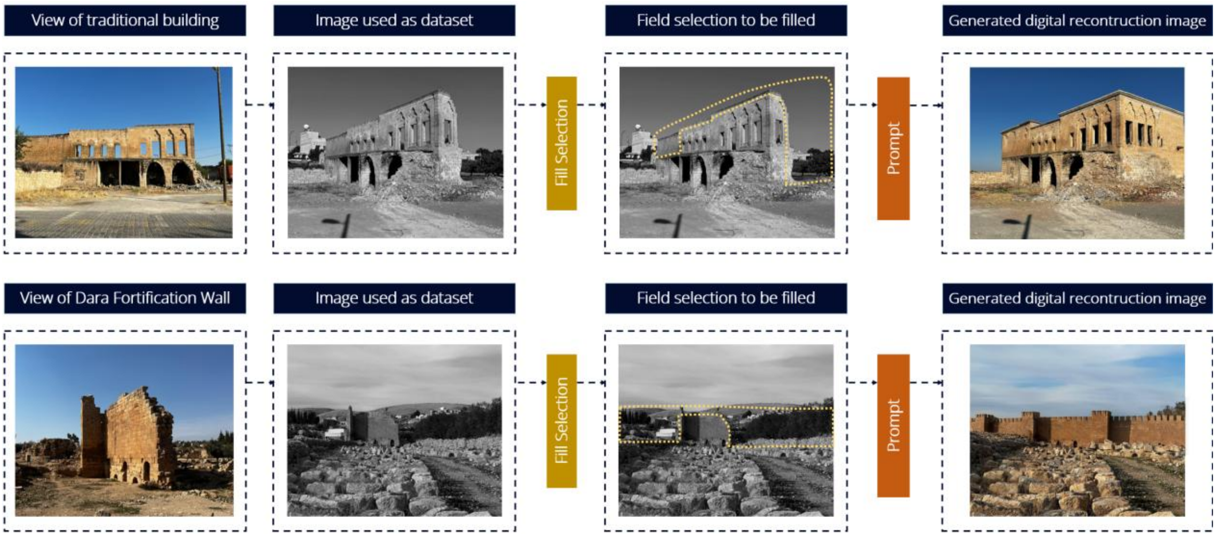

Fig. 5. Reconstructing images from photos datasets with Photoshop Beta

Although the methodological difference between DALL-E 3 Inpainting's ability to produce from scratch and Photoshop Beta's ability to complement the existing image is obvious, both tools offered different levels of intervention and representation. These two AI models can help recreate damaged parts of heritage buildings, explore different possibilities and assess how representative these new images are of the originals. Artificial intelligence can help create digital images of historical buildings, improving how visitors experience them, especially when it's difficult to preserve the actual structures. However, the process of interpreting the resulting images requires not only algorithmic accuracy but also consideration of heritage-orientated evaluation criteria, such as historical authenticity, formal similarity, and consistency.

4. Evaluation and Discussion

The literature reviews and bibliometric analysis conducted in this study indicate that the use of AI technologies in the field of cultural heritage is increasing. However, much of this increase is focused on technical applications, and the basic principles of heritage conservation, such as cultural context, authenticity, and ethical verification mechanisms, are not sufficiently discussed. This situation reveals that AI-assisted digital reconstruction research in the field of cultural heritage is still underdeveloped. Despite the preservation, documentation, and reconstruction opportunities offered by digital technologies in cultural heritage sites, it's noticeable that most of the existing research is focused on fields such as biomedical engineering, road infrastructure, and energy engineering. It is clear that AI applications in areas with unique cultural heritage contexts have not yet reached a sufficient conceptual framework and depth of application. Existing studies have focused on technical issues, such as data management, semantic segmentation, and digital transformation strategies.

Digitisation and modelling processes of heritage sites provide data production that can be integrated into different fields. Survey-restoration studies can be conducted through the models, as well as process-follow-up analysis studies, cultural-urban landscape studies, and structural analysis processes that can be performed in light of these data. The digital models produced in the study not only prepared the basis for AI-assisted production stages but also served as a high-accuracy archive in documenting the current status of cultural heritage assets. Documentation of historical buildings on digital platforms can be considered an important method for the sustainability of heritage, especially in areas where physical intervention is not possible or inconvenient.

Developing technologies in the twenty-first century have also improved the tools used in documentation studies. Unmanned aerial vehicles (UAVs), one of these tools, enable the production of 3D models by taking images from heritage structures that are difficult to access. In this way, the necessary data for research can be produced without the need for physical intervention. The models can be imported into interactive environments such as VR and AR, and a metric virtual platform can be developed for conservation processes. The photogrammetric documentation and 3D digital modelling of the buildings within the scope of the study enabled the detailed recording of both the formal and topological features of the buildings. The point cloud-based modelling techniques used in this process have also visualised the surface features, structural deformations or the extent of future damage. Thus, digital models are no longer just visual representations but have become an analytical resource that provides data-based contributions to intervention planning and reconstruction strategies.

The AI-assisted reconstruction process, conducted after digital modelling, provided the opportunity to comparatively evaluate different production strategies for cultural heritage buildings. In this context, the text-to-image generation realised with the DALL-E 3 Inpainting model produced representations based on the digital model of the existing building. However, these images are produced by taking references from the existing architectural context. Therefore, there is a possibility that the building may be far from the original proportions and architectural data in its original state. This situation reveals that AI should be used for inspirational and idea development purposes, especially in early and rapid production stages. It indicates that detailed restitution studies must be carried out during intervention and decision-making. Despite these limitations, DALL-E's form suggestion capacity and visual completion skills contributed significantly to developing an intuitive perspective on the original architectural style of the building. On the other hand, Photoshop Beta's generative fill tool offered a more controlled and building-specific complementarity in terms of allowing reconstruction directly based on the context of the existing image. Photoshop Beta was able to produce more reliable results in terms of environmental integrity and ratio consistency, especially in completing demolished areas through the digital model. Photoshop Beta cannot produce effective results when completing the image due to the large scale of the structures in the study and the presence of parasites around them. For this reason, Photoshop Beta is expected to produce more effective results for small-scale damages like cracks, moisture, stone spillage, and fractures. However, the historical accuracy of the images produced by both DALL-E 3 Inpainting and Photoshop Beta should not be regarded as certain. The quality of the outputs produced is directly related to the diversity of the dataset on which the model is trained, the capacity of the algorithm used to establish visual logic, and the level of clarity contained in the prompt. AI models produce probabilistic representations by inferring from existing data (Fig. 6). However, these productions should be considered as a vision offering suggestions rather than a scientific representation unless they are supported by restitution principles, archaeological traces, and archival documents.

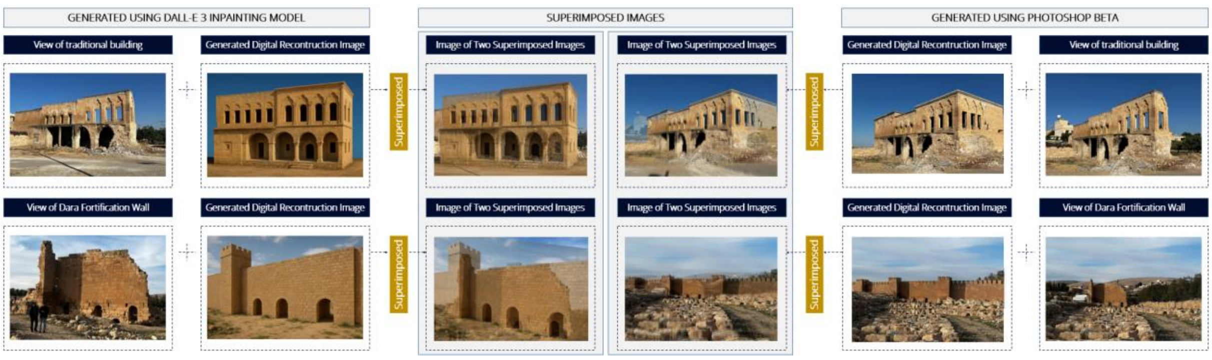

Fig. 6. Superimposing the current state images with the generated artificial intelligence-assisted digital reconstruction images

All these findings and evaluations reveal that the interaction between digitalisation, AI, and cultural heritage requires redefinition not only at the visual but also at the methodological, theoretical, and ethical levels. Digital models and AI-assisted reconstruction practices are creating new areas of responsibility within the conservation discipline. The creation of digital twins of cultural heritage enables not only the production of physical data but also the construction of historical memory through multiple representations. In this context, it is essential to consider not only the development of digital reconstruction tools but also the principles of cultural, historical, social, and ethical verification that will govern their use.

5. Conclusions

This study reveals the applicability, limitations, and potential of AI-assisted digital reconstruction processes in the field of cultural heritage within the framework of a multi-layered analysis. Bibliometric analysis has revealed that, although the concepts of digital reconstruction and AI are rapidly gaining place in scientific literature, cultural heritage has not been sufficiently integrated with these technological developments. The limited number of such applications primarily focus on technological disciplines and healthcare. They are not yet supported by ethical and interdisciplinary approaches shaped according to the requirements of the historical and cultural context.

The digital documentation and modelling of the traditional house in Midyat and the fortification wall in the ancient city of Dara, located within the borders of Mardin, can be considered as concrete examples of applications in the field of technology and heritage. The representations generated by the point cloud-based modelling process also served as datasets that could be considered references for AI-assisted reconstruction applications. Generative AI tools, such as DALL-E 3 Inpainting and Photoshop Beta, interacted with these models to produce alternative completions and visualisations, which proved to be an effective method, especially for early decision-making processes and idea development stages. However, the outputs of these tools do not meet the standards of scientific preservation in terms of historical accuracy and contextual appropriateness. Therefore, AI-assisted digital reconstruction methods should be evaluated only in terms of generating visual suggestions and providing intuitive analysis. Archaeological traces and visual archival documents should support restitution principles before using them as a final decision-making tool. Nevertheless, the rapid development of these technologies indicates that much more effective and reliable representations of cultural heritage can be produced in the future.

As a result, this study presents an original example of the integration of digital technologies and generative AI in the field of cultural heritage. Through an applied field study, an assessment of both modelling and AI-assisted visual production processes is conducted. This approach provides a suggestion that decision-making mechanisms in conservation practice can be assisted by digital tools.

Preliminary research on two ancient aqueducts in the fortress of Amasya

Feyza Aykutlu*[1], Nuran Kara Pilehvarian[2]

[1] Amasya University, School of Design, 05100 Amasya, Turkiye
[2] Yıldız Technical University, Department of Architecture, 34349 Istanbul, Türkiye

Abstract. Amasya, located in north-central Anatolia, was founded in the valley where the Yeşilırmak River flows. Archaeological findings suggest that it has been continuously inhabited since the Neolithic Period. The earliest known communities in Amasya are the Hattians (3000 BC) and Hittites (2000 BC). The most glorious period of Amasya in its history was the Hellenistic Pontus Kingdom, which ruled in the 2nd-3rd centuries BC, when it was the capital of this state. The remnants of this period are still visible in the city's cultural hubs, including fortress of Amasya, in the present day.

Overlooking the valley where the city founded, the Amasya fortress is situated on Harşena Mountain, which is located on the northern side of Yeşilırmak. It is regarded to date back to the Bronze Age and has been occupied continuously throughout its history. The oldest architectural remains in the fortress today date back to the Hellenistic Period. While the community on Acropolis hill relied on cisterns and stepped tunnels, which were constructed in various periods, to meet its water needs, the lower settlements benefited from the development of aqueducts.

This research focuses on Karaman and Helkıs aqueducts, two ancient aqueducts located on Harşena Mountain where the fortress of Amasya was built. For this purpose, architectural characteristics, the construction techniques, and the locations of the aqueducts have been investigated. Additionally, the springs of the aqueducts and the destinations they were constructed to supply for discussed. Finally, evaluations were made regarding the period in which the structures in question were built and their effects on the development of the settlement.

Keywords: Fortress of Amasya; Mount Harşena; ancient; aqueduct

---

1. Introduction

According to Thales, water, which is the "*arkhe*" of everything (Kranz, 1994), is one of the basic substances that ensure the continuity of life on earth. Being a source of life has made it one of the most important elements determining the settlements of human beings since prehistoric times (Ramsay, 1960). However, many and various types of water structures have been built in these settlements in order to meet the need for water.

Founded in the center of North-Central Anatolia, in the valley where Yeşilırmak gives life, Amasya has a history of approximately 8000 years. Archaeological researches conducted in Doğantepe Village of the center revealed remains dated to the Neolithic Period (Özdemir, Uçar, Mecek, & Yılmaz, 2007). The Hatti Period artifacts discovered in Mahmatlar Village of the center and called Mahmatlar Treasure (Koşay & Akok, 1950) and the statue of the Hittite Storm God Teşup (Alp, 1961) found in Doğantepe are important findings that point to the settlement history of Amasya in the 2nd and 3rd millennium BC. The presence of Scythian and Median communities in the city is mentioned until the Persian domination (Achaemenid Empire) which started in 546 BC. According to Strabo, the city was the center of the 19th Persian Satrapy during the Persian rule that lasted for about 2 centuries (Strabo, 2000). Important finds related to this period in the city are the Persian Road uncovered during the excavations at Oluzhöyük, a place of worship and the first known firepit of Anatolia (Dönmez, 2018). Amasya entered the borders of the Cappadocia Pontica State (Katpatuka) in 360 BC and became the first capital of this state in 281 BC. During this period, intensive construction movements occurred in the city and rock tombs, walls, bridges, altars, temples, cisterns, stepped tunnels and aqueducts were built (Strabo, 2000).Amasya Fortress is the place where the textures of the Hellenistic Period can be observed the most in Amasya today.

Although the recent excavations in Amasya Fortress yielded objects dated to the Early Bronze Age (3000-2500 BC) (Naza-Dönmez, 2012), the earliest surviving architectural textures belong to the Hellenistic Period. The

fortress consists of 3 levels depending on the elevation of Mount Harşena on which it is located. These are the acropolis at the top, the Kızlar Palace and the rock tombs in the middle, and the part on the banks of Yeşilırmak, which is today called İçerişehir. In these regions, which are known to have been inhabited without interruption, palaces, residences, baths, religious and military buildings were built from various periods, and cisterns, stepped tunnels and aqueducts were built to meet the water needs of the users (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017) (Aykutlu, 2023). Karaman and Helkıs Aqueducts, which are the subject of our study, are water structures built to meet the water needs of these settlements in Amasya Fortress in the historical process.

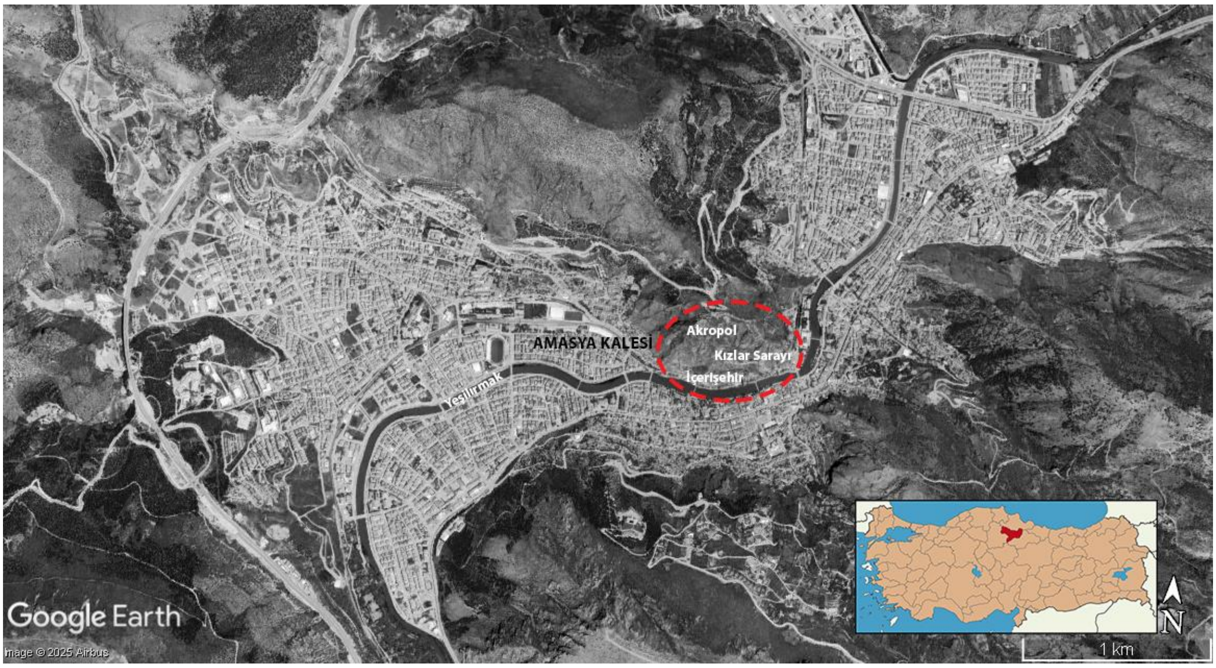

Fig. 1. Amasya, Settlements of Amasya Fortress on Mount Harsena

2. Findings

2.1. Karaman Aqueduct

2.1.1.. Location and Course

Karaman Aqueduct is the transmission line that delivers water to the İçerişehir district, which is the lowest settlement of Amasya Fortress and located on the banks of Yeşilırmak. It was carved into the rocks on the slope of Mount Harşena, north of the railroad that passes through here.

According to Göztaş et al. the source of Karaman aqueduct is located in Yuvacık Village (Karaman District), 3.3 km northwest of the Fortress. Today, the water source continues to flow with a flow rate of 15-30 l/sec in a pool arranged under the Şeyhcui Baba Mosque in the center of Yuvacık Village. There is also a water trough carved into the monoblock rock in front of the mosque with grooves on the sides. It is believed to be a part of the Karaman water transmission system with the function of water distribution (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017) (Fig.2).

The best preserved parts of the Karaman Aqueduct were found on the cliffs of the Kurşunlu Quarter in the western neighborhood of Amasya Fortress. From here, the canal, which continues towards the Fortress by carving openly into the rocks, pierces the walls and continues for about 1 km along İçerişehir and cannot be observed after the registered building, which is used as the Municipal Guest House today, due to the destruction caused by time. Amasya Museum Director Özdemir states that in its original form, the Karaman Aqueduct terminated at the Büyük Kaya Cistern about 100 m east of the Guest House, where the water left over from the distribution was stored (Özdemir, 2001) (Fig. 3).

Fig. 2. Karaman Aqueduct, Source and Taksim Stone (Aykutlu, 2023)

Fig. 3. End of Karaman Aqueduct, Büyük Kaya Cistern

The parts of the aqueduct continuing to the source in the west direction after the Kurşunlu Quarter cannot be observed. Göztaş et al. (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017) state that The aqueduct originating from the site of Karaman Mountain initially extended through underground terracotta pipelines, then it was built as a masonry covered canal until it passed the necropolis northwest of the Kurşunlu Quarter. As a matter of fact, during the interviews conducted during the fieldwork, it was stated that the terracotta pipelines mentioned by Özdemir were found in some construction foundations in the Şeyhcui neighborhood, which is the entrance area of the canal to the city after Yuvacık Village. In addition, it was learned that the water of Hızırpaşa (Sümbül) Bath House, located between Yuvacık Village and Kurşunlu Neighborhood, came from this source in previous periods.

Based on this information, distance and elevation values were calculated. Accordingly, it was determined that the distance between Hızırpaşa Bath and the point where the canal terminates in İçerişehir is 1600m and the elevation difference between these two points is approximately 15m. As a result of the calculations, it was found that the Karaman aqueduct has a slope of 0.0093 (0.93%) between the mentioned points. This is in accordance with the suggestion of Vitruvius in the ancient period.[1]

There is a great elevation difference of 140m at a distance of about 2km between the bathhouse and the spring. There are two possibilities here: Either the aqueduct maintained the same slope for some time after the bathhouse and then steepened too much - there must have been different systems integrated into the aqueduct to balance the pressure - or the slope must have increased after the bath and continued with this slope until the spring.

According to the Amasya Museum, the remains of a fountain were found on the Karaman Aqueduct. The fountain, which was carved into the rock, was supplied with water from the Karaman Aqueduct through a smooth vertical groove that provides direct flow from the Aqueduct, and this groove ends with the gutter of the fountain. On the central axis of the flattened rock surface where the vertical groove is located, a cross motif was carved into the rock. On both sides of the flattened surface there are two square holes drilled in a regular quadrilateral form. There is also a trace of a 3-step ladder on the right side of the rock block where the fountain is located (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017). It was recorded that the fountain on the Karaman Aqueduct was provided with a small and continuous flow of water from the aqueduct in its original condition (Fig. 4). No fountain was encountered during the on-site surveys of this research.

[1] Vitrivius recommends that the slope of aqueducts should be 1 meter or more per 200 meters (Vitruvius, 2015)

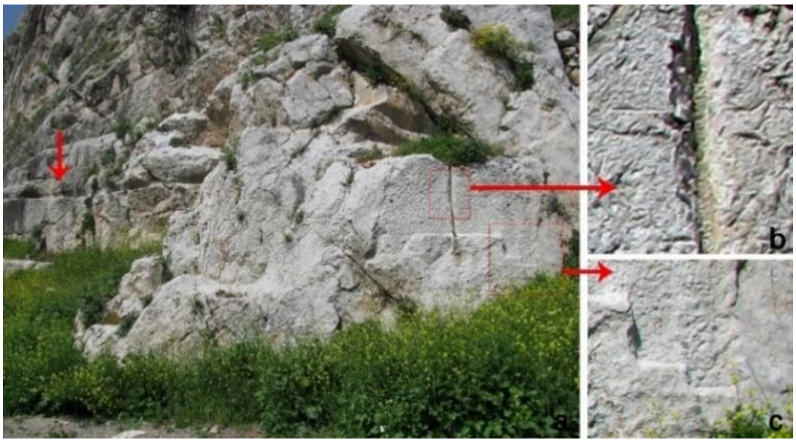

Fig. 4. Karaman Aqueduct, Fountain Remains

2.1.2.. Technic and Architecture

It can be assumed that Karaman Aqueduct was constructed with 3 different techniques along its route starting from its source in Yuvacık Village: The terracotta pipeline organized under the ground in the initial parts, the masonry covered channel in the middle parts, and the section carved into the open rock near the Amasya Fortress (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017). Of the entire transmission line, only the part carved into the open rock can be observed today due to construction and being under the ground.

During the on-site investigations, the last parts of Karaman Aqueduct, which were carved into the rock, were encountered. These parts start from the slopes of Mount Harşena to the northeast of the Kurşunlu neighborhood, continue eastward to İçerişehir and end at a point close to the Büyük Kaya cistern after entering İçerişehir by piercing the city walls. It was observed that the channel was carved into the rock with a very neat workmanship in the vicinity of Kurşunlu Quarter. The base width of the channel was measured as 15-20 cm and the height as 30 cm. The net height of the deep part that holds the water is 18-20cm.

Fig. 5. Karaman Aqueduct, Rock-cut Sections Through the Fortress

Today, differences were observed between the remains of the canal due to the destruction of the canal over time. In the better preserved remains, it was observed that on both sides of the canal, 18-20 cm high and 6-10 cm wide benches were formed. It is understood that this arrangement was made to cover the canal with cover stones (Fig. 7-8). As a matter of fact, similar arrangements to protect the water from external influences are known both in Anatolia and in the historical aqueducts in Amasya (Aykutlu & Kara-Pilehvarian, 2024). Traces of the rock-carving workmanship of the Karaman Aqueduct can be found close to the Fortress walls. It is understood that the rocks were carved with a chisel-like tool (Fig.7).

The construction date of the Karaman Aqueduct, which is the highest capacity water transmission line known to the old settlement area known as Amasya İçerişehir, is not certain. Mustafa Vazıh Efendi, the first Amasya city historian, states in his work that the Seljuk Sultan Sultan Abû Saîd Mes'ud brought water from Şeyhcui and Kavaklı (Karaman) for his palace and settlements in İçerişehir (Mustafa Vazıh Efendi, 2014). If what is meant here is the Karaman Aqueduct, it seems more plausible that Sultan Masoud utilized this aqueduct for his palace in İçerişehir, rather than building it during the Seljuk Period as M. Vazıh states. Because both the rock-carved structure of the aqueduct and the history of its destination indicate that it was built long before the Seljuk rule. Although there is a possibility that this aqueduct may have been a new aqueduct other than the Karaman aqueduct built for the Seljuk palace, no trace of such a aqueduct has been found so far.

Göztaş et al. suggest that the aqueduct was built in the 4th century BC (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017). Considering that the Achaemenid Empire, which included Amasya, was divided in the 4th century BC (360 BC) and the city remained within the borders of the Pontic Cappadocian State afterwards, it is possible that there may be hesitation as to whether the Karaman Aqueduct is an Achaemenid or Pontic Cappadocian Period work. However, considering that the city experienced its most brilliant period during the Pontic Kingdom period with the title of capital and that many construction activities were carried out in the city during this period, it seems more reasonable that the Karaman Aqueduct was built during the Hellenistic Period Pontic Kingdom Period.

Fig. 7. Karaman Aqueduct, Kurşunlu District ve Chisel Marks

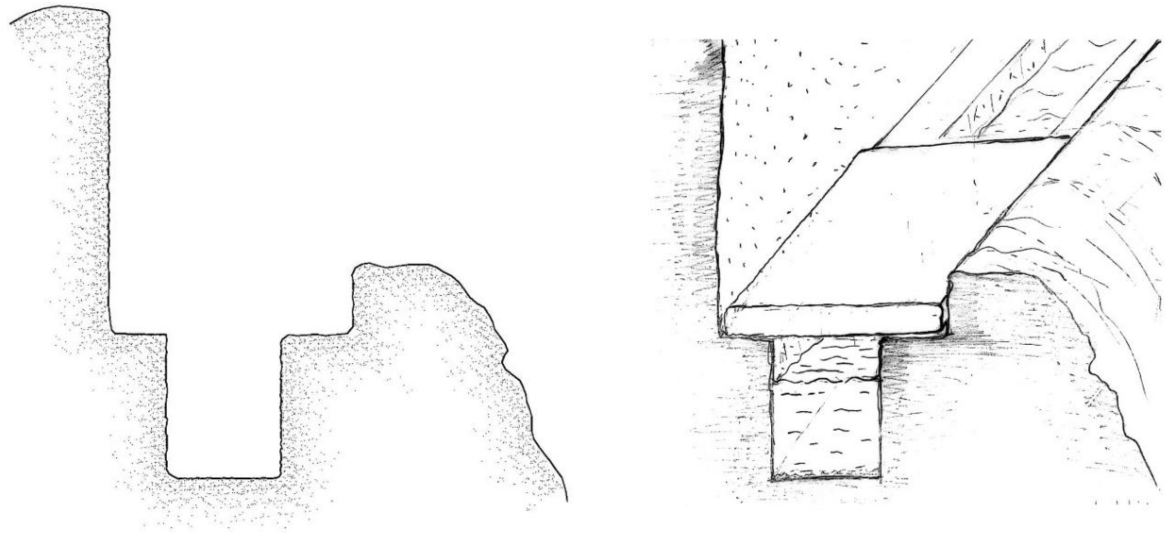

Fig. 8. Karaman Aqueduct, Survey and Reconstruction

2.2. Helkıs Aqueduct

2.2.1. Location and Course
Lennep, who visited Amasya in the 2nd half of the 19th century, noted that a water channel was built on the eastern side of the valley where the Fortress is located, by carving rocks in front of the hard rocks. The said canal, which he stated continued for about 3 miles (about 4.8 km) at that time, must have been the Helkıs Aqueduct (van Lennep, 1870).

Helkıs Aqueduct was located at a level between the Acropolis Hill of Amasya Fortress and the *Kızlar* Palace and its remains can be seen today on the northern and eastern slopes of Mount Harşena. Göztaş et al. state that the canal was built to convey water from a water source on the eastern slopes of Kırklar Mountain to the *Kızlar* Palace (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017).

Today, the rock-carved parts of the Helkıs Aqueduct can be traced for about 1 km on the northern slopes of Mount Harşena. Göztaş et al. suggest that it conveyed water to the *Kızlar* Palace and ended at the corner of the rock grave no. 1 near the *Kızlar* Palace. It is also reported that there is a cistern on the route of the canal north of the Fortress, which is currently used for agricultural irrigation purposes, and it is not known whether the cistern is related to the canal or not (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017).

During the on-site investigations, it was determined that the Helkıs aqueduct is located at +540 on the northern slopes of Mount Harşena, while the location of the *Kızlar* Palace is at +440 levels and there is a level difference of approximately 100 meters between them. As a result of the calculations, it is understood that the aqueduct could not have been built in relation to the *Kızlar* Palace as it has a slope of 0.96%. The level of the aqueduct passes just below the *Top Kulesi* in the lower levels of the Fortress. The Helkis Aqueduct must have been built to serve other buildings between the Acropolis Hill and the *Kızlar* Palace. At this level, especially on the western slopes of the Fortress, the remains of some buildings can be recognized.

A water tunnel was identified on the eastern slopes of Kırklar Mountain called Yiğitoğlu Forest and near the İhsaniye Neighborhood. The entrance of the tunnel is about 2.5 meters below the ground level and today it is covered with a reinforced concrete cover. The walls of the tunnel, which continues under the ground, are built of rough masonry stones and covered by a triangular vault built of rough masonry stones. The tunnel is about 70 cm wide and 1.5 m high, and although the base of the tunnel is covered with vegetation, Yavuz Tokmak, the former headman of Ihsaniye Neighborhood, who guided the fieldwork, stated that a channel-like arrangement about 25 cm wide continues at the base during the cleaning works. Approximately 15 meters up from the tunnel mouth, a well-like structure was encountered which seems to be in line with this line. It is thought that the structure, which was built of large rough masonry stones similar to the tunnel, may be an air shaft built in relation to the tunnel by opening to this water tunnel (Fig 10).

2.2.2.. Technic and Architecture
During the field study, it can be concluded that Helkis Aqueduct was constructed with 2 construction techniques; open rock carving and underground masonry structure. In addition, terracotta pipes were also found in situ (Fig 11). A layer of mortar can be observed at the joints of the pipes with an average length of 46 cm. This layer must

be the layer of *lökün* applied for insulation purposes at the joints of the terracota pipes during the Ottoman Period (Çelik , 2009). It is believed that this pipeline was constructed during the Ottoman period when the canal was idle in order to convey the water of the spring to the structure known as the Yukarı Türbe or Şirvanlı İsmail Türbe. As a matter of fact, this transmission continues partially today with plastic pipes.

The base width of the channel was measured as 19-22 cm and the depth as 25-27 cm in the rock-carved sections. In the part on the slope, an average depth of 60 cm was opened and the channel was formed. No bench-like arrangement was found within the channel (Fig 12).

Göztaş et al. state that the Helkıs Aqueduct, a significant part of which has disappeared today, was built by the Pontic Kingdom in the 4th century BC during the Hellenistic Period and was used until the end of the Ottoman Period (Göztaş, Doğanbaş, Özdemir, & Mesci, 2017). The technical and architectural features of Helkıs Aqueduct, which is examined within the framework of this study, are similar to the Hellenistic Period aqueducts. In addition, considering the historical geography of the city, it is thought to have been built during the Pontic Kingdom Period of the Hellenistic Period, when there was significant construction in Amasya Fortress.

3. Conclusions

In addition to the water resources that Amasya has had since the Neolithic Period, the influence of the Harşena Mountain, which is extremely suitable for building a Fortress as a defensive structure, is undeniable. From the foothills of Mount Harşena on the banks of Yeşilırmak to the Acropolis hill, a significant part of Amasya Fortress has been the construction area of Amasya Fortress throughout history. Cisterns, stepped tunnels and aqueducts were the water transmission structures that fed these settlements.

Karaman and Helkıs Aqueducts, which were examined within the scope of the study, are the structures that transmit water to Amasya Fortress from the east and west. Both of them have mixed structural systems such as rock-carved and masonry. It is thought that the Karaman Aqueduct, which was built with the optimum slope accepted in the ancient period, served the settlement on the banks of Yeşilırmak, while the Helkıs Aqueduct served the settlement between the Acropolis and the *Kızlar* Palace and closer to the Acropolis.

Considering the construction techniques and the historical geography of Amasya, it is understood that these structures were built during the Pontic Kingdom Period of the Hellenistic Period, when the city experienced its most brilliant period and received the title of Metropolis. The results of the research once again reveal the physical development and especially the vitality of the Fortress settlements in Amasya during the Pontic Kingdom.

Although these water structures, which fed the settlements of Amasya Fortress for centuries from the Hellenistic Period onwards, are inactive today, the springs from which they were fed are still actively serving life.

Acknowledgments
The researchers express their gratitude to Mehmet Hilmi Aykutlu for his contribution to this study, as well as to Yavuz Tokmak and Ömer Erkek for their guidance to field work

Masculine spaces and feminine spaces in rural settlements: The case of Ankara Çamlıdere

Ayşegül Sondaş*[1], , Feyza Halı Kabataş[1] ,Özlem Sağıroğlu Demirci[1]

[1] *Gazi University, Department of Architecture, 06570 Ankara, Türkiye*

Abstract. In rural settlements, public spaces are shaped according to production dynamics, local materials, period technology, mastery knowledge, and traditions. In these places, individuals who come together for a specific purpose achieve this purpose by sharing information and socializing. In rural settlements, spaces that align with gender roles attract attention. This study focuses on masculine and feminine spaces in rural settlements, which differ under the influence of production dynamics and are shaped in line with gender roles. Masculine spaces are areas such as village rooms and coffeehouses where men are more visible daily. Feminine spaces are places such as bakeries, fountains, and laundries, which are shaped around tasks that are under women's responsibility and where women take an active role in the production and sharing processes. This distinction reflects the structure of rural life based on production and social division of labor. These places in social memory are essential in understanding rural settlements' cultural and social structure. Analyzing masculine and feminine spaces is valuable for preserving architectural heritage and social memory. Conservation efforts should consider the functional and cultural identities of places and their physical structures, considering their place in social memory. This study examines the typologies of masculine and feminine spaces in rural settlements with the perspective of preserving their physical and social functions. With the literature review and field study method, the dimensions, features, locations, relations with gender roles, and transformations of the spaces from past to present are discussed.

Keywords: Çamlıdere, Rural Architectural Heritage, Public Spaces, Masculine Spaces, Feminine Spaces.

1. Introduction

Studies on the documentation and protection of rural architectural heritage, which is included in the "endangered heritage" list prepared by UNESCO, have gained momentum. To keep cultural heritage alive without disappearing, it is essential to document and reveal the rural architectural heritage in different geographies of Türkiye without losing its originality. There are original examples of rural architectural heritage in the villages of Çamlıdere district of Ankara. These villages have settlement characteristics suitable for topography and climate conditions. Structures ideal for daily life practices were built with rational and practical solutions in the light of material knowledge and mastery accumulation. These structures constitute a valuable heritage regarding environmental sustainability and social context. The biggest reason for this rapid disappearance is the migration of villages. The number of people in the villages is decreasing. The best-preserved structures among the structures examined within the scope of rural architectural heritage in the district are the houses. Even if they are not used in summer and winter, the villagers, especially those living in Çamlıdere and Ankara, spend time in their villages during the summer months. The common-use areas examined outside the houses are rapidly disappearing. The decrease in the village population has caused a reduction in the need for these areas.

Gender roles shape public spaces in rural areas. Accordingly, separations are seen in spatial organization. There are also significant differences in the use of space. Masculine and feminine spaces are separated in line with gender roles. Spaces where men and women are visible in daily life emerge. These important architectural structures reflect the cultural and social structure of rural settlements. These are the data sources of social memory.

2. Public Space: Masculine Spaces and Feminine Spaces

The environment is a spatial formation to which it belongs. Space is a structure in which culturally meaningful categories exist in a particular order. These categories are established through specific diseases, place changes, and direct relationships with humans. The environment includes physically structured formal features, social components, and order. For example, while a house reflects what kind of a company it is and its cultural values, a settlement's public and private historical actuality reveals its social lifestyle and cultural codes (Karasözen, 1993).

* Corresponding author, E-mail: aysegulsondas@gmail.com

https://doi.org/10.31462/icearc2025_a_car_936

The definition of public space has been questioned by many thinkers in the historical process. The concept of public space has been discussed to solve the social structure. Because public space is human-centered and holds various potentials together, it finds a place in interdisciplinary studies today. Especially in terms of architecture, It gives clues about the social structure in analyzing the relations between settlements and their users. Public spaces, which have gained importance in daily life, witness the entire historical process and even become the scene of historical changes. If we need to reach a common idea within the scope of literature studies, it is seen that many thinkers define the public as open to everyone (Özcan Uslu, 2018).

Public space is the area of both cultural symbols and lifestyle practices. Public space is where social values and lifestyles are adopted and reproduced. Public space is the center of social relations (Canaran, 2018). While spaces define areas where individuals continue their lives within the social structure, these areas also reflect gender-related meanings. Different ways of offering freedom, setting boundaries, and providing opportunities to women and men actively shape how space functions. Gender roles shape space and assign it meaning. Researchers have conducted various studies showing that different gender groups experience space differently, that space and gender interact dynamically, and that space actively shapes and reproduces gender roles (Dinçtürk, 2019). People also shape and namespace according to gender, not only in public settings but also within the household. In other words, both public and private spaces are often organized as gender-specific areas (Siwach, 2020).

Historically, the separation of masculine and feminine spaces dates back to ancient times. In ancient times, stoas and agoras, where men socialized in public spaces such as shopping, chatting, and philosophy, were depicted as masculine spaces. In everyday life, it is understood from the depictions of women in public spaces that they were in front of fountains. There are examples where women come to the fountain and chat, and the fountain is described as a gathering area (Fig. 1.) (Açıl, 2018; Canaran, 2018).

Fig. 1. Jewellery box, fountain scene, circa 460 BC, Hydria, women at a fountain, circa 530 BC (Açıl, 2018)

When the distinction between masculine and feminine spaces is examined within the scope of the field study and literature study, feminine spaces are not spaces used entirely by women but spaces where women are present and dominant. Men can also enter these spaces. However, it is seen that women are not included in masculine spaces belonging to men. However, it shows that women are primarily used in spaces described as women's spaces. Men are not excluded in these spaces. However, women do not use spaces described as men's spaces (Siwach, 2020). Public space studies mainly focus on public spaces located in cities. However, public spaces in rural settlements are essential in understanding the relationship between people and space. The definition of public space in rural settlements needs to be made. Although studies continue today, studies on common-use spaces in rural settlements are limited.

3. Çamlıdere Rural Settlements

Çamlıdere is a district of Ankara province that stands out with its natural and cultural values. The entire Köroğlu Mountains are located. It is adjacent to Gerede in the north, Kızılcahamam in the east and northeast, Güdül in the south, and Beypazarı in the southwest. The city is approximately 100 km away. The district is significant because of its forested areas and plateaus. The culture of the people of the region, which is located in the plateau district in a large area, continues today. It has a rugged terrain structure. Çamlıdere, due to its location, has a transition zone between the Black Sea Region and the Central Anatolia Region. For this reason, it has a denser forest area than the rest of Ankara. 52% of the region is covered with forests (Arslan Takcı, 2022; Begiç & Sarıcan, 2021; Sarıcan, 2021).

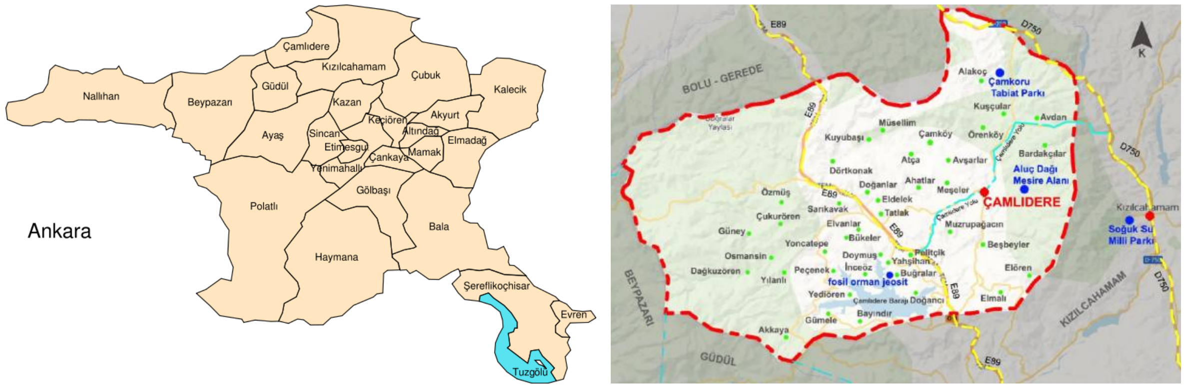

Fig. 2. Ankara province map (URL-1) Villages of Çamlıdere district (Arslan Takcı, 2022)

Çamlıdere district is one of the regions where animal husbandry is carried out due to its forest presence and topography. Animal husbandry and forest products are the most important sources of income for Çamlıdere district (Arslan Takcı, 2022).

Fig. 3. Çamlıdere rural settlements

There are 48 neighborhoods in Çamlıdere district. According to metropolitan law, the settlements with village status have been transferred to neighborhood status (URL-2). A settlement pattern has been created in the villages on sloping land by adapting to the topography. Since livestock farming is a livelihood in the region, places for animals stand out. In addition, since the region has a dense forest area, wood is considered the primary building material. Rural settlements have various places such as houses, mosques, barns, haylofts, sheep pens, woodsheds, village rooms, and schools. However, most of these places are either never used or are used during specific periods of the year. Unused places are idle. With the migrations experienced in rural neighborhoods, the population decreases, and the buildings deteriorate.

Today, in the villages where documentation was conducted within the scope of fieldwork, most houses are used during certain months of the year or are not used at all. It is observed that to provide comfortable conditions in the houses in the villages, new houses are built within the parcel, new reinforced concrete houses are built nearby, or the original houses are demolished and replaced with new houses. This situation negatively affects the rural settlements in Çamlıdere district and many other rural settlements and causes significant damage to the original texture.

The structures in the rural settlements of Çamlıdere district contain many wooden materials due to the dense forest. The structures built with traditional construction techniques are built with the stacking and carcass system. The structures constructed with the stacking system are wood and stone stacking, and the structures built with the carcass system are built with fillings of different materials between the wooden frames. Two types of structures are built with the wooden stacking (cantı) technique, which is densely formed in the region. The first type is the structures of single-story warehouses, haylofts, etc., with different functions developed only with the cantı technique. The second type is generally used as a construction technique in houses, where the first floor is made of masonry and the second floor is built with the cantı system (Sağıroğlu, Toğay and Toğay, 2019).

Fig. 4. Traditional houses in Çamlıdere district

In rural residences in Çamlıdere district, houses are generally built as two-storey. However, the examples of houses with intermediate floors are 3-storey. Ground floors are used for animal living and storage. These floor entrances are generally independent of the living and are provided through single or double-wing doors. In some examples, there is a connection between the ground floor and the living floor. The ground floors of the houses are generally built with a stacked stone system, and the windows are small.

Fig. 5. Çamlıdere Çamköy village traditional housing plan sketches (Sağıroğlu et al., 2019;Arslan Takcı, 2022)

Traditional houses are accessed from the road or the garden. Outbuildings, which are essential elements of rural life in the garden, are located adjacent to the house or close to the house within the parcel. Although structures such as woodsheds, haylofts, warehouses, and chicken coops are not in a designated place within the parcel, they are generally positioned in a way that they are in visual relation with the house. However, haylofts, which are not located within the parcel in the region, are generally placed on sloping areas, and direct access is provided from the upper level.

Fig. 6. Haystacks

4. Masculine Spaces and Feminine Spaces in Ankara Çamlıdere Rural Settlements

Within the scope of this study, the detection and documentation work in the villages was detailed and photographed. These settlements are Ahatlar, Atça, Avdan, Avşarlar, Beşbeyler, Çamköy, Dörtkonak, Kuşçular, Meşeler, Müsellim, Muzrupağacın. Within the scope of the survey carried out in the field, the existence of outbuildings and housing sections, haylofts, woodsheds, and wild animals was determined, although their use is limited. Within the scope of the field study, the focus was on public spaces. In terms of masculine and feminine spaces, the village rooms were masculine spaces, and the fountains and residences were feminine spaces. With the migration of Çamlıdere rural settlement over time, the number of people living in the areas decreases, the population ages, and production activities decrease. With the decrease in population, the demand for spaces used together by the villagers also decreases. The few remaining everyday use spaces are also in the process of becoming obsolete. With changing living conditions, the culture of spending time in shared spaces decreases. For this reason, within the scope of the study conducted in the field, it is essential to come across perhaps the last users who use traditional structures and to obtain information about the places where they spend time together.

In the rural area of Çamlıdere, village rooms are at the forefront among the common-use areas where men spend time. These areas are used only by men, but women do not use them. Also, children do not use these areas. In the interviews conducted with the users who use traditional village rooms, it was learned that since they usually gather in these areas in the evenings, entertainment/games are also played in addition to chatting. Meals are also eaten in these areas. Village rooms, which are places for socializing, are essential among the everyday use areas where the village people spend time together. Village rooms are also open to guests coming to the village. Village rooms are places where travelers who come to the village can stay, meet their basic needs, and be hosted until they leave the village. They are also social spaces where villagers come together, especially in the evenings, to chat, discuss, and play various games. These rooms, which also serve as venues for mass events such as weddings and funerals, are among the rural structures where hospitality and social solidarity are embodied. It is known that the guests coming to the village keep their animals in the village rooms, which usually have a barn on the lower floor. While these rooms are sometimes built by the joint efforts of the villagers, they are often built by the village elders in their names and brought into the village life (Yılmaz, 2023).

The number of village rooms in the villages varies. In some villages, there is one village room, while in some villages, there is more than one village room. For example, in Muzrupağacı village, there are three village rooms. The number of village rooms is classified according to the village size or the number of neighborhoods in the village. If there is more than one neighborhood in the villages, each neighborhood may have its village room. The maintenance and use of that village room is the responsibility of the neighborhood's residents.

Village rooms are generally close to the village square and/or mosques (Çamköy). They usually communicate visually with the mosque. There are also village rooms (Müsellim village) adjacent to the mosque. In interviews with the villagers, it was learned that men go to the village chamber after the evening prayer and gather there. Today's reinforced concrete village rooms are also close to the village mosques.

Fig. 7. Village rooms

The village rooms that have survived today are similar to Çamlıdere traditional houses in terms of construction system and architectural elements. They are 1 or 2 storeys. There are two types of 2 stories. In the first type, the ground floor is a barn with rooms or rooms on the upper floor. In the second type, there are rooms on both floors. The single-story village rooms are used only by the village people or people who come to the village as guests. Village rooms, similar to traditional houses in terms of construction, were built with a stack and wooden frame system. There are a few rotten examples of the original village rooms. Some village rooms have lost their original features due to unconscious durability and have been damaged. This system was built unconsciously without intervention from the system systems but without adding or removing the interior architectural elements of the space (Fig. 8.)

Fig. 8. Çamköy village room

In most rural settlements of Çamlıdere, reinforced concrete village rooms or village mansions are built with contemporary construction techniques. Reinforced concrete village rooms are generally rebuilt on the parcels of traditional village rooms that were demolished. Today, these spaces are used for mass events such as dinners, weddings, and funerals. However, today, village rooms are not only used by men but also by women. Different village rooms have been built for women and men in some villages. There are also dining hall sections in these village mansions. The sofa system continues in the interior design of the newly built village rooms. Interior arrangements are similar to traditional village rooms. In rural architecture, the demolition of the old and the reconstruction of spaces with the same function are also encountered in village rooms.

Fig. 9. Dörtkonak, Müsellim, Atça, Kargalar village rooms

The village room in Muzrupağacın village has survived to the present day in its original state. However, it is not used. In the 2-story village room, three walls of the room on the upper floor are surrounded by divans. On the other wall, there is a stove in the middle and wooden cabinets on both sides of the furnace. The divans are 20 cm high and 100 cm wide. The floor and ceiling are covered with wood. The room size on the upper floor is 480-675 cm (Fig. 10).

Fig. 10. Muzrupağacın village rooms

In the Anatolian countryside, women commonly use spaces in rural settlements, generally laundries, ovens, and fountains. Apart from these public spaces, women spend most of their time in their homes. In the study conducted in the rural settlements of Çamlıdere, no structures could be defined as private spaces specifically designated for women. There are no communal village ovens; instead, women bake their bread in the stoves located within their homes. Laundries, which are observed in other regions, are places where women spend time together, socialize, and wash their laundry. However, no such laundries were found in the settlements examined during the field study. Interviews with village women revealed they wash their laundry by the streams or at fountains.

Fountains are also used for washing clothes. In the village of Çamköy, it was mentioned that there used to be a washing stone placed in front of the fountain for this purpose, but these stones have since been removed (Fig. 11).

Fig. 11. Çamköy, Müsellim, Kuşçular village fountains

Fountains, defined as women's spaces in rural settlements, are not actively used today because all houses have water. However, one of the striking aspects of the field trip was that just as men were seen around mosques and village rooms, women were also seen at the fountain. Chats were held with women living in the village at the fountain (Fig. 12).

Fig. 12. Village fountains and women

When the past and present are compared, the body codes carried by the space change with its users, the perception of society, and the dynamics of time. In the trilogy of time, space, and humans, the images, visions, and symbols that define spaces as masculine and feminine and generalize throughout the historical process change. Differentiations are experienced (Yağçı, 2014).

5. Conclusions

Çamlıdere is one of the crucial settlements with its historical and cultural texture, located northwest of Ankara. The originality of the district is reflected not only in its natural beauty but also in the places that keep its social memory alive. These places are houses, mosques, haylofts, barns, village rooms, fountains, and other structures that convey the technical and mastery knowledge of the time. These structures have an essential place in the daily rural life of Çamlıdere.

In rural settlements, spaces are produced depending on production dynamics—public spaces where time is spent together store essential data of social memory. Just as there are spaces shaped according to gender codes regarding public space in urban life, there are also spaces that differ in rural settlements. The spaces used predominantly by women are called feminine spaces. Both men and women use these spaces. However, only men use masculine spaces. It has been determined that the masculine spaces in Çamlıdere rural area are village rooms. Village rooms were multifunctional social structures at the center of village life in the past; men gathered, discussed issues, hosted guests, and made decisions. These rooms are physical structures and carriers of social belonging and shared cultural memory. In this sense, the village rooms in Çamlıdere reflect traditional Turkish hospitality and the culture of collective life. In these rooms, folk tales were told, local games were played, worship was held, and solidarity was established among the villagers. The elderly advised the young, and information was transferred between generations. Therefore, the village rooms served as the cornerstones of education, communication, and the culture of living together. In the rural area of Çamlıdere, feminine spaces appear as houses and fountains. Women spend more time in the house, which is a private area. There is no area specific to women in the public area. Today, with the phenomenon of migration, technological changes, and the decrease in the population in rural areas, traditional houses and public buildings are rapidly disappearing. The buildings are losing their original functions. Many buildings are in disuse. The physical damage to the buildings is significant. This situation threatens cultural continuity and limits our ways of connecting with the past.

Observations made within the scope of the study revealed that the use of public spaces in rural settlements has decreased, and most of these spaces have become dysfunctional and abandoned. As a result of the continuous migration of the population to big cities, especially Ankara, traditional public structures such as fountains, village halls, laundries, and similar structures are left abandoned, and this valuable spatial heritage reflecting local knowledge and production styles is disappearing without being documented. In this context, ensuring the return of the local people to the area will contribute to the re-functioning of public spaces along with rural life and, thus, to the preservation and maintenance of these structures. To re-establish the balance between conservation and use, civil society organizations, local governments, and universities must produce concrete projects in cooperation and take the necessary steps. Preserving public spaces will ensure the continuation of not only the physical structures but also the social practices and memory related to these spaces.

Sustainable interior design in Algeria: Blending tradition and innovation for a greener future

Meryem Kadri*[1]

[1] *University of Oum El Bouagui, Department of Architecture, 04000 Oum El Bouagui, Algeria*

Abstract. Interior design in Algeria is experiencing a transformative shift toward sustainability, aiming to harmonize aesthetic appeal with environmental responsibility. This study investigates sustainable interior design practices tailored to Algerian residential spaces, focusing on optimizing material selection, energy efficiency, and spatial organization to meet the unique cultural and climatic context of the country. The methodology involves a field analysis of residential projects in urban and rural areas, complemented by interviews with design professionals and surveys with homeowners. A comparative study of traditional and contemporary designs highlights how integrating natural and locally sourced materials, such as terracotta, stone, and wood, reduces environmental impact while maintaining cultural authenticity. Results reveal that sustainable interior design in Algeria significantly benefits from passive design strategies, such as maximizing natural ventilation, optimizing daylighting, and using thermally efficient materials to reduce energy consumption. Furthermore, incorporating modular furniture and multifunctional spaces enhances the adaptability and functionality of interiors. Challenges include limited awareness of sustainable practices among homeowners and the higher costs of eco-friendly materials. However, success stories from pilot projects demonstrate that these hurdles can be overcome through education and policy incentives. This work concludes by proposing a framework for promoting sustainable interior design in Algeria, emphasizing professional training, public awareness campaigns, and partnerships with local artisans and material suppliers. The study aims to inspire designers and policymakers to adopt practices that blend modern functionality with cultural and environmental sustainability, paving the way for a greener future in Algerian homes.

Keywords: Sustainable design; Interior architecture; Algeria; Energy efficiency; Cultural authenticity

1. Introduction

In the face of growing environmental concerns and increasing energy demands, sustainable design practices have become a priority across all sectors of construction and architecture (Edwards, B, 2005). In Algeria, where traditional architecture holds a rich cultural heritage, interior design is undergoing a subtle yet transformative shift toward greener practices (Fathy, 1986). This study explores how sustainable interior design, when rooted in Algeria's climatic and cultural specificities, can successfully merge tradition and modern innovation to create environmentally responsible and culturally authentic living spaces.

2. Context and Importance of Sustainable Interior Design in Algeria

Algeria's diverse geography—from the Mediterranean coast to the vast Sahara—has historically shaped vernacular architecture that responds intelligently to environmental constraints (Ghouma & Bellal, 2012). Traditional Algerian homes, through their thick walls, small openings, and patios, offer valuable lessons in passive design strategies (Mehal, 2020). However, rapid urbanization and globalization have introduced modern building practices that often disregard climatic adaptation, leading to increased energy consumption and environmental degradation (Baniyounes & Ghoul, 2017).

The interior design sector, particularly in residential projects, presents a significant opportunity to reintroduce sustainability at the heart of living spaces (Boutabba & Sassi, 2018). Sustainable interior design not only aims to minimize ecological footprints through responsible material use and energy efficiency but also seeks to enhance occupants' well-being by creating healthier indoor environments. In Algeria, embracing sustainability within interior spaces can serve as a bridge between preserving cultural identity and meeting contemporary needs for comfort, efficiency, and aesthetics.

3. Methodology

This research adopts a mixed-methods approach, carefully combining qualitative and quantitative data collection to capture a comprehensive understanding of sustainable interior design practices in Algeria.

Field Analysis: Site visits were carried out across a curated selection of residential projects in both urban and rural settings. In urban areas, projects in Algiers and Constantine were analyzed, while in rural regions, the focus was on Ghardaïa and Boussaâda, two cities known for their rich vernacular traditions. The analysis involved a detailed observation of material choices, spatial organization, energy consumption patterns, and environmental performance of interiors. Data such as thermal comfort levels, daylighting quality, and natural ventilation effectiveness were systematically recorded during site assessments (see Fig. 1).

Fig.1. Geographical distribution of surveyed residential projects in Algeria

Interviews: Semi-structured interviews were conducted with a diverse group of 15 professionals, including interior designers, architects, and sustainability consultants. The interviews explored their practical experiences, challenges faced when implementing sustainable principles, and perceptions regarding the evolution of client expectations. Open-ended questions allowed interviewees to elaborate on specific projects and innovations they had applied or witnessed in the field.

Surveys: Parallel to the professional interviews, a structured questionnaire was distributed among homeowners who had either recently renovated or built their homes. A total of 82 valid responses were collected. The survey assessed perceptions of sustainability, priorities in material and design choices, willingness to invest in eco-friendly solutions, and awareness of traditional passive design strategies.

Comparative Study: A comparative analysis was undertaken to juxtapose traditional Algerian interiors with contemporary residential designs. Traditional examples included homes from the Casbah of Algiers, the M'zab Valley in Ghardaïa, and old dwellings in Boussaâda, all of which demonstrate sustainable design principles inherently embedded within cultural practices. Key features such as the use of local materials (e.g., clay, natural stone, palm wood), the optimization of natural lighting, and passive thermal regulation were examined. Contemporary designs, often characterized by modern materials and construction techniques, were assessed to identify gaps and opportunities where integrating vernacular knowledge could improve environmental performance.

To structure this comparative evaluation, a set of sustainability indicators was established, including material lifecycle impact, energy efficiency, thermal comfort, and cultural authenticity. Each interior was then scored based on these indicators to derive meaningful patterns and insights.

4. Results and Discussion

4.1 Field Analysis Results

The field analysis revealed notable differences between urban and rural residential projects regarding sustainable interior practices.

In urban homes (Algiers, Constantine), modern materials such as concrete, ceramic tiles, and synthetic paints dominated. However, some efforts were made to introduce double-glazed windows and insulated walls to improve thermal efficiency.

In rural homes (Ghardaïa, Boussaâda), traditional materials like mudbrick, stone, and lime-based plasters were still prevalent. These materials provided excellent natural insulation and thermal inertia, especially against the region's extreme temperatures.

Moreover, passive strategies such as inner courtyards, thick walls, small window openings, and orientation optimization were recurrent features in rural designs but largely absent in new urban constructions.

Table 1. Summarizes the prevalence of different materials

Material Type	Urban Projects (%)	Rural Projects (%)
Locally Sourced Stone	15%	68%
Mudbrick	3%	72%
Concrete	85%	28%
Ceramic Tiles	90%	45%
Wood (Palm/Walnut)	20%	62%

4.2 Interview Findings

The interviews highlighted several key themes:

Awareness Gap: Although professionals were generally aware of sustainable design principles, many emphasized that client's prioritized aesthetics and costs over sustainability.

Material Availability Issues:

Several designers noted difficulties in sourcing certified eco-friendly materials locally, leading to compromises in project design.

Positive Trends: Younger designers and boutique studios are increasingly experimenting with recycled materials, earth plasters, and modular furniture systems.

Quote from an Interviewee: "Clients are becoming more curious about natural materials, but when they see the cost difference compared to conventional options, many hesitate. Education is crucial." (Architect, Algiers).

Table 2. Emerging Themes from Professional Interviews

Theme	Frequency of Mention (%)	Description
Cost Concern	88%	High costs of sustainable materials limit adoption.
Material Scarcity	76%	Difficulty accessing eco-friendly, local materials.
Cultural Heritage	64%	Desire to preserve traditional design elements.
Eco-Innovation	59%	Interest in using modern green technologies creatively.
Client Awareness	52%	Clients' lack of knowledge about sustainable interiors.
Policy Support Need	48%	Lack of supportive regulations or incentives.

4.3 Survey Results

The survey conducted among homeowners yielded the following insights:

Awareness Levels: 37% of respondents reported familiarity with the concept of sustainable interior design, while 63% were unfamiliar or only vaguely aware.

Priorities in Design Choices: Homeowners primarily valued durability (87%), aesthetics (81%), and cost (76%), with environmental impact (42%) ranking lower.

Interest in Eco-Friendly Solutions: When informed about the potential energy savings and health benefits, 68% expressed willingness to consider sustainable design in future projects.

Table 3. Homeowner Priorities When Selecting Interior Materials

Priority Factor	Percentage of Respondents
Durability	87%
Aesthetic Appeal	81%
Cost	76%
Environmental Impact	42%
Cultural Authenticity	35%

4.4 Comparative Study: Traditional vs. Contemporary Designs

The comparative study revealed that traditional Algerian interiors already embody many sustainable strategies that contemporary designs could adapt and modernize.

Traditional Interiors: Use of natural ventilation (wind towers, shaded courtyards). Strategic sunlight control (small openings, thick walls). High thermal inertia (materials like adobe and stone). Minimalist furnishing reducing material consumption.

Contemporary Interiors: Often rely heavily on mechanical cooling/heating. Extensive use of imported, energy-intensive materials. Poor consideration of orientation and solar gains.

Table 4. Comparison of Sustainability Features

Feature	Traditional Interiors	Contemporary Interiors
Natural Ventilation	Strongly Present	Weak
Solar Shading	Strongly Present	Moderate
Use of Local Materials	Dominant	Rare
Energy Consumption	Low	High

4.5 Discussion

The results indicate that returning to vernacular wisdom while integrating modern technology offers the most effective pathway toward sustainable interior design in Algeria.

Passive Design Strategies inherited from traditional architecture outperform many modern systems in terms of energy efficiency.

Material selection is crucial; the use of locally sourced, natural materials reduces embodied energy and carbon emissions.

Homeowner education plays a vital role: increasing awareness significantly boosts willingness to adopt sustainable solutions.

Cost barriers remain a challenge, but emerging practices like modular design and local artisan partnerships can offer scalable, cost-effective alternatives.

The synergy between tradition and innovation can provide Algerian interiors with not only environmental benefits but also stronger cultural identity in a rapidly globalizing market.

5. Recommendations:

5.1 Integration of Local and Natural Materials

Traditional Algerian interiors extensively use materials such as terracotta, stone, palm wood, and lime-based plasters—all sourced locally and requiring minimal processing. Contemporary sustainable projects that consciously reintroduce these materials show a reduction in embodied carbon emissions and better thermal performance compared to conventional modern interiors reliant on imported synthetic materials.

5.2 Passive Design Strategies

Passive cooling and lighting techniques, observed in both traditional and modernized interiors, significantly improve energy efficiency. Techniques include:

Maximized natural ventilation through cross-breezes enabled by strategic window placement.

Daylighting optimization via central courtyards (patios) and light wells.

Thermal mass utilization to stabilize indoor temperatures despite harsh external climates.

Residences employing these strategies recorded energy savings of up to 35% in cooling needs compared to standard designs without passive elements.

5.3 Spatial Organization and Functional Adaptability

Sustainable interiors increasingly feature modular furniture, multifunctional spaces, and flexible layouts to enhance adaptability and maximize use of available space. This design philosophy echoes traditional multi-purpose rooms found in older Algerian homes, where living areas often served dual functions.

5.4 User Awareness and Material Perception

Surveys revealed a limited understanding of sustainability among homeowners. Although there is strong cultural attachment to traditional aesthetics, few participants associated traditional materials with environmental benefits. Eco-friendly materials were also perceived as costlier, discouraging broader adoption.

6. Challenges and Opportunities

Despite promising examples, the widespread adoption of sustainable interior design in Algeria faces several challenges:

Economic Barriers: Higher initial costs of eco-friendly materials and technologies.

Lack of Awareness: Limited public knowledge about the benefits of sustainable interiors.

Policy Gaps: Absence of strong regulatory incentives promoting green interior practices.

However, these challenges present corresponding opportunities:

Educational Programs: Integrating sustainability into design education can equip future professionals with essential skills.

Public Awareness Campaigns: Media initiatives can reshape public perceptions and highlight long-term cost savings.

Local Artisan Partnerships: Collaborations with local craftsmen can promote the use of traditional, sustainable materials while supporting local economies.

7. Proposed Framework for Promoting Sustainable Interior Design

Based on the findings, a multi-faceted framework is proposed to embed sustainability into Algerian interior design practices:

Professional Training: Specialized workshops and certification programs for designers and architects on sustainable materials, energy-efficient strategies, and vernacular design principles.

Policy Initiatives: Government incentives, such as subsidies or tax reductions, for projects incorporating green interior strategies.

Community Engagement: Interactive exhibitions and participatory workshops with homeowners to raise awareness about sustainable living spaces.

Strengthening the Local Supply Chain: Investing in local production of sustainable materials to lower costs and ensure accessibility.

By implementing these measures, Algeria can cultivate an interior design culture that not only respects its rich traditions but also contributes actively to global environmental goals.

8. Conclusion

Sustainable interior design offers a meaningful pathway to harmonize Algeria's cultural heritage with contemporary environmental imperatives. By intelligently integrating local materials, passive strategies, and adaptable spaces, interior environments can significantly reduce ecological impacts while enhancing quality of life. Although barriers exist, a combination of professional education, public outreach, and supportive policies can accelerate the transition toward greener interiors. As Algeria navigates its path toward sustainable development, interior spaces, where daily life unfolds, must not be overlooked. They hold immense potential to embody the values of resilience, identity, and ecological stewardship essential for a greener future.

Acknowledgments

The author would like to express sincere gratitude to all the architects, interior designers, and homeowners who generously shared their experiences and insights during the course of this research. Special thanks are also extended to local artisans and material suppliers for providing valuable information on traditional and sustainable building materials. This study would not have been possible without their collaboration and openness.

Shaping behavior and emotions through urban design: tackling social inequality

Amjad Miyan[1], Neslihan Aydın Yönet*[2]

[1] *Bahçeşehir University, Graduate School, Architecture Master Program, 34353 İstanbul, Turkey*
[2] *Bahçeşehir University, Faculty of Architecture and Design, Department of Architecture, 34353 İstanbul, Turkey*

Abstract. Rapid urbanization leads to major problems such as overcrowding, social fragmentation, and unequal distribution of resources in cities. Urban Design is an important tool to solve urban problems via design. In light of that, this study examined urban design approaches and their psychological impacts, exploring the role of urban design in influencing behaviors, emotions, and social equity with detailed case studies. The literature review of the study mainly focuses on urban design strategies, the psychological effects of the urban environment, the role of inclusive design, and the promotion of social cohesion. These theoretical foundations are reinforced by case studies focusing on various urban spaces implementing innovative design strategies to enhance social interaction and emotional well-being. The findings have revealed that well-designed urban spaces can foster positive behaviors, reduce stress, and improve overall emotional health. The study demonstrates a positive correlation between inclusive urban design and enhanced emotional well-being, social cohesion, and equity.

Keywords: Urban design; inclusive design; public space; social equity; emotional well-being.

1. Introduction

Urban design plays a crucial role in shaping human behavior, enhancing pedestrian safety, ensuring accessibility, and optimizing the use of public spaces. Cities around the world have adopted various urban design strategies to foster healthier, more inclusive, and socially cohesive communities.

This research paper explores the impact of urban design on human behavior and social dynamics through case studies. In recent years, urban design theories have transcended traditional boundaries, addressing not only aesthetic and functional aspects but also the social and psychological well-being of citizens. Examining case studies offers valuable insights into how design interventions can promote physical activity, reduce traffic congestion, enhance community interactions, and improve all quality of life (Gehl, 2010; Mueller et al., 2020).

This paper is structured into three primary sections, which are behavioral, social, and emotional influences of urban design. This study further investigates specific case studies elucidating how urban design can substantively influence behavior, facilitate social interaction, and enhance emotional well-being. The paper focused on defining the relationship between urban design elements and social outcomes by analyzing "the impact of urban design on people's behavior and emotion" and "the impact of urban design on the level of social inequality".

2. Literature review

Urban design is one of the important factors in shaping human experiences by influencing behavior, social interactions, and emotional well-being. Various studies have explored how spatial configurations, accessibility, and inclusivity impact social cohesion and individual perceptions of safety and belonging (Gale, 2010; Jacobs,1961). The contemporary urban design highlights the importance of creating public space and fostering community engagement, reducing social inequalities, and promoting healthier lifestyles. This chapter provides an overview of the theoretical framework and previous research related to urban design's behavioral, social, and emotional effects, setting the foundation for the case studies analyzed in the later sections.

2.1 Behavioral influence of urban design

The design of urban spaces significantly shapes individual behaviors, with open forms and spatial configuration playing a crucial role in guiding movement and interactions (Southworth,2016). People experience the city

* Corresponding author, E-mail: neslihan.yonet@bau.edu.tr

https://doi.org/10.31462/icearc2025_a_urb_157

kinesthetically, navigating through sequences of urban spaces that influence their perception and engagement with the environment (Cullen,1971/2012).

A key factor in this experience is street layout, which directly impacts walkability, social interactions, and preferred residential and business environments. Grid patterns, characterized by numerous intersections, facilitate shorter distances and ease of navigation, encouraging walking and cycling over car use. This interconnectedness enhances social engagement by fostering stronger community ties and a sense of belonging (Frank et al., 2006). Beyond mobility, urban design also affects neighborhood security through the principle of natural surveillance. Jacobs (1961) introduced the concept of “eyes on the street,” highlighting how well-designed streets that promote visibility contribute to a watchful environment, discouraging crime. By strategically positioning physical spaces, activities, and individuals to maximize visibility, open planning can create safer, more connected communities where positive social interactions thrive.

Natural surveillance in street design is intended to improve community safety and build social bonds. Features like low shrubs, street lights, pedestrian-friendly sidewalks, and transparent fences create a safety- and invitation-oriented environment. That encourages citizens to expose themselves to their environment, community, and well-being (Jacobs, 1961). Additionally, the design of public places is a crucial consideration in urban environments. Well-designed public spaces create a sense of community by providing for socializing. These public spaces, such as parks, plazas, and recreational areas, all citizens must be found safe and inviting (Gehl, 2010; Whyte, 1980). Public space design that focuses on more inclusive and accessible approaches ensures that citizens, regardless of social status, benefit from public spaces. These principles contribute to efficient and well-being urban environments, creating favorable conditions for social equity and social cohesion (Gehl, 2010; Whyte, 1980; Talen, 2000). Designed urban spaces significantly shape individual and collective behaviors by influencing movement patterns, social interactions, and perceptions of security. Walkable neighborhoods with interconnected streets encourage activities, mobility, spontaneous social engagement, and a stronger sense of community belonging. This behavioral shift can reduce automobile dependency, promoting environmentally sustainable habits and healthier lifestyles.

2.2 Social influence of urban design

Inclusive urban design plays a crucial role in fostering community engagement by creating well-designed spaces that encourage social interactions (Gehl, 2010). Mixed-use developments, which integrate residential, commercial, and recreational areas, contribute to social integration by promoting diverse interactions among citizens (Whyte, 1980). Providing spatial justice in urban design with the notions of accessibility, sociability, and diversity is possible, particularly concerning public open spaces (POS), by addressing their inherent complexity (Jian et al., 2020).

Walkability, affordability, and safety are key variables in assessing the inclusivity and accessibility of urban environments (Gehl, 2010). Within this framework, sociability and diversity represent the ability of POS to facilitate meaningful social interactions, contributing to stronger community bonds (Whyte, 1980). Furthermore, factors such as activity support play a vital role in enhancing engagement within public spaces (Gehl, 2010; Whyte, 1980). However, despite the access to POS, he highlights socioeconomic differences among various groups, reflecting border issues of equity and inclusion in urban planning (Jiang et al., 2020). Evaluating these disparities provides insights into how effectively POS can create inclusivity for diverse users (Talen, 2000). By prioritizing accessibility, safety, and social integration, urban design can foster cohesive communities and equitable public spaces.

On the other side, other justice-related studies stated that spatial justice emerged quite late and is still an undefined concept (Pereira et al., 2017). Earlier, researchers used to mention the terms "territory justice" (Harvey, 1973) or "social justice in space" (Pirie, 1983) to elaborate their research interests and spill their focus on spatial perspective. The theoretical foundations of this have led some scholars to mark a distinction between spatial justice as opposed to the general view of justice. Among different kinds of spatial injustice, two crucial forms, the involuntary clustering of a particular group into a confined space (as segregation) and the allocation of resources unfairly, are identified (Marcuse, 2009, p. 1).

Meanwhile, Lefebvre's concept of "the right to the city" has reached many urban researchers, and they have started to rethink justice from distributional rights to the right to participation in the making of the city (Fainstein, 2014). Soja's (2010) theory echoes in that argument. The author elaborates spatial justice through a triangular framework made up of three components, namely physical justice, urbanization of social justice, and right to the city that centered his critiques of injustice on the locational bias, the political organization of space, and the inequality in distributional outcomes that overlooked the production process (Iveson, 2011).

Well planned public spaces encourage social engagement by creating environments that support accessibility and inclusivity reinforcing trust and positive interactions within the community however disparities in access to public spaces highlight awarded issue of equity as some groups may face limitations due to locations or socioeconomic factors thoughtful urban design must balance accessibility and community engagement promoting social cohesion and overall wellbeing.

2.3 Emotional influence of urban design

The integration of green spaces and aesthetically pleasing environments in urban design significantly enhances mental and physical health. Biophilic designs, which emphasize incorporating natural elements into built environments, increase interaction and overall life satisfaction (Mitchell & Popham, 2008). These designs create spaces where people can connect with nature, fostering a sense of wellbeing and belonging among city inhabitants. Access to natural environments plays a crucial role in stress reduction and promoting relaxation. Ulrich (1984) found that exposure to natural settings, such as infant parks, can reduce stress levels and contribute to emotional well-being.

Culturally significant landmarks, appealing architecture, and design evoke feelings of pride and a sense of place. Appealing public spaces and aesthetically pleasing environments create positive emotions and contribute to the quality of life. Designing public spaces that are inviting, accessible, and conducive to social interactions, and these spaces for citizens of the community enhance the emotional and psychological well-being of the citizens. The integration of green spaces, natural environments, culturally significant landmarks, and urban design significantly improves well-being and reduces stress (Gehl, 2010). By prioritizing these elements, designers can create environments that promote social cohesion, cultural identity, and overall satisfaction (Mitchell & Popham, 2008; Ulrich, 1984; Gehl, 2010). Mental and physical health are factors to consider when designing spaces that enable people to connect with nature, as this connection can significantly enhance their emotional and physical well-being while also promoting stress reduction.

3. Case studies

Case studies from Copenhagen, Portland, and Barcelona illustrate how different cities have effectively utilized urban design strategies to enhance human behavior, promote pedestrian safety, improve accessibility, and optimize the use of public spaces to address social inequality.

Each case study presents a unique approach that offers a diverse range of insights. For instance, Copenhagen employs a network of interconnected bike lanes and pedestrian streets, while Portland adopts a grid street layout. In Barcelona, the implementation of "Superblocks" transforms streets into public spaces through these distinct urban design strategies. Each city focuses on improving accessibility, pedestrian safety, and equitable use of public spaces, making significant strides in addressing social inequality through thoughtful spatial planning. The behavioral, social, and emotional impacts of urban design were analyzed through the selected case studies presented below.

Table1. Behavioral Influence

			Name location	Copenhagen, Denmark (2010)	Portland, Oregon, USA (2009)	Barcelona, Spain (2006)
Features	Interconnected bike lanes, pedestrian streets.	Grid street layout.	"Superblocks" concept, restricted traffic, repurposed streets as public spaces.
Outcomes	High physical activity, reduced traffic congestion, and enhanced community interaction.	Promoted sustainable living, reduced car dependency, and vibrant local communities.	Reduced traffic accidents, noise pollution, air pollution, and more social interaction areas.
Effects on behavior and security	Increased daily exercise, greater social cohesion, healthier lifestyle choices Improved pedestrian crossings.	Increased local shopping, more community engagement, greater sense of belonging Community policing, safe routes for walking and biking.	Reduced car speeds, surveillance cameras for safety in outdoor activities, and stronger community ties.
References	Gehl, J. (2010). Cities for People.	Portland Plan, City of Portland (2009).	Mueller, N., et al. (2020). Changing the urban design of cities for health: The superblock.

As shown in Table 1, Copenhagen, Portland, and Barcelona are cases of how urban design can affect people's actions and address social inequality. In Denmark, the 'Five-Finger Plan' integrates cycle lanes with pedestrian ways to create a space for active lifestyles and improve connectivity between neighbourhoods. Such a design can allow citizens from differing socio-economic backgrounds to engage in activities that promote health and create a culture of cycling and walking. Improved pedestrian crossings and traffic calming measures further ensure that even those in lower-income areas can navigate the city's streets safely, promoting inclusivity and encouraging them to participate in community life (Gehl, 2010). More green spaces equate to more livability for Copenhagen, further creating environments where people can be outside and engage in physical activities.

Parks and public squares act as places for collective gatherings where socializing and community events happen, creating a sense of belonging and shared identity for the citizens. They also act as an escape from urbanity, providing space for comfort and mental refreshment (Gehl, 2010). In Portland, with local street layout and the '20-minute neighborhood' concept, access to basic services for the citizens of different income levels is assured. This scenario, therefore, minimizes the car travel expense that is most burdensome for low-income households and helps invigorate local communities.

The urban design of Portland encourages healthy options: walking to shop in the neighborhood. It intervenes across economic lines, fostering a place to become increasingly vibrant with community participation, in turn, generating a feeling of belonging (City of Portland, 2009). Essentially, the city of Portland has thrown more weight upon the design and construction of walkable neighborhoods and well-connected public transportation systems. This has led to a more equitable city in which the neighborhood citizens have easy access to schools, workplaces, and recreational areas. Such neighborhoods include community centers, farmers' markets, and local businesses to strengthen the social fabric and invigorate the local economy. Finally, they straightaway bring down the need for long distance commuting and reduce car dependency, promoting environmental sustainability and enhancement of quality of life for Portland's city dwellers (Talen, 2012)

Spain's "superblocks," which are exclusively pedestrian and bicycle-accessible, are one of the frontier representative examples of creating inclusive urban environments. The affordances include minimal noise and air pollution, thereby improving the environment of all citizens-pore to pore comparisons between the most oppressed and well-established create socially cohesive spaces for interaction, recreation, and activity for different groups (Mueller et al., 2020). Success, such as that which cities like Barcelona enjoy with superblocks, demonstrates that people can be prioritized over cars by careful design in urban settings, thereby transforming the ecosystem into one that supports health and wellness. Such street configurations are made to serve as public spaces, where children can play in safety, seniors walk without risk, and neighbors gather for social interaction. Superblocks' addition of greenery and recreational facilities creates a sense of lifetime community and motivates citizens to live an active and healthy life (Gehl, 2010). While these urban strategies foster social inclusion and well-being, their effectiveness depends on continuous adaptation to demographic shifts, infrastructure demands, and evolving community needs.

Table 2. Social Influence

			Name location	Bryant Park, New York City (1947) redeveloped in (1988)	Federation Square, Melbourne (2002)	The High Line, New York City (2009)
Features	Open lawn for events, outdoor seating, including various movable seating options.	The central plaza for public events and performances, cafes and restaurants for social interactions, and the square hosts cultural and community events.	"The park features art installations, diverse programs, an elevated greenway besides interactive programs, guided tours, and educational events.
Outcomes	Improved public perception of safety, highlighting the vibrant parks, can deter criminal activity by increasing pedestrian presence and fostering collective community ownership.	Transformed Federation Square into a central hub for social and cultural activities, enhancing urban vibrancy.	Transformed an industrial space into a vibrant public park, creating biodiversity and attracting millions of visitors.
Social influence	Encourage daily social interactions, assemble a community, and provide a simple and accessible environment for all ages.	Enhances open social life and promotes inclusivity and accessibility by fostering public interactions through diverse cultural events.	Encourages walking and interaction along its path, creating unique surface spaces within an open setting and enhancing community engagement through art and nature.
References	Urban Land Institute [ULI], Padua et al., 2022; Goldberger, 1992.	Lu, 2022; Bates & Davidson, 1997	Aitani, 2017; Soria, 2016

Table 2 highlights how urban design significantly influences social interactions and community participation in various locations, including Bryant Park in New York City, Federation Square in Melbourne, and the High Line, also in New York City. Bryant Park, with its open lawns, outdoor seating, and seasonal events, serves as a vibrant hub for social activity and has fostered increased public participation, reclaiming space in the urban environment.

These design features encourage daily social interactions, creating community spaces that are accessible and safe for people of all ages, from infants to the elderly (Kaufman, 2016; Padua et al., 2022). In contrast, Federation Square, which includes a public plaza, cafes, and public art, is essential to the cultural and social fabric of the city. It contributes to urban vibrancy and tourism, fostering a sense of pride within the community by activating social and cultural experiences. By hosting a variety of cultural and social events in its popular spaces, it facilitates gatherings for both visitors and citizens alike (Lu, 2022; Bates & Davidson, 1997).

The High Line, an elevated linear park, transforms an industrial space into a lively social artery, featuring a diverse array of plantings, walking paths, and art installations. This unique design encourages social interactions along its route, creating distinct social spaces within the urban setting. It enhances community engagement through art and nature, and economic activity, contributing to social change alongside increases in green space and biodiversity (Aitani, 2017; Soria, 2016). These urban spaces effectively shaped behaviors by fostering inclusive interactions, cultural engagement, and a shared sense of belonging, demonstrating how design can transform public participation and community cohesion.

Table 3. Emotional Influence

			
Name location	Central Park, New York City (1858) designed, major restorations in (1934 & 1980s)	Cambridge Road Community Resilience Project, Singapore (2018)	Punggol Waterway Park, Singapore (2011)
Features	The design mimics natural landscapes with rolling meadows, tranquil lakes, and wooded areas, integrating diverse plant species and creating both active and reflective spaces.	Central plaza for public events and performances, cafes and restaurants for social interactions. The square hosts cultural and community events.	Human-made waterway integrated with recreational facilities, landscaped parks, and green corridors; designed for both active and passive recreation.
Outcomes	The park serves as a natural sanctuary, with a network of trails, sports fields, and recreational areas that encourage physical activity, contributing to lower obesity rates and improved cardiovascular health among citizens.	Community-led climate action plan, green corridors, and improved public infrastructure.	Transformed an industrial space into a vibrant public park, creating biodiversity and attracting millions of visitors.
Emotional Influence	Reduces stress, anxiety, and mental fatigue; promotes relaxation and mental rejuvenation; allows people to feel close to nature amidst urban density.	Reduces stress by providing cooler, shaded areas; fosters a sense of belonging and community support through collaborative efforts.	Enhances emotional well-being through access to nature, leisure activities, and scenic views; reduces stress and promotes relaxation.
References	Ulrich, 1984; The Central Park Conservancy, 2024.	Chengyan et al., 2024.	Huang & Lin, 2017.

As shown in Table 3, New York City's Central Park possesses an intriguing characteristic, its features include green areas and diverse, well-planned landscapes that mimic various natural environments, even in heavily populated urban settings. This provides a respite from the hustle and bustle of city life, reducing mental strain and allowing individuals to reconnect with nature (Ulrich, 1984; Kaufman, 2016; Padua et al., 2022).

The Cambridge Road Community Resilience Project in Singapore stands out due to its community action approach and the creation of green corridors and shaded pedestrian walkways that contribute to a cooler, less stressful environment. These initiatives create a sense of belonging and enhance community support through collaborative efforts, significantly increase social resilience and inclusivity (Chengyan et al., 2024; Centre for Liveable Cities, 2018).

Punggol Waterway Park is unique in Singapore for integrating an artificial waterway with recreational facilities and landscape parks designed for both active and passive recreation. This city park enhances the general public's emotional well-being by promoting connections with nature, offering leisure activities, and providing good views. It also nurtures social networks and community involvement by linking various residential areas (Huang & Lin, 2017). Together, these examples illustrate the potential of well-thought-out and systematic urban strategies to enhance emotional well-being and strengthen community ties.

4. Conclusion and Discussions

This study has highlighted the critical role that urban design plays in shaping human behavior, social interactions, and emotional well-being.

The evaluation of case studies from cities like Copenhagen, Portland, and Barcelona, as well as various urban settings, reveals that inclusive urban design can significantly boost accessibility, safety, and social equity. For instance, the impact of urban design on behavior was particularly visible in pedestrian-friendly streets and cycling networks, which promoted healthier lifestyle choices. Similarly, vibrant public spaces were shown to strengthen community connections and ensure equitable access for all citizens. Moreover, emotional benefits were noted in designs that incorporated green spaces, calming landscapes, and cultural landmarks, which contributed to enhancing well-being and fostering a deeper connection to urban environments.

Overall, the findings underline that well-designed urban spaces not only encourage physical activity but also help reduce traffic congestion, enhance social engagement, and elevate the overall quality of life. Additionally, environments rich in natural elements play a significant role in reducing stress and improving emotional resilience among city citizens.

This paper contributes to existing literature by offering insights into the evolving role of urban design. From an interdisciplinary perspective, a link between urban design and behavioral studies was explored to provide an equitable city development approach by comparing multiple case studies.

This research extends discussions on urban intervention strategies that prioritize human-centered design, the exploration of social equity further aligns with the concept of right to the city, advocating for urban spaces that cater to diverse socioeconomic groups, besides highlighting the need for continuous adaptation of urban environments. Cities that accommodate shifting demographics and developments should prioritize inclusive public spaces to ensure accessibility for all citizens and encourage sustainable mobility by integrating cycling and pedestrian infrastructure, which fosters social interactions while reducing congestion additionally strengthening community participation.

Sustainable landscape planning in Muradiye Külliyesi historical area

Nurul Wahdaniyah*[1], Arda Tuncer[1]

[1] *Bursa Technical University, Department of Urban and Regional Planning, 16310 Bursa, Türkiye*

Abstract. Bursa, one of the earliest capitals of the Ottoman Empire, is home to many historical buildings that reflect Islamic civilization and architectural tradition which are still observable in the city center. One prominent historical site is the Muradiye Külliyesi area, which includes mosques, madrasas, bathhouses, public kitchens, and 12 tombs. The surrounding neighborhood also boasts several museums and historical sites, such as the Şair Ahmet Paşa Medresesi, Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum, Osmanlı Ev Museum, Hüsnü Züber House, Romangal İpek Fabrikası, and Hamza Bey Külliyesi. These historical buildings are located in Osmangazi, Bursa's most populous district. The district has a variety of improvement areas in and beyond its historical core where revitalization could lead to changes in infrastructure, technology, and lifestyle, positively influencing how the historic buildings are preserved and managed. This research focuses on identifying the landscape elements in the Muradiye Külliyesi area, assessing the quality of the historical landscape, and developing strategies for sustainable landscape planning in urban historic areas. This is expected to provide sustainable benefits while minimizing the possibility of negative social, economic and environmental impacts. The research methods include landscape element analysis, historical landscape quality assesment, and spatial analysis. The potential of historic building elements was included in the quality of historical landscape assesment showed a high value. Spatial analysis divides the area into three zones: Tourist Active Zone, Local Community Zone, and Buffer Zone.

Keywords: historical buildings; landscape quality; spatial analysis; landscape planning; sustainability

1. Introduction

In the multifaceted and complex field of urban planning, sustainable development is an indispensable element. The concept of sustainable development refers to efforts to meet the needs of the present without compromising the ability of future generations. The same concept also applies to the sustainability of historic areas, which play an important role in maintaining the history and development of a city. In the context of sustainability, sustainable landscape planning is evolving as an approach that emphasizes the importance of balance between ecological integrity, social needs, and aesthetic values. This approach encourages landscape design and management that not only considers ecological functions, but also responds to human interests and creates visually interesting environments. In other words, the main strength of sustainable landscape planning is the ability to create harmonious and resilient landscapes that provide long-term benefits for both people and the environment (Bariş & Kaygusiz, 2023).

Bursa as the capital of the Ottoman Empire, which became the political and cultural center of the time, holds historical value for the development of cities in Türkiye. In the aftermath of the conquest of Bursa, there have been multiple periods of building efforts and repairs which ensured that many structures from those periods survive to the present day. Afterwards, additional development also took place in the late 19th century which contributed to the cityspace, especially in the city center. Bursa is the cradle of important cultures. In Bursa, which is a transition zone between East and West, we see traces of Hittite, Phrygian, Lydian, Roman, Byzantine, Seljuk and Ottoman cultures. Thus, Bursa has an important place in the history of Türkiye with its geographical location, historical heritage and as the home of earliest capital of the Ottoman Empire.

Bursa, an important city during the Turkish history, has a rich Ottoman cultural heritage such as mosques, complexes and traditional markets. One of these historical buildings is the Muradiye Külliyesi area, which was the last külliye built in Bursa. Muradiye Külliyesi is home to a number of mausoleums in the Turkish-Islamic world with 12 mausoleums in addition to mosques, baths, madrasas and tombs. There are also many historical buildings around the Müradiye Külliyesi. Some of these historical buildings are the Şair Ahmet Paşa Madrasa, Uluumay

*Corresponding author, E-mail: nurulwahdaniyah96@gmail.com

https://doi.org/10.31462/icearc2025_a_urb_216

Osmanlı Halk Kıyafetleri ve Takıları Museum, Osmanlı Ev Museum, Hüsnü Züber House, Romangal İpek Fabrikası and Hamza Bey Külliyesi (Elbas, 2011).

The existence of Müradiye Külliyesi in Osmangazi, the most populous district of Bursa, may change the way people perceive historical heritage. Urban centers that are closely related to revitalization can cause changes in infrastructure, technology, and lifestyle, which can affect the way historic buildings are evaluated and managed. In general, urban revitalization and urban conservation projects have been supported by the European Union for projects focused on improving sustainability, culture, tourism, and urban image in recent years. Urban revitalization is the overall actions taken to bring a more dynamic economic, social and cultural position from the existing situation of a certain region of the city (Büyük, 2019).

This research aims to identify and understand the historic buildings within the Müradiye Complex. By recognizing these historic structures, we can assess and understand the spatial characteristics of urban areas with historical value. This knowledge allows for more precise planning to ensure the preservation and sustainability of these areas, keeping their identity and historical heritage in line with the city's development.

2. Methods

2.1. Location

This study is located in Osmangazi, Bursa City, Türkiye (Fig. 1). This location was chosen based on the consideration that there are historical building sites such as Muradiye Külliyesi (Muradiye Complex), Şair Ahmet Paşa Medresesi, Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum, Osmanlı Ev Museum, Hüsnü Züber House, Romangal İpek Fabrikası, and Hamza Bey Külliyesi (Hamza Bey Complex).

Fig. 1. (a) Bursa City; (b) historical object in Muradiye Külliyesi
Source: Wikimedia Commons contributors and map digitation from Google Earth, © Google, Inc.

2.2. Data Collection

The data was collected by: (1) observations on the elements of the historic landscape; (2) reviewing previous research and local government online reports related to the study area; and (3) observations on the management of historic buildings.

2.3. Data Analysis

2.3.1. Historical Landscape Image Element Analysis

The analysis of historical landscape image elements was adopted from the concept of the city image and its elements by Kevin Lynch (1964) (Lynch, 1964), which analyzed the effects of physical objects that can be seen based on social, functional, or historical meanings. The image of the landscape can be seen in terms of physical form, which is classified into five types of elements;

(1) Path are the pathways or routes that observers use to move around the city. These can be roads, public sidewalks, transit lines, rivers, railway lines or frequently used pedestrian routes;

(2) Edge is a linear element that acts as a boundary between two specific areas, although it is not always used as a road. For example, it can be a beach, a wall or the boundary between an urban area and an open space such as a railway;

(3) District is an area within a city that shares similar characteristics in shape, pattern and form. Districts or areas have clear boundaries and are often recognized as distinct areas within the city. Districts can be seen as an internal or external reference. Districts have a better identity if their boundaries are clearly defined and their functions are clear;

(4) Nodes are points or areas where directions or activities converge and can be changed to other directions or activities. For example, traffic intersections, train stations, airports, bridges or places where people feel they are in the center of the city; and
(5) Landmarks are visual elements that attract attention within the city, even if people cannot enter them. They serve as easily recognizable reference points and help observers navigate the city. For example, tall buildings, towers, mountains or striking historical buildings.

2.3.2. Landscape Quality Assessment

The landscape analysis of this historical area was conducted using the assessment method of authenticity and uniqueness based on Harris and Dines (1988), significance (Supriadi, 2010), and comfort aspects. The result of this process is to identify the character of each historical landscape and the values contained in the landscape (Surur et al., 2016).

Table 1. Quality Assessment Criteria of Historical Landscape (Rizki Mulya et al., 2016)

No	Criteria	Value		
		Low (1)	Moderate (2)	High (3)
Authenticity				
1	Land use	>50% changing	25-50% changing	<25% changing
2	Building	There are structure and element changing in the building. Does not show the classic style. Only have one element >50 years	There are structure and element changing in the building but show classic style. There are 2-5 historical elements >50 years	There are not structure and element changing in the building and show classic style. There are >5 historical elements >50 years
3	Circulation	There are addition of road and character changing	There are additions of road but the character not changin	There is not addition of road and the character not changing
Uniqueness				
1	Historical association	Landscape/element has not historical association	Landscape/element has low historical association.	Landscape/element has strong historical association
2	Integrity	Historical landscape element scattered in small amounts and not harmonious	Historical landscape element scattered in moderate amounts and harmonious	Historical landscape element scattered in large amounts and very harmonious
3	Different diversity	Landscape only has one historical element	Landscape has 2-5 historical elements	Lanscape has >5 historical elements
4	Aesthetic value	Landscape element has not distinctive style	Landscape element has distinctive style	Landscape element and detail of ornament has distinctive style
Significance				
1	History	Historical resource not scarce and not memorable by most society	Not the only one but scarce, not too old, and memorable by most society	Only one, scarce, very old, and memorable by most society
2	Science	There is not important value of science in landscape or object	There is important value of science in landscape or object, not the only one but scarce	There is important value of science, scarce, and only one
3	Culture	Cultural resource not abundant and not old	Cultural resource not the only one but abundant, but not too old	Cultural resource abundant, the only one, and very old

Table 1 continued

No	Criteria	Value		
		Low (1)	Moderate (2)	High (3)
Comfortness				
1	Clean from rubbish	Each 1 meter on landscape there are rubbish or there many rubbish in the core object	Each 5 meter on landscape there are rubbish or there some rubbish in the core object	There isn't rubbish on landscape and also in the core object
2	Clean from vandalism	There are >30% vandalism on landscape or there are vandalisms in core object	There are <30% vandalism on landscape but there is not vandalism in core object there are vandalism in core object	There is not vandalism on landscape and also in the core object

2.3.3. Spatial Analysis

Spatial analysis was carried out by mapping the distribution of zones from the results of the spatial identity assessment in historic urban areas in the context of sustainable development. The division of functional areas was grouped according to user groups such as tourists and residents (Zhu, 2021)

- Tourist Active Zone (TAZ): is the area with the highest concentration of tourist activities. It is the core formed by a cluster of tourism services, facilities and attractions. This sub-region not only needs concentrated tourism businesses to reduce costs or improve the efficiency of operations, but also fully develops services and businesses to make the area maximally attractive to consumers of the tourism area.
- Local Community Zone (LCZ): A concentrated area for the local community with a large number of dwellings. The main objectives of this zone are to create a safe, healthy and stable community environment, to promote the protection of existing residential areas from encroachment of excessive tourism development. This zone should be regenerated in line with the principles of guaranteeing the well-being and benefits of residents, providing daily services and facilities, reducing chaos and interference from tourists' activities, and conditionally restricting the expansion of tourism.
- Buffer Zone (BZ): It is a natural area that serves to separate the resident and tourist zones, while at the same time providing an immediate setting for a certain adjustment and further development of the above two zones.

3. Result and Discussion

3.1 Historical Landscape Elements

The historical evidence of Bursa as the political and cultural center of the Ottoman Empire can be seen in the historical buildings and museums that can be found nowadays. The historic buildings in the Muradiye Külliyesi area form a unique integration and can be easily accessed due to their close location. The historical elements that can be identified in this area are not only Muradiye Külliyesi but also historical buildings and several museums that can be found around it.

3.1. 1 Muradiye Külliyesi (Muradiye Complex)

The Muradiye complex containing twelve tombs (türbe) was constructed according to the instructions of Sultan Murad II after the completion of the Yeşil Mosque in Bursa. In this area, apart from tombs, there are also mosque, madrassas, bathhouses and public kitchens. The complex underwent a major restoration after the earthquake of 1855 that damaged most of the buildings. The restoration proceeded in stages: the first period from 1855 to 1967, the second period from 1947 to 1962, and lastly from 2012 to 2015 (Tupal Yeke, 2024).

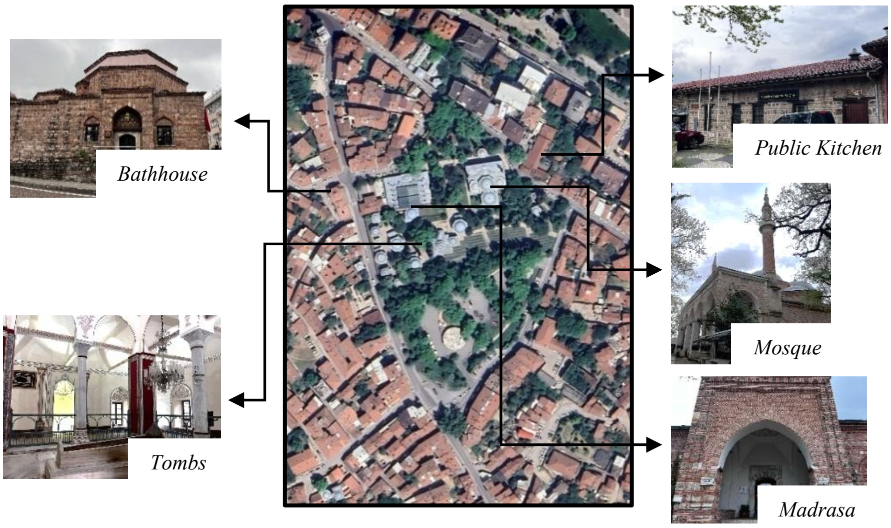

Fig. 2. Muradiye Külliyesi

3.1. 2 Şair Ahmet Paşa Medresesi

Ahmet Pasha Sultan II, a famous poet and statesman during the reign of Fatih Sultan Mehmed, was the son of Kazasker Murad, Veliyüddin Efendi. His tomb is located to the east of the madrasa he built, known as the Geyikli Madrasa. The madrasa was built in the 15th century and has been used for various purposes since then. After a restoration in 1967, it became the Muradiye General Education Center (Bursa Turizm Portalı, 2021).

The madrasa has a rectangular design with classrooms covered by a single dome, a portico with pointed arches, mirrored vaults, and eleven cells that each have a fireplace and small windows. These cells face the courtyard and are equipped with doors for natural lighting. Şair Ahmet Paşa, the founder of the madrasa, was a friend, teacher and vizier of Sultan Mehmed during the conquest of Istanbul, and left an important heritage in Muradye in the form of this madrasa (Türkiye Kültür Portalı, 2021).

Fig. 3. Şair Ahmet Paşa Tomb

3.1. 3 Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum

The museum is located inside the Şair Ahmet Paşa Madrasa and was opened on September 18, 2004. The museum exhibits a collection that Esat Uluumay, one of the founders of the Anatolian Folklore Foundation, collected over 45 years. The collection includes 70 sets of traditional clothing as well as more than 400 pieces of jewelry from Anatolia, Ottoman and Rumelia which originated in the 15th century. Other artifacts include Turkish coffee-making equipment, Ottoman bathing equipment, horse breeding equipment, as well as guns, knives and swords. The museum also contains an Ottoman Tea Garden, which provides a unique and enriching experience for visitors (Elbas, 2011).

Fig. 4. Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum

3.1. 4 Osmanlı Ev Museum

The museum is located about 100 meters from Muradiye Külliyesi and features 17th-century Ottoman history. Structurally the building has two floors, made of wood which represents the civil architecture of traditional Ottoman construction. The building has been restored and repaired several times until it was permanently opened in 2023 until now. The museum displays several examples of traditional Bursa houses, the uses of each room of the house, several examples of door styles, as well as Ottoman culture of dressing and the culture of coffee drinking in the 17th century.

Fig. 5. Osmanlı Ev Museum

3.1. 5 Hüsnü Züber House

After restoring a historic Ottoman-era house in the Muradiye District, Hüsnü Züber opened it as a "Living Museum" on December 27, 1992. On the first floor of his two-story house, visitors can find spoons and various wooden objects carved with Turkish motifs using a beautiful etching technique. There are also graphic works by Hüsnü Züber and important documents. Meanwhile, on the second floor, the living room, bedroom and main room house ethnographic collections and antiques used in daily life, providing an in-depth look into the culture and history of the past (Türkiye Kültür Portalı, 2021b).

Fig. 6. Hüsnü Züber House

3.1. 6 Romangal İpek Fabrikası

This weaving factory was built in the 19th century. First owned by Madame Brotte, it later passed into the hands of Monsieur Romangal, a Frenchman of Jewish descent. The Romangal family lived in the house facing Kaplıca Street within the factory complex until 1938. The building also served as the French Consulate for some time. In 1938, Monsieur Romangal sold the silk factory to Faik Yılmazipek, the father of Turgut Yılmazipek, who continued silk production here. The building consists of three floors with a wooden frame structure and brick walls, while the roof is covered with wooden tiles. In the factory area there are eight buildings surrounded by high walls. Most of these buildings were used as workshops for silk production and agricultural activities (Elbas, 2011).

Fig. 7. Romangal İpek Fabrikası

3.1. 7 Hamza Bey Külliyesi (Hamza Bey Complex)

The complex was originally composed of a mosque, madrasa, charity house and tombs, but only the mosque and three tombs still exist today. This mosque, the largest in Bursa at the time of Fatih Sultan Mehmed, is the main part of the Hamzabey Complex built by Hamza Bey. The building is categorized as a Zawiyali mosque, with main prayer rooms, gathering places, and guest houses on both sides. The mosque has a minaret with a single balcony, and in the complex are three tombs belonging to Hamza Bey in the northwest corner of the mosque courtyard, his wife and daughter are to the west of the mosque, while Kara Mustafa Pasha's tomb, built by his grandson, holds five coffins (Elbas, 2011) (Bursa Kültür Portalı, 2021).

Fig. 8. Hamza Bey Tomb and Mosque

3.2 Landscape Quality Assessment

The character of each historical landscape in Muradiye Külliyesi Area and its values can be seen in the area landscape assessment for each site.

Tabel 2. Landscape Assessment Results

No	Criteria	Muradiye Külliyesi (Muradiye Complex)			Şair Ahmet Paşa Medresesi			Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum			Osmanlı Ev Museum			Hüsnü Züber House			Romangal İpek Fabrikası			Hamza Bey Külliyesi (Hamza Bey Complex)		
Landscape Assessment		L (1)	M (2)	H (3)	L (1)	M (2)	H (3)	L (1)	M (2)	H (3)	L (1)	M (2)	H (3)	L (1)	M (2)	H (3)	L (1)	M (2)	H (3)	L (1)	M (2)	H (3)

	TOTAL	**34**			**30**			**30**			**30**			**28**			**28**			**31**		

Based on the results of the landscape quality assessment in the Muradiye Külliyesi area, the core zone can be divided into two: the first core zone, Muradiye Külliyesi, includes mosques, tombs, bathhouses, public kitchens and madrasas with a total landscape value of 34, while the second core zone is Hamzah Bey Külliyesi with a value of 31.

3.3 Landscape Planning Concept

3.3.1. Image of Muradiye Külliyesi Historic Area

(1) *Path*

The Muradiye Külliyesi area has several paths that are routes or connecting between landscape elements. In this regard, three degrees of hierarchy can be identified for the paths. The first degree path is the one that connects the first core zone, Muradiye Külliyesi with the supporting zones, which are Osmanli Ev Museum, Şair Ahmet Paşa Madrasa and Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum. The second degree is the path connecting Hamzah Bey Külliyesi with other landscape elements that runs straight through Muradiye Külliyesi, Hüznü Züber House until Romanggal İpek Fabrikası. The third one is a pathway that connects landscape elements with local community settlements.

(2) *Edge*

The boundaries of the Muradiye Külliyesi area were determined based on the physical elements present in the area by taking the outline of the road that naturally divides the study area from its surroundings based on differences in spatial characteristics and functions. In the north, the boundary is formed by the road that separates the Muradiye Külliyesi area from the green area of Bursa Millet Bahçesi, which has a public recreation function and open space characteristics. Meanwhile, in the south, the boundary is marked by the road that separates the research area from the hillside area, which has higher contours and different ecological functions than the core area of Muradiye Külliyesi.

(3) *District*

The district in this area can be classified as a spatial unit that has a strong visual identity and characteristics, making it easily recognizable as a distinct identity from the surrounding area. This district is Muradiye Külliyesi, which is the core of the area's landscape elements. Muradiye Külliyesi takes a central position in the spatial layout of the area, surrounded by various supporting elements that strengthen its role as a visual and spatial orientation center. The presence of green open space in the form of a park located at the back of this complex serves as a buffer while emphasizing the image of the area, thus increasing the legibility and imageability of the area in the context of landscape perception.

(4) *Nodes*

The intersection at Muradiye Külliyesi plays an important role in the spatial structure of the area and can be categorized as a node in the area's movement system. This point is the center of concentration of mobility for both vehicles and pedestrians, connecting Muradiye Külliyesi with other landscape elements such as green open spaces, residential areas, and historical landscape elements in the surrounding area. The intersection not only serves as a movement route, but also helps users understand direction and position and effectively connects different parts of the area.

(5) *Landmarks*

The landmark of the area is Muradiye Camii, a historic building that is easily recognizable due to its distinctive architectural form that is different from other elements. Although not in an open area, the minaret of the mosque makes it stand out and the mosque is also surrounded by other historic buildings and elements that have a strong visual and aesthetic integrity. The presence of Muradiye Camii in the middle of this historic complex strengthens the identity of the area and becomes an important point in recognizing and understanding the spatial structure around it.

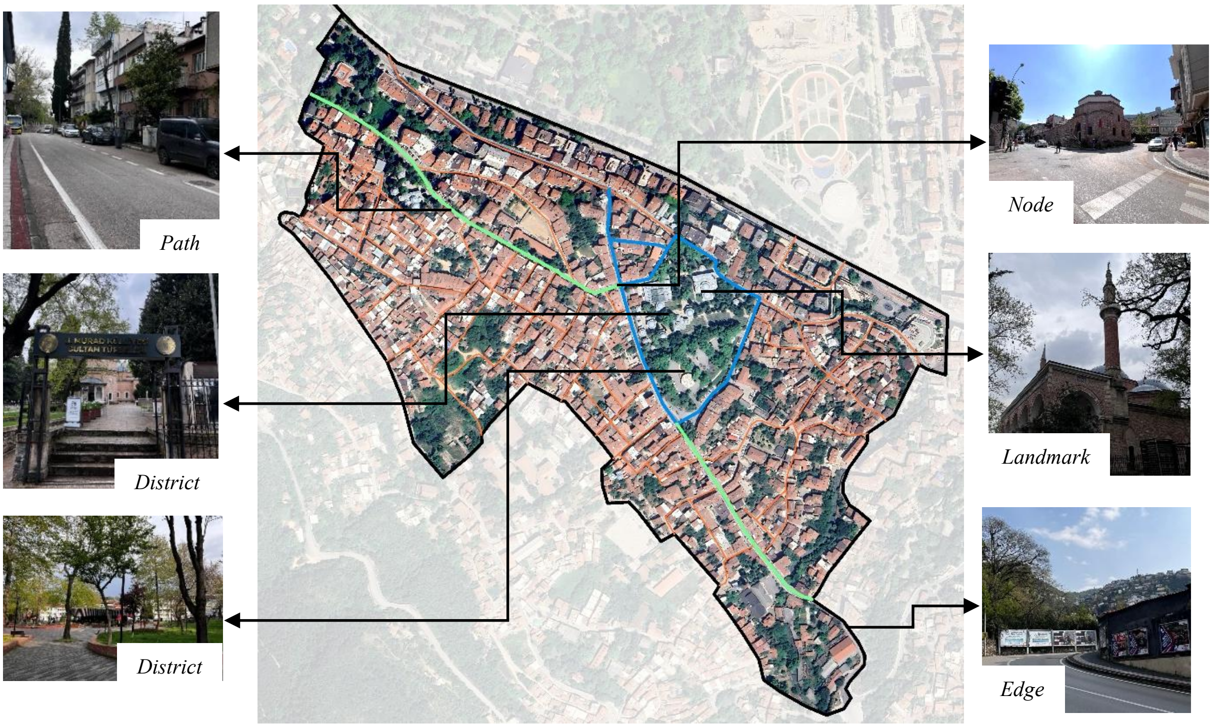

Fig. 9. Image of The Muradiye Külliyesi Historic Area

3.3.2. Spatial Analysis

The concept of landscape planning in the Muradiye Külliyesi area is by dividing zones based on the results of landscape assessment and distributed through the division of functional areas based on user groups such as tourists and residents. This division of zones can support sustainable landscape planning by considering social, economic and environmental in order to maintain the historical value of the Muradiye Külliyesi area.

(1) **Tourist Active Zone (TAZ):** This zone is located in an area that has a concentration of historic buildings and has been evaluated through a spatial and comprehensive landscape assessment process. Based on the results of the evaluation, the area was classified into two categories of Tourist Active Zones, including core zone and supporting zone. The core zone consists of Muradiye Külliyesi and Hamzah Bey Külliyesi, both of which showed the highest landscape quality as well as dominant historical and architectural significance. Meanwhile, other historical buildings such as Osmanlı Ev Museum, Şair Ahmet Paşa Madrasa, Uluumay Osmanlı Halk Kıyafetleri ve Takıları Museum, Hüznü Züber House, and Romangal İpek Fabrikası are functionally categorized in the supporting zones that complement the area's tourist attractions. This classification aims to manage the area based on the preservation of cultural values and optimize the potential of cultural tourism. The existence of this Tourist Active Zone is expected to encourage an increase in tourist flow and contribute to sustainable local economic growth.

(2) **Local Community Zone (LCZ):** The residential neighborhoods in this tourist area play a strategic role in maintaining the social stability of the community while supporting the preservation of historic buildings. These settlements have developed in phases since the past and continue to expand as the growth of Bursa City. The dynamics of settlement growth in this area contributes positively to improving the quality of facilities and infrastructure, both for tourist attractions and for the needs of local residents. In addition, the settlement area also serves as a supporting element for tourism activities through the provision of services, tourist information, and culinary facilities. Therefore, the harmonious development between the Tourist Active Zone and the Local Community Zone is a crucial aspect in supporting the sustainability of tourism activities and improving the welfare of the local community.

(3) **Buffer Zone (BZ):** Sultan Murad II Park is the primary green open space in the area. Its location directly behind the Muradiye Külliyesi complex makes it a transitional element that technically separates the historic zone from the residential area. The park not only functions as an ecological and visual element, but also as a public space that supports social interaction by various user communities. From a spatial point of view, this park is located in a strategic position (in the middle of the area) giving it high accessibility and easily accessible by both local people and tourists. This multifunctional park is an important node in the integration between cultural preservation, environmental comfort, and tourist activities.

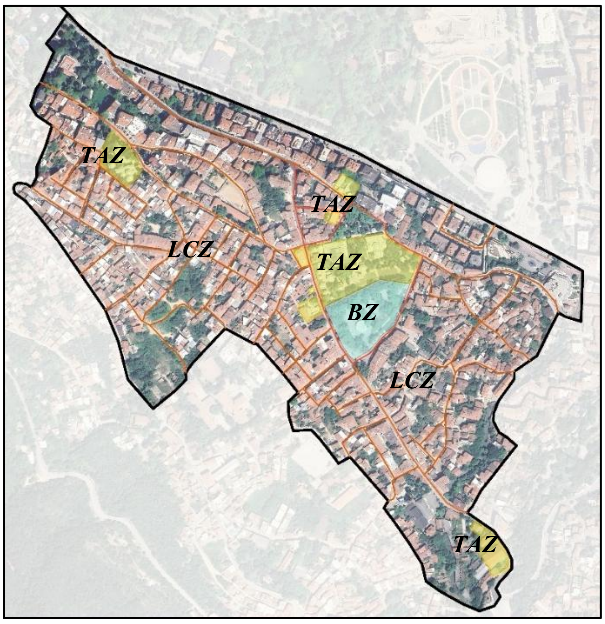

Fig. 10. Planning Zone Distribution in The Muradiye Külliyesi Historic Area

4. Conclusion

The Muradiye Külliyesi area in Bursa, Türkiye, represents an important part of the city's historical and cultural heritage, reflecting the richness of Ottoman architecture and spatial planning. Through the identification and assessment of landscape elements, this study showed that the area has high historical, architectural and spatial value.

The landscape quality assessment results showed that Muradiye Külliyesi and Hamza Bey Külliyesi became the main core zones due to their high level of authenticity, uniqueness and significance. Supporting buildings such as Şair Ahmet Paşa Medresesi, Osmanlı Ev Museum, and others also contribute to enriching the cultural landscape character of the area. Through Kevin Lynch's city image analysis approach, important elements such as paths, edges, districts, nodes, and landmark were identified and carried out to clarify the spatial legibility in the area.

The area planning strategy through the division of zones, which are the Tourist Activity Zone (TAZ), Local Community Zone (LCZ), and Buffer Zone (BZ) is a sustainable approach that emphasizes the balance between preservation, tourism development, and community welfare. This division supports the sustainability of the historic area without ignoring social, economic, and environmental aspects.

Sustainable landscape planning in the Muradiye Külliyesi area does not only preserve cultural and historical values, but also promotes urban livability and sustainable tourism. The methodology can be further improved through community participation. Ultimately, this integrated approach provides a model for the management of other historic areas that have similar challenges and potential.

The role of public buildings in the urban memory of Ankara

Zeynep Yılmaz Bayram[1], Parla Güneş[*2],

[1]*Karadeniz Technical University, Department of City and Regional Planning, 61080 Trabzon, Türkiye*
[2] *Ankara University, Department of Real Estate Development and Management, Besevler/Ankara*

Abstract. Urban memory encapsulates the spatial, social, and cultural elements that shape a city's identity within collective consciousness. This study explores the role of public buildings in Ankara's urban memory by comparing older (Ulus, Kızılay) and newer (Çayyolu, Yaşamkent) residential areas. Through surveys and mental mapping, it investigates how public buildings are perceived in different spatial contexts. Survey participants evaluated public buildings in terms of accessibility, usage, and contribution to urban identity, while mental mapping revealed perceptual differences between areas. The study emphasizes the significance of spatial continuity and regional mapping in understanding how public buildings are cognitively positioned within the urban landscape. Additionally, it analyzes large-scale public developments, such as city hospitals, focusing on integration with the urban fabric, user accessibility, functional harmony, and the potential to strengthen urban memory. Findings underline the necessity of design strategies that enhance both physical and perceptual connections, especially in newly developed areas. The research proposes human-centered and sustainable urban planning approaches that preserve cultural memory while fostering urban identity. For Ankara, the study recommends reinforcing the perceptual continuity of public buildings, integrating them meaningfully into the urban context, and adopting planning processes that support spatial and symbolic coherence. This work contributes to urban studies by offering strategies to bridge the gap between historical identity and contemporary development, ensuring public buildings remain active components of collective memory.

Keywords: Public building, Urban Memory, Urban identity, Spatial continuity, Cognitive Map.

1. Introduction

Urban memory is a dynamic process that preserves and transmits a city's social, cultural, and spatial characteristics within the collective consciousness (Assmann, 2011). In this context, public buildings function not merely as physical structures but also as carriers of urban identity (Rossi, 1982). As the capital city of Turkey, Ankara has been a significant site where processes of modernization and planned development have been intensely experienced. Accordingly, public buildings hold a special place in the urban memory of Ankara, both physically and symbolically. However, the recent rapid urban sprawl, unplanned construction, and emergence of new residential areas have increasingly called into question the role of public buildings within this collective memory (Erkip, 2000; Altaban, 2009). The physical and functional relationships that public buildings establish with their surroundings directly influence how individuals experience and remember these spaces. While structures located in historical centers such as Ulus and Kızılay stand out as tangible elements of Ankara's modernization process, public buildings in newer residential areas like Çayyolu and Yaşamkent create a comparatively weaker perceptual impact (Tümertekin & Özgüç, 2009). This situation contributes to the weakening of spatial continuity and urban identity.

This study aims to evaluate the role of public buildings in Ankara's urban memory by comparing older (Ulus, Kızılay) and newer (Çayyolu, Yaşamkent) residential areas. It analyzes individuals' perceptions of public buildings, the relationship these structures establish with urban identity, and the degree of spatial continuity. A mixed-methods approach was adopted, incorporating both qualitative and quantitative research methods. Surveys and cognitive mapping (mental mapping) techniques were utilized to uncover how individuals from diverse socio-economic and cultural backgrounds engage with these structures. The study also assesses the extent to which large-scale public projects (such as city hospitals) integrate with the existing urban fabric, their effects on social life, and their potential to reinforce urban memory. Based on the findings, planning and design recommendations have been developed to enhance the perceptual continuity of public buildings and their contributions to urban identity.

2. Urban Memory and Its Determinants

Urban memory is defined as the sum of the meaning relationships that individuals and communities establish with spaces within the city (Halbwachs, 1992; Lynch, 1960). This memory is recognized as a fundamental component of urban identity, carrying traces of the past into the experiences of the present. As emphasized in Kevin Lynch's seminal work *The Image of the City* (1960), the cognitive images formed by city dwellers play a critical role in shaping how the physical environment is perceived and remembered. These images include squares, public buildings, roads, and other symbolic elements. Pierre Nora's (1989) concept of *lieux de mémoire* (sites of memory) provides a theoretical framework for understanding how specific spaces serve as carriers of collective memory. Structures embedded in the memory of cities are not merely architectural elements; they are spatial reflections of social memory. Public buildings, in particular, play a crucial role in the social production of meaning within urban spaces. Rossi (1982) argues that public buildings are urban elements imbued with "collective memories" and that they constitute the core spaces forming urban identity. Especially institutions such as government offices, courthouses, schools, and hospitals occupy a central place in public life, thus securing a significant position within collective memory (Vale, 2008). These structures are not only functional but also carry symbolic meanings.

In the context of Turkey, public buildings constructed during the early years of the Republic were seen as representations of the modernization process and served as instruments in the construction of a new national identity (Bozdoğan, 2001). The public buildings planned with Ankara's designation as the capital city shaped not only the physical environment but also the collective urban memory. As articulated in Yi-Fu Tuan's (1977) concept of *topophilia*, individuals' emotional attachment to a place is rooted in the meanings attributed to it. Public buildings in older settlements tend to produce this emotional and symbolic meaning more intensely. Thus, public buildings are not merely service delivery points but also key carriers of collective memory. In the framework of Halbwachs' (1992) theory of collective memory, such buildings function as spatial markers of a memorable past. While this function is strongly preserved in historical city centers, the conscious planning of public spaces becomes increasingly necessary to reconstruct public memory in newer residential areas. Moreover, the concept of *place attachment* proposed by Low and Altman (1992) underscores the importance of not only physical continuity but also social and symbolic continuity. Based on these perspectives, this study emphasizes that public buildings should be evaluated not merely for their functional roles but also as spatial elements that reinforce collective memory.

Following the 1980s, Turkish cities underwent a rapid transformation under the influence of neoliberal policies, with urban planning processes increasingly shaped by market dynamics (Keyder & Öncü, 1994). Urban sprawl refers to low-density and often unplanned developments emerging in areas distant from the city center (Bruegmann, 2005). This phenomenon can lead to the fragmentation of spatial integrity and the weakening of urban identity. In Ankara, newly developed areas, particularly those expanding westward—such as Batıkent, Ümitköy, and Çayyolu—are recognized as typical examples of this unplanned sprawl. Public buildings in these areas, often shaped by fragmented planning decisions, have generally failed to fully integrate with the city's identity (Altaban, 2009).

Ankara was initially constructed as a "planned capital" following the proclamation of the Republic. Hermann Jansen's master plan of 1932 proposed a city model centered around public spaces (Tankut, 1990). Public buildings located in central areas such as Ulus and Kızılay were designed in accordance with this plan, intended to serve as the physical representations of the modern and secular Republic of Turkey (Çelik, 1993). However, the increasing population, irregular urban growth, and rising vehicle traffic after the 2000s have begun to diminish the perceptibility and significance of these structures within collective memory. While large-scale public projects have created new centers, the emotional and cultural bonds between these new structures and the broader urban fabric remain weak, making it difficult for such projects to leave a lasting imprint on urban memory (Köksal & Özsoy, 2016).

3. Research Methodology

This research aims to analyze the impacts of public buildings on urban memory in both the older (Ulus, Kızılay) and newer (Çayyolu, Yaşamkent) residential areas of Ankara, focusing on the dimensions of physical and perceptual continuity. The study adopts a mixed-methods approach, combining both qualitative and quantitative research methods. Data were collected through two main techniques: (1) a survey study and (2) cognitive mapping analysis. Through these methods, user experiences, perceptual differences, and levels of spatial continuity were systematically examined.

The survey was conducted with 240 participants selected from the four districts of Ankara (Ulus, Kızılay, Çayyolu, Yaşamkent), representing diverse socio-economic and demographic backgrounds. Participants varied in terms of age, educational attainment, length of residence, and patterns of daily use of public spaces. This diversity enabled a comparative analysis of different spatial experiences and memory patterns (Lynch, 1960; Tuan, 1977).
Within this study, a survey with 240 participants and a cognitive mapping exercise involving 145 participants were employed to reveal the multifaceted position of public buildings within individual and collective memory.

Participants were evenly distributed across demographic variables, and perceptions and feelings of attachment toward public buildings were analyzed based on factors such as age, education, and length of residence (Table 1).

Table 1 Detailed Analysis of the Survey

Variable	*Category*	*Frequency (n)*	*Percentage (%)*
Total Number of Participants		*240*	*100*
Distribution by Region	*Ulus*	*60*	*25*
	Kızılay	*60*	*25*
	Çayyolu	*60*	*25*
	Yaşamkent	*60*	*25*
Age Distribution	*18–30*	*84*	*35*
	31–50	*96*	*40*
	51 and above	*60*	*25*
Gender	*Female*	*128*	*53,3*
	Male	*112*	*46,7*
Educational Level	*High school or below*	*38*	*15,8*
	Bachelor's degree	*122*	*50,8*
	Master's/Doctorate degree	*80*	*33,4*
Length of Residence	*0–5 years*	*56*	*23,3*
	6–15 years	*88*	*36,7*
	16 years ve above	*96*	*40*
Frequency of Public Space Usage	*Several times a week*	*156*	*65*
	Monthly or less	*84*	*35*

The survey form consisted of multiple-choice and open-ended questions designed to examine the physical locations, accessibility levels, frequency of use, environmental integration, and impacts of public buildings on urban identity. Data collected through the survey were analyzed using SPSS software. In the first phase, descriptive statistics (frequency distributions, means, and standard deviations) were calculated. These analyses provided an overview of participant profiles and general trends regarding perceptions of public buildings. In the second phase, cross-tabulations and chi-square (χ^2) tests were conducted to explore the relationships between demographic variables (such as age group, education level, and residential area) and participants' perceptions and usage habits related to public buildings.

The primary aim of the survey was to understand how public buildings are represented in individuals' cognitive maps and how these structures contribute to urban memory. In addition, abstract elements such as spatial continuity and the sense of belonging were analyzed (Altman & Low, 1992). The sample size was determined by considering the standards set by similar studies on urban memory, targeting a minimum 95% confidence level with a ±6.3% margin of error (Neuman, 2014). Participants were selected through purposive sampling, with approximately 60 individuals recruited from each of the four regions. This method aimed to enable an in-depth analysis of the experiences and perceptions of individuals with distinct spatial backgrounds (Patton, 2002). Participants exhibited diversity in terms of age, gender, education level, income status, length of residence, and frequency of public space usage. In the Ulus and Kızılay regions, participants tended to be older, long-term residents with deep-rooted urban experiences. In contrast, newer residential areas such as Çayyolu and Yaşamkent were predominantly inhabited by individuals who had more recently joined urban life, belonged to higher income groups, and were generally younger with relatively shorter durations of urban experience. This diversity allowed for a comparative analysis of different spatial experiences and memory patterns (Lynch, 1960; Tuan, 1977). The survey was conducted through a hybrid method, combining face-to-face interviews with an online questionnaire.

During the cognitive mapping process, participants were asked to create freehand drawings representing public buildings and significant surrounding spaces within their residential areas. These drawings revealed participants' individual perceptions of urban space and the buildings that held a prominent place in their memories. The maps were evaluated based on how structures were represented in terms of scale, orientation, location, and symbolic meaning (Downs & Stea, 1973). The data obtained through cognitive mapping focused not on the physical accuracy of building locations but rather on the symbolic meanings and environmental relationships associated with these structures within urban memory. Although most of the drawings lacked precise spatial scale, they provided valuable insights into the semantic patterns of memory. The findings demonstrated that public buildings assume not only functional roles but also significant emotional and social roles in fostering a sense of belonging (Table 2).

Table 2 Detailed Information on Cognitive Mapping Analysis

Application	Number (n)	Percentage (%)
Number of participants who created cognitive maps	145	60,4
Drawing Method	Hand-drawn maps	92
	Digital map annotation (online)	53
Proportion of maps with building identification	138	95,2
Proportion of maps indicating environmental relationships	119	82,1
Proportion of maps containing semantic value	103	71,0
Number of maps transferred to digital format for GIS-based analysis	145	100

Although approximately 80% of the maps lacked spatial accuracy, they revealed significant patterns in terms of **semantic intensity**. The cognitive maps were digitized and analyzed using **GIS-based software (QGIS and ArcGIS Pro).** Some participants also provided locational indications through an online map-marking tool. The maps were coded according to **three main categories**:

1. **Identified Structures**: The frequency and manner in which public buildings were named and represented.
2. **Environmental Relationships**: The connections established between public buildings and surrounding roads, squares, and green spaces.
3. **Semantic Values**: The meanings attributed to the buildings depicted on the maps (e.g., "the place where I spent my childhood," "the building frequently visited for official procedures").

These categories were thematically classified through **content analysis.**

4. Fieldwork Analysis

The planned urbanization process, which gained momentum with Ankara's designation as the capital city, gradually gave way to uncontrolled urban sprawl and functional fragmentation over time. While the master plans developed since the 1930s primarily structured central areas such as Ulus and Kızılay, post-2000 urban development has been predominantly oriented westward, leading to the emergence of new residential areas like Çayyolu and Yaşamkent (Tekeli, 2011). This spatial rupture has contributed to discontinuities within the city's collective memory.

Ulus and Kızılay represent the planned urban cores of the early Republican period. These areas are characterized by their historical buildings, public institutions, and pedestrian-oriented public spaces. In contrast, Çayyolu and Yaşamkent are defined by large-scale residential projects, shopping malls, and highway connections; however, public life and urban memory in these newer districts remain more fragile and fragmented (Erkip, 2000). According to the survey and cognitive mapping data, participants' perceptions of public buildings varied depending on their residential area. Participants from Ulus and Kızılay associated these buildings with "historical belonging and collective memory," whereas participants from Çayyolu and Yaşamkent primarily referred to public buildings in terms of "accessibility" and "everyday functionality." In older settlements, public buildings were generally located along pedestrian-oriented axes, while in newer residential areas, access was predominantly automobile-dependent. This spatial distinction has also influenced levels of participation in public spaces. Regular use of public buildings was found to be higher among participants from Ulus and Kızılay, whereas visitation frequency was lower in the newer settlements.

Participants described public buildings as contributing more significantly to urban identity in the older districts. In particular, historical structures such as former governor's offices, government mansions, and parliamentary buildings were perceived as "centers of collective memory" (Assmann, 2011). The physical analysis evaluated the spatial placement, environmental connectivity, and functional integration of public buildings. Participants residing in Çayyolu and Yaşamkent exhibited a statistically significant tendency to characterize public buildings as "accessible but lacking a sense of belonging" ($p < 0.05$). Furthermore, the relationship between the contribution of public buildings to urban identity and variables such as frequency of use and accessibility was tested using **Pearson correlation analysis**. The results indicated a strong positive relationship between physical accessibility and cognitive representation ($r = 0.62$; $p < 0.01$). The historical Governor's Building in Ulus was drawn or mentioned by 74% of participants, whereas public service buildings in Yaşamkent were represented by only 31% of participants. The findings align with Lynch's (1960) concepts of "landmarks" and "paths," revealing how individuals navigate and form memories of the urban environment. Cognitive maps were analyzed in comparison with the physical regional map of Ankara. Particularly in the older districts, the denser placement of public buildings within the city center was reflected in higher cognitive visibility. In contrast, public buildings in Çayyolu and Yaşamkent were predominantly represented in a "peripheral" and "neutral" manner. This outcome highlights the parallel between **spatial memory and physical location** (Montello, 2002).

In the perceptual analysis, the visibility and degree of meaning attribution to public buildings in participants' cognitive maps were examined. Within this framework, a direct relationship was identified between the contribution of public buildings to urban memory and their physical spatial arrangement. In the cognitive maps, public buildings located in older settlements were generally positioned at central locations and at the intersections of social interaction networks. In contrast, in newer residential areas, these structures appeared less prominent, situated at marginal locations, and were often described solely through functional terms (Tuan, 1974; Lynch, 1960). While public buildings along the Ulus-Kızılay axis were perceived as key carriers of urban memory, those in the Çayyolu-Yaşamkent areas became increasingly anonymized, with lower levels of identifiability. This difference is attributed not only to the physical characteristics of the structures but also to the continuity of spatial experience. Cognitive maps revealed memory fields that partially overlapped with, but also diverged from, the physical urban maps. In particular, stronger environmental connections between public buildings and their surroundings were represented in Ulus and Kızılay, whereas in the newer settlements, these connections appeared weaker and more fragmented. The degree of physical integration of public buildings with their environment was identified as a critical factor influencing their embedding in urban memory. In Ulus and Kızılay, the organic structure of the urban fabric reinforced the significance of public buildings, whereas in newer areas, artificial and fragmented development patterns weakened these relationships (Jacobs, 1961).

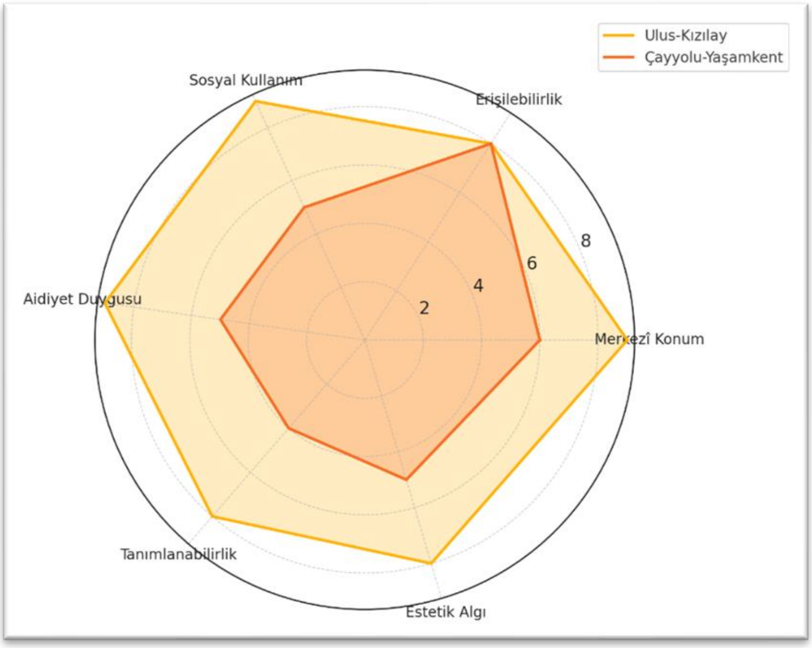

Fig. 1. Comparative Radar Chart of Perceptual Evaluations of Public Buildings in the Ulus-Kızılay and Çayyolu-Yaşamkent Regions

The radar chart (Fig. 1) was created to visualize the regional comparison of perceptual criteria related to public buildings based on the survey data. In this context, participants evaluated key thematic dimensions—such as **central location, accessibility, social use, sense of belonging, identifiability, and aesthetic perception**—using a 10-point Likert scale. The data were separately coded for the **Ulus-Kızılay (older settlements) and Çayyolu-Yaşamkent (newer settlements)** regions, and visualized using a multi-axis radar chart generated with the Python programming language and the matplotlib library. This chart not only provides **a numerical comparison of the survey findings** but also **intuitively illustrates perceptual differences** and their representations within spatial memory. Moreover, it serves as a supportive dataset that strengthens methodological triangulation by aligning with the tendencies identified through the cognitive mapping analyses.

In the radar chart, participants' perceptual evaluations of public buildings in the Ulus–Kızılay and Çayyolu–Yaşamkent regions are **comparatively presented** under six thematic categories. As clearly illustrated in the chart, the **Ulus-Kızılay region** occupies a broader surface area across all dimensions, indicating that public buildings are not only more prominently positioned within the urban fabric but also leave a deeper imprint on participants' cognitive memory. The differences are particularly pronounced in more abstract dimensions such as sense of belonging, **social use, and identifiability**. This finding suggests that public buildings contribute to urban memory not merely through their physical presence but also through their symbolic and social qualities (Tuan, 1977; Halbwachs, 1992). In contrast, although the **Çayyolu-Yaşamkent** region achieves a comparable score in the more technical criterion of accessibility, it displays significantly lower scores across all other dimensions. This outcome indicates that public buildings in newer residential areas lack perceptual continuity and tend **toward anonymity within the collective urban memory** (Lynch, 1960). Furthermore, the radar chart supports the findings from the cognitive mapping analysis, demonstrating that symbolic representations are predominantly concentrated in the older settlements. Thus, the chart serves as a powerful methodological tool, illustrating how survey findings and cognitive mapping analyses collectively produce meaningful insights. It also concretely highlights that spatial perception is shaped not only by **physical planning but also by social interaction, historical attachment, and aesthetic experience.**

Participants reflected their perceptions of the architectural language, scale, and aesthetic integration of the buildings with their surroundings. It was particularly emphasized that historical public buildings evoked feelings of "trust, continuity, and rootedness." The survey data revealed that the social and physical connections established by public buildings with their surrounding environment significantly influence user experience. The presence of elements such as green spaces, bus stops, and public squares enhances the "liveliness" of a public building (Gehl, 2011). It was observed that public buildings function not only as service points but also as spaces of public interaction, serving purposes such as gathering, waiting, and hosting events. This multifunctionality plays a crucial role in the formation of social memory. The association of public buildings with collective memories demonstrates that these structures are powerful not only physically but also symbolically. They help city residents forge connections with the past and preserve a sense of community identity (Halbwachs, 1992). Cognitive maps especially revealed greater visibility for spaces used for events (e.g., ceremonial grounds, cultural performance halls). This finding underscores that experiential engagement with space significantly enhances its memorability within the collective urban consciousness.

The mixed-methods approach employed in this study provided a **multi-layered analysis** by integrating both quantitative and qualitative data collection techniques. Through the survey study, measurable variables such as the physical accessibility of public buildings, frequency of use, and their contribution to urban identity were assessed, while cognitive mapping allowed for the visualization of participants' spatial perceptions, memory traces, and symbolic attributions. This methodological **diversity enabled** the development of a more **holistic understanding**—not only of user experiences but also of how these experiences relate to perceptual continuity (Creswell & Plano Clark, 2018). The high sense of attachment scores attributed to historical public buildings in Ulus and Kızılay in the surveys, combined with their frequent central and symbolic representation in the cognitive maps, serves as a striking example of methodological convergence. This integrated approach also revealed the intersections between spatial context and social memory. The visual representations that emerged from the cognitive maps demonstrated that individuals' relationships with space are shaped not solely by physical location but also by subjective layers such as past experiences, collective memory, and aesthetic perception. This finding aligns closely with Lynch's (1960) principle of **"visual identifiability"** and Tuan's (1977) concept of "emotional attachment." Moreover, by digitally processing the cognitive maps and comparing them with regional physical maps, mismatches between cognitive perception and the physical environment were also identified. In planned but emotionally detached areas such as Çayyolu and Yaşamkent, despite the strong physical presence of public buildings, their weak representation in cognitive maps clearly illustrated that physical existence alone is **insufficient for the formation of urban memory** (Montello, 2002). Therefore, cross-methodological comparisons not only enhanced data diversity but also significantly enriched the conceptual depth of the study.

The findings of the study (Table 1) reveal that the role of public buildings in urban memory differs spatially and cognitively between the older (Ulus-Kızılay) and newer (Çayyolu-Yaşamkent) residential areas of Ankara. According to the survey results, public buildings located in Ulus and Kızılay occupy a strong position in participants' memories; these structures evoke a high degree of identifiability and a sense of belonging through the historical continuity established with daily life. A similar tendency was observed in the cognitive maps, where public buildings in the older centers were represented more frequently and with greater detail. This pattern indicates that spatial memory is firmly established in these areas and that public buildings serve as foundational elements in the construction of collective urban memory. The convergence between the quantitative and qualitative findings underscores the significance of public buildings not merely as functional spaces but also as symbolic anchors of historical and social continuity within the urban fabric.

An examination of the spatial positioning of public buildings within the urban fabric reveals that, according to the survey data, these structures maintain a central character in the older districts, whereas in the newer residential areas, they are distributed in a more dispersed and directionless manner. This spatial fragmentation is also reflected in the cognitive maps: in Ulus and Kızılay, public buildings were predominantly placed near the center of the maps, while in Çayyolu and Yaşamkent, their positional ambiguity was notable. The frequency of use of public buildings as venues for social activities emerged as another factor influencing spatial memory. In the older centers, public buildings hosted a variety of social, cultural, and administrative activities, whereas in the newer districts, such functions were weaker, resulting in a more limited imprint on collective memory. Regarding the sense of belonging and identity, public buildings with historical and symbolic value were found to be more strongly represented in the older areas, while the potential of buildings in newer settlements to foster a sense of belonging remained limited. This difference is clearly evident in both the survey findings and the cognitive maps.

In terms of physical accessibility, the functional adequacy and ease of access to public buildings were particularly emphasized in the Ulus-Kızılay region. This was visually expressed in the maps through the distinctiveness of road networks and the proximity of public buildings to major transportation hubs.

A more complex pattern emerged concerning environmental integration and aesthetic perception. Participants noted that historical buildings were more harmoniously integrated into their surroundings and exhibited distinctive aesthetic qualities, a finding supported by the detailed representation of these structures in cognitive maps. In contrast, public buildings in newer areas were often perceived as neutral, lacking in aesthetic significance, and occupying a more marginal position in memory. Finally, regarding identifiability, public buildings in the older centers were recognized as symbolic landmarks, whereas in newer areas, despite their physical presence, they remained largely cognitively anonymous. The absence or vague representation of these structures in cognitive maps indicates that their physical existence did not translate into a symbolic presence within the urban memory.

Table 3. Methodological Convergence and Divergence Between Survey and Cognitive Mapping Findings in Terms of Urban Memory

Criteria	Survey Findings	Cognitive Mapping Findings	Analysis
Position of public buildings in memory	High in Ulus-Kızılay, low in Çayyolu-Yaşamkent	Consistent; denser representation in older centers	High convergence – strong spatial memory
Central location of public buildings	Centrally located in older centers, dispersed in newer areas	Ulus-Kızılay positioned at the center of cognitive maps	Full convergence – high cognitive visibility
Use of public buildings as social activity spaces	Regular use in Ulus-Kızılay; rare in newer areas	Social spaces more frequently represented in older centers	Convergent – social functions leave a memory trace
Sense of belonging and identity	High attachment to historical buildings; neutral in newer ones	Symbolic structures represented only in older areas	Convergent – belonging linked to symbolic value
Physical accessibility	High accessibility and functional adequacy	Physical access also indicated in cognitive maps	Supportive – physical features embedded in memory
Environmental integration and aesthetics	Harmonious in historical context; weak in newer area	Aesthetic elements drawn more detailed for historical buildings	Partial convergence – stronger entry into historical aesthetic memory
Identifiability of public buildings	Symbolic in Ulus-Kızılay; anonymous in new areas	Vague representations in new areas; lack of symbolic features	Divergence – physical presence but weak cognitive perception

The comparative analysis of the survey and cognitive mapping findings presents a strong methodological intersection in terms of **data integrity and validity**. In particular, the relationship between the physical centrality of public buildings and their visibility in individuals' cognitive representations is consistently reflected across both the survey and cognitive map data. Survey findings indicate that public buildings in older residential areas such as Ulus and Kızılay are characterized as centrally located, highly accessible, and frequently used structures. This pattern is corroborated by the cognitive maps, where these buildings are positioned centrally alongside other significant spatial references. This finding directly aligns with Kevin Lynch's (1960) concept of *imageability*, which posits that higher perceptibility within urban space enhances the prominence and functionality of that space in individuals' cognitive maps.

In this study, the high degree of representation of public buildings in Ulus and Kızılay—both in terms of physical positioning and cognitive visibility—supports this theoretical framework. Methodologically, this convergence strengthens the reliability of the mixed-methods approach employed; the consistency of results obtained through different data collection techniques reinforces the study's **internal validity and enhances data triangulation** (Creswell & Plano Clark, 2018). Accordingly, the observed consistency between spatial organization and cognitive perception carries both theoretical and practical significance for understanding how public buildings are positioned within urban memory.

5. Conclusions

The methodological structure of this study was deliberately built upon a **mixed-methods approach to enable a comprehensive analysis** of the role of public buildings in urban memory. Quantitative indicators derived from the **survey data** and **qualitative pattern**s emerging from the cognitive maps mutually reinforced one another, generating a multidimensional understanding. Within this framework, **data triangulation** was employed to test the consistency of findings obtained from different sources, thereby ensuring the methodological **validity of the results** (Creswell & Plano Clark, 2018). The identification of public buildings in Ulus and Kızılay as having high levels of attachment and usage in the survey data, coupled with their frequent representation in cognitive maps, stands as a strong outcome of this integrated structure. Similarly, the matching of cognitive maps with spatial analyses in digital environments enabled the establishment of meaningful connections between physical placement and perceptual representations.

This comparative analysis not only provided insights into spatial organization but also revealed the extent to which individual experience, social context, and symbolic meanings influence the formation of urban memory (Montello, 2002; Tuan, 1977). Therefore, one of the most significant contributions of this study is its ability to articulate the relationship between **physical space** and **collective memory at both measurable and semantic levels**. This framework also forms the basis for the recommendations presented in the subsequent sections, ensuring that they are grounded both technically and culturally

The research findings demonstrate that the physical locations of public buildings and their relationships with the surrounding environment play a significant role in determining their place within urban memory. It was observed that in historical centers such as Ulus and Kızılay, public buildings are more visible and meaningful in both individual and collective memory, whereas in newer residential areas such as Çayyolu and Yaşamkent, these structures, although functionally utilized, remain perceptually less prominent. This finding aligns with Kevin Lynch's (1960) principles of *visibility* and *identifiability*.

Based on the case of Ankara, the following recommendations have been developed:

- The site selection of public buildings should consider regional memory and the cultivation of a sense of collective belonging.
- In new residential developments, public buildings should be integrated with symbolic elements that contribute to the construction of public memory, such as squares, monuments, and ceremonial spaces.
- Urban planning strategies should account not only for accessibility but also for spatial continuity and the potential for public engagement and use.

It has been understood that the presence of public buildings in urban memory is not solely determined by their physical existence, but rather shaped by multidimensional factors such as user experience, event memory, and spatial context. Particularly in the historical centers, public buildings have been anchored in memory through experiences carried from childhood to the present, whereas in newer districts, the construction of such continuity still needs to be fostered. This highlights the necessity for urban planning policies to emphasize not only physical aspects but also symbolic connections. This study specifically analyzed the role of public buildings in urban memory within the case of Ankara. However, future research could expand upon this work by conducting comparative studies across different cities, focusing on various age groups or user types (such as individuals with disabilities, children, or migrants), and integrating digital mapping and AI-supported perception analysis with urban memory research. Building perceptual bridges between older and newer settlements is crucial. Site selection processes should be informed by participatory planning practices grounded in user experiences, where memory itself becomes an input for urban design. Ultimately, to strengthen the role of public buildings within urban memory, the following recommendations are proposed: public buildings must be not only physically accessible but also symbolically meaningful. The strong memory traces associated with historical districts should be preserved, while in newer areas, experiential spaces that can cultivate memory must be created. Moreover, the relationship between public buildings and their surroundings should be designed in social, aesthetic, and functional terms.

Abstract
Urban spaces are the settings of daily life and are used by heterogeneous groups of people. Despite sharing the same physical spaces, individuals may have vastly different experiences. Given that spatial regulations are typically shaped by certain standards and generalizations, disadvantaged groups—compared to healthy and male individuals—often exhibit heightened spatial sensitivities. In professional fields such as architecture, urban and regional planning, and landscape architecture, the promotion of inclusive planning and design approaches within educational processes serves as a critical tool in achieving spatial equity for vulnerable groups.

In this context, the aim of the study is to analyze the presence and content of courses addressing disadvantaged groups (e.g., women, the elderly, children, individuals with special needs) within the undergraduate, graduate, and doctoral curricula of architecture, urban and regional planning, and landscape architecture departments in universities across Turkey. The study seeks to answer the following research questions: "At which educational level are courses on the design of the built environment for disadvantaged individuals concentrated?", "What themes are addressed in these courses?", and "Do these courses vary across different educational levels (undergraduate, graduate, doctoral)?". The objectives and contents of both compulsory and elective courses in relevant departments of public universities were subjected to qualitative content analysis, and the data were analyzed using the Maxqda 24 software.Considering the three educational levels, 47 relevant courses were identified in Architecture, 33 in Urban and Regional Planning, and 28 in Landscape Architecture—figures that remain relatively low in light of the current curricula.

Keywords: Disadvantaged individuals; Spatial design; Planning;Content analysis

1. Introduction

Space, defined as the place of a person or group, encompasses a range of spatial scales—from small physical areas to broader contexts such as our homes, neighborhoods, cities, regions, and nations, extending up to the global level. Societies are composed of heterogeneous groups of people, and while individuals may occupy the same spaces, their experiences can differ significantly. When spatial arrangements are typically guided by generalized standards and norms, certain users may be adversely affected by such frameworks. In particular, women, older adults, children, and individuals with special needs (i.e., disadvantaged groups) tend to exhibit greater spatial sensitivity compared to healthy, male individuals. Although often unintentional, the failure to account for the specific needs and priorities of these groups during spatial design processes can result in negative impacts on their lives.

Issues such as women's access to and safe use of public spaces, children's integration into play and social environments, mobility for the elderly, and accessibility demands of individuals with special needs represent distinct and critical concerns that must be considered in built environment design. Integrating these needs into spatial planning and design processes not only enhances individual quality of life but also strengthens social cohesion and the notion of inclusive cities. Design approaches that address the spatial needs of disadvantaged groups must go beyond basic physical accessibility and safety to also encompass opportunities for social interaction, psychological well-being, and self-realization.

In the planning and design of housing, transportation, open and green spaces, public spaces, and urban services—which directly shape daily life practices—students in architecture, urban and regional planning, and landscape architecture must adopt an inclusive and equity-oriented perspective that recognizes individual and

* Corresponding author, E-mail: n.hekimoglu001@gmail.com

https://doi.org/10.31462/icearc2025_a_urb_242

social differences. In this regard, enhancing inclusive planning and design approaches in both the professional practice and educational curricula of architecture, urban and regional planning, and landscape architecture plays a vital role in achieving spatial equity for vulnerable populations.

Architecture is a discipline concerned with designing and constructing human environments in accordance with aesthetic, functional, and technical principles. Vitruvius's triad of "firmness, utility, and beauty" (*firmitas, utilitas, venustas*) (Vitruvius, 1st century BCE) still constitutes the foundational pillars of architectural education and practice today. Architectural education aims to cultivate students' creative thinking, technical skills, and sense of social responsibility (Salama, 2015). Urban and regional planning is a discipline that guides the economic, social, environmental, and spatial development of settlements and regions. According to the United Nations Human Settlements Programme (UN-Habitat, 2020), urban planning serves as a tool to promote social justice, environmental sustainability, and economic efficiency. Landscape architecture, on the other hand, involves the design of natural and built environments to serve aesthetic, ecological, and social functions. As defined by the American Society of Landscape Architects (ASLA, 2021), the discipline encompasses the sustainable management of open spaces, urban areas, and natural systems, aiming to create healthy, livable environments through the integration of ecological, sociological, and aesthetic principles.

These disciplines play a critical role in shaping the built environment, which directly affects individual quality of life. Their curricula typically consist of studio courses (applied project work), theoretical courses, and technical courses. Architecture programs often emphasize foundational design studios, building technologies, architectural history, building physics, and urban studies. Urban and regional planning curricula tend to focus on planning theory, spatial analysis, transportation planning, and environmental planning. In landscape architecture programs, courses in ecology, plant materials, design studios, and environmental planning are prioritized. While required courses in these disciplines largely focus on technical and theoretical knowledge transfer, issues concerning social sensitivity and disadvantaged groups are often relegated to elective courses (Salama, 2016; Dovey, 2010). This trend is also observed in curricula across Turkish universities (Erbaş & Yücesoy, 2018).

In recent years, leading universities around the world have begun to offer more inclusive courses addressing the needs of disadvantaged groups. For example, the Harvard Graduate School of Design (GSD) offers courses such as *Urban Inclusion and Social Equity*, which focus on spatial rights and social equity in urban planning (Harvard GSD, 2022). University College London (UCL), through its Bartlett Faculty of the Built Environment, offers *Designing Inclusive Places*, addressing the representation of groups such as the elderly, children, and individuals with disabilities in urban spaces (UCL Bartlett, 2021). Similarly, Delft University of Technology (TU Delft) offers the *Inclusive Environments* course, which introduces architecture students to the importance of addressing diversity in design at both conceptual and practical levels (TU Delft, 2020).

Despite such progress, literature reviews indicate that most architecture and planning programs still inadequately address the spatial needs of disadvantaged groups in their core curricula (Ahrentzen, 2015; Salama, 2016). Ahrentzen (2015) argues that architectural education is often based on the idea of an "average user" and fails to sufficiently accommodate differences. Although universal design principles have been internationally recognized (Center for Universal Design, 1997), their integration into academic curricula remains inconsistent. Particularly at the undergraduate level, inclusive design approaches are not systematically incorporated into studio instruction (Heylighen, 2012).

The United Nations' Sustainable Development Goals (SDGs), comprising 17 global objectives to be achieved by 2030, aim to end poverty, protect planetary sustainability, and enhance human well-being. Among these, Goal 5 promotes gender equality and the empowerment of women and girls, while Goal 11 advocates for inclusive, safe, resilient, and sustainable cities and human settlements (UN-Habitat, 2020). In this context, it is expected that education in planning and design disciplines should reflect these goals by incorporating socially inclusive and equitable content. However, literature suggests that these goals are often addressed at the policy level without being meaningfully integrated into academic curricula (Alawadi, 2020; Madanipour, 2006). Even when SDGs are referenced in educational programs, the connection is often superficial, with little application in design studios or project-based learning (UNESCO-UIA Charter, 2017).

Against this backdrop, the aim of this study is to examine the presence and content of courses addressing disadvantaged individuals (e.g., women, the elderly, children, and individuals with special needs) in undergraduate, graduate, and doctoral curricula within architecture, urban and regional planning, and landscape architecture departments at universities in Turkey. The research seeks to answer the following questions: "At which educational levels are courses on the design of the built environment for disadvantaged individuals most concentrated?", "What themes are covered in these courses?", and "Do these courses vary across different educational levels (undergraduate, graduate, doctoral)?"

2. Research Methodology

This study investigates the presence and content of courses aimed at disadvantaged users within the undergraduate, graduate, and doctoral programs of architecture, urban and regional planning, and landscape architecture departments—disciplines that play a key role in the production of space and the built environment—in universities operating in Turkey. According to 2024 data from the Turkish Higher Education Council (YÖK) Atlas, there are 167 architecture, 41 urban and regional planning, and 42 landscape architecture undergraduate programs offered by public and foundation universities in the country (URL 1). Within the scope of this research, only programs at public universities that rank among the top 15 in national university entrance rankings or that enroll 20 or more students were included.

In cases where a single university hosts two or all three of these departments, all relevant departments were considered. Consequently, the study examined the undergraduate, graduate, and doctoral programs of departments in 32 public universities. Both compulsory and elective courses were included, and their objectives and contents were analyzed using qualitative content analysis. The data were processed and analyzed with the Maxqda 24 software. Course information was obtained by accessing the official websites of the respective departments and reviewing the available course catalogs.

Table 1 presents the number of undergraduate, graduate, and doctoral programs in architecture, urban and regional planning, and landscape architecture departments at the selected 32 public universities. Due to its earlier establishment in Turkish higher education compared to the other two disciplines, the number of architecture programs is relatively higher.

Table 1. Number of educational programs in relevant departments (Compiled by authors)

	Architecture	Urban and Regional Planning	Landscape Architecture
Undergraduate	26	26	16
Master's	23	17	14
Doctorate	20	13	13

3. Findings

A total of 108 courses addressing disadvantaged individuals were identified in departments of Architecture, Urban and Regional Planning (URP), and Landscape Architecture that offer education at least at one of the levels of undergraduate, master's, or doctorate. As shown in Table 2, the distribution of these courses by department indicates that 47 are in Architecture, 33 in URP, and 28 in Landscape Architecture. When examining the distribution of these courses across educational levels, 75 are at the undergraduate level, 17 at the master's level, and 16 at the doctoral level.

In terms of the proportion of courses within each educational level, Architecture departments at the doctoral level have the highest rate of courses on disadvantaged groups at 3.1%. This is followed by URP undergraduate programs (2.9%) and Landscape Architecture undergraduate programs (2.6%). The Landscape Architecture doctoral programs have the lowest rate, with only 1.3% of courses addressing these topics.

Table 2. Distribution of courses addressing disadvantaged groups across educational levels and departments

	Programs														
	Undergraduate					Master's					Doctorate				
Departments	Other Courses		Courses Addressing Disadvantaged		Total Number of Courses	Other Courses		Courses Addressing Disadvantaged		Total Number of Courses	Other Courses		Courses Addressing Disadvantaged		Total Number of Courses
	N	%	N	%		N	%	N	%		N	%	N	%	
Architecture	1137	97,5	30	2,5	1167	331	97,7	8	2,3	339	280	96,9	9	3,1	289
Urban and Regional Planning	804	97,1	24	2,9	828	234	98	5	2	239	153	97,5	4	2,5	157
Landscape Architecture	785	97,4	21	2,6	806	243	98,4	4	1,6	247	218	98,7	3	1,3	221

Universities are expected to contribute to their respective professional fields, particularly within their cities, regions, and at the national level. Equipping professionals involved in the production of the built environment/space with the necessary knowledge and skills to address the needs of disadvantaged individuals is crucial for achieving Gender Equality (SDG 5) and Sustainable Cities and Communities (SDG 11). When all state university programs in architecture, urban and regional planning, and landscape architecture in Türkiye are evaluated collectively, it becomes evident that the proportion of such courses is highest in the relevant departments located in Istanbul (Fig. 1). This is followed by departments in the Marmara Region. Despite its geographical distance from central regions, the high proportion of such courses at Karadeniz Technical University is also noteworthy. This may be explained by the fact that the relevant departments at KTÜ were among the first to be established in the country.

UNIVERSITY NAME	NUMBER OF COURSES	UNIVERSITY NAME	NUMBER OF COURSES	UNIVERSITY NAME	NUMBER OF COURSES
İstanbul Teknik Ünv.	16	Bursa Teknik Ünv.	4	Ortadoğu Tek. Ünv.	1
Yıldız Teknik Ünv.	13	İzmir Demokrasi Ünv.	4	İzmir Yüksek Tek. Ünv.	1
Mimar Sinan Güz. San. Ünv.	11	Onsekiz Mart Ünv.	4	İstanbul Ünv.	1

Konya Teknik Ünv.	6	Namık Kemal Ünv.	2		

Fig. 1. Universities in Türkiye Offering Courses Focused on Disadvantaged Groups and Their Geographical Locations

4. Thematic Content Analyses of the Courses

A total of 108 courses from the departments of Architecture, Urban and Regional Planning (URP), and Landscape Architecture were examined. Course objectives and contents were accessed from online course information packages; courses without publicly available information were excluded from the evaluation. The objectives and contents of the courses were subjected to content analysis in the Maxqda program, and separate word clouds were generated for each department, followed by a combined word cloud for all departments. Word clouds are a tool used in content analysis methods within social sciences. These visual representations highlight the frequency of words in a text, but they do not provide deeper linguistic analysis (Jones, 2018). Word clouds are a visualization tool that quickly highlights important words in large datasets and allow users to easily identify key terms in the content (Brown, 2017). In these visuals, there is a linear relationship between the size of a word and its frequency of use in the text.

When analyzing the word clouds created based on the themes/concepts in the course content of departments providing professional education in spatial production processes, differences between the departments are evident. In the Architecture department, “universal design” stands out; in URP, “urban design” is prominent; and in Landscape Architecture, the themes of “child” and “play” come to the fore. When all departments are evaluated together, it was found that the most frequently used themes, in order, are universal design, social, community, and urban design (Table 3).

Table 3. Word clouds based on course content in the departments

Department of Architecture

Department of Urban and Regional Planning

Department of Landscape Architecture

All Departments

When all courses across the three departments and educational levels are evaluated collectively, the themes of design, social dimension, environmental dynamics, behavior & perception, and planning & the city emerge as prominent. The frequency and sub-themes of each theme/concept, based on course content, are listed below:

1. Design: Identified in 10 courses, encompassing various sub-topics such as Universal Design and User-Centered Design.
2. Social Dimension: Found in 8 courses, covering topics such as gender, inequality, and inclusivity.
3. Environmental Dynamics: Present in 6 courses, addressing issues like environmental psychology and sustainability.
4. Behavior & Perception: Observed in 5 courses, including subjects related to spatial behavior and perception.
5. Planning & the City: Featured in 4 courses, encompassing themes such as urban design and public spaces.

Undergraduate education is structured to provide foundational knowledge necessary for entering professional life. While the master's level aims to develop specialization in a specific field, doctoral education is designed to enable original academic contributions within the relevant professional domain. Therefore, the content and depth of courses at these three educational levels differ significantly.When courses related to disadvantaged groups are evaluated in general terms, the following themes emerge: at the undergraduate level, accessibility and environmental psychology; at the master’s level, environmental psychology and gender; and at the doctoral level, user-centered design and the psychology of disability.An analysis of the content of both compulsory and elective courses across all three educational levels reveals that compulsory courses primarily focus on accessibility (Design for All and universal design principles), environmental psychology (human-environment interaction and behaviors), and gender (the spatial implications of gender). In contrast, elective courses prioritize themes such as children's play spaces, barrier-free design, and user-centered design.

The analysis conducted to identify the thematic focuses within the departments of Architecture, Urban and Regional Planning, and Landscape Architecture revealed three overarching themes across all disciplines: accessibility (a significant focus area in each department), environmental psychology (a critical theme for understanding human behavior in spatial design), and gender (studies on the role and impact of gender in spatial design).When examined separately by department, thematic focuses in the Architecture department include accessibility, environmental psychology, gender, and design for all. In the Urban and Regional Planning (URP) department, the prominent themes are urban space and human interaction, gender and space, child-friendly cities, and the psychology of disability. In the Landscape Architecture department, key focuses include accessible landscape design, children's play areas, universal design, and environmental impacts.These conceptual relationships among themes are also detailed in the departments' conceptual network diagrams (Fig. 2).

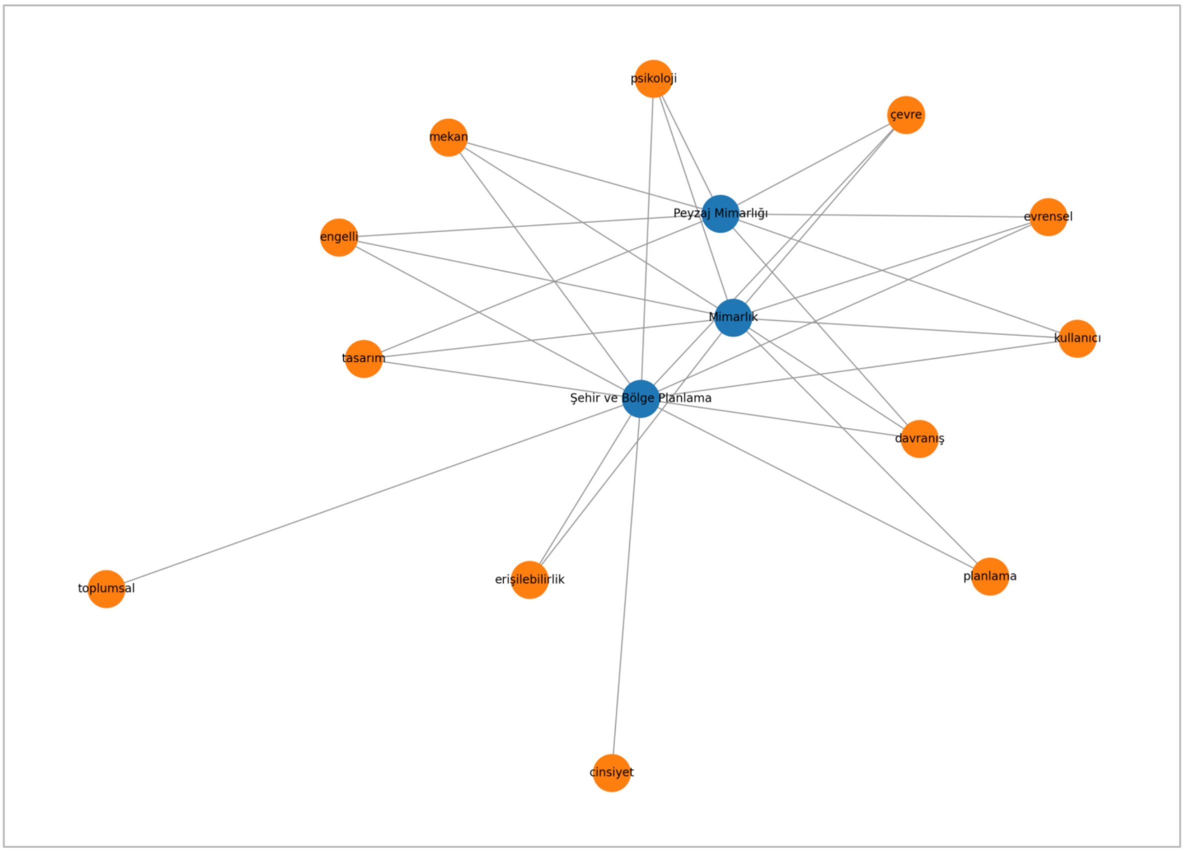

Fig. 2. Departments and conceptual relationship networks

In architecture, urban and regional planning, and landscape architecture departments offering undergraduate, master's, and doctoral education in Turkey, the following themes have been identified as underrepresented in courses addressing the needs of disadvantaged groups:

1. Child-Friendly Design: Studies focusing on children's use of space and their specific needs are less prevalent than expected. This theme particularly emphasizes children's play areas and their experiences within urban environments.
2. Disability Psychology: Courses addressing the psychological needs of individuals with disabilities and the spatial implications of these needs are limited. This theme is of critical importance in terms of spatial use and social integration of people with disabilities.
3. Gender and Space: The impact of gender on space is not sufficiently explored in depth at some universities. This theme offers a crucial perspective on gender equality and spatial justice.
4. Sustainable Design: The theme of sustainability is less frequently covered than expected, particularly in architecture and urban planning curricula. It is essential for reducing environmental impacts and creating sustainable living environments.

5. Conclusion

In Turkey, the number of courses addressing the needs of women, the elderly, children, and individuals with special needs within undergraduate, master's, and doctoral curricula in the departments of architecture, urban and regional planning, and landscape architecture remains quite limited. The existing course contents tend to concentrate on specific themes. Undergraduate education, in particular, holds critical importance for cultivating well-qualified professionals. In all three departments, the proportion of such courses at the undergraduate level is approximately 2.5%, and these are offered as elective courses. The predominance of technical and general design-oriented compulsory courses at the undergraduate level results in issues such as social equity and inclusivity being relegated to the periphery of the curriculum, addressed only through electives.

The proportion of relevant courses at the master's and doctoral levels is similarly low, averaging around 2.5% across all three departments. The curriculum at these levels in the field of landscape architecture falls below this average. Enhancing the number and content of such courses is of vital importance for advancing expertise at the doctoral level, which can contribute to the professional fields from the perspective of producing equitable spaces for disadvantaged groups.

Despite global frameworks such as the United Nations Sustainable Development Goals emphasizing and promoting inclusive space-making, academic programs in Turkey have yet to fully align with these objectives. Moreover, there is a clear need for systematic efforts to cultivate a highly qualified professional workforce and domain-specific experts. Centralizing principles such as social justice, accessibility, and diversity within educational programs is a critical step toward creating sustainable and just cities and public spaces.

The richness of academic staff in Turkey's leading universities in the fields of architecture and planning has brought with it greater diversity in course offerings. However, there are significant regional disparities in the availability of courses focused on disadvantaged groups. Particularly in recently established departments with limited academic personnel, such courses are often absent from the curriculum. Given that universities are expected to contribute first to their local and regional contexts, and subsequently to national professional development, incorporating the courses examined in this study into departmental curricula in a way that addresses regional disparities is both a necessary and urgent priority. Expanding the number and enriching the content of inclusive and equity-focused courses in academic curricula is essential for building sustainable societies and livable urban environments. In line with this objective, it is also recommended that departments commence instruction in these areas only when they have reached a sufficient number of academically qualified staff equipped with the necessary disciplinary expertise.

Acknowledgements and Statement

This paper analyzes course content in architecture and planning education with a focus on disadvantaged groups, revealing the current state of inclusivity and social equity. In alignment with the Sustainable Development Goals, the study emphasizes the need to transform curricula to promote a more equitable and accessible built environment. I would like to express my gratitude to my academic advisor for their invaluable support, to my colleagues who contributed during the data collection and analysis processes, and to the universities that provided open-access resources. I am also thankful for the national and international academic sources that guided the content analysis.

A multi-criteria decision-making framework for optimal sustainable facade selection in residential buildings of Tabriz

Mahsa Faramarzi Asli[1], Seyed Mahdi Ghoddusifar[*1]

[1] *Islamic Azad University, Department of Architecture and Urban Design, Tabriz, Iran*

Abstract. This research introduces a robust multi-criteria decision-making (MCDM) framework designed to evaluate and prioritize sustainable facade options specifically for residential buildings in Tabriz, Iran. Addressing the city's distinct cold semi-arid climate and valued architectural heritage, this study explicitly incorporates local climatic challenges, architectural identity considerations, and urban context specifics. A comprehensive set of evaluation criteria—encompassing aesthetic, environmental, economic, and technical dimensions—was meticulously derived from literature and regional expert consultation. The Analytic Hierarchy Process (AHP) was strategically employed to quantify the relative importance of these criteria, authentically reflecting priorities of key local stakeholders (residents, architects, municipal officials). Subsequently, the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) was utilized to rank fourteen diverse facade alternatives (including conventional, smart, and green types). AHP results revealed compatibility with the urban context and aesthetic quality as paramount criteria for Tabriz stakeholders, a potentially distinguishing regional finding. The TOPSIS analysis identified smart and green facades as the most advantageous options, exhibiting superior overall performance, particularly in energy efficiency and environmental impact, corroborated by quantitative energy simulations. This study's primary contribution is a validated, context-sensitive framework for optimizing facade selection, uniquely integrating subjective local priorities with objective performance data. Findings offer actionable guidance for advancing sustainable building practices in Tabriz and analogous settings.

Keywords: Sustainable facade; Residential buildings; Multi-criteria decision-making (MCDM); Tabriz; Context-specific design

1. Introduction

The global proliferation of multi-story construction presents significant sustainability challenges concerning resource depletion and environmental degradation (Ghasemi Gilvaei & Ghorbani Param, 2024). This global trend impacts Iranian cities like Tabriz, where rapid urbanization interfaces with distinct environmental conditions and cultural heritage (Rahnama & Abbaszadeh, 2006; Gorji Mahlabani, 2010). Building facades, as the critical interface between interior and exterior environments, profoundly influence building energy performance, occupant thermal and visual comfort, and the overall urban aesthetic (Ahmadi et al., 2019). Consequently, facade selection represents an increasingly complex design problem, demanding sophisticated trade-offs among energy performance, environmental footprint (including embodied impacts), life-cycle cost-effectiveness, technical durability, and aesthetic integration within the urban fabric (e.g., Shafiee et al., 2022). For Tabriz, characterized by a cold semi-arid climate necessitating substantial heating energy and possessing a unique architectural identity demanding preservation, the imperative for contextually sensitive, high-performance facades is particularly acute. This need is amplified by known issues and deficiencies in the facade treatments applied to a significant portion of the city's building stock, highlighting an urgent need for effective sustainable solutions.

Sustainable facade design endeavors to mitigate environmental impact, enhance occupant well-being, and preserve urban character through informed material selection, resource management, and appropriate technology integration (Pearce et al., 1989; Abbaspour, 2007; Rogers, 2007). However, achieving an optimal balance among diverse criteria—aesthetics, environmental sustainability, cost-effectiveness, technical feasibility, and urban compatibility—remains a central challenge (Ghodsipour, 2006). Although global research on sustainable facades is extensive, context-specific assessments that rigorously integrate local climatic data, urban fabric constraints, and crucially, socio-cultural stakeholder priorities remain scarce, particularly for cities like Tabriz exhibiting such distinct characteristics. This study directly addresses this gap. Multi-Criteria Decision-Making (MCDM) methodologies provide structured, transparent frameworks ideal for tackling such complex decision problems

[*] Corresponding author, E-mail: m_ghoddusi@yahoo.com

https://doi.org/10.31462/icearc2025_a_urb_392

(Zavadskas et al., 2024; Cinelli et al., 2022). Therefore, this research develops and validates an optimal sustainable facade selection framework tailored for low-rise residential buildings (<10 stories) in Tabriz (District 1), utilizing an integrated approach combining the Analytic Hierarchy Process (AHP) and the Technique for Order of Preference by Similarity to Ideal Solution 1 (TOPSIS), augmented by energy simulation. The novelty of this work lies in its specific application to the under-researched Tabriz context, its integration of quantitatively assessed local stakeholder priorities (particularly the high value placed on aesthetics and context) with objective performance data, and the resulting provision of localized, actionable recommendations.

2. Materials and Methods

This study employed a sequential mixed-method design integrating expert surveys, MCDM modeling, and building energy simulation. The overall process of this research is shown in Fig. 1 as a flowchart.

2.1. Criteria and Alternatives Identification

Nine key evaluation criteria pertinent to facade sustainability within the Tabriz context were systematically identified: Energy Consumption (-), Aesthetics (+), Compatibility with Urban Architecture (+), Environment/Sustainability (+), Cost (-), Implementation Time (-), Maintenance (-), Contractor Skill (+), and Ease of Procurement/Execution (+). Fourteen representative facade systems were evaluated: Natural Stone, Natural Stone Composite, Artificial Stone, Glass Curtain Wall, Aluminum Composite Panel, Bayramix, Ceramic Tile, Brick, Monolithic Cement Render, Standard Cement Render, Expanded Metal Mesh, Timber Cladding, Green Facade, and Smart (Adaptive) Facade.

2.2. Data collection

Data collection involved literature synthesis, review of relevant official reports and standards, and field surveys. Structured questionnaires and interviews were conducted with 71 purposively selected local experts (architects, developers, contractors, municipal officials) to elicit judgments on criteria importance and alternative performance.

2.3. MCDM Framework

The synergistic application of AHP and TOPSIS was chosen for its suitability. AHP effectively handles the hierarchical structuring of the decision problem and captures subjective expert judgments for criteria weighting. TOPSIS provides a rational and practical method for ranking alternatives based on multi-attribute performance relative to ideal solutions. This combined AHP-TOPSIS methodology is well-established for complex selection problems in building design and engineering (Jagarajan et al., 2020; Zavadskas et al., 2024).

2.3.1. Analytic Hierarchy Process (AHP)

AHP was employed to derive the relative weights of the nine criteria. Pairwise comparisons were gathered from 71 experts (using Saaty's 1-9 scale (Saaty, 1980)), aggregated using the geometric mean, and consistency-checked (CR = 0.08). Expert Choice software was utilized.

2.3.2. Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS)

TOPSIS was utilized to rank the 14 facade alternatives. The decision matrix integrated AHP weights with performance scores derived from expert ratings and supplementary quantitative data (e.g., energy simulation outputs, cost estimates). Standard TOPSIS calculations were performed using MS Excel.

2.4. Energy Simulation (Supporting Analysis)

Building energy simulations (Design Builder/EnergyPlus; PHPP) were conducted to provide objective, quantitative data for the 'Energy Consumption' criterion and to support cost-benefit analysis. A representative residential typology for Tabriz was modeled to compare baseline performance against an optimized case (aligned with Iranian National Building Regulations [NBR] Topic 19) and evaluate relative energy demands of different facade systems.

2.5. Data Analysis Tools

Software utilized included SPSS (descriptive statistics), Expert Choice (AHP), MS Excel (TOPSIS), Design Builder, and PHPP (Energy Simulation).

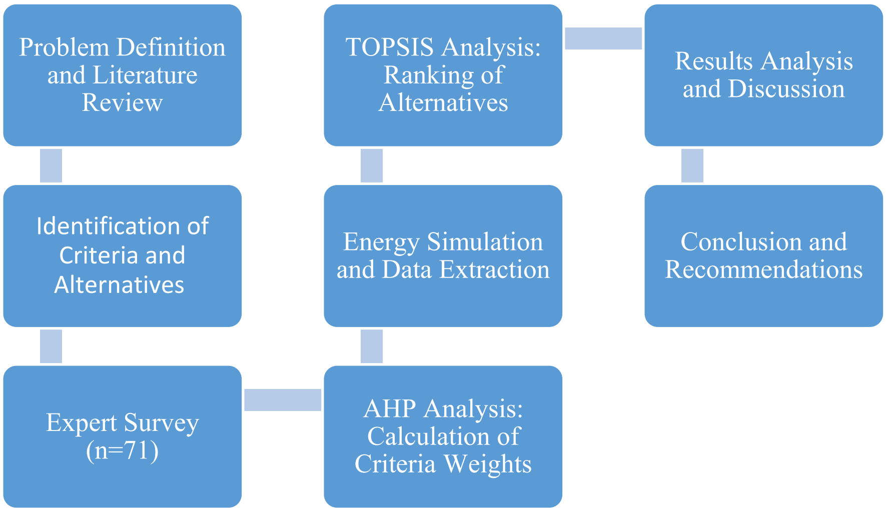

Fig. 1 Research methodology flowchart

3. Results and Discussion

The integrated analysis yielded pertinent insights into sustainable facade selection dynamics in Tabriz.

3.1. AHP Results: Criteria Weights

The results from the AHP analysis, which determine the final weights and relative importance of the nine facade evaluation criteria, are summarized in Table 1. As clearly shown in this table, local experts and stakeholders assigned the highest priority to 'Compatibility with Urban Architecture' (TM) with a relative weight of 0.186 and 'Aesthetics' (Z) with a weight of 0.177. This finding indicates the paramount importance of preserving the city's visual and cultural identity alongside the facade's appearance for the local community. Following these two, 'Environment/Sustainability' (MZ) with a weight of 0.156 and 'Maintenance' (TN) with a weight of 0.137 hold the next ranks of importance, reflecting attention to long-term performance and sustainability aspects. Conversely, criteria such as 'Implementation Time' (ZE) with a weight of 0.033 and 'Ease of Procurement/Execution' (ST) with a weight of 0.050 had the lowest importance from the participants' perspective. This weighting emphasizes that in the specific context of Tabriz, cultural-visual and long-term sustainability considerations take precedence over purely executional or initial cost (H with a weight of 0.094) factors.

Table 1. AHP Criteria Weights (Final values based on analysis)

Row	Criterion	Abbreviation	Final Weight
1	Compatibility with Urban Architecture	TM	0.186
2	Aesthetics	Z	0.177
3	Environment & Sustainable Dev. Principles	MZ	0.156
4	Maintenance	TN	0.137
5	Energy Consumption	ME	0.104
6	Cost	H	0.094
7	Technical Ability & Contractor Exp.	TP	0.062
8	Ease of Procurement & Execution Method	ST	0.05
9	Implementation Time	ZE	0.033

3.2. TOPSIS Results: Facade Option Ranking

Table 2 presents the final ranking results for the 14 facade alternatives using the TOPSIS method based on the criteria weighted by AHP (shown in Table 1). This ranking is also depicted graphically in Fig. 2 to facilitate visual comparison of the scores. The results (clearly observable in both Table 2 and Fig. 2) indicate that 'Smart Facade' with the highest CLi value (0.8872) was identified as the most preferable and optimal option for Tabriz conditions (considering all criteria). Following that, 'Green Facade' ranked second with CLi=0.7945. These high rankings demonstrate the superior overall performance of these two innovative systems across the multiple evaluated criteria. In the subsequent ranks, stone-based systems (composite with CLi=0.668, artificial with CLi=0.6541, natural with CLi=0.5823) and brick (CLi=0.5756) were placed, indicating the relative acceptability of traditional and common materials in the region. At the bottom end of the spectrum, as specified in Table 2 and Fig. 2, 'Standard Cement Render' ranked as the least desirable option within this evaluation framework with the lowest CLi value (0.175).

Table 2. TOPSIS Final Ranking and Relative Closeness (CLi) Values

Rank	Facade Alternative	CLi Value
1	Smart Facade	0.8872
2	Green Facade	0.7945
3	Natural Stone Composite	0.668
4	Artificial Stone	0.6541
5	Natural Stone	0.5823
6	Brick	0.5756
7	Aluminum Composite Panel	0.5217
8	Bayramix	0.5217
9	Timber Cladding	0.5207
10	Glass Curtain Wall	0.5203
11	Monolith Cement Render	0.4667
12	Ceramic Tile	0.4239
13	Expanded Metal Mesh	0.3564
14	Standard Cement Render	0.175

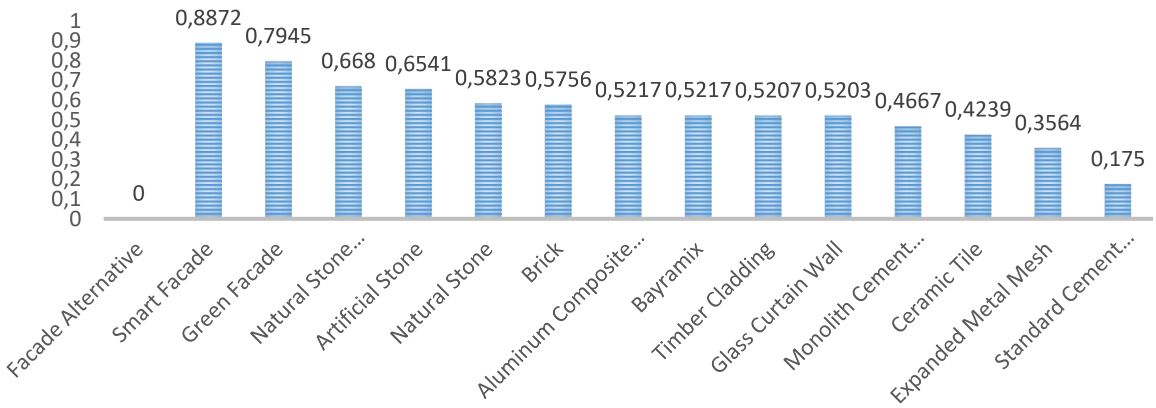

Fig. 2 Final ranking of facade alternatives based on TOPSIS (CLi) scores

3.3. Energy Simulation and Cost-Benefit Insights

To quantitatively investigate one of the key criteria, 'Energy Consumption', and also to support the cost-benefit analysis, energy simulations were performed. Table 3 presents the comparative results of annual energy consumption (disaggregated into heating and cooling, then summed) for selected facade types under Tabriz climatic conditions. This comparison is also graphically illustrated in Fig. 3. These results clearly show a very significant difference in the energy performance of various facades. As seen in Table 3 and Fig. 3, 'Smart Facade' (total annual consumption 50 kWh/m²) and 'Green Facade' (60 kWh/m²) exhibited the lowest predicted energy consumption, confirming their excellent performance in energy optimization. Conversely, common options like 'Glass Facade' (210 kWh/m²/year) and 'Standard Cement Render' (150 kWh/m²/year) (whose stark difference is also evident in Fig. 3) show considerably higher energy consumption, highlighting the need to move towards more efficient alternatives. These simulation findings strongly support the high ranking of smart and green facades in the TOPSIS analysis from an energy performance perspective. In addition to the comparison between facades, simulation results indicated significant energy saving potential (approx. 30 GJ/year) through basic facade upgrades (insulation, better glazing, shading) compared to a baseline case without these measures. The preliminary cost-benefit analysis based on these savings (using 2019 cost data) suggested an approximate five-year payback period for investments in these energy efficiency measures, indicating the favorable medium-term economic justification for such upgrades.

Table 3. Comparative Simulated Energy Consumption by Facade Type (kWh/m².year)

Facade Type	**Heating Energy (kWh/m².year)**	**Cooling Energy (kWh/m².year)**	**Total Energy (kWh/m².year)**
Smart (Adaptive) Facade	35	15	50
Green Facade	40	20	60
Double Skin Facade	45	25	70
Timber Cladding	60	40	100
Composite Panel	65	45	110
Stone Facade	70	50	120
Brick Facade	75	55	130
Cement Facade	85	65	150
Glass Facade	120	90	210

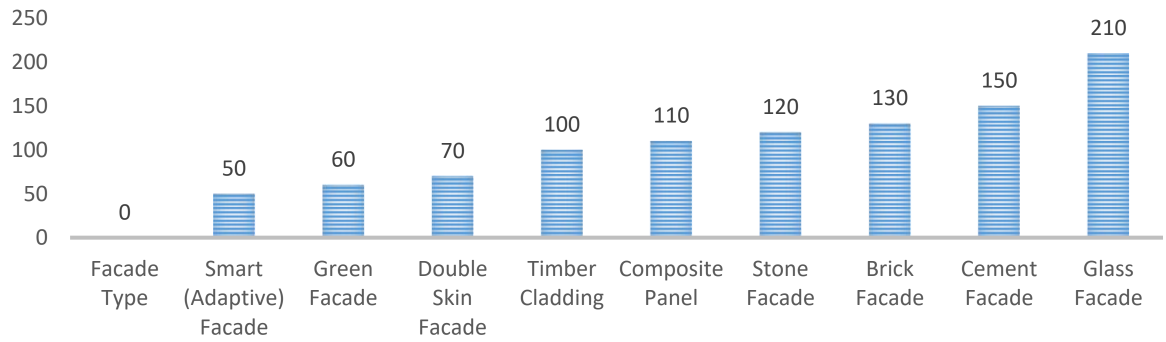

Fig. 3 Comparative total annual energy consumption for different facade types in Tabriz climate

3.4. Discussion

The study findings strongly advocate for adopting a holistic, context-sensitive strategy for sustainable facade selection in Tabriz. The superior ranking of smart and green facades aligns with international findings on their capacity for enhanced energy performance and broader environmental advantages (Favoino et al., 2020; Jim, 2021). The adaptability of smart facades allows for optimized responses to varying conditions (Tabadkani et al., 2021), while green facades offer valuable passive cooling and ecological benefits (Hopkins et al., 2022). Their top ranking confirms their potential suitability for Tabriz, contingent on addressing specific implementation and maintenance factors locally.

A key finding contributing to the novelty of this study is the pronounced importance assigned to 'Compatibility with Urban Architecture' and 'Aesthetics' by Tabriz stakeholders. This provides novel insight into regional priorities, potentially diverging from purely techno-economic or globally standardized environmental assessments (e.g., focusing solely on metrics like embodied carbon; cf. Pomponi & Moncaster, 2018; Shafiee et al., 2022). It highlights that sustainable solutions in culturally rich contexts like Tabriz must integrate socio-cultural values alongside technical performance. The economic analysis, while preliminary, supports the financial feasibility of adopting higher-performance facades (cf. Islam et al., 2019 on LCCA). The methodological contribution lies in the successful integration of subjective local priorities (via AHP) with objective performance data (simulations informing TOPSIS), creating a balanced and robust decision-support framework specifically validated for the Tabriz residential context.

4. Conclusions

This research successfully developed, applied, and validated an integrated MCDM framework (AHP-TOPSIS) coupled with energy simulation to optimize sustainable facade selection for residential buildings in Tabriz. It offers a structured, context-sensitive methodology that systematically balances diverse criteria reflecting local conditions and stakeholder values.

Key conclusions are:

- Tabriz stakeholders prioritize contextual compatibility and aesthetics alongside environmental performance and maintenance in residential facade selection.
- Smart (adaptive) and green facade systems emerge as the most advantageous solutions overall for Tabriz, based on a multi-criteria assessment incorporating local priorities and simulated performance.
- Investments in energy-efficient facade systems demonstrate economic viability within an approximate 5-year payback period, supporting their adoption.

This study's principal contribution lies in delivering a validated, context-specific MCDM framework for sustainable facade selection in Tabriz, uniquely integrating quantitatively assessed local stakeholder priorities with technical and environmental performance metrics. This provides a significant advancement over generic or purely technical assessments for this specific regional context. The findings offer practical, evidence-based guidance for stakeholders. Limitations include reliance on expert judgment and scope constraints. Future research should prioritize detailed Life Cycle Assessment (LCA) and Life Cycle Cost Analysis (LCCA) for the top-ranked systems, investigate locally adapted, cost-effective smart/green facade prototypes suitable for Tabriz's climate and construction practices, and potentially integrate post-occupancy evaluation feedback into the framework.

Acknowledgments

The authors sincerely thank the experts and stakeholders in Tabriz whose participation provided invaluable data and insights for this research.

[2] Bursa Technical University, Department of Architecture and Design, 16310 Bursa, Türkiye.

Abstract. Globalisation has accelerated production and consumption dynamics in Istanbul, driving spatial transformations, constant demolition, and the infill of urban voids. These rapid changes reduce the time individuals spend experiencing urban spaces, fragmenting spatial perception and preventing the full registration of transformation processes in memory. Consequently, a phenomenon of "forgetting" emerges. The discontinuity of memory spaces weakens spatial memory, deepening this condition. This paper examines the notion of "forgetting" within the context of global capital's large-scale urban projects, focusing on the Beyoğlu-Bomontiada industrial heritage site as a space resisting the temporal pressures of transformation. Through on-site analysis, the physical, functional, and socio-spatial structures of Bomontiada will be examined to visualise the impact of its transformations on spatial and temporal perception. The conversion of the historic brewery and its surrounding structures, along with shifts in temporal perception, will be documented through qualitative content analysis. The various manifestations of "forgetting" observed in the site will be analysed in relation to their effects on collective memory and spatial outcomes. The study will employ written, visual, and digital sources, including reports, official documents, newspapers, archival records, news websites, and social media databases. The findings will contribute to a deeper understanding of the interaction between urban interventions and memory spaces, offering insights into strategies for safeguarding spatial memory in future urban developments.

Keywords: Memory, Bomontiada, Places of Memory, Globalizing Istanbul, Forgetting

1. Introduction

The Bomonti district is one of the central, lively, cosmopolitan and oldest districts of Istanbul. It is a region that has undergone transformation through the city's cultural and artistic industries. It has significant importance as one of the most important private factory initiatives in Türkiye's economic history. The name Bomonti comes from the Bomonti Beer Factory, founded by the Bomonti brothers in 1890. It was named after the Bomonti Beer Factory, and also earned the nickname "Chocolate Scented Neighborhood" due to the Nestlé factory (Toprak & Hacihasanoglu, 2025). Bomonti has undergone significant changes driven by political policies, economic and spatial interventions from past to present.

Globalization is a comprehensive transformation process characterized by the acceleration of social, cultural and economic interactions. The acceleration of globalization and urbanization processes profoundly reshapes the social, economic and spatial structures of contemporary cities. In large metropolises like Istanbul, this transformation leads to the intensification of production and consumption dynamics, the continuous restructuring of urban space and the reuse of urban spaces with new functions. This intense and ongoing change affects not only the physical environment but also the way individuals relate to the city and the formation of urban collective memory.

The distinguishing feature of collective memory is its repetitive dynamic structure that forms within the ordinariness of daily life and maintains a sense of continuity with the past (Halbwachs, 2020), (Çolpan, 2017). This dynamic structure reveals that collective memory is not static, but rather a constantly reshaped process affected by changing social conditions. Today's city dwellers tend to establish shorter and more superficial relationships with places due to the acceleration of life and spatial discontinuities, which reduces the possibility of these places settling in memory. In the context of temporal compression and shallow experiences, both individual and collective memory have difficulty establishing a connection with urban space, which leads to the disruption of memory formation. In cities like Istanbul, which are open to constant change and intervention, this phenomenon weakens the continuity of memory spaces and triggers a collective state of 'forgetting' at the urban scale.

https://doi.org/10.31462/icearc2025_a_urb_468

Capital-driven large-scale projects and megastructures often erase the existing urban fabric and integrate new functions, architectural typologies and perceptions of time into urban life. This transformation sometimes clashes with historical layers, sometimes makes them invisible and erases the traces of the past. Bomontiada, located in the Bomonti district of Şişli, Istanbul, is a strong example in this context. The transformation of the old Bomonti Beer Factory, once a symbol of industrial production, into a cultural complex has led to a significant change in both its functional and socio-spatial context, despite preserving its physical structure. This study aims to examine the effects of urban transformation on the relationship between place, time and memory through the example of Bomontiada. By investigating the 'states of forgetting' observed during the transformation of the area, it will analyze the existence of industrial memory from the past in the new context surrounded by contemporary megastructures. In this context, qualitative content analysis based on visual and digital sources will be used to reveal the effects of spatial discontinuities in the city on collective memory. The research aims to develop a critical perspective on how spatial memory can be reconstructed or preserved within the rapidly changing urban structure of Istanbul and to contribute to a broader discussion on the relationship between memory, space and time.

2. Conceptual Framework: The Concepts of Memory and Forgetting

2.1. Memory

The concept of memory has been the subject of many thoughts and studies since ancient times. Memory is individual, but it cannot exist independently of society. It is the mental space in which a person preserves all the conditions, images, and information experienced throughout their life by passing them through the perceptual filter of their senses (Bartoletti, 2011). Memory, the most important tool for carrying the traces of the past into the present, is one of the key factors that both shapes and influences individual and collective consciousness (Orianne & Eustache, 2023). Memory is not a simple record of the past, it is a reconstructive process that continues in the present as a dual operation of the past (Cubitt, 2013).

Memory is defined not merely as a neurological function, but as a sociological concept. Like emotions, memory is a phenomenon that can be experienced and is influenced by its surroundings. It can be seen as a reflection of personal, cultural, psychological, neurological, political, religious, social, and ethical influences. The understanding of time resulting from a person's inner experience and life's encounters forms memory. Since memory involves the evocation of past perceptions that resemble everyday perception, selecting images and impressions from them, it can be said that memory has the characteristic of being shaped by experiences within the ongoing flow of the present (Zafer, 2019).

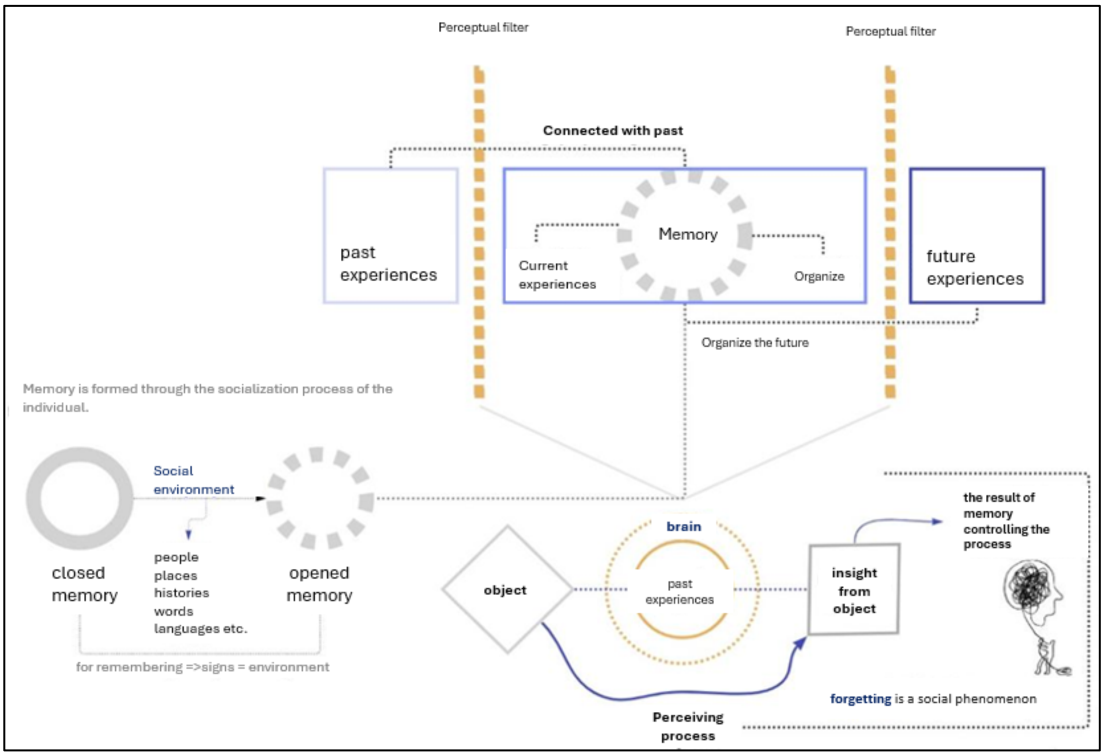

Fig. 1. Functioning of memory diagram

The concept of collective memory emerges from the influence of society on individual memory. Individual memory is not separate from society and its shared memory. In the broadest sense, collective memory refers to the memories shaped by the societies and cultures in which individuals live (Whitehead & Rossington, 2007). Collective memory is an image of the past and allows the group to recognize itself through a series of collective images (Hutton, 1988). Society and environment are the key actors in the formation of memory. Based on the connection of the memory concept with the past, it would not be wrong to say that collective memory is also connected to the past of society. In this case, the memory that emerges consists of the shared memories of society (Wertsch, 2009). In this way, the concept of collective memory is defined by its mediating role between individuals who make up society and across different periods of time. It has been stated that collective memory has a dimension that can reach individuals through the life experiences of a person and their contemporaries. Based on this, it can be said that the concept of collective memory also involves the collective retrieval of the past through remembering and its disappearance through forgetting. Through Remembering/Forgetting, collective memory continues its existence by constantly redefining and producing itself. Fig. 1 shows the functioning of memory.

2.2. Memory- Time- Place Relationship

The concepts of collective memory and place are closely connected. While memory originates from individual experiences, it becomes collective through sharing in public places. The actors who construct collective memory encounter and interact within physical place. The actors hold a spatial dimension because they shape the social reality of the present moment and represent the past by externalizing it once again (Kansteiner, 2002). Fig. 2 presents the connection between memory, place, and experience.

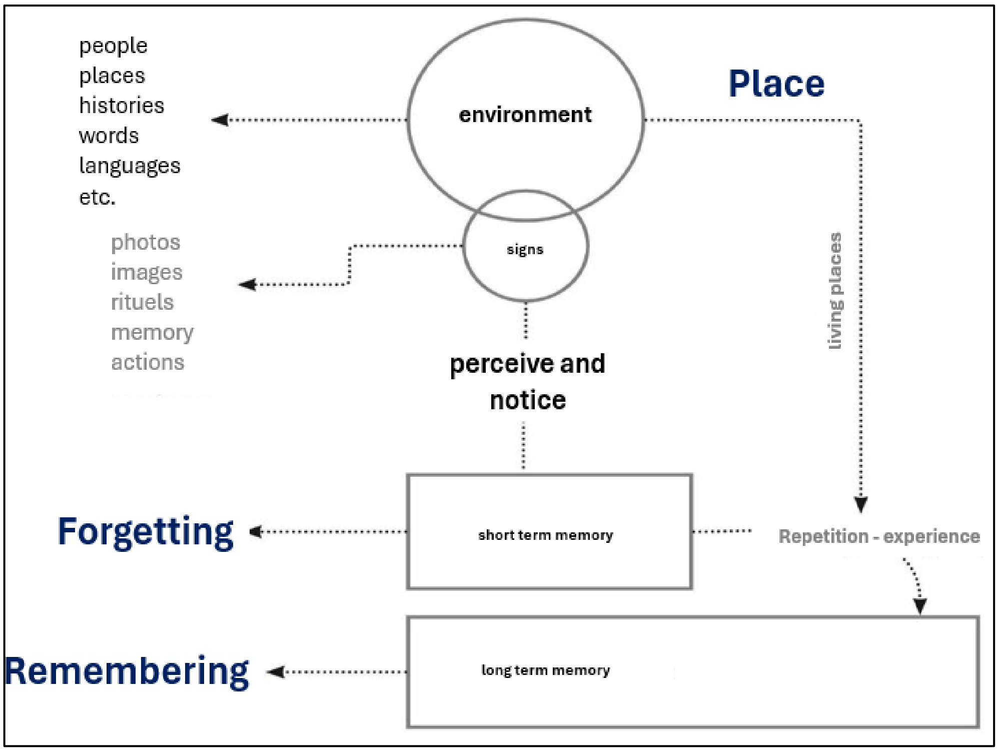

Fig. 2. Memory-Place-Experience diagram

Similar to memory, space acquires significance through lived experience. Architectural structures are socially constructed and reinterpreted through the ways they are experienced by individuals and communities (Lefebvre, 1991, 2014). When buildings are socially experienced, they are continuously reinterpreted and reproduced. For a space to become a "place," it must be nourished over time by memories. This makes memory and space inseparable concepts. Collective memory depends on space, and this relationship is clearly observable. As the concept of speed enters the equation, the boundaries of time expand, perceptions shift, and the interactions that shape memory begin to transform. In this process, the phenomenon of forgetting becomes more prominent.

3. States of forgetting in Bomontiada and its surroundings

The act of forgetting occurs as a result of insufficient time being dedicated to the historical layers and experiences of the city and its inhabitants. Several factors contribute to the act of forgetting. Urban policies, interventions in urban space, technology, transformations in human life, metropolitan living, transportation, socio-cultural conditions, and habits all influence the passage of time, and in turn, the speed at which it changes. This speed alters our perception of time and space. Due to the variety of factors that affect speed, there are also various forms of forgetting. We typically read the history of the city within a previously established framework; however, as identities shift, this situation manifests as urban or historical amnesia, or memory loss. Amnesia occurs involuntarily and refers to individual forgetting, while societal forgetting is a dimension that can be organized (Kankal, Akpınar, Kömürcü & Özşahin, 2011). The situation described in Akpınar's definition refers to the displacement of identities in line with urban political policies, as well as the destruction, transformation, and changes that occur in order to control urban life or guide city dwellers. These actions may lead to organized amnesia, or forgetting, resulting from such interventions. Fig. 3 shows the contexts in which states of forgetting emerge.

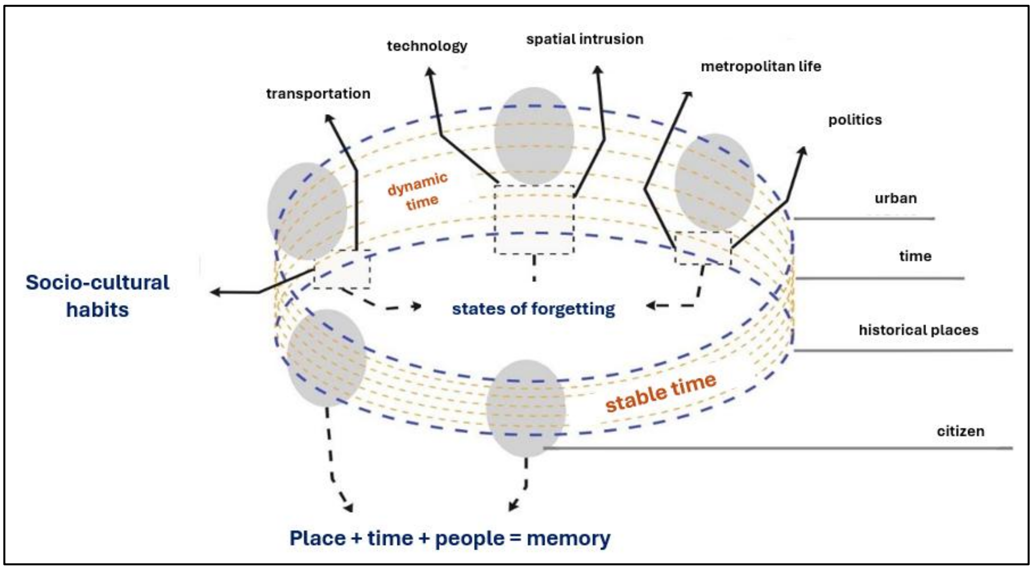

Fig. 3. The gaps in which states of forgetting

In 1890, Bomonti was a rural area on the outskirts of Istanbul. With the industrialization policies of the Ottoman Empire, along with the Brewery, industrial buildings increased, and this area became an industrial zone (Kaya & Arıkan, 2009). Although it continued as an industrial zone until the 2000s, with the influence of neoliberal policies and the privatization initiatives that began in Turkey, factories closed or moved to the city's new outskirts. As a result of this transformation, the industrial area changed into residential and commercial spaces. Due to its location and the vast empty spaces created after the relocation of factories, the area became highly valuable for urban transformation. The value of the land, particularly for new housing, is significant. One of the vacant spaces is the Bomonti Brewery itself. Although it was placed under protection in 1998, it remains an excellent location for urban transformation. Therefore, in 2010, the brewery area underwent a restoration process as part of a cultural transformation project and began operations in 2015 under the name Bomontiada, functioning as a hotel, entertainment, and cultural center (Mert-Travlos, 2021).

The Bomonti neighborhood, with its transformations and changes, is a site rich in layers of collective memory, where each layer is still visible and can be read alongside new layers. This makes it a valuable area for memory studies. Its location is also easily accessible and offers a safe environment for its users. With all these characteristics, it has been chosen as our study area. The research problem addresses the act of forgetting, which will be analyzed within the context of Bomontiada, aiming to identify the states of forgetting. Bomontiada, being a continuously evolving space both functionally, socio-culturally, and spatially, contains multiple aspects of forgetting. To identify the states of forgetting in Bomontiada and its surroundings, key breaking points throughout its history have been mapped and analyzed, as shown in Fig. 4a and 4b. Referring to our diagram of the states of forgetting, it has been determined that the act of forgetting in Bomontiada and its surroundings is shaped by political policies, demographic changes, and spatial interventions, as depicted in the Fig..

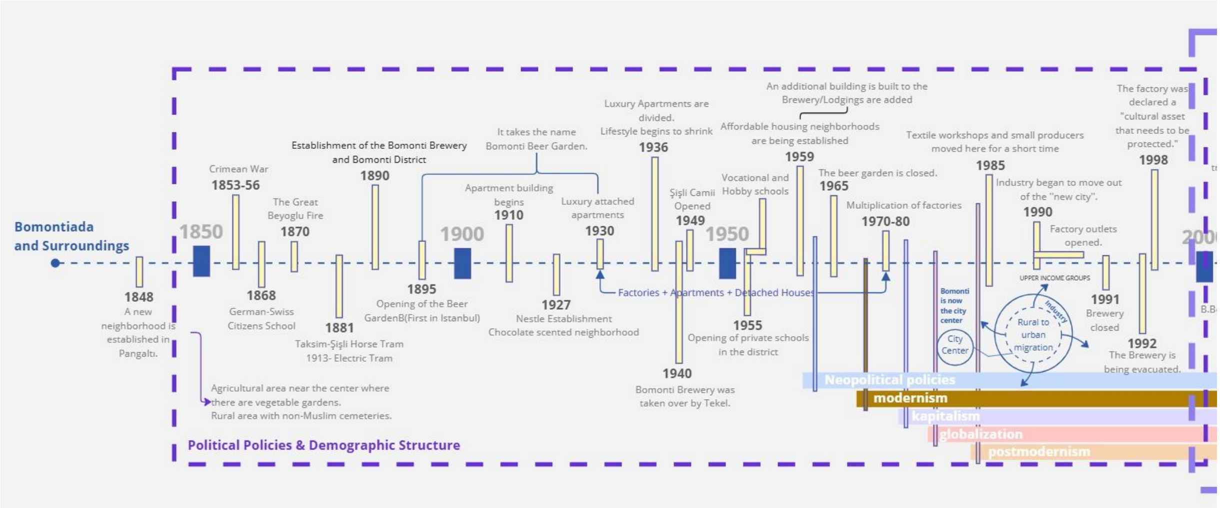

Fig. 4a. Breaking Points in history for Bomontiada and its surroundings

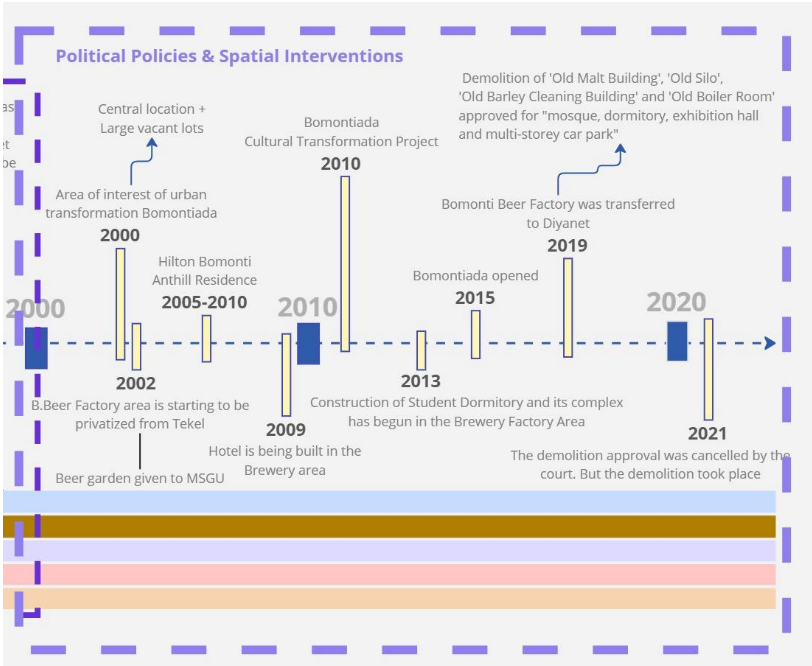

Fig. 4b. Breaking Points in history for Bomontiada and its surroundings

3.1. States of Political Policies and Demographic Structure

3.1.1. 1850-1950 Industrialization Period

Thanks to the industrialization policies of the Ottoman Empire in the second half of the 19th century, the Bomonti brothers obtained a concession to open a factory in Istanbul (Çelik, 1993). The establishment of the Bomonti Brewery is directly linked to these industrialization policies (Kaya & Arıkan, 2009) The policies played a key role in the creation and identity of the Bomonti neighborhood. Following the Crimean War (1853-1856), many foreigners settled in Istanbul, especially in the rural outskirts like Bomonti. Bomonti was established by Levantines, and evidence of this can be seen in the non-Muslim cemeteries in the area. The Bomonti Brewery opened in 1891 as a Brewery and Nectar Factory (Keyder & Quataert, 1994). A new way of life based on production was adopted, and the area became both an industrial hub and a multicultural neighborhood. Socio-economic diversity and a strong sense of belonging based on production were prominent. As industrialization spread across Turkey, a large migration from rural areas to Istanbul took place. Bomonti became an attractive destination for the new working class. Neighborhood culture, solidarity, and class unity grew stronger (Özden, 2024). In 1926, a state alcohol monopoly was introduced, and the Bomonti Brewery continued operations under a

Turkish-Joint Stock partnership. In 1938, the factory was closed for two years, and in 1940, Tekel took full control. Fig. 5 shows key events from this period.

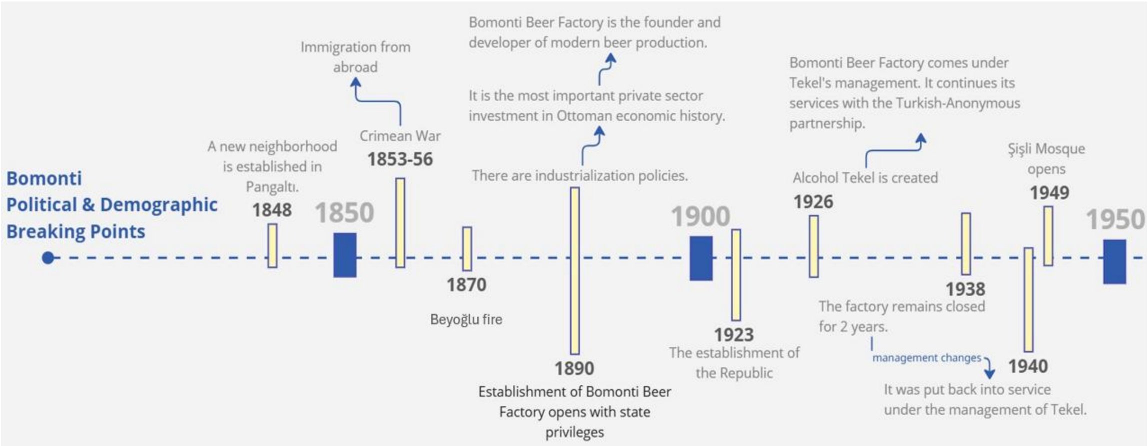

Fig. 5. 1850-1950 Political and demographic breakthroughs

3.1.2. 1950-2000 Neoliberal Policies and Deindustrialization

Until the 1980 coup, Bomonti remained an industrial area, but after the coup, neoliberal policies began to take hold and their impact increased (Mert-Travlos, 2021). In 1984, deindustrialization policies were adopted, and major institutions became dysfunctional. Turkey experienced an economic crisis, and the Bomonti Brewery closed in 1992. With the growing influence of neoliberal policies and the decline of industry, job losses began to rise (Şenses, 2012). The buildings became old and neglected, rents increased, and the neighborhood culture started to weaken. This period is marked by economic decline and spatial degradation. However, despite all these changes, Bomonti has continued to be a preferred neighborhood due to its proximity to central locations, safe community environment, and cultural activities. Fig. 6 shows the key events that occurred during this period.

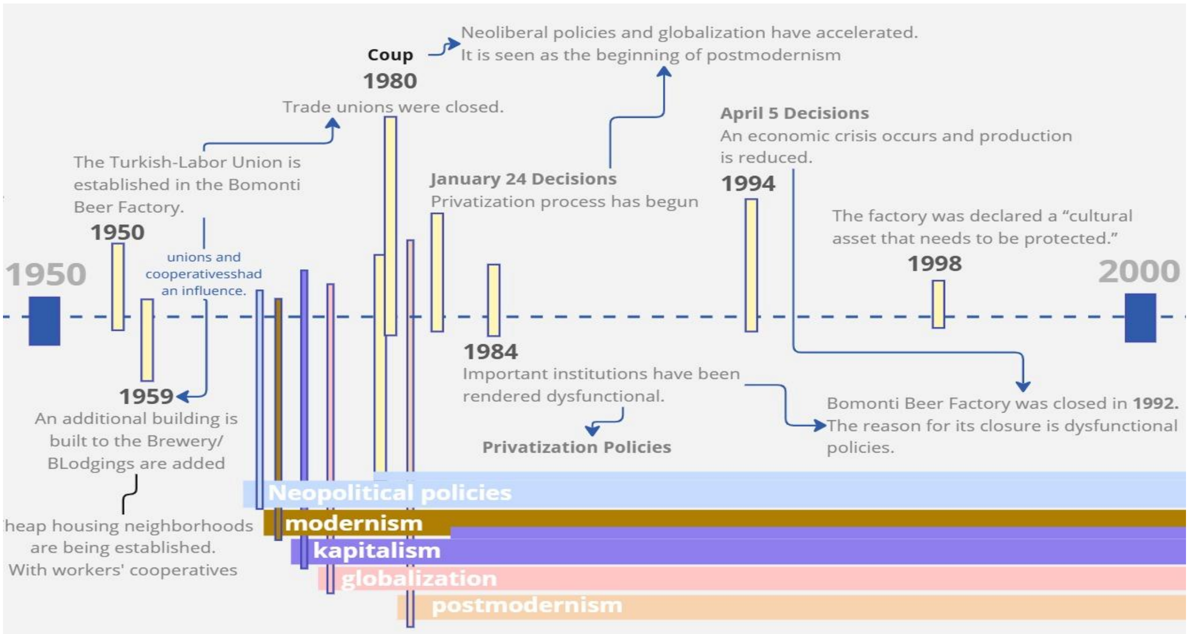

Fig. 6. 1950-2000 Political and demographic breakthroughs

3.1.3. 2000-2025 Gentrification and Globalization

After the 2001 economic crisis, the impact of globalization began to grow in Turkey. Urban transformation projects started, and the Bomonti area began to increase in value. The factories became a significant opportunity for gentrification and urban renewal (Guven, 2017). Old working-class families have been replaced by young professionals and investors, marking the first strong wave of gentrification in the area (Paton, 2016). By 2015, with the opening of Bomontiada and the surrounding hotel and residential projects, Bomonti transformed into a global investment hub. The neighborhood now hosts: foreign residents (especially individuals from creative industries), high-income professionals, and short-term rental groups for tourism purposes (Garay-Tamajón, Lladós-Masllorens, Meseguer-Artola, & Morales-Pérez, 2022). The area has transformed from a production zone into a consumption zone. This change has led to shifts in spatial practices and user identities, ultimately resulting in the disruption of urban memory. Fig. 7 illustrates the key events that occurred during this period.

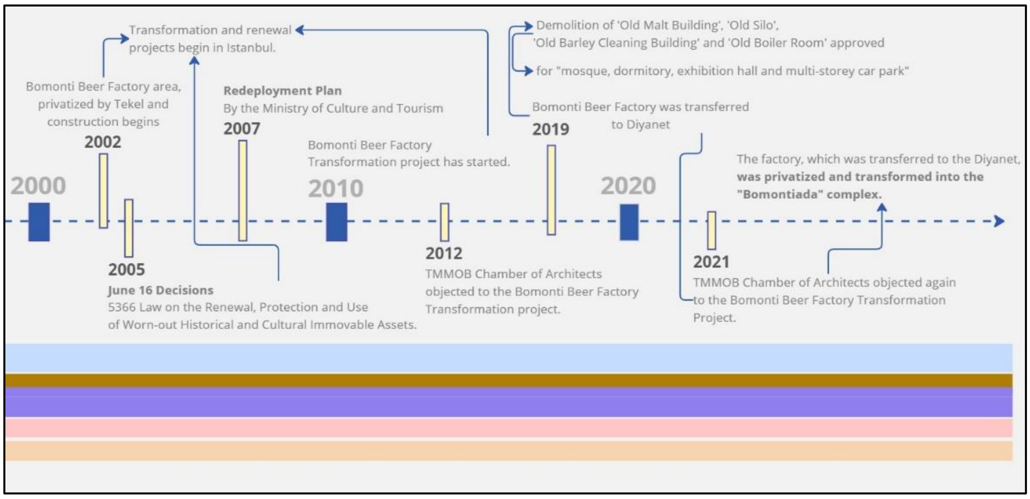

Fig. 7. 2000-2025 Political and demographic breakthroughs

3.2. Spatial transformation analyses in Bomontiada and its surrounding

3.2.1. Spatial Intervention
Space is not only a physical entity but also a carrier of social relations, everyday life practices, and collective memory (Lefebvre, 1991, 2014). However, when interventions in space, especially those driven by global capitalist dynamics and large-scale developments, occur, this carrier function can be disrupted (Harvey, 2008). The Bomonti neighborhood in Istanbul provides a characteristic example of this process. Historically associated with industrial production and neighborhood culture, Bomonti has undergone significant transformation in the last thirty years due to spatial interventions, leaving permanent marks on urban memory. This urban transformation is shown in Fig. 8.

Fig. 8. The spatial condition resulting from urban transformation. (IBB 3D City Planning website, Kovanlıkaya, Ç., Fırat, D., Yılgür, E., Aslan, Ş., & Özarslan, A. D. (2021)).

This transformation process has not only involved the reorganization of the physical environment but also weakened the emotional and historical connections that urban dwellers have with the space. The disruption of spatial continuity interrupts the experiences accumulated over time, causing perceptions of the past to blur and the memory of the place to fade. As a result, the relationship between time and space becomes superficial, and the space transforms into something "forgotten" rather than "reminiscent." (Boyarin, 1994). In the case of

Bomontiada, the transformation of places bearing traces of industrial heritage into cultural consumption spaces leads to the suppression of historical context and the gradual weakening of the collective memory of the place. As a result of this transformation, the continuity of urban memory is disrupted, and the meaning of the place becomes detached from its historical context. Another example is the Bomonti Brewery Garden, located adjacent to the Bomonti Brewery, a space where workers and neighborhood residents socialized and integrated into daily life (Turhan, 2018). This area has since been transformed into a cultural heritage site and is now used as a university building, currently home to Mimar Sinan University. The space has ceased to be a public area, and one of Bomonti's most significant social memory sites has vanished. As it is now used as an educational building, the most important memory space of the Bomonti district has been forgotten. Fig. 9 shows the Bomonti Brewery Garden past and present.

Fig. 9. Bomonti Brewery Garden Transformation (Kovanlıkaya, Ç., Fırat, D., Yılgür, E., Aslan, Ş., & Özarslan, A. D. (2021) , Google Search).

3.2.2. Construction in Bomontiada and its surrounding

The first traces of construction in the Bomonti area began to emerge in the 1860s with the establishment of the Bomonti Brothers' beer factory. This industrial structure became not only an economic production site but also a place where working-class neighborhoods were formed (Bellamy, 2019).

By the 1920s, the residential fabric, religious buildings, educational institutions, and small-scale commercial units that developed around the area allowed Bomonti to create a unique collective memory. The construction during this period strengthened the spatial identity and created reference points that became embedded in the memory of the city's inhabitants (Boyer, 1994). In the early 2000s, the privatization and sale of public lands disrupted the spatial continuity of Bomonti for the second time (Keyder, 2005). The transfer of the Bomonti Factory land to private investors weakened the representation of production areas within collective memory and caused the space to lose its sense of being "public."

In the 2010s, the Bomontiada project, which transformed the old factory structure into a cultural, artistic, and entertainment space, led to a third transformation in the identity of the place. While the cultural use may appear to claim "memory preservation" on the surface, the representation of the space's production history has, in fact, been reduced to a mere stage set (Erdoğan, 2013). The production history has been reconstructed within the framework of consumption-driven activities and the experience economy. At the same time, the construction of mega structures such as the Hilton Bomonti Hotel, Anthill Residences, and Spine Tower around the Bomonti area has dramatically changed the spatial scale of the neighborhood (Shatkin, 2017).

These massive structures, which are incompatible with the neighborhood fabric, have caused both physical and perceptual scale disruptions. The horizontal continuity of everyday life has been replaced by a vertical and fragmented urban experience. After 2020, Bomontiada and its surroundings have become heavily commercialized and turned into a tourist destination (Zukin, 1995). Cultural activities have been replaced by consumption-focused festivals, and branded events. This process has further led to the erasure of local cultural practices and traces of 0everyday memory. Fig. 10 shows the map of construction from the past to the present.

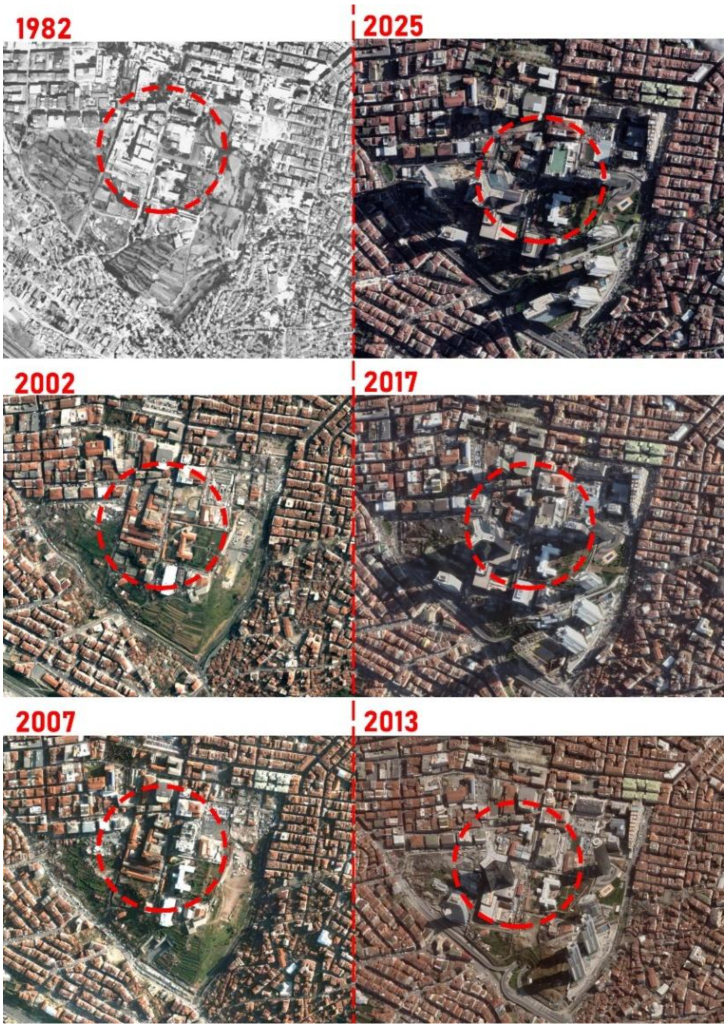

Fig. 10. Construction Maps from Past to Present (Google Maps).

As a result, the fragmentation of the neighborhood fabric has led to the loss of the multilayered meanings the space carried from the past to the present. The emergence of dysfunctional areas within the same street that cannot relate to each other has disrupted users' sense of continuity with the space. This transformation affects not only the physical environment but also the memory connections established with the space. While this transformation causes the region's cultural identity to be forgotten, it also weakens users' sense of spatial continuity and belonging.

4. Bomontiada Among Megastructures

Symbolic structures, one of the carrier elements of urban memory, are architectural and historical elements that form the identity of a place and add meaning to the collective experiences of city dwellers. Bomontiada, which has an industrial production center in Istanbul, has gained a strong place in urban collective memory with its ymbolic value. The old and new states of this symbolic structure are shown in Fig. 11 and Fig. 12.

Fig. 11. The Old and New Forms of Symbolic Structures (Kovanlıkaya, Fırat, Yılgür, Aslan & Özarslan, 2021)

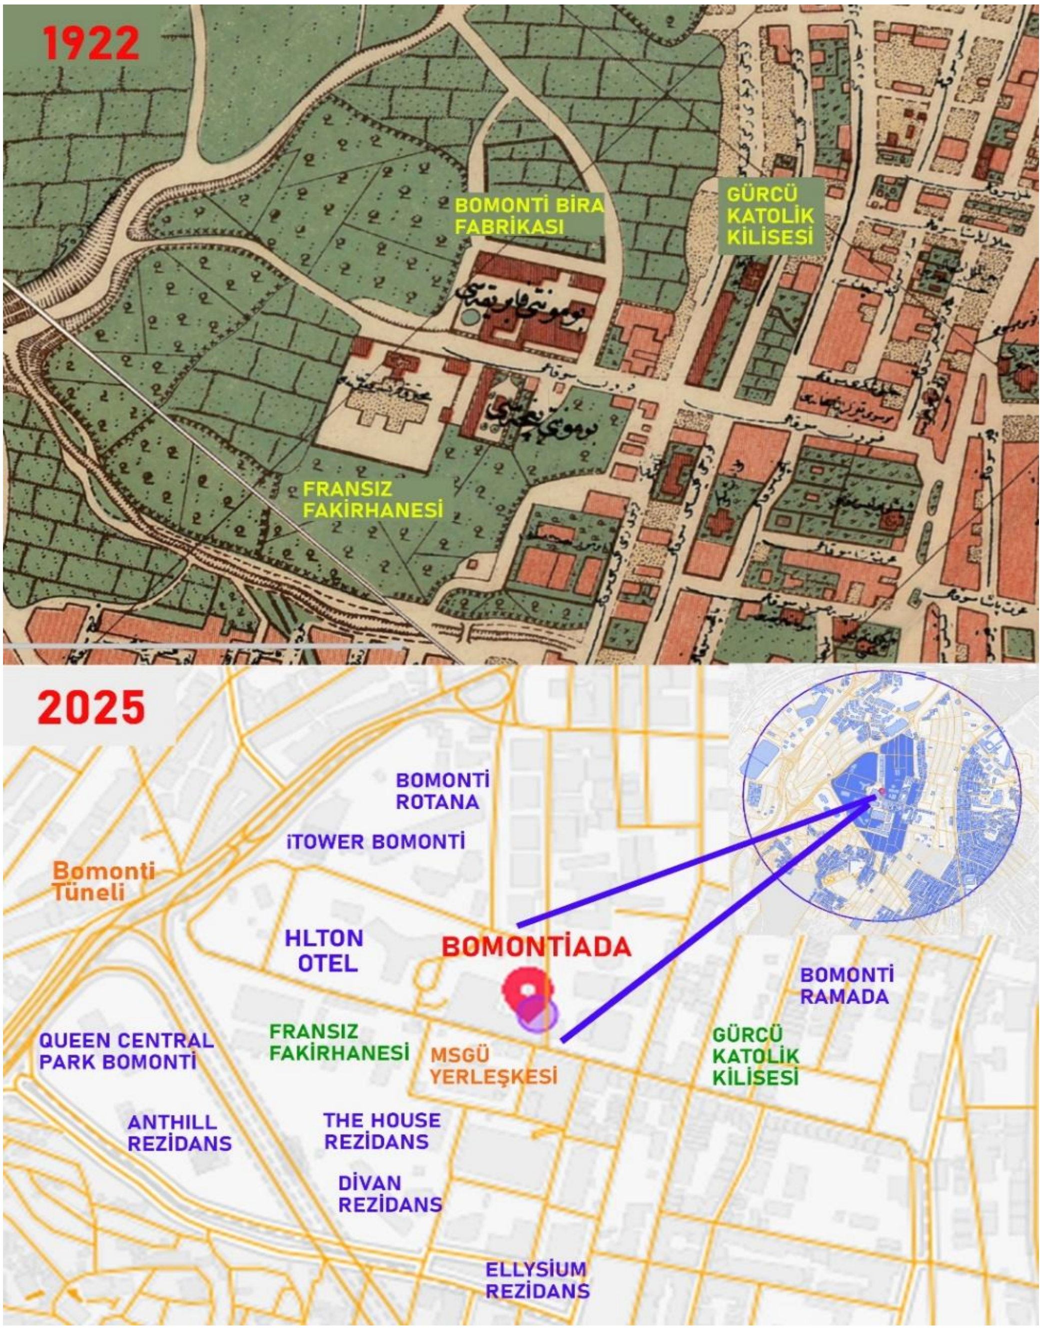

Fig. 12. Bomontiada and Its Construction (istanbulurbandatabase.com, Google Maps).

Although the physical appearance of the structure has been preserved, its content and historical context have faded into the background, and elements that nourish the memory of the space have largely disappeared. This is not merely a physical repurposing but also a transformation of historical and social meaning. An example of this is the significant disruption in the spatial and economic memory of the neighborhood when the Bomonti Beer Factory ceased its production function in the 1990s (Öncü, 2011). The closure of the factory not only created a physical void but also weakened the working-class culture in the neighborhood. This process led to the erasure of collective life practices based on production, and the first voids began to form in the spatial memory (Gürleyen, 2018). Changes that focus solely on the exterior of symbolic structures disrupt the continuity of urban memory, causing the meaning these structures carry in collective memory to become superficial. As a result, buildings that once represented the past lose their significance in the present through forgetfulness. As shown in Fig.s 12 and 13, Bomontiada and its surroundings have been filled with mega structures since the past.

Fig. 13. Bomontada’s Silhouette Changes Over Time (Quoted From Sanalarch.)

Fabrika, which was the focal point of its surroundings from the first years of its operation until its closure, continues to be a focal point with a different culture today. With the consumer culture and the accelerating understanding of life spread to the district by mega structures, the factory area has turned into an entertainment venue. The production culture has been erased from memory and has remained as a pleasant memory, replaced by the consumer culture. This is even reflected in the silhouette in Fig. 13.

4. Conclusion

The spatial changes of Bomontiada and its surroundings due to political reasons and spatial interventions from the past to the present were examined with qualitative research techniques. As a result of this examination supported by images, we can say that the concept of forgetting, which we consider as a problem, is visible at certain points, but it has not completely taken over Bomontiada.

First of all, when we look at the spatial transformation, which is one of the states of forgetting, we observe that the ease of transportation, which was important during the first period of Bomonti's establishment, continues. Especially today, with its proximity to the E-5 Highway and the construction of the Dolmabahçe-Bomonti Tunnel, access to Bomontiada has become quite easy. With this, it is still a very preferred district as it was in the past with its preservation of its vitality and job opportunities. It appeals to various user types with its education centers, luxury residences and food sector, and this actually ensures that it maintains its cosmopolitan neighborhood identity as it was in the past. On the other hand, luxury residences and apartments have transformed Bomontiada from its old focal point in terms of structure scale into a new place. It has become difficult to notice among mega structures, and due to the profiteering transformation, it has lost its additional buildings to these mega structures. Although the Bomonti Beer Factory is known by name thanks to the efficiency of the Ara Güler Museum and Restoration work, the old production culture is unfortunately not continued. In this case, the production culture has been forgotten from memory and has now remained as an entertainment center in the memories of new users. Another place of memory that is as important as the Beer Factory for Bomonti is the Beer Gardens. Unfortunately, this area has been sacrificed to profiteering transformation and its transformation has been carried out with a political subconscious. It has been completely removed from its public space nature and a building belonging to MSGÜ has been built in its place, but unfortunately, even the landscape of the building has not been designed as a public space. As a result of the examination of Bomontiada and its surroundings, the states of forgetting, its historical period and the effects of these states are shown as in Fig. 14.

Evaluating the healthy city approach in the context of urban design competitions

Ece Varol*
* *Research Assistant, Faculty of Engineering and Architecture, Department of Architecture, Recep Tayyip Erdoğan University, Rize, Türkiye*

Abstract. Today, rapid and uncontrolled population growth along with increasing urbanization leads to serious environmental problems in cities. Unhealthy conditions emerging in physical spaces lead to the formation of unequal living spaces. This situation brings one of the fundamental goals of urban design, which is to create equal and fair living spaces for everyone, back to the forefront. The healthy city approach adopts an urban planning approach focused on equality in health and prioritizes considering different cultures and needs. In this context, it is important to evaluate how the healthy city approach finds a response in urban design projects. There are many prestigious competitions in Europe that increase the visibility of architecture and urban design and reward them. The projects that have won awards in recent years provide an important field of examination that shows how the healthy city approach aligns with its goals. Especially in the post-pandemic period, urban health and environmental issues have become the focus of competition projects. This study examines the last 5 projects that received awards in some prestigious competitions held in Europe such as the Veronica Rudge Green Prize and The European Prize for Urban Public Space within the framework of the concept of healthy city.The research was conducted on the credentials and explanatory reports of the award-winning projects; the relationship between urban design decisions and healthy city principles was comparatively assessed. It was determined that the award-winning projects mostly focused on themes such as accessibility of public spaces, environmental sustainability and promoting public health. While the Veronica Rudge Green Prize focuses on large-scale urban transformation and infrastructure projects, The European Prize for Urban Public Space touches on urban space with smaller-scale interventions. The projects reveal that the concept of healthy city is prioritized in topics such as increasing green areas, improving air quality, developing pedestrian-friendly spaces and promoting community participation. In addition, universal health goals such as ensuring social justice and resilience to climate change are among the prominent elements. This assessment highlights the critical role that award-winning projects play in creating healthy cities and the impact of urban design competitions in this process.

Keywords: Healthy city; Urban health; Sustainability; Competition projects; Community health

1. Introduction

Today, the urbanization process brings with it serious environmental and social problems due to rapidly growing population and uncontrolled development. Rapid urbanization destroys natural ecosystems, while unplanned growth and inadequate infrastructure create unhealthy living conditions. Especially with the increasing population, large cities are rapidly migrating, spatial inequalities are increasing, and low-income groups are mostly forced to live in unhealthy and low-quality living spaces. One of the primary goals of urban design, 'creating equal, sustainable and accessible healthy living spaces for everyone', is becoming even more important.

Urban design and planning approaches are in a state of transformation due to increasing population, developing technology, and global disasters, epidemics, and wars. This dynamic process directly affects the spatial organization and quality of life of cities. In this respect, approaches to sustainable, resilient and flexible urban design are becoming increasingly important. In this context, smart city technologies, ecological planning strategies, healthy city models and human-centered design principles have become essential components in contemporary urban planning processes. The developing interdisciplinary understanding requires that cities be considered not only as physical spaces but also as dynamic systems in which social, cultural and economic interactions take shape. Urban design and planning decisions are expected to have approaches that offer more holistic and future-oriented solutions.

The concept of urban design has developed various movements and urban planning approaches throughout history depending on social, economic, environmental and technological factors. The Bahçeşehir Movement,

* Corresponding author, E-mail: eceseyhanvarol@gmail.com

https://doi.org/10.31462/icearc2025_a_urb_659

which emerged in the late 1800s, proposed a model that combined the advantages of rural and urban life against the unplanned urbanization brought by the industrial revolution, while the Beautiful City Movement, which emerged in the early 90s, developed regular and symmetrical plans that emphasized urban aesthetics. In the 1920s, with Modernism, urban approaches based on functionality and rationality, high-rise buildings and wide open spaces came to the fore. The New Urbanism approach (1960s) advocated pedestrianization and a more neighborhood-oriented design approach as a reaction to automobile-focused urbanization. Postmodernism (1970s) brought a more aesthetic, flexible and historical reference-emphasized approach against the strict rules of modernism. In the 1980s, the Healthy City Approach was initiated by the World Health Organization. This approach aimed to increase the physical, social and environmental well-being of cities. Later, ecology and sustainability concepts came to the forefront in both planning and design approaches. Sustainable Urban Design (1990s) focused on energy efficiency and ecological planning as a solution to environmental crises. Later, with the developing technology, the Smart City Approach (2000s) suggested the integration of digital technology into urban design and planning. The Green Capital Movement (2010s) pioneered sustainable urbanism projects that encouraged environmental policies. When we look at all of these movements, we can see that they are a response to the changing needs of cities.

The concept of healthy city aims to increase the physical, mental and social well-being of individuals and aims to create sustainable and livable urban environments (Başaran, 2007). This approach, which was developed under the leadership of the World Health Organization, aims to increase the quality of life of the society by adopting a health-focused perspective in urban planning (Barton et al., 2010). Healthy cities should be supported not only by health services but also by elements such as housing quality, transportation, green areas, social integration and environmental sustainability (Aydın, 2019). In this direction, interdisciplinary cooperation, community participation and environmental factors should be taken into account in urban planning (Belli, 2019). The Healthy Cities Association has been established in Turkey within the framework of this understanding and encourages the active participation of municipalities in the process (Başaran, 2007). The healthy city approach stands out as a strategy that aims to make cities more livable in terms of physical, social and environmental health. This approach, emphasized by the World Health Organization, places health, sustainability and social equality at the center of urban policies. Increasing green areas, creating pedestrian-friendly spaces, improving air quality and encouraging community participation are among the fundamental elements of healthy cities.

In order for cities to be healthy and livable, urban design must be shaped in accordance with these principles. At this point, international urban design competitions play an important role in encouraging innovative solutions that support healthy city principles. Prestigious architecture and urban design competitions in Europe increase awareness in this area by rewarding projects that support the healthy city vision.

This study aims to analyze how the healthy city approach is represented in prestigious urban design competitions in Europe. In particular, the study examines five recent projects that have won awards in international competitions such as the Veronica Rudge Green Prize for Urban Design and The European Prize for Urban Public Space. The spatial and environmental qualities of these projects are comparatively evaluated in the context of healthy city principles. By analyzing how urban health and environmental sustainability issues are addressed in the competitions, especially in the post-pandemic period, it is revealed how the award-winning projects contribute to the health-oriented transformation of urban space.

In this context, the main questions of the study are as follows:

- How are healthy city principles reflected in the award-winning projects?
- How do urban design competitions contribute to the development of healthy city policies?
- How do the award-winning projects address issues such as accessibility, environmental sustainability and public health?

Within the framework of these questions, the award-winning projects of the selected competitions within the scope of the research were analyzed through their explanatory reports and project descriptions, and how urban design is integrated with healthy city goals was evaluated. The findings emphasize the critical role that award-winning projects play in improving urban health and supporting sustainable city policies.

2. Healthy City Approach and Principles

According to the World Health Organization (WHO), a healthy city is a settlement area that offers a sustainable environment where individuals can maximize their physical, mental and social well-being and includes the entire society. WHO considers healthy cities not only in terms of preventing diseases but also in terms of creating urban policies and infrastructures that support healthy lifestyles (WHO, 1998). Healthy cities should be shaped based on basic elements such as clean water and air, adequate housing, effective transportation systems, accessible health services, social justice and social participation (WHO, 2010). In this context, a healthy city should be planned with a multidimensional approach that includes economic, social and cultural factors as well as the physical environment (WHO, 2021). Healthy urban planning is a dynamic process that aims to reduce social and physical inequalities in urban space. This process takes shape through experimentation, intervention, observation, learning and adaptation. It aims to strengthen social integration through urban design and planning, especially in areas where disadvantaged groups live, where spatial segregation is intense, and to continuously improve healthy living conditions for all city residents (Corburn, 2013). In this context, incorporating the principle of accessibility into urban planning not only ensures the removal of physical barriers but also helps to reduce the spatial impacts of social exclusion. In this way, it contributes to addressing inequalities within the city (Söylemez, 2021).

Healthy cities should be planned in line with the principles of sustainable environment, society and economy. The environmental dimension should protect the health of the physical environment and promote green areas, safe and inclusive spaces, and healthy housing. In the social dimension, consciousness and awareness should be increased, equality and inclusiveness should be ensured and solidarity between individuals and institutions should be strengthened. In terms of policies and services, participatory governance should be adopted, and basic urban services such as education, health, social services and transportation should be improved. This holistic approach aims to increase the quality of life of urban dwellers and support sustainable urban development (Gür, 2024). In this framework, the “Health Map for Local Human Settlements” developed by Barton and Grant (2006) offers a holistic model that conceptualizes the multi-layered structure of the healthy city approach. This model, where the individual is positioned at the center, visualizes the mutual interaction of many factors such as physical environment, lifestyle, social relations, access to services, economic structure and natural environment on health. The map is not only spatial planning; It also emphasizes that social policy, environmental sustainability and economic justice are directly related to health, and reveals the importance of interdisciplinary cooperation and long-term strategic approach in healthy urban planning. In this respect, the health map is a guiding tool in making cities more livable, inclusive and resilient. (Fig.1)

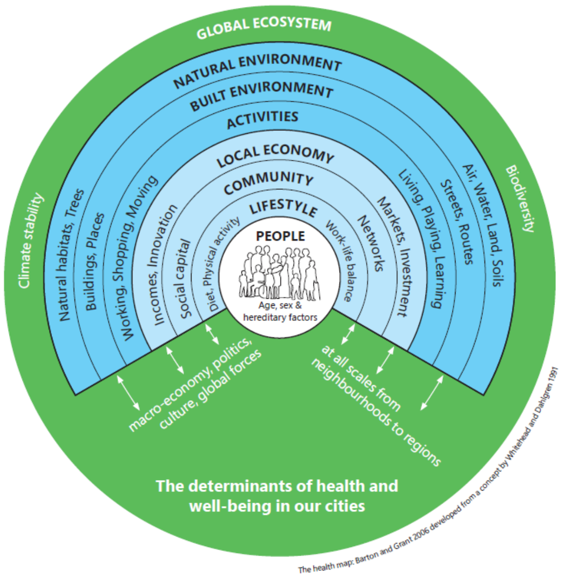

Fig.1. Conceptual Health Map for Healthy Living Areas (Barton ve Grant, 2006)

The healthy city approach consists of basic elements such as accessible and safe public spaces, environmental sustainability, community participation and social justice. These elements increase the quality of life of individuals and promote equality and justice in urban areas. Green areas and pedestrian-friendly cities create a sustainable environment that supports environmental health and increases resilience to climate change. Therefore, this holistic approach is of great importance in the construction of healthy living environments.

3. Urban Design Competitions and Healthy City Concept

Architectural competitions are important tools that enable the emergence of innovative ideas in spatial design. Since the projects presented in competitions are mostly evaluated in terms of aesthetic and visual quality, user needs and spatial performance may remain in the background. As a matter of fact, the dominance of subjectivity in the specification structures and jury evaluation processes of competitions is one of the main factors that negatively affects the functionality of the design (Akçay, 2021). "Urban design competitions should be evaluated not only based on aesthetic qualities, but also according to criteria such as sustainability, accessibility, and healthy living conditions." (Arkun, 2021).

Architectural design competitions are important tools that encourage the development of innovative and qualified solutions in the field of urban design. They bring together different perspectives, enable the emergence of creative ideas and pave the way for designs that are in the public interest. Especially in projects for public spaces, competitions provide a transparent and participatory process, contributing to the selection of applications that increase the quality of the urban environment. It is an effective method for local governments to achieve sustainable, accessible and socially sensitive designs.

Within the scope of this study, the definition and objectives of two international project competitions closely related to the urban design discipline are explained. Then, the projects that have won awards in the last five years have been examined with visuals in line with the official websites of the competitions and project description reports. The aspects of each project that can be associated with the healthy city approach have been determined and evaluated under these headings. Thus, how healthy city principles are reflected in contemporary urban design practices has been revealed through concrete examples.

Peter G. Rowe (2021) emphasizes that the Veronica Rudge Green Urban Design Award plays an important role in evaluating innovative approaches in the urban design discipline and highlighting successful projects. According to Rowe, this award provides an important opportunity to understand the design problems faced by cities on a global scale, to compare the effectiveness of different approaches and to determine successful strategies. This award, given by Harvard University since 1986, rewards projects that reflect the core values of urban design, focusing on large-scale urban transformation projects, infrastructure development works and public space designs. Thus, the award encourages urban design practices that support not only the physical structure of cities but also social and environmental sustainability (Rowe, 2021, https://urbandesignprize.gsd.harvard.edu/). The Veronica Rudge Green Urban Design Award rewards exemplary urban design projects that reveal a humane and valuable aspect in the design of urban environments.

The European Prize for Urban Public Space Award is an international awards program that has been organized every two years since 2000 and encourages the creation, reuse and improvement of public spaces in European cities. The main aim of the competition is to emphasize the importance of public space as a democratic value and to make visible the contribution of disciplines such as architecture, landscape and urbanism to urban life. Taking as its evaluation criteria qualities such as social inclusiveness, environmental sensitivity and cultural continuity as well as physical quality, this award aims to support the common culture of public space production of European cities.

3.1. Review of Selected Competition Projects

3.1.1.Veronica Rudge Green Prize for Urban Design -2023 Award- Grand Paris Express

The 14th Veronica Rudge Green Urban Design Award was awarded to the Grand Paris Express, a large-scale public transport project currently under construction in and around the Paris metropolitan area. The Grand Paris Express aims to change the mono-centric urban model of Paris and make public transport more inclusive. The project promotes more efficient transport by reducing the use of private cars and reducing the carbon footprint. It aims to increase the sustainability of Paris by establishing fast and environmentally friendly connections between the existing city peripheries and developing areas. These connections support the creation of new urban centres. A transport network has been created that connects the outer regions without directly passing through the city centre. The architectural projects connected to the Grand Paris Express are developed independently and are carried out by architects, designers and artists. Each project is shaped by local needs and adheres to community participation processes. It follows the general principles set for public spaces and future projects.

Fig.2. The Grand Paris Express project (URL-1, URL-2)

Design approaches that stand out in relation to Healthy City:

- Sustainable Transportation and Reduced Carbon Footprint
- Inclusive and Accessible Public Transportation
- Environmental Sustainability
- Art and Cultural Integration
- Innovative and Sustainable Design Approaches

3.1.2. Veronica Rudge Green Prize for Urban Design-2017 Award- High Line (New York)

The High Line project is an innovative public space project that combines urban transformation and landscape architecture. Created by transforming a disused industrial railway line in New York, this urban park adopts sustainable design principles. The landscape is shaped with dynamic routes that encourage pedestrian circulation, and the use of public space is increased. It creates a green corridor within the dense building texture of the city by combining architectural, ecological and social components. Independent pedestrian flow from ground level increases mobility within the city, while providing a natural environment rich in flora and fauna. The project supports social interaction with contemporary spatial interventions while preserving urban heritage. The High Line is considered an exemplary model in terms of sustainable urban design and re-functioning of public spaces.

Fig.3. High Line Project (URL-3)

Design approaches that stand out in relation to Healthy City:

- Green Space and Biodiversity
- Pedestrian Friendly Urban Design
- Re-Functioning of Public Spaces
- Encouraging Physical Activity
- Environmental Sustainability
- Social Integration and Community Participation
- Improving Air Quality and Urban Microclimate

3.1.3.Veronica Rudge Green Prize for Urban Design -2015 Award- Madrid Rio (Madrid, Spain)

The Madrid Río project is a comprehensive public space intervention that aims to transform urban infrastructure and integrate it into urban life. The area gained by moving the M-30 highway underground has been transformed into a linear landscape park on the riverside. The project provides spatial continuity with green infrastructure, ecological corridors, recreational areas and social facilities. This design, which integrates historical structures with contemporary elements, establishes a balance between cultural heritage and current needs. It encourages collective life with a pedestrian-first circulation system, bicycle paths and public meeting areas. Madrid Río is one of the examples of healthy urban environment production with its sustainability, accessibility and multifunctionality principles.

Fig.4. Madrid Río Project (URL-4)

Design approaches that stand out in relation to the Healthy City:

- Putting the highway underground, green space and clean air
- Creating a linear landscape axis
- Strengthening pedestrian and bicycle infrastructure
- Recreational and cultural open spaces
- Preservation and integration of historical structures

- Water management and environmental resilience
- Inclusive and interactive public spaces

3.1.4. Veronica Rudge Green Prize for Urban Design -2013 Peer Award -Metro do Porto (Porto, Portugal)
There are two projects that have been awarded the Veronica Rudge Green Urban Design Award in 2013:

1. Metro do Porto (Porto, Portugal): Designed by architect Eduardo Souto de Moura, this project aims to increase urban mobility by improving the public transportation infrastructure of the city of Porto.
2. Northeastern Urban Integration Project (Medellín, Colombia): Sponsored by the Municipality of Medellin, this project aims to strengthen social and spatial integration in the northeast of the city.

The Metro do Porto project has advanced with a respectful approach to the historical heritage while transforming the urban fabric on a large scale. The design, developed under the leadership of Eduardo Souto de Moura, has transformed the transportation infrastructure into spatial elements that are not only functional but also support public life. The stations are considered as open spaces integrated with the city; topography and architecture are integrated harmoniously with the environmental context. This approach reflects a sustainable and holistic design vision that enhances the quality of the public space beyond transportation.

Fig.5. Metro do Porto Project (URL-5)

Design approaches that stand out in relation to the Healthy City:

- Development of accessible public transport infrastructure
- Production of public spaces sensitive to historical texture
- Pedestrianization of public spaces and environmental improvement
- Promotion of sustainable urban transport
- Support for social integration

3.1.5. Veronica Rudge Green Prize for Urban Design 2013 Peer Award- Northeastern Urban Integration Project (Medellin, Colombia)
This project, implemented in the marginalized northeastern neighborhoods of Medellin, is a social transformation program that aims to reduce spatial inequalities. While access is provided in the steep topography with the MetroCable system, an inclusive urban network has been built with new public spaces, education and cultural structures. The design process was shaped by a participatory approach; a strategy focused on social belonging, security and quality of life was adopted beyond physical interventions. The project is a holistic intervention that reveals the capacity of architecture to produce social impact.

Fig.6. Northeastern Urban Integration Project (URL-5)

Design approaches that stand out in relation to Healthy City:

- Equal access despite topographic barriers
- Increasing the quality of public life in low-income neighborhoods

- Inclusive urban infrastructure strategy
- Community participation-based decision-making process
- Safe and socially functional open space production

3.1.6. Veronica Rudge Green Prize for Urban Design –2010 Award-Cheonggyecheon Restoration Project (Seoul, South Korea)
The Cheonggyecheon Stream Restoration Project stands out by transforming a defunct highway in the center of Seoul into an ecological corridor that revitalizes public life. The project demonstrates the transformative power of urban design by combining environmental sustainability, social integration, and economic revitalization. The system, integrated with topography and infrastructure, was implemented with public participation, political will, and interdisciplinary collaboration; while improving the natural ecosystem, it strengthens public transportation and pedestrian connections. As a symbol of qualitative transformation in Asian urban design, Cheonggyecheon offers a contemporary model that aligns with healthy city principles.

Fig.7. Cheonggyecheon Restoration Project (URL-6)

Design approaches that stand out in relation to Healthy City:
- Restoration of green space and natural water ecosystem
- Microclimate arrangements that reduce urban heat island effect
- Pedestrian priority circulation network and public space continuity
- Improvement of air quality and environmental health through ecological restoration
- Social spaces and cultural areas that encourage public life
- Integrated consideration of social, economic and environmental sustainability in the city center

The European Prize for Urban Public Space is an international evaluation platform held every two years, aiming to recognise and make visible work on the design, improvement and re-functioning of public spaces in European cities.

3.1.7.The European Prize for Urban Public Space-2024 Award- Park at the Warsaw Uprising Mound Warsaw (Poland)

The new park in the centre of Warsaw was built by reusing the remains of World War II. This approach combines historical memory with contemporary landscape design. The park offers a multi-layered spatial structure that combines commemoration, ecological sensitivity and public life. It provides an inclusive public experience through walking routes compatible with the topography and accessible circulation systems. With silent commemorative areas, green infrastructures and flexible spatial arrangements that allow for outdoor activities, the project demonstrates a design approach that is in line with healthy city principles.

Fig.8. Park at the Warsaw Uprising Mound Project (URL-7)

Design approaches that stand out in relation to the Healthy City:

- Inclusive design that makes historical memory visible in public spaces
- Environmental sustainability through the transformation of war remains
- Accessible, disabled-friendly pedestrian paths and circulation systems
- Nature-based landscape design compatible with topography
- Recreational public spaces suitable for outdoor activities
- Green infrastructure applications that increase ecological sensitivity
- Multifunctional spaces that support silent commemoration, social interaction and physical activity
- Public use that keeps urban memory alive and supports cultural continuity

3.1.8. The European Prize for Urban Public Space -2022 Prize-Catharijnesingel- Utrecht (Netherlands)
Catharijnesingel is a design intervention focused on ecological restoration and re-functioning of public space, implemented by reclaiming a historical water channel in the city center of Utrecht, the Netherlands. The old channel, which was converted into a motorway in the 1970s, was rebuilt with a contemporary landscape approach based on the integration of water and green space. While reviving the urban memory, the project also fulfills environmental functions such as rainwater management and heat island reduction in the context of the climate crisis. Pedestrian and bicycle-oriented circulation systems encourage sustainable transportation by pushing the priority use of cars into the background. Catharijnesingel is a qualified example of urban transformation that contributes to healthy city goals with nature-based solutions, historical continuity and public accessibility principles.

Fig.9. Catharijnesingel Project (URL-8)

Design approaches that stand out in relation to the Healthy City:

- Ensuring ecological integrity by restoring the historical water channel
- Rainwater management and microclimate regulation
- Sustainable transportation system focused on pedestrians and bicycles
- Improving air quality by reducing motor vehicle traffic
- Increasing accessibility of public spaces
- Increasing urban resilience with nature-based solutions
- Strengthening cultural continuity and place identity related to urban memory

3.1.9. The European Prize for Urban Public Space -2018 Award-Renovation of Skanderbeg Square Tirana (Albania)
Skanderbeg Square represents the transformation of Tirana's center from a car-focused area to a people-focused and public space. The project aimed to create a multifunctional open public space that would breathe life into the city by pedestrianizing the 40,000 m² central area. It was designed with a spatial structure that regulates the urban microclimate and directs public circulation with its slightly elevated form and surrounding green belt. The use of local stone materials emphasized geographical identity and cultural diversity; the square was transformed into a center that allows flexible use for ceremonies, rest, socializing and daily life. This approach is integrated with healthy city principles such as the strengthening of public life, accessibility and environmental awareness.

Fig.10. Renovation of Skanderbeg Square Project (URL-9)

Design approaches that stand out in relation to the Healthy City:

- Pedestrianized city center by removing vehicle traffic
- Accessible and disabled-friendly public space design
- Opportunity for physical activity and socialization with wide open spaces
- Cultural continuity and place identity emphasis with the use of local stone
- Multifunctional and flexible use areas that support public life
- Surface design integrated with topography and gently sloping square design
- A symbolic, inclusive and democratic public space production

3.1.10. The European Prize for Urban Public Space -2016 Award- Recovery of the Irrigation System at the Thermal Orchards Caldes de Montbui (Spain)

This project aimed to re-establish both ecological functionality and cultural continuity through the restoration of the traditional irrigation system in Termal Bahçeler, a historical agricultural area. This rural landscape, which functions as a social production area, was re-functioned with nature-based solutions and low-intervention strategies; and opened to public use through a process developed on the basis of community participation. The project is an example of spatial integrity across scales, bringing together healthy urban components such as food production, water management, heritage protection and social interaction.

Fig.11. Recovery of the Irrigation System at the Thermal Orchards Caldes de Montbui Project (URL-10)

Design approaches that stand out in relation to Healthy City:

- Preservation of traditional irrigation infrastructure and restoration of its ecological function
- Promotion of food security through community-supported agriculture
- Sustainable approach to water management and natural resource use
- Creation of production-based social interaction environments in public open spaces
- Protection of rural landscapes
- Development of environmental awareness through nature-based solution proposals

3.1.11.The European Prize for Urban Public Space-2014 Co-Prize- The Braided Valley, Elche (Spain)

The Braided Valley is the re-use of a long-abandoned area along the Besòs River in the north of Barcelona, through a process of ecological rehabilitation and public transformation. The project integrates green infrastructure, walking and cycling routes, natural floodplains and ecological landscape elements, with the aim of revitalizing the aquatic ecosystem and creating a network of open spaces integrated with the surrounding settlements. Its name, meaning “braided valley”, represents a permeable public space structure where the natural topography and the cultural landscape are intertwined. The project is an example of a holistic urban ecology based on the principles of water management, environmental sustainability and accessibility, in line with the healthy city approach.

Fig.12. The Braided Valley Project (URL-11)

Design approaches that stand out in relation to Healthy City:

- Creating accessible linear green corridors closed to vehicle traffic
- Strengthening pedestrian and bicycle connections connecting the two sides
- Revitalizing the river ecosystem and protecting the natural landscape
- Nature-based solutions that support climatic and ecological diversity
- Open spaces that support social integration and healthy lifestyles

3.1.12.The European Prize for Urban Public Space -2014 Co-Prize-Redevelopment of the Old Port Marseille (France)

Redevelopment of the Old Port is a comprehensive transformation project that aims to reintegrate the historic port area of Marseille into urban life by freeing it from the pressure of motor vehicles. The project has created a public space with pedestrian priority by limiting vehicle traffic around the port and has provided uninterrupted circulation along the port's coastline. The use of natural stone and spatial simplicity in surface arrangements have given it a character that is in harmony with the historical context. In addition, open spaces suitable for multifunctional use revitalize public life for both daily socializing and cultural events. The project supports a healthy city approach with the principles of social inclusion, accessibility and sustainable design compatible with the coastal ecosystem.

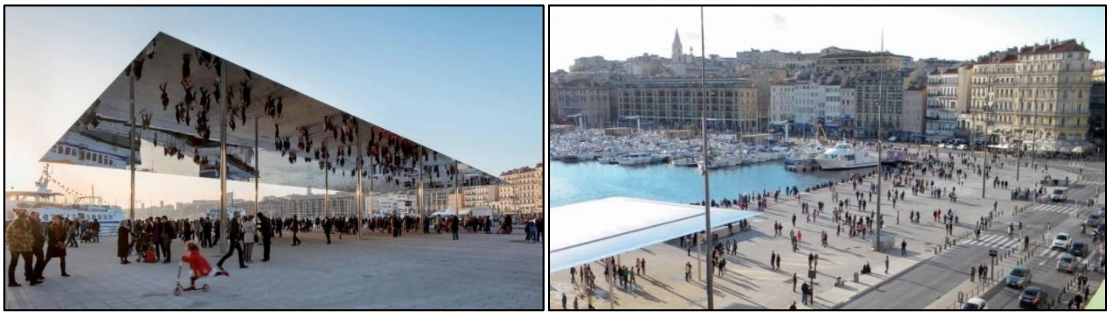

Fig.13. Redevelopment of the Old Port Marseille Project (URL-11)

Design approaches that stand out in relation to the Healthy City:

- Reducing vehicle traffic and creating pedestrian-first public space
- Establishing a circulation system that provides uninterrupted access along the coast
- Multi-functionality in public space: socializing, resting, cultural activities
- Harmonizing the environmental and historical context with natural stone floor coverings
- Accessible design for everyone, including the disabled
- Open space strategies that strengthen the city-coast relationship
- Improving microclimate comfort with shade and open surfaces

4. Finding

Within the scope of this study, the evaluations regarding the projects under consideration were carried out based on the project identities, explanatory texts and documents containing the project scopes on the official websites of the relevant competitions. The explanatory reports detailing the architectural approach, implementation process and objectives for each project were examined; in line with these documents, nine basic principles that can be associated with the healthy city approach were determined. These principles represent the intervention areas that contribute to urban health or aim to improve this area in the projects in question.

Then, analytical tables containing the titles "Healthy City Principle", "Justification / Need" and "Intervention / Application Method" were created within the framework of these principles for each project. The basic assumption here is that the projects aim to intervene in these deficiencies by identifying some healthy living conditions that are seen as deficient or problematic in cities. The evaluation method developed within this framework offers a reading style that establishes a cause-effect relationship in the competition projects and aims to reveal how the design interventions overlap with the healthy city components.

The projects analyzed in this study were evaluated based on the implementation levels of the healthy city approach in line with the principles set forth by the World Health Organization and contemporary literature. These principles were grouped under the following headings: green space / ecological corridor, pedestrian-friendly transportation, accessibility, air quality / ecological restoration, water management, environmental sustainability, social equality and inclusiveness, community participation, and integration of cultural and historical heritage. Each project was examined separately within the scope of these principles; it was not expected that all principles would be present in each project.

Healthy City Principles Based on Tables (headings)

- Green Area / Ecological Corridor
- Pedestrian Friendly Transportation
- Accessibility
- Air Quality / Ecological Restoration
- Water Management
- Environmental Sustainability
- Social Equality and Inclusion
- Community Participation
- Integration of Cultural and Historical Heritage

Table 1. Healthy City Principles in Urban Design Competitions: Project-Based Comparative Table of Interventions and Rationales

Competition	Winning Project Information	Healthy City Principle	Reason / Need	Intervention / Application Method
Veronica Rudge Green Prize	2023– Grand Paris Express- Paris / France	Accessibility	Lack of integration of urban peripheries with the center, unequal transportation network	New metro lines integrated peripheral areas into the center; direct connection to the ring system was established
		Community Involvement	Necessity of user-centered solutions in complex spatial networks	Architectural projects were developed independently according to regional needs, participatory processes were adopted
		Environmental Sustainability	Reducing vehicle dependency, targeting reduction of carbon emissions	Public transport infrastructure was strengthened; private car use was designed to be reduced
		Social Equality and Inclusion	Unequal use of urban opportunities by those living in urban peripheries	New lines provided spatial integrity that reduced social exclusion
Veronica Rudge Green Prize	2017– High Line- New York / ABD	Green Space / Ecological Corridor	Lack of contact with nature in urban density, inadequate public green spaces	Abandoned railway line transformed into a linear public park, natural vegetation redesigned
		Pedestrian Friendly Transportation	Lack of safe and uninterrupted pedestrian routes due to traffic density	Planned as a raised, traffic-free pedestrian path; entire route made accessible
		Environmental Sustainability	Need to reduce water waste, reduce urban heat island effect	Environmentally friendly landscape design implemented with drip irrigation system, drought-resistant plants and water-retaining surfaces
		Community Participation	Need for local communities and users' opinions in the design process	Public feedback was received during the planning process, volunteer-supported maintenance processes were developed
		Social Equity and Inclusion	Need for different age and social groups to meet in common areas	Socialization was encouraged with public event spaces, seating and rest areas
Veronica Rudge Green Prize	2015 – Madrid Río- Madrid / Spain	Green Space / Ecological Corridor	The need to reintegrate the green tissue interrupted by the busy highway	The highway was taken underground; a linear ecological corridor was created with 120 hectares of green space, parks and vegetation

Table 1.Continued

		Pedestrian Friendly Transportation	Access problems and inadequate urban circulation due to vehicle-oriented planning	30 km of bicycle and pedestrian paths were built; 11 new pedestrian bridges facilitated circulation on both banks of the river
		Water Management	Uncontrolled use of riverbeds and flood risk	The Manzanares River area was arranged with ecological landscaping; the water regime was balanced
		Social Equality and Inclusion	Inequality in the sharing of urban spaces among social groups	Various uses such as sports, culture, recreation and children's games were provided in public areas
		Integration of Cultural and Historical Heritage	Historical structures had a weak relationship with the current environment	Historical bridges and infrastructures were restored and integrated with new green spaces
Veronica Rudge Green Prize	2013 – Metro do Porto	Environmental Sustainability	The need to increase the quality of urban life and strengthen the relationship with nature	Sustainable transportation, natural landscape elements and recycling systems were integrated
		Accessibility	Structural inequality in transportation from the city periphery to the center	Inclusive transportation provided with the metro network
		Pedestrian Friendly Transportation	Lack of pedestrian movement around stations	Pedestrian-oriented areas were created with environmental design
		Integration of Cultural and Historical Heritage	Necessity of compliance with UNESCO area	Sensitive transitions were provided in the architectural language
		Environmental Sustainability	Carbon impact of vehicle dependency	Carbon footprint was reduced with public transportation
	2013 – Northeastern Urban Integration Project	Accessibility	Physical obstacles in transportation of steeply sloped areas to the center	Neighborhoods were connected to the city center with the MetroCable system
		Social Equity and Inclusion	Social exclusion due to poverty and lack of services	Quality of life was increased with public facilities and social spaces
		Community Participation	Exclusion of local people in the urban transformation process	Public participation was ensured in decision-making processes
		Environmental Sustainability	Intensive construction and loss of natural areas	New public spaces and green areas were integrated
Veronica Rudge Green Prize	2010 – Cheonggyecheon- Seul / South Korea	Green Space / Ecological Corridor	Lack of green space in the city center and the river being hidden in a concrete channel	The highway was removed and a linear ecological green corridor was created
		Air Quality / Ecological Restoration	Increased air pollution and heat island effect due to vehicle traffic	The highway was removed, the microclimate was improved with green areas and water elements
		Water Management	Flood risk and uncontrolled water regime	The natural flow of the river was restored, water management infrastructure was integrated
		Community Participation	Public support in urban-scale transformation and the need to determine user needs	Public information and broad participation consultations were carried out during the design process
		Social Equity and Inclusion	Different user profiles not being able to meet in a common area	Public spaces were made accessible to various age and social groups
The European Prize for Urban Public Space	2024 – Storm Action Park-Warsaw / Poland	Integration of Cultural and Historical Heritage	The forgotten historical memory of the World War II ruins area	Topography preserved, historical memory spatially represented without monumental elements
		Green Area / Ecological Corridor	Lack of contact with nature in urban density	Unbuilt areas reorganized as green areas
		Social Equality and Inclusion	The need for children, the elderly and different social groups to access a common space	Inclusive public space design including play and recreation areas
		Environmental Sustainability	Promotion of permeable surfaces compatible with the natural water cycle	Low-impact solution implemented by considering water management and green infrastructure together

Table 1.Continued

The European Prize for Urban Public Space	2022- Catharijnesingel – Utrecht	Water Management	Loss of ecological functions of canal filled in 1970s	The canal was reopened to restore natural water flow and biodiversity
		Green Space / Ecological Corridor	Break of ecological connections in urban areas	The urban ecology was revitalized with linear green areas and natural habitats
		Pedestrian Friendly Transportation	Car-focused planning limits pedestrian mobility in city centers	Vehicle paths were removed and the canal shore was transformed into walking paths
		Environmental Sustainability	Need for urban nature-based solutions to combat climate change	Water, green infrastructure and biophilic design were implemented in a holistic manner
The European Prize for Urban Public Space	2018- Renovation of Skanderbeg Square Tirana (Albania)	Pedestrian Friendly Transportation	The density of vehicle traffic and inadequacy of pedestrian areas in the city center	The square was completely pedestrianized, vehicle traffic was eliminated and wide pedestrian areas were created
		Integration of Cultural and Historical Heritage	Emphasizing the historical importance of the square and reflecting the national identity	Mosaic patterns were created on the floor with stones brought from different parts of the country
		Green Area / Ecological Corridor	Lack of green space in the city center and the need to increase biodiversity	12 green gardens were added around the square to support urban ecology and improve microclimate
		Social Equality and Inclusion	Limitations in access of different social groups to common public spaces	The square was designed as an inclusive and accessible public space open to all citizens
The European Prize for Urban Public Space	2016 – Thermal Orchards- Caldes de Montbui / Spain	Water Management	Pollution of irrigation system with sewage and lack of clean water	Sewage was rerouted to provide clean water to old irrigation areas
		Green Space / Ecological Corridor	Loss of environmental and ecological function of abandoned agricultural lands	Gardens were repurposed and transformed into productive green spaces connected to the city
		Community Participation	Dispersion of gardening community and weakening of social interaction	A collective design and implementation process was carried out with the participation of more than seventy gardeners
		Accessibility	Difficult access to gardens, disconnection from urban center	A new network of pedestrian paths was created connecting the gardens to the town center
The European Prize for Urban Public Space	2014 – The Braided Valley-Elche / Spain	Pedestrian Friendly Transportation	The riverbed is a barrier dividing the city into two and pedestrian access is limited	The two sides of the city were connected with a network of pedestrian paths and bridges
		Green Space / Ecological Corridor	The riverbed is inactive and has low ecological value	An ecological corridor was created by landscaping with local plant species
		Community Participation	The risk of ignoring user needs in the project design	A temporary office was established and the most preferred routes by users were determined and integrated into the design
		Accessibility	The riverbed is disconnected from the surrounding neighborhoods	Connections between neighborhoods were strengthened with pedestrian paths and bridges
The European Prize for Urban Public Space	2014- Redevelopment of the Old Port – Marseille	Pedestrian Friendly Transportation	Restriction of pedestrian mobility due to heavy vehicle traffic around the port	The port area was cleared of vehicles, pedestrian paths were widened and public spaces were created
		Accessibility	Lack of barrier-free and equal access to public spaces	The port and its surroundings were arranged to be accessible to everyone, including disabled individuals
		Environmental Sustainability	Increased heat island effect due to dense hard surfaces	Permeable, environmentally sensitive surfaces were created using natural granite stone
		Social Equity and Inclusion	Ownership of the port by only certain user groups	With inclusive spatial arrangements, the port was made an area that everyone can use

The tables presented above reveal that award-winning urban design projects implemented in different geographies and scales provide multidimensional contributions to the healthy city approach. A large portion of the projects include strategic interventions aimed at improving the quality of urban life in areas such as social equality, participation, protection of cultural heritage and environmental sustainability, as well as improving the physical environment. In these projects, topics such as pedestrian-first transportation, increasing green areas and increasing contact with nature are widely prominent; processes that encourage community participation are supported by solutions that are sensitive to local needs. The findings obtained from the table show that healthy city principles are not only a theme in current urban design practices, but also a holistic approach. Table 2 presents the extent to which the healthy urban design principles defined within the scope of this study are addressed in award-winning urban design projects. Due to visual constraints, the column headers in the table are numbered as follows: (Item-1) Green Space / Ecological Corridor, (Item-2) Pedestrian-Friendly Mobility, (Item-3) Accessibility, (Item-4) Air Quality / Ecological Restoration, (Item-5) Water Management, (Item-6) Environmental Sustainability, (Item-7) Social Equity and Inclusiveness, (Item-8) Community Participation, and (Item-9) Integration of Cultural and Historical Heritage. Similarly, the analyzed projects are coded as Project-1, Project-2, etc., in accordance with the order mentioned above. In this way, the degree to which each project aligns with the healthy city principles can be analyzed in a systematic and comparative manner.

Table 2. Urban Health Principles in Design Competitions: A Thematic Summary

Project Name	**Award Year**	**Item-1**	**Item-2**	**Item-3**	**Item-4**	**Item-5**	**Item-6**	**Item-7**	**Item-8**	**Item-9**
Project-1	2023			✓			✓	✓	✓	
Project-2	2017	✓	✓				✓	✓	✓	
Project-3	2015	✓	✓			✓	✓	✓		✓
Project-4	2013		✓	✓			✓			✓
Project-5	2013			✓			✓	✓	✓	
Project-6	2010	✓			✓	✓		✓	✓	
Project-7	2024	✓					✓	✓		✓
Project-8	2022	✓	✓			✓	✓			
Project-9	2018	✓	✓					✓		✓
Project-10	2016	✓		✓		✓			✓	
Project-11	2014	✓	✓	✓					✓	
Project-12	2014		✓	✓			✓	✓		

As a result, the table showing the distribution of projects according to principles visually demonstrates how the healthy city approach finds a response in different scales and contexts within the scope of competition projects. It is observed that the vast majority of the twelve projects examined focus particularly on the principles of green areas/ecological corridors, environmental sustainability and pedestrian-friendly transportation. This situation indicates that the reorganization of the physical environment and the creation of spaces integrated with nature are prioritized in terms of urban health. On the other hand, the fact that socially focused principles such as community participation, integration of cultural heritage and social equality are represented in a more limited number of projects shows that these headings are not addressed as strongly as spatial intervention. Nevertheless, the majority of the projects simultaneously meet at least three or more healthy city principles; this reveals that multi-dimensional, integrated approaches are adopted in the design process. As can be visually observed in the table, the concept of healthy city is not limited to the physical environment in competition projects, but is addressed together with social and ecological integrity goals.

5. Evaluations and Conclusion

When the competition projects are evaluated based on their description reports and project identities, it is observed that a significant portion of the projects that have won awards in recent years overlap with the healthy city approach at various levels. The findings reflected in the table show that there is an awareness of the principles of green space production, pedestrian-friendly transportation and accessibility in most of the projects. These topics stand out as recurring themes in the context of both large-scale infrastructure transformations and small-scale spatial interventions.

In contrast, principles such as social equality and inclusiveness, air quality and ecological restoration are emphasized in fewer projects. This may suggest that in some projects the social dimension is not directly reflected in spatial design or is not sufficiently visible in the disclosure reports. Similarly, the integration of cultural and historical heritage is also highlighted in a limited number of projects as a principle that only comes to the fore in the context of certain cities.

In particular, projects such as Cheonggyecheon, Madrid Rio and the High Line respond to a large number of healthy city principles, while some projects are more limited but deepen in certain themes. This distribution reveals that the projects that won awards in the competitions were shaped at different scales and contextual conditions, and therefore their contributions to the healthy city approach were also affected by these differences.

Although this study is not based on the assumption that the competition projects are directly produced in line with healthy city principles, as a result of the examinations, it has been observed that many projects develop spatial approaches that are consistent with these principles. In line with the themes highlighted in the explanatory reports; it is understood that the projects generally carry partnerships aimed at transforming cities in a more livable, accessible and public health-supporting manner. In this context, beyond producing only aesthetic or technical solutions, competition projects offer significant potential in reflecting the healthy city vision on space and in this respect create a remarkable intellectual environment for future urban design policies.

The impact of socio-cultural change in rural areas on the built environment: The case of Ataköy, Trabzon

Hülya Çakmak [*1], Ahmet Melih Öksüz[2]

[1] *Karadeniz Technical University, Graduate School of Natural and Applied Sciences, 61080 Trabzon, Türkiye*
[2] *Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye*

Abstract: The rural area, until recently defined by its independent, unique and autonomous characteristics, is now in an intense and inevitable interaction with urban areas and communication networks. While this interaction is changing the economic, cultural and social structure of the rural area, it is also bringing about its spatial transformation.. This interaction, while causing changes in the economic, cultural, and social structure of the rural, also brings about its spatial transformation.The study focuses on the impact of the socio-cultural change caused by the population movement that began in the 1950s and continues in various forms today on the rural built environment and aims to open a discussion on the possibility of preserving the traditional built environment in a rural settlement where the traditional way of life has lost its influence by addressing the residential buildings in Ataköy neighbourhood of Çaykara district, Trabzon province, in chronological order. In this context, the aim is to examine the socio-cultural change in the settlement and its impact on the space by determining the current adaptation strategies and house preferences in Ataköy. The study makes use of archival work, field observation and structural environmental analysis.

Keywords: Socio-cultural change; Rural area; Migration; Traditional built environment; Ataköy

1. Introduction

1.1. Rural-Urban Interaction

The interaction that began with the Industrial Revolution and continued under the influence of globalization, the spatial boundaries between rural and urban areas have been disappearing, and rural areas have been increasingly becoming extension of the urban(Ceylan & Somuncu, 2018). Rural areas are transforming into urban areas, used by urban populations and controlled and managed by urban institutions (Ceylan & Somuncu, 2020). With the urbanization of rural areas, it is argued that entire of the world will eventually become urban space and that it is no longer possible to stop urbanization (Ceylan & Somuncu, 2018; Tekeli, 2011: 496-497).

The rural area, by nature, has a permeable structure (Kaya, 2011) and this permeable structure of the rural area and its spontaneous formation make it easily influenced by the dynamics it is exposed to. Until recently, the rural area has been defined by its independent, unique, and autonomous characteristics. However, today, it is engaged in intense and inevitable interaction with urban and its communication networks. This interaction, while causing changes in the economic, cultural, and social structure of the rural, also brings about its spatial transformation.

Socially, the rural area has a community structure based on personal trust, moral norms, and traditions, developing an autonomous system through kinship/neighborhood relationships. In this context, it is far from the social order developed within the framework of institutionalized mechanisms and legal regulations in the city (Altun et al., 2020:43). However, as the rural area enter the urban production and consumption networks and become part of urban production economically, its self-sufficient autonomous structure is damaged. While the pursuit of a better life and employment opportunities draws rural families to the cities, adaptation to urban forms of relationships becomes an obligation. With the influence of urbanization and globalization, members of the community who become part of a shared cultural system become more inclined to seek return their local identities and make a place their own in rural area with a sense of belonging. For members of the community who have migrated to urban, the rural continues to hold symbolic significance as "ancestral land" or the "father's house." It becomes a place to which they return during holidays. For some, it is the residence of extended family members; for others, it represents the setting of their childhood; and for many, it is where the graves of deceased relatives are located (Altun et al., 2020: 53). In this context, the rural area becomes the source of collective memory, keeps

golden light publishing

the community together and playing a crucial role in sustaining the cultural continuity (Altun et al., 2020: 53). On the other hand, it also provides an opportunity for individuals who, through migration from rural to urban, have achieved economic, cultural, and social gains and ascended to a higher social status, to showcase their gains. These dynamics create disintegration in the social and cultural structure of the rural area, while also affecting its spatial structure. While traditions, the norms that bring the community together, and the spiritual feelings related to space are relatively fading, the symbolic role of traditional values is taking precedence over their functional role (Altun et al.,2020:44) The individualization and consumer culture associated with globalization, along with the change in social class, leads to the desire for a more comfortable life and the tendency to display the new identity and status gained by individuals. This situation creates problems in the adaptation of individuals returning to the countryside to the rural built environment designed according to traditional production and lifestyles, and leads to the emergence of different coping strategies in achieving adaptation. Gür (1996) mentions three strategies for individuals to achieve harmony with their environment: changing the macro-environment (relocation, migration, etc.), changing the meso or micro-environment, i.e. changing housing or behaviour, or changing values and perceptions, and states that this is the only way to prevent cognitive dissonance. Rapoport (2005) and Berry (1980), on the other hand, state that adaptation is achieved through four types of methods: changing actions and behaviours (reaction), altering or redesigning the environment (adjustment), relocation (withdrawal), and surrender (giving up).

1.2. Rural-Urban Interaction and Migrations in Turkey

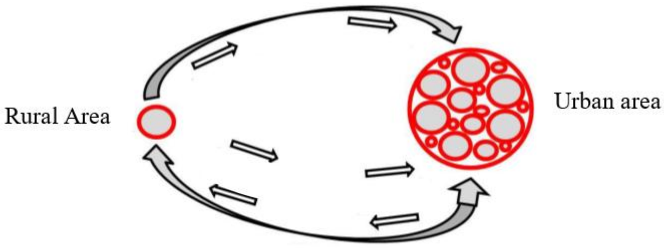

Fig. 1. Population movement between rural and urban areas in Turkey (Özden&Özden,2019)

Although the interaction between rural and urban areas in Turkey was weak until the early years of the republic, economic development efforts that began in the 1950s and improvements in transportation and communication facilities such as highways and radio made cities attractive to rural people and triggered rural-urban migration. In the 1970s, rural areas were seen as places that needed to be improved or reformed as an expression of backwardness; while migration from rural area to urban increased, various projects were developed by the state for the development and modernization of rural areas (Tunçdilek, 1978; Ceylan & Somuncu, 2020; Özden & Özden, 2019). In the 2000s, while improvements in technology, mass media and infrastructure systems allowed individuals to move more easily, population growth in cities and problems arising from globalization caused reverse migration from urban to rural areas (Fig. 1).Güreşçi (2010) states that this population movement causes individuals to prefer their place of residence and consequently to change their place in the social stratum and that migration is one of the most important reasons for economic, social and cultural change in Turkey. Migration is defined as a movement of population, which basically refers to the physical attachment of people to certain places, starting in one place and ending in another, arising from the search for a better life (Südaş & Mutluer, 2010). However, with globalization and the transition to the information society, relocation is no longer a rare and obligatory event, but has become a part of life. For this reason, it is stated that the concept of migration is insufficient to understand today's population movements (Tekeli,2007:471). Developing communication and transportation facilities liberate individuals from being tied to certain centers and offer opportunities that respond to the desire to live using more space. Today, this allows for a different kind of population movement, characterized by people who are not tied to one place, who have the ability to move, and who have a relatively high level of well-being. In the background of this mobility, there is the idea of living in a settled spatial and social environment, engaging in gardening, etc., spending time with family elders and children, taking longer vacations with less expenditure, and gaining status in society by owning a second home. Migration may have been permanent or seasonal, with time spent in the destination ranging from half the year, almost the entire year, or the whole year. The duration could vary depending on factors such as family, relatives, and children connections, ongoing work, or health issues (Südaş & Mutluer, 2010).

1.3. Aim and Scope

The study focuses on the impact of the socio-cultural change caused by the population movement that began in the 1950s and continues in various forms today on the rural built environment and aims to open a discussion on the possibility of preserving the traditional built environment in a rural settlement where the traditional way of life has lost its influence by addressing the residential buildings in Ataköy neighbourhood of Çaykara district, Trabzon province, in chronological order. In this context, the aim is to examine the socio-cultural change in the settlement and its impact on the space by determining the current adaptation strategies and house preferences in Ataköy. The study makes use of archival work, field observation and structural environmental analysis.

2. Material and Method

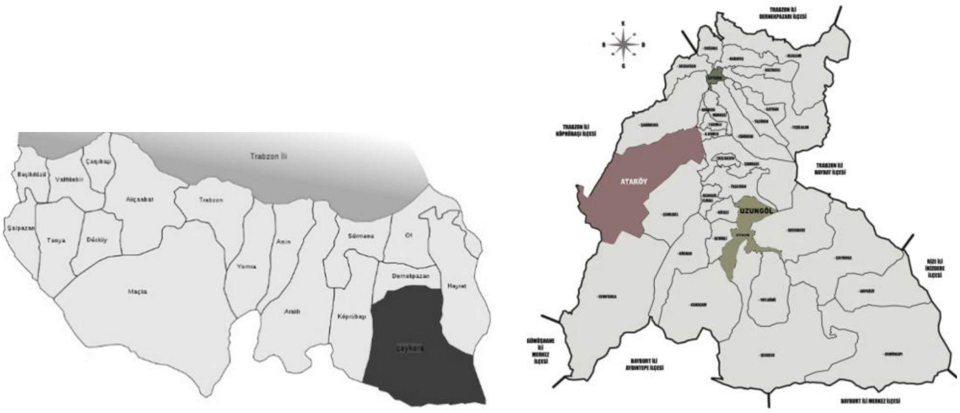

Fig. 2. On the left, the location of Çaykara in Trabzon, on the right, the location of Ataköy in the district

Table 1. Population of Ataköy over the years (URL1,2025)

Year	1960	1970	1980	1990	2000	2010	2024
Population	2037	2747	1478	1220	711	1691	631

Ataköy is located in the southwest of the Çaykara District in Trabzon Province, approximately 9 kilometers from Çaykara (Fig.2). The settlement, which gained the status of a town municipality in 1957, was transformed into a neighborhood under the Metropolitan Municipality Law in 2014. Since the 1960s, development of building environment was visioned according to zoning plans however, these plans have not evolved into an effective implementation to date. Parallel to the evaluation of the settlement as “deep rural” in the literature (Öksüz, et al., 2014), it is difficult to say that Ataköy has an economic potential. It does not seem possible to say that the increasing tourism activity in the region in the last decade has had a significant impact on both the physical and economic development of the settlement. On the other hand, Ataköy is a settlement that is inward-looking, primarily consisting of local residents or individuals connected to the community. The buying and selling of land or buildings to outsiders or those not originally from the region is highly restricted and even closed off. Despite its rural character, economic limitations, and introverted social structure, Ataköy has experienced intense and increasing construction activity in recent years, primarily in the form of secondary housing. This trend makes the settlement atractive for the study.Unlike many villages in Turkey that are in danger of abandonment, Ataköy is a settlement where life continues with different intensity throughout the year. It is possible to say that migration in Ataköy has been an ongoing phenomenon from the beginning of the twentieth century to the present day (Yeni,2015:176-177). However, the phenomenon of migration never severs the connection of the local people with the settlement. Although there is a significant decrease in the resident population compared to the past (Table 1), families who migrate to the city return to the settlement as seasonal residents in the spring and especially in the summer months. This leads to fluctuations where the current population doubles or triples during the year.The socio-cultural change that the community has gone through as a result of migrations affects the built environment, and the effects of this change can be read at both the housing and settlement scale.

Firstly, all houses in the settlement were scanned using the built environment analysis in order to determine the housing type and housing use diversity. Videos featuring the entire settlement of Ataköy recorded by drone, shared on social media platforms (URL 2), as well as current cadastral maps obtained from the municipality, were utilized. All the residences in the settlement were classified into three groups—traditional, hybrid, and modern—based on their facade characteristics, building materials, and architectural formation, and were mapped onto the current cadastral plan (Fig.3). What distinguishes the group referred to as "hybrid" from the other two is that, while it employs contemporary building materials and construction techniques, it retains features similar to traditional houses in its facade and plan. To determine whether any of these groups is preferentially more prominent within the settlement, numerical data based on the building scale were utilized. Although each group exhibits qualitatively different characteristics, they have been associated with the period in which they were built, as they reflect the architectural features of their respective construction periods. Based on the information (Interviews with community members, 2023) that traditional housing production continued until the 1960s, traditional houses have been associated with the pre-1960 period. The first multi-storey apartment buildings were matched with the hybrid group until the 1990s, and with the contemporary housing group after 1990s, when low-rise/multi-storey apartments and detached houses started to become widespread. The fact that each of these groups reflects a specific period raises the question of whether there are distinct thresholds or breaking points in the settlement's development. In the second stage, the relationship between migration patterns and these breaking points within the settlement is examined.

3. Results

3.1. Current Adaptation Strategies and Housing Preferences

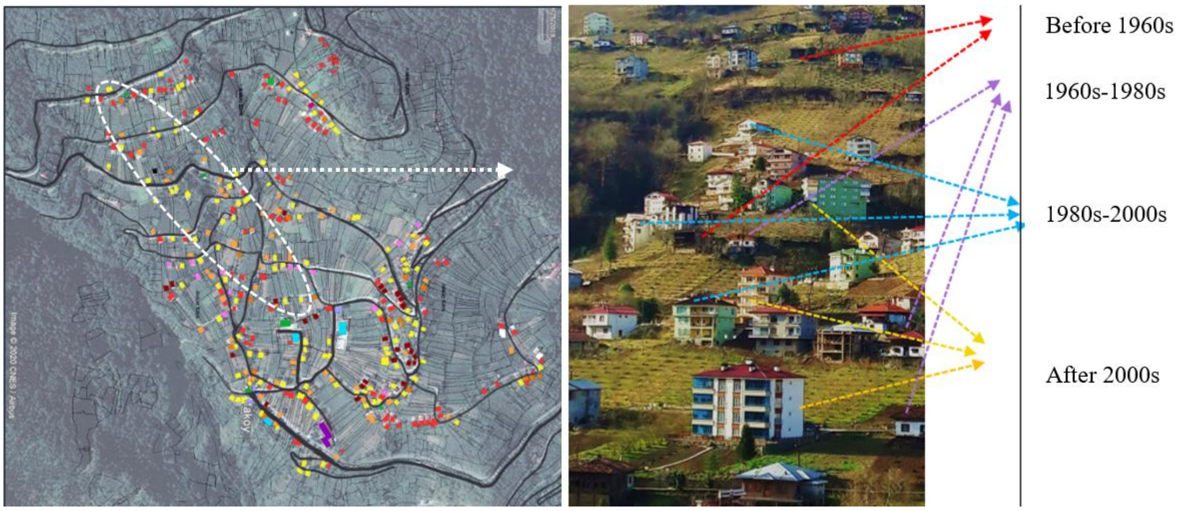

Fig. 3. On the left is the built environment analysis, on the right is a section containing part of the settlement

Table 2.Numbers and rates of housing types determined in Ataköy.

Traditioanal	Hybrid	Modern
170 houses (57 houses abondend)	73 houses	177 houses
%27(actively used)	%17	%42

According to the built environment analysis, contemporary residences were found to be the most numerous among a total of 420 houses (Table 2). It should be noted that this proportion would be even higher if determined based on the number of households rather than at the building scale. 33% of existing traditional housing is not used, and those that are used include interventions or additions of varying sizes. In addition, it was determined that 12 traditional houses were registered by state within the scope of protection and registration activities.

Recently, globalization and exposure to urban culture, along with increased mobility of individuals both in terms of communication and economy, have led to changes in lifestyle habits and preferences. This, in turn, has resulted in greater diversity in housing production and usage practices within the settlement. User preferences have come to the forefront, and factors such as limited land availability, fragmented ownership patterns, and the inability of traditional houses to meet current housing needs in their existing form have all contributed to this diversity.

In reference to Gür (1996) and Berry (1980), it is possible to identify three distinct strategies—reaction, adjustment, and abandonment—regarding the adaptation of community members to the existing housing and built environment (Table 3). Each of these strategies has its own unique dynamics, yet both directly and indirectly, they develop through traditional houses. The presence of the existing traditional rural fabric and the integrity of the built environment present various opportunities and threats. In the reaction strategy, although it does not meet current needs, it is aimed to benefit from the limited opportunities offered by the existing housing. Financial insufficiency, inheritance problems and short-term use are among the reasons for this strategy. In the arrangement, partial or comprehensive interventions or additions are made to existing houses in order to meet current needs. Partial intervention includes additions aimed at specialized space needs (such as wet areas, kitchens, etc.), as well as applications to extend the lifespan of the building, such as modifications to the façade, roof covering, or structural system. In a comprehensive intervention, while the main structural system remains intact, the entire building is renovated, with changes made to the façade character and spatial layout. In the abandonment strategy, the traditional house is either abandoned or demolished to make way for the construction of a contemporary dwelling. It is preferred due to reasons such as the inability to resolve inheritance issues, and the existing house lacking sufficient size, comfort, and privacy to accommodate the expanding family members. In the absence of sufficient land or financial resources to build a detached house suitable for each family, apartment buildings become an effective option. Apartments can be low-rise (maximum three floors) or high-rise (more than three floors), depending on the number of heirs and economic power. In most cases, the shift towards contemporary housing leads to the abandonment or demolition of traditional houses. (Fig. 4-5).

Table 2. Adaption Strategies

Strategies	Reaction (R) (adaptation to the current situation)	Arrangement (A) (modification/redesign)	Abondenment (AB) (relocation/destruction)
Outcome	Traditional House	Traditional House	Detach house, apartment

Fig. 4. When traditional housing is no longer sufficient to meet the needs of an expanding family and inheritance is divided, some heirs can opt to retain the traditional house, while others can prefer modern (detach/apartment) house, depending on the availability of suitable land.(1,2,3,4)

Fig. 5. The transformation of the same location before (on the left) and after 2000(on the right)

3.2. Socio-Cultural Changes Due to Migration and Their Effects on the Built Environment

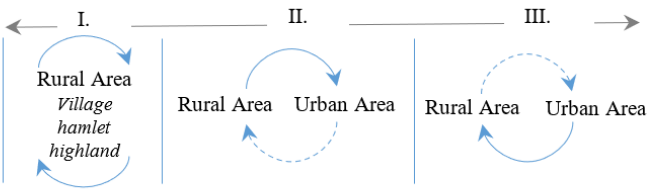

Fig. 6. Migration movements in Ataköy according to periods

In the pre-1960 period, due to limited climatic conditions and agricultural lands, compulsive seasonal migrations occurred between the village, hamlet, and highland within Ataköy. However, the limited and laborious nature of agricultural production, due to the conditions of the period, led the community to move towards cities after 1960 in search of a better life and future. This situation has led to a decline in the settlement's population over time and has altered the state of agricultural activities as the primary source of income. However, after the 2000s, with improvements in communication and transportation facilities and the increasing level of prosperity, it can be said that migration from cities to settlements continued. It can be said that this migration, unlike the seasonal migration that occurred before 1960 between village, hamlet, and highland, is now between cities and Ataköy(Fig.6). The settlement becomes a place of residence during the spring and especially summer seasons for community members who are bored with urban life and want to spend time in connection with nature.

4. Evaluation and Conclusion

Fig. 7. Two images reflecting the situation of the same location before 1960 and after 2000, taken from similar angles

Table 4. Periods and generations

← Villager / Urban Resident →

Traditional	Hybrid		Modern
Before 1960's	1960-1980	1980-2000	After 2000's

Although the local community's internalization of Ataköy as their homeland and the settlement's non-abandonment with a strong sense of place attachment is viewed as positive, demographic fluctuations which the population doubles or triples throughout the year (especially during the summer months), the rapid and unregulated construction activities driven by increasing housing demand, lack of an infrastructure system that can respond to a fluctuating population, the decline in sustainable agricultural activities, an increasing tendency toward consumption rather than production can be listed as some of the risks that threaten the settlement. On the other hand, population movements that have developed due to migration from the past to the present cause economic, social and cultural changes in the community, and these changes affect the built environment(Fig.7).

In contexts where the terms 'villager' and 'urbanite' are defined by lifestyle and daily practices (Ceylan& Somuncu 2018), the community can be characterized as 'villagers' in the pre-1960 period, when agriculture was the primary mode of production. Between 1960 and 2000, as contact with cities and urban production forms increased, the incomplete abandonment of rural production methods and lifestyles transformed the community into a 'hybrid' structure. After 2000, migration to urban by a significant portion of the population led to a decline in the rural population and resulted in a community composed predominantly of urban residents. This shift marked a transition from a rural-based identity to an urban-oriented social structure (Table 4), bringing about significant changes in value systems, lifestyle habits, expectations, and preferences.Individuals who turn to the settlement in search of a sense of belonging and an escape from urban chaos face challenges in adapting to the existing built environment and solve them with different strategies. However, these strategies cause various problems for the integrity of a healthy built environment and the traditional rural texture in the context of the settlement. One of the most prominent issues is that construction activities are often carried out not within a legal or regulatory framework, but rather—much like in the times when traditional lifestyles were dominant—within an informal system (or lack thereof) that relies on neighbourhood relations, customs, and mutual trust. It is evident that the traditional settlement pattern—characterized by houses of similar size and density, which did not obstruct each other's light or privacy and created a unique organic fabric in the past—can no longer be sustained due to today's changing needs and housing diversity. It is worrying that modern houses are being built independently of legal frameworks and without the guidance of expert-designed plans. However, after the Metropolitan Municipality Law there are licensed modern buildings in the settlement but their numbers are few. The second issue to be highlighted in this study is the community's lack of sensitivity towards traditional houses and the traditional settlement texture. Traditional houses can be easily demolished depending on the conditions or subjected to significant interventions in line with the needs. What is interesting here is that the intervention in the traditional house is based on the idea of 'preserving the ancestral home'. The lack of awareness and sensitivity regarding the fact that traditional housing and settlement textures are cultural heritage that need to be protected is seen as a significant issue or paradox, not only in Ataköy but also in most rural settlements across Turkey. What is even more interesting is that, in recent years, some individuals, upon hearing that their traditional houses might be registered through preservation efforts, prefer to demolish their house to make space for contemporary housing construction, in order to avoid undergoing the process. Most individuals whose traditional houses are registered face financial burdens and challenges in carrying out maintenance and repairs in accordance with legal obligations.Apart from its own unique context, Ataköy is an example that carries similarities in terms of changes, opportunities, and risks with many rural settlements in Turkey. In line with current dynamics, the boundaries between rural and urban areas are disappearing, and the common cultural system imposed by the new world order is simultaneously and multidimensionally infiltrating both rural and urban areas. Even though the unique and local identities of rural settlements have not yet vanished and the traditional architectural environment has not disappeared, it is crucial to conduct studies that highlight the value of traditional rural architectural heritage, raise societal awareness, and establish the necessary legal deterrents and incentives.

Enhancing urban resilience: A comparative study of Dubai and Trabzon

Laya Mostofi*[1], Cengiz Acar[1]

[1] *Karadeniz Technical University, Department of Landscape Architecture, 61080 Trabzon, Türkiye*

Abstract. This study addresses the challenges caused by climate change and cities' adaptation strategies and potentials based on their urban morphologies to enhance their urban resilience. Its primary focus is on the implementation of nature-based solutions and blue-green infrastructure.
A comprehensive case study and literature review examines the adaptation of landscape strategies and their integration into city plans. Focusing on Dubai, UAE, and Trabzon, Türkiye, due to their contrasting contexts, this study offers insights on broader sustainability applications.
Findings reveal both cities aim to apply these initiatives soon to prepare for climate adversities. Both Dubai's 2040 Masterplan and Trabzon's sustainability initiatives emphasize the implementation of United Nations Sustainable Development Goals (SDGs), which also complies with the Global Reporting Initiative (GRI)'s topic standards. These guidelines provide a framework for global strategy execution
This study provides a novel approach to ecological services integration into urban planning of Dubai and Trabzon as case studies, using their diverse context to offer unique insights into the practical application of these initiatives.
This research focuses on two case studies, offering detailed insights.Future research could expand by including a broader range of cities with different geographical and urban contexts.
Practical implications: The proposed initiatives can be used by policymakers and urban planners to embed ecological services into city plans, such as Dubai's 2040 Masterplan, thereby enhancing sustainability and urban resilience.
Enhancing urban resilience reduces financial losses from climate disasters. Additionally, we can expect to see more job opportunities in environmental management, construction, and tourism sectors.

Keywords: Urban Resilience; Blue-Green Infrastructure; Sustainability Initiatives; Nature-Based Solutions; Climate Change Adaptation

1. Introduction

1.1. General Background

The modern urban landscape in progressively facing various challenges due to climate change, society and economic changes, and environmental breakdown. Urban systems ability to absorb, recuperate and adjust against different natural shocks, is known as Urban Resilience. This concept has risen as the main principle in discussions of sustainable urban development (Sharifi & Yamagata, 2016).

The necessity of making cities resilience has transformed from theory and conceptualization into practical manuals and under globally acknowledged guidelines; particularly mandates set by United Nations Sustainable Development goals (SDGs) and the Global Reporting Initiative (GRI) Standards (GRI, 2021) as shown in Fig. 1.

*Corresponding author, E-mail: layamostofi@yahoo.com

https://doi.org/10.31462/icearc2025_a_urb_890

Fig. 1. United Nations Sustainable Development Goals (Pudke, 2023).

In this shifting environment, cities with varied climatic and morphological pattern must use localized resilience guidelines which is to answer their distinctive susceptibility while using the global standards as their basis. The implementation of landscape architecture and urban design strategies, especially with the use of nature-based solutions (NBS) and blue-green infrastructure (BGI), has gained recognition as a central tactic to enhance urban resilience.

1.2. Landscape Strategies for Urban Resilience

Urban resilience strategies are undergoing a transformative shift, moving from rigid grey infrastructure models toward adaptive ecological systems that are multifunctional and nature based. These solutions, green roofs, constructed wetlands, vegetated drainage systems, and permeable urban surfaces—are now acknowledged for their role in improving urban thermal control, stormwater mitigation, and biological diversity (Frantzeskaki, 2019). Additionally, blue-green infrastructure initiatives support integrated planning that connects hydrological management with green space design, thus enhancing the capacity of cities to withstand and adapt to hydrometeorological extremes.

Evidence from contemporary studies has demonstrated that landscape-driven interventions substantially improve urban adaptability across varying scales, ranging from small-scale neighborhood greening to expansive regional ecological corridors (Sharifi & Yamagata, 2016). However, the realization of these strategies is tightly interlinked with localized governance models, economic heterogeneity, and the existing spatial structure of the urban fabric, making tailored, context-sensitive implementation essential.

1.3. Aim of Research

This research conducts a comparative analysis of landscape-driven resilience strategies in two distinct urban environments: Dubai, characterized by arid desert conditions, and Trabzon, marked by a humid subtropical coastal climate. These contrasting ecological and governance settings present a valuable opportunity to explore how context-specific factors influence the implementation and performance of nature-based solutions for urban resilience.

The research aims to fulfill three core objectives:

- It investigates each city's urban form, governance structures, and vulnerability to climatic stressors.
- It evaluates ongoing landscape infrastructure practices through a SWOT framework, with particular attention to blue-green infrastructure and social inclusion.
- It identifies and compares how resilience strategies are embedded within the planning systems of both cities, whether already in place or projected for future deployment.

By weaving together theory, policy review, and empirical analysis, this study seeks to elucidate the real-world implementation dynamics of landscape-oriented resilience strategies. It further aims to distill actionable, transferable insights that can inform urban planning in similarly challenged ecological and socio-economic settings.

2. Material and Methods

This study aligns with established methodological expectations in resilience studies by employing a qualitative comparative case study framework. A triangulated review of documentary sources ensures both validity and conceptual integrity. The design supports a detailed interpretation of how policies, spatial plans, and governance structures interact in shaping landscape-based urban resilience efforts.

2.1. Data Sources and Scope

This study draws upon a critical review of official urban planning documents, long-term development strategies, and institutional sustainability frameworks. The primary sources informing this analysis are:

- Dubai Urban Master Plan 2040 (Dubai Executive Council, 2021),
- Trabzon İl Planlama 2015–2023 (Trabzon İl Planlama Müdürlüğü, 2015),
- GRI Sustainability Reporting Standards (GRI, 2021),
- UN 2030 Sustainable Development Goals (United Nations, 2015),
- And supplementary insights from literature on NBS and governance dynamics (Frantzeskaki, 2019; Sharifi & Yamagata, 2016; Pudke, 2023).

The case study method is justified given the stark ecological, spatial, and institutional distinctions between Dubai and Trabzon. These contrasting urban contexts present a compelling comparative lens for examining how landscape infrastructure planning is differentially articulated within resilience-oriented urban strategies

2.2. Methodological Phases

The methodology is systematically divided into three logically ordered and interdependent stages, each building upon the findings and processes of the preceding one:

Phase 1: Policy Content Analysis

In the first phase, a structured content analysis was conducted on urban plans at both municipal and regional levels to identify themes related to urban resilience. Using a combination of manual and software-assisted coding, the study captured recurrent policy signals in areas such as blue-green infrastructure, land use flexibility, ecological restoration, and spatial inclusivity. These documents were then mapped to the Global Reporting Initiative's (GRI) disclosures (GRI 2021:1; 2021:3) and evaluated against relevant Sustainable Development Goal (SDG) benchmarks.

Phase 2: SWOT Analysis Implementation

A SWOT matrix was applied to both cities to assess strategic conditions surrounding landscape infrastructure. This framework enabled classification into four categories:

- Strengths, such as available ecological resources and spatial capacity.
- Weaknesses, including planning or technical gaps.
- Opportunities, which represent possibilities for policy advancement and synergetic benefits.
- Threats, involving risks of environmental degradation, socio-political barriers, or economic constraints.

To accommodate contextual differences, separate SWOT matrices were developed for Dubai and Trabzon. This allowed tailored evaluations and facilitated cross-case comparison. Methodological reliability was ensured through procedural consistency testing methods, following guidelines established by Ozturk Saka & Erdogan (2022).

Phase 3: Cross-Case Comparative Synthesis

To synthesize both shared and divergent elements of resilience strategies in Dubai and Trabzon, a cross-comparative matrix was constructed. This matrix captured resilience indicators across urban form, planning instruments, participatory governance, and the institutional uptake of nature-based solutions (NBS). A systems thinking perspective guided the interpretation, revealing key interdependencies and areas of strategic intervention.

3. Results and Discussion

3.1. Policy Content Analysis

This phase centered on a structured review of urban policy documents and resilience strategies from Dubai and Trabzon, with the goal of identifying thematic elements related to nature-based solutions (NBS), landscape planning, and governance systems. Primary planning sources included the Dubai Urban Master Plan 2040 as shown in Fig. 2. (Dubai Executive Council, 2021) and Trabzon's 2015–2023 regional plan (Trabzon İl Planlama Müdürlüğü, 2015) as depicted in Fig. 3, alongside international sustainability frameworks such as the GRI Standards (GRI, 2021) and the UN Sustainable Development Goals (UN, 2015).

Fig. 2. Dubai Urban Master Plan 2040 (Dubai Executive Council, 2021).

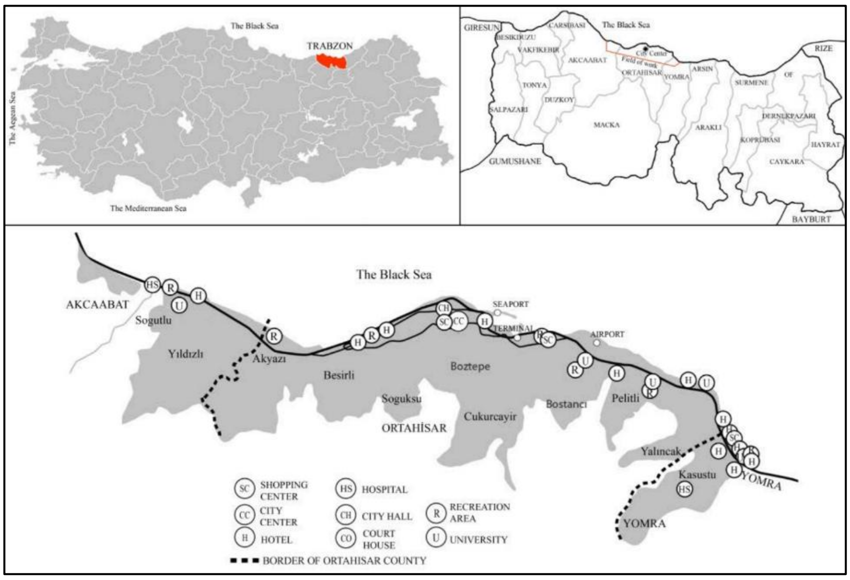

Fig. 3. Trabzon Urban Regions (Ünlü Öztürk & Türk, 2021).

This analytical framework addressed six dimensions: (i) institutional aspirations for resilience; (ii) spatial coherence of green and blue infrastructure networks; (iii) governance configurations and stakeholder inclusivity; (iv) climate adaptation policy; (v) restoration priorities; and (vi) mechanisms of participatory engagement. An iterative coding process enabled cross-comparative evaluation of how each urban policy environment aligns with resilience theory and global sustainability benchmarks.

Dubai's urban planning exhibits integrated vertical coordination, enabled by regulatory authority and financial capital to implement resilience policies across spatial tiers. In contrast, Trabzon’s policy framework centers on local-scale ecological coherence and traditional landscape practices, though it falls short in hierarchical consistency and international standardization. The analysis illustrates a bifurcated approach to resilience-building—Dubai mobilizes global indicators and centralized governance, whereas Trabzon fosters bottom-up, context-sensitive adaptation processes (Ozturk Saka & Erdogan, 2022).

3.2. The General Structure of the Case Cities

3.2.1. Dubai: Urban Morphology and Governance Context

Dubai, located in the hyper-arid environment of the Arabian Peninsula, has developed into an urban landscape marked by vertical expansion, controlled development clusters, and expansive infrastructure systems. This growth has occurred under a centrally coordinated governance model led by the Dubai Executive Council, operating through royal decrees and significant financial power (Dubai Executive Council, 2021). The city's spatial structure reflects its aim for global economic prominence, featuring dense commercial hubs, arterial transit infrastructure, and designated zones for tourism, industrial, and logistical activity.

High-profile urban districts such as Downtown Dubai and Dubai Marina underscore the city's prioritization of visually iconic, vertical urban forms. While large-scale greening efforts—ranging from afforestation to engineered islands—have been deployed to reinforce environmental narratives, the prevailing spatial logic remains automobile-dependent. Fragmentation of green space networks and limited walkable environments persist as key urban design challenges.

Dubai faces harsh climatic conditions characterized by intense evapotranspiration, scarce rainfall, and regular dust storms, all of which heighten environmental stress. In response, the city's resilience strategies have emphasized water-sensitive planning, efficient desalination, and reliance on solar technologies. Institutional frameworks are further strengthened through alignment with global standards such as the GRI (2021) and the SDGs (United Nations, 2015), Dubai's SWOT analysis is as shown in Fig. 4.

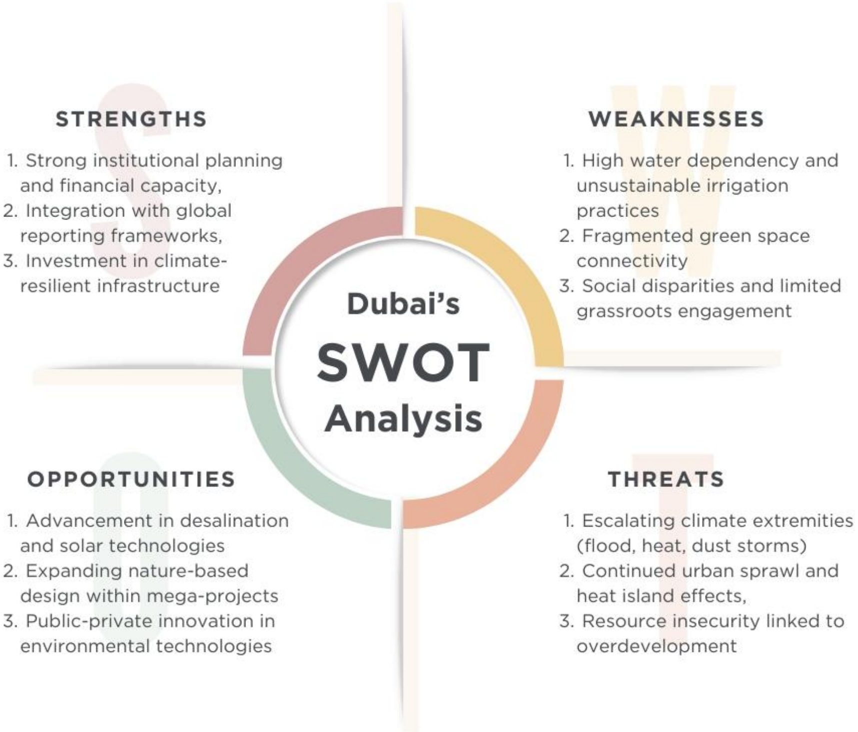

Fig. 4. Dubai's SWOT analysis.

3.2.2 Trabzon: Spatial Structure and Institutional Complexity

Trabzon, positioned on Turkey's northeastern Black Sea coast, exemplifies a divergent urban condition characterized by hilly terrain, coastal adjacency, and an organically formed settlement network. In contrast to Dubai's master-planned urban modernism, Trabzon's urban structure reflects a layered evolution shaped by geography and longstanding cultural and historical processes (Trabzon İl Planlama Müdürlüğü, 2015).

Trabzon exhibits a compact spatial form in its historic center, which gradually becomes more fragmented and expansive in the peripheral zones as housing developments extend into hilly terrains. Industrial and agricultural uses are often situated close to one another, raising land-use coordination challenges. Vital ecological features, including rivers and wetlands, are integral to the city's landscape identity but face pressures from urban sprawl and weak zoning enforcement.

Trabzon's governance framework is characterized by a layered structure that includes municipal, regional, and national authorities. While less financially independent and not strongly integrated into global resilience reporting systems relative to Dubai, Trabzon's planning documents prioritize key environmental strategies such as conserving ecological corridors, ensuring slope stability, and managing coastal zones. These strategies are enriched by the use of traditional knowledge and active local stakeholder participation (Ozturk Saka & Erdogan, 2022), the SWOT analysis of Trabzon is showcased in Fig. 5.

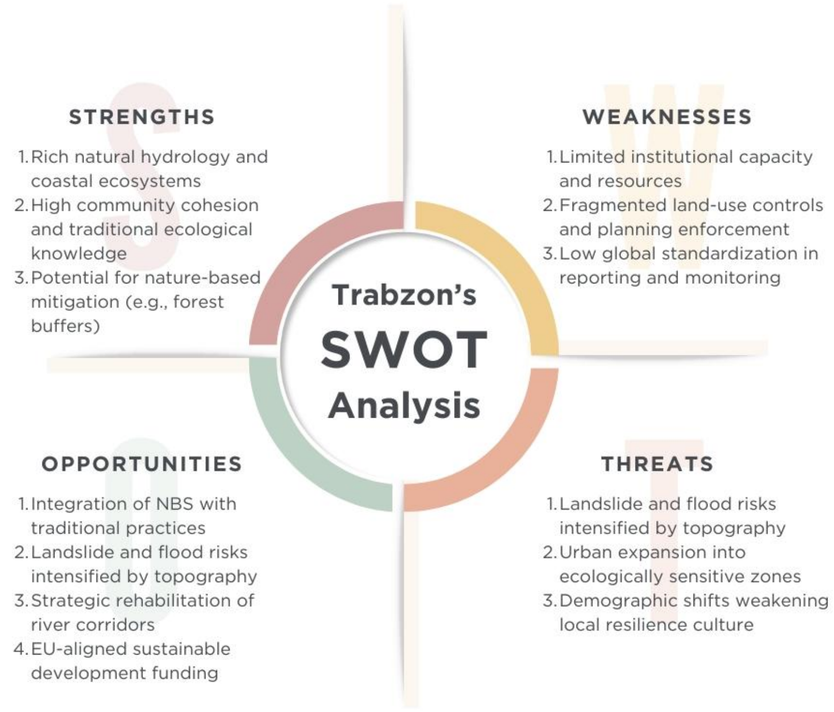

Fig. 5. Trabzon's SWOT analysis.

3.3. Landscape-Based Resilience Systems

3.3.1. Blue-Green Infrastructure

Blue-green infrastructure (BGI) is central to resilience planning in both Dubai and Trabzon. In Dubai, the strategy focuses on engineered landscapes such as constructed wetlands, artificial lakes, and delineated green zones, as detailed in the Dubai Urban Master Plan 2040 (Dubai Executive Council, 2021). These systems are designed to counteract the impacts of intense urbanization and extreme climate conditions like heat and aridity. The city's BGI is executed through hierarchical, top-down planning frameworks, bolstered by coordinated investments from state entities and private sector actors.

Trabzon approaches BGI by leveraging its rich natural environment—streams, wetlands, and forested slopes serve as the foundational elements. Its humid climate and rugged terrain create dual dynamics: abundant rainfall supports dense vegetation but also increases susceptibility to surface flooding and erosion. This necessitates BGI that functions in tandem with hydrological systems (Trabzon İl Planlama Müdürlüğü, 2015). Compared to Dubai's formalized and top-down model, Trabzon's BGI is less structured but deeply embedded within traditional land practices and organic ecological management.

Dubai's BGI framework is notable for its scale and forward-looking vision, yet it is heavily engineered and demands substantial upkeep. In contrast, Trabzon benefits from an inherently resilient ecological base that supports more passive, low-energy BGI systems, though its effectiveness is limited by weak institutional coordination and ad hoc implementation. These differences highlight the importance of tailoring BGI strategies to local climatic, topographic, and governance contexts.

3.3.2 Social Dimensions of Urban Resilience

The social structure of a city plays a decisive role in shaping how BGI is adopted, governed, and sustained by communities. In Dubai, the diverse demographic profile introduces both challenges and opportunities. On one hand, the city's multicultural makeup drives the need for multifunctional, inclusive public spaces that address varied cultural, economic, and visual expectations. This is evident in the implementation of walkable urban districts, adaptable park designs, and green infrastructure embedded within residential developments (Awad & Jung, 2022). However, Dubai's socio-economic stratification, particularly affecting migrant labor groups, limits equitable participation in planning and diminishes the resilience potential of such systems.

Trabzon exhibits a socially cohesive population shaped by historical continuity and territorial rootedness, which translates into strong environmental stewardship, particularly on the rural-urban fringe. This social cohesion fosters resilience through communal networks and participatory cultural norms (Trabzon İl Planlama

Müdürlüğü, 2015). Yet, such informal strength can be seen as a weakness as it will cause the initiatives lack diversity.

In summary, Dubai's socially heterogeneous landscape enables ambitious urban innovation, but challenges remain in ensuring inclusive stakeholder engagement. Trabzon, with its cohesive social networks, supports grassroots resilience efforts, though its systems lacks variety when taking initiatives. Addressing these limitations demands context-specific planning: Dubai must strengthen inclusive representation mechanisms, while Trabzon should focus on enhancing it's heterogeneous outlook.

3.3.3 Nature-Based Solutions Integration

In urban planning, nature-based solutions (NBS) refer to the intentional use of ecological systems to address challenges such as heat, flooding, and biodiversity loss, while also providing economic and social benefits. Dubai's approach to NBS emphasizes large-scale ecological interventions, including desert greening, the introduction of salt-tolerant urban trees, and the stabilization of coastal dunes with bio-barriers (Dubai Executive Council, 2021). These efforts are part of the broader Dubai 2040 vision and are tracked through GRI sustainability indicators to ensure comprehensive ESG performance reporting (GRI, 2021).

Trabzon's nature-based strategies diverge from technocratic planning models, evolving instead through organic integration with cultural land practices. Examples include community-managed rainwater capture systems, terraced cultivation for slope erosion control, and the landscape use of native plant species (Trabzon İl Planlama Müdürlüğü, 2015). Though informal and often absent from formal policy instruments, these interventions embody adaptive, place-specific knowledge embedded in human-ecological interdependence.

Dubai and Trabzon diverge fundamentally in their approach to nature-based solutions, particularly regarding scale and institutionalization. Dubai's system is structured through formal governance instruments and prioritizes centralized, resource-intensive interventions. Conversely, Trabzon's strategy is diffuse, adaptive, and rooted in localized environmental practices. Despite these structural differences, both models reinforce the necessity of context-sensitive NBS frameworks—those which align with governance modalities, urban configuration, and sociocultural traditions to support resilient urban futures.

3.4. Urban Resilience Strategies and Discussion

Although both Dubai and Trabzon embed resilience within their landscape frameworks, their strategic orientations diverge across several dimensions. Dubai operates within a highly formalized and centrally coordinated governance structure that aligns with global standards. In contrast, Trabzon's resilience efforts are more fragmented, grounded in locally adaptable knowledge systems and responsive to socio-ecological conditions.

3.4.1. Dubai's Strategic Approach to Resilience

Dubai's resilience framework is embedded in the Dubai Urban Master Plan 2040, which envisions sustainability as a central pillar of urban development. The strategy prioritizes enhanced liveability via pedestrian-friendly districts and accessible green areas, the development of green corridors to foster ecological connectivity, investments in renewable energy and efficient water use, and transparent sustainability reporting aligned with international standards such as the GRI (GRI, 2021).

Nature-based solutions in Dubai are deployed through a technologically advanced and capital-intensive framework. These include engineered wetlands to manage runoff, vertical forest systems for microclimate regulation, and biosaline cultivation techniques to address water scarcity (Dubai Executive Council, 2021). While structurally innovative, the approach is marked by limited civic involvement, which may hinder social acceptance and reduce the flexibility required for long-term urban resilience.

Although challenges persist, Dubai excels in unifying its urban design, climate adaptation strategy, mobility planning, and economic development under a coherent framework. Its alignment with global sustainability agendas and strong international positioning make it a prominent experimental site for resilient infrastructure in hyper-arid regions.

3.4.2. Trabzon's Contextual and Community-Based Strategies

Trabzon employs a context-sensitive resilience model grounded in ecological awareness and spatial limitations. Its approach, though less formalized, incorporates community knowledge and adaptive land-use responses. Notable strategies include the stabilization of slopes using forest retention and terracing, watershed rehabilitation to mitigate hydrological hazards, and community-anchored greening initiatives informed by long-standing local traditions (Trabzon İl Planlama Müdürlüğü, 2015).

The nature-based strategies adopted in Trabzon emphasize socio-ecological resilience, favoring minimal-impact interventions, community-driven management, and the adaptive reuse of landscape assets. Although these practices are not formally benchmarked to global indicators such as the GRI or SDGs, they demonstrate high congruence with local cultural values and spatial realities—an important condition for durable resilience in smaller cities.

Trabzon's resilience efforts are constrained by key institutional barriers—namely, a lack of standardized planning frameworks, restricted budgets, and limited monitoring capacity. These limitations impede the scalability and transferability of locally successful initiatives. Even so, Trabzon provides a compelling example of how resilience can emerge from community-based knowledge, ecological synergy, and decentralized governance structures.

3.5. Comparative Discussion

The comparative analysis highlights distinct models of urban resilience:

- Dubai's approach is marked by formalized planning, large-scale engineered infrastructure, and top-down governance mechanisms aligned with international benchmarks.
- Trabzon emphasizes localized ecological insight, adaptive and incremental planning processes, and strong community participation in shaping resilient outcomes.

These two models of urban resilience illuminate broader theoretical contrasts—between rigidity and adaptability, technocratic control and ecological responsiveness, and top-down coordination versus participatory governance. Crucially, each framework offers unique operational strengths while also revealing its contextual limitations.

Dubai's resilience model demonstrates efficiency in infrastructure rollout and achieves defined environmental metrics, yet its limited local engagement and top-down implementation may compromise adaptability and social inclusion. Trabzon, on the other hand, prioritizes ecological fit and participatory processes, though its lack of fiscal and institutional strength inhibits replication and system-wide expansion.

This discussion highlights that resilience cannot be universally prescribed. It must be crafted through an assemblage of context-sensitive strategies that align environmental systems, built infrastructure, and social dynamics. To be effective, future frameworks for resilience must aim to:

- Enable productive interfaces between top-down governance and community-driven experimentation.
- Link local action plans to international reporting frameworks such as GRI or the SDGs, while maintaining fidelity to indigenous and contextual knowledge systems
- Construct infrastructural systems that are both ecologically adaptive and socially embedded.

Dubai and Trabzon offer contrasting yet synergistic resilience logics. The integration of Dubai's advanced infrastructural planning and formal governance with Trabzon's participatory ethos and ecological embeddedness presents a compelling composite model. Such hybridization holds the potential to guide next-generation urban resilience strategies that are both structurally robust and socio-culturally attuned.

4. Conclusion and Suggestions

4.1. Conclusion

By comparing Dubai and Trabzon, this study confirms the centrality of landscape-focused planning in shaping resilient responses to climate stress, urban growth, and ecological transformation. Despite shared use of nature-based solutions, their approaches differ sharply—shaped by geography, institutional frameworks, cultural practices, and divergent urban development paths.

Dubai's approach to resilience is grounded in centralized governance and strategic urban design, strongly tied to global benchmarks such as the GRI and SDGs (GRI, 2021; UN, 2015). This model enables the deployment of engineered blue-green infrastructure and technologically intensive nature-based solutions, offering measurable and system-wide results. However, the reliance on artificial ecosystems, substantial energy inputs, and limited grassroots involvement raises questions about the city's long-term adaptability and ecological legitimacy in the face of dynamic climate challenges.

Trabzon presents a resilience paradigm centered on decentralization, cultural continuity, and ecological embeddedness. Through community-led efforts, the city advances small-scale ecological restoration and fosters cohesion at the neighborhood level. Though underrepresented in global reporting systems, this model demonstrates the viability of locally adapted, participatory resilience-building. However, policy fragmentation, fiscal limitations, and the absence of institutional mechanisms for broad replication hinder its scalability.

A direct comparison between Dubai and Trabzon surfaces several key takeaways that illuminate how urban resilience strategies are shaped by context, capacity, and governance orientation:

- Resilience is context-sensitive by necessity: Strategies must reflect the socio-ecological specificity of place—factoring in biophysical conditions, institutional dynamics, and cultural patterns. When implemented in a vacuum, generalized or top-down approaches risk inefficiency, social disengagement, and ecological mismatch.

- BGI must be contextually responsive: Successful blue-green infrastructure should be adapted to fit local conditions—including urban form, climate variability, and governance systems—rather than relying purely on engineered complexity. The contrast between Dubai's constructed wetlands and palm groves and Trabzon's river rehabilitation and terraced slopes illustrates the importance of situational appropriateness.
- Social inclusion is an underdeveloped pillar of resilience: Although ecological adaptation is prioritized in both Dubai and Trabzon, the social components—particularly participation, cultural relevance, and equity—receive insufficient attention. Effective resilience planning must increasingly center on inclusive engagement and community empowerment.
- NBS must be embedded in urban systems: For nature-based strategies to be effective, they must operate within the logic of comprehensive planning—connecting with transport, housing, water, and energy systems. Fragmented application risks underperformance and system inefficiency.
- Global goals require local translation: The value of standards like SDGs and GRI lies not in adoption alone, but in meaningful implementation through localized planning, budgeting, and enforcement. Dubai reflects alignment through formal systems; Trabzon presents the need for adaptive, culturally embedded interpretation.

4.2. Suggestions

Drawing from the comparative conclusions outlined above, the following policy and research recommendations are offered to inform future urban resilience planning and implementation:

- Synthesize centralized formality and decentralized adaptability: Resilience models should integrate Dubai's structured, globally aligned planning systems with Trabzon's locally grounded, participatory approaches to support comprehensive and scalable resilience design.
- Support local institutional development: To enable cities like Trabzon to scale their resilience strategies, focused investment is needed in governance infrastructure, planning skillsets, and mechanisms for international knowledge exchange.
- Promote inclusive planning platforms: To enhance resilience outcomes, both cities must invest in participatory mechanisms such as community mapping exercises, collaborative design processes, and citizen science initiatives that allow residents to actively shape their urban environment.
- Institutionalize dynamic assessment systems: To ensure accountability and learning, cities should implement ongoing monitoring frameworks that evaluate both ecological function and social inclusivity of BGI and NBS projects, using a blend of international benchmarks and locally tailored indicators.
- Enable cross-city learning ecosystems: Cities operating under differing environmental and institutional regimes should participate in global resilience coalitions to co-develop and share technical frameworks, policy instruments, and context-sensitive design practices for landscape-led adaptation.
- Advance durable ecological integration: Urban resilience requires the reclassification of ecological infrastructure as a long-term investment priority. This entails institutional protection, sustained funding, and incorporation into formal urban development strategies.

4.3. Future Research Directions

To strengthen the evidence base for urban resilience, future research should:

- Conduct empirical fieldwork assessing the long-term ecological and social outcomes of BGI and NBS projects in diverse contexts.
- Explore how emerging digital technologies can support adaptive and real-time landscape management
- Investigate how issues of climate justice influence equitable access to resilient infrastructure
- Broaden comparative analysis to include smaller cities and informal settlements that often experience acute but underexamined resilience deficits.

The impact of migration on spatial organization and sociological change: an analysis of cognitive mapping in Yomra district, Trabzon province

Yeşim Tanrıvermiş[1], Harun Tanrıvermiş[1], Parla Güneş[*1]

[1] *Ankara University Graduate School of Natural and Applied Sciences, Department of Real Estate Development and Management, Ankara, Turkey*

Abstract. The transformations experienced by cities throughout history are not limited to their physical structures but are also evident in their sociological dimensions. In periods of significant migration, the cultural structures of individuals in affected areas have also undergone changes alongside the transformation of settlement patterns. The phenomenon of migration has multifaceted impacts, influencing individuals' residential preferences and the developmental cycles of cities. Study aims to demonstrate that the effects of migration on spatial transformations extend beyond the physical dimension, exploring how individuals perceive these changes and the influence of settlement patterns on urban dynamics. Changes in real estate values and their influence on residential preferences were investigated through face-to-face and online surveys conducted with property owners in the Yomra district. The mobility in real estate acquisitions before and after migration was analyzed to reveal how this mobility reflects changes in urban space and individual perceptions. Using this method, the shift in spatial perception from Trabzon city center to Yomra district and the social and physical impacts of preferred new areas on individuals are examined. Cognitive mapping serves as an effective tool to understand individuals' spatial memory and perceptual changes. The primary factors influencing migrants' preferences are identified as increases in real estate values and changes in the social structure. By addressing both the physical and social effects of migration, research underscores the importance of multidimensional analysis in understanding the impact of migration on urban spatial organization.

Keywords: Spatial impact; Perception of space; Migration, Real estate mobility analysis

1. Introduction

Throughout history, cities have undergone significant transformations not only in their physical structures but also in their social fabrics. One of the most fundamental and persistent drivers of these transformations is the phenomenon of migration. Migration is a multidimensional process that reshapes not only the spatial mobility of individuals but also the physical organization, social composition, and cultural identity of urban areas (Castles, de Haas, & Miller, 2014; İçduygu, 2020). Migration movements, whether voluntary or forced, particularly those directed from rural to urban areas or from city centers to peripheries, can lead to outcomes such as spatial sprawl, class-based segregation, and social inequality. In this context, migration is not merely a demographic movement that expands the physical boundaries of cities; it is also a dynamic force that transforms individual-level perceptual processes such as spatial perception, urban memory, sense of belonging, and wayfinding behaviors. Especially for individuals whose settlement preferences change due to migration, meaningful spaces, central areas, and public structures within the city are redefined, directly affecting their levels of urban belonging and modes of social interaction (Tuan, 1977; Lynch, 1960).

The tendency toward settlements distant from city centers not only generates new residential areas but also causes a rupture in individuals' emotional and cognitive connections with the city. In this regard, the province of Trabzon offers a particularly compelling case. Located in Turkey's Black Sea region, Trabzon has recently become a major attraction for international migrants, particularly those from the Middle East and the Caucasus. Due to the city's coastal morphology, limited housing supply, and density in central areas, the incoming population tends to move toward surrounding districts. Within this context, Yomra district stands out due to its rapid spatial development, demographic transformation, and significant increases in real estate values. Over the past decade, notable trends such as population growth, development pressure, rising housing demand, and changes in the social composition have rendered Yomra a unique case for analyzing spatial transformation.

https://doi.org/10.31462/icearc2025_a_urb_898

The primary objective of study is to analyze the impacts of migration on urban space not only at the physical level but also through individuals' spatial perceptions, wayfinding practices, and levels of social belonging. The study reveals the perceptual shift of urban centers resulting from migration flows from city centers to peripheral districts and evaluates the multidimensional effects of this process on individual/public space perception, urban memory, and social integration. Within the scope of the research, the migration movements from Trabzon's city center toward the Yomra district have been taken as the basis, and the study interrogates the impacts of these movements at both physical and perceptual levels. Yomra district was selected due to several factors: the rapid pace of housing development following migration, the increasing interest of international investors, significant shifts in real estate market values, and the observable diversification of the social structure. Moreover, Yomra's geographical position, lying along the eastern coastline, plays a critical role within the broader macroform expansion of the city of Trabzon, further enhancing the regional relevance of the study. In this context, the research adopts a multi-layered methodological approach, focusing on data collection at both spatial and perceptual levels. Initially, demographic and economic data specific to the Yomra district within the province of Trabzon were analyzed, assessing trends over the past decade, including population growth, rising housing demand, and observable transformations in the social fabric.

As part of the fieldwork, surveys were conducted through online methods with homeowners residing in the Yomra district to investigate their housing acquisition preferences, spatial settlement decisions, and the social and economic factors influencing these decisions before and after the migration process. One of the most distinctive aspects of study is the use of the cognitive mapping method. Through this approach, the study examined how participants' spatial perceptions transformed in response to the settlement shift from Trabzon's city center toward Yomra and visualized the phenomenon of "perceptual center displacement" as reflected in participants' mental maps. In this respect, the study demonstrates that migration affects not only the production of physical space but also transforms individuals' cognitive, emotional, and experiential relationships with the city through a multidimensional process. By employing this perspective, the research addresses the relatively underexplored relationship between migration and spatial perception in the existing literature, offering both theoretical and empirical contributions. Thus, the study advances the understanding of migration-induced spatial dynamics by providing an original and comprehensive framework.

2. Literature review

The phenomenon of migration is a multilayered process that entails not only physical expansion in the spatial organization of cities but also class-based, cultural, and perceptual segregation (Harvey, 2012). In particular, new residential areas emerging on the urban periphery are often characterized by the concentration of low-cost housing production, limited infrastructure services, and the clustering of socio-economically vulnerable groups (Erder, 1996; UN-Habitat, 2020). Although such peripheral zones gradually develop their own internal social and economic patterns, individuals moving away from city centers frequently face significant barriers in accessing essential urban services such as public transportation, healthcare, education, and public spaces (Bayırbağ, 2010). In this context, migration becomes not merely a spatial relocation but a process through which intra-urban inequalities are reproduced.

Studies focused on the Black Sea Region have demonstrated that Trabzon and its surrounding areas have undergone significant spatial transformation processes in recent years due to increasing international migration (Yılmaz & Durmuş, 2021). Specifically, the district of Yomra has emerged as a micro-geography in which this transformation becomes particularly visible, reflected through new housing developments, land use changes, and shifts in social structure. Migrants' housing preferences tend to favor peripheral districts that offer more affordable options compared to central areas, a trend that accelerates spatial segregation and gives rise to cultural, class-based, and perceptual boundaries between local populations and migrant communities (Kaya & Kentel, 2005; Cernea & Maldonado, 2020). It is well-established in the academic literature that such boundaries shape not only social relations but also individuals' urban experience and their sense of spatial belonging. Space should not be regarded merely as a physical entity; rather, it must be understood as a multilayered construct shaped by individuals' everyday practices, experiences, memories, and navigational behaviors. Yi-Fu Tuan's (1977) distinction between "space" and "place" underscores the emotional and cognitive bonds individuals establish with their environment. In this regard, experiencing the environment not just as a neutral "space" but as a meaningful "place" plays a central role in the formation of social belonging and urban memory. As Kevin Lynch (1960) emphasized in his seminal work *The Image of the City*, the way individuals perceive, remember, and mentally organize the city directly influences their spatial experience. Symbolic structures, paths, edges, and nodes within the urban landscape serve as key reference points in individuals' mental maps. Cognitive mapping, a method introduced by Downs and Stea (1973), provides a powerful analytical tool for understanding how people perceive urban spaces, how they engage with them, and which areas they find meaningful. This technique makes it possible to visualize individuals' processes of orientation, attachment, and symbolic association within the urban fabric. Migration processes, particularly in the context of urban peripheries, are not solely limited to population growth or spatial dispersion but also entail deep transformations in land use, housing demand, and socio-spatial relations. In this regard, Tanrıvermiş (2022), in her contribution to the volume edited by Arda Özkan, emphasizes that internal migration in Turkey—especially toward secondary urban centers and coastal districts—triggers significant structural shifts in local real estate markets and accelerates the redefinition of urban boundaries. Her analysis highlights that migration-induced housing pressure frequently results in the proliferation of unplanned settlements, increasing the need for inclusive and adaptive planning tools that consider not only physical infrastructure but also the social integration of newcomers. The findings from Yomra reflect similar dynamics, where migration has led to not only a quantitative expansion of the housing stock but also to qualitative changes in spatial perception, access to services, and property ownership patterns. Montello (2002) further argues that cognitive maps reflect not only personal memory traces but also collective perceptions and representations of the city. In this context, spatial changes driven by migration also imply a restructuring of individuals' mental maps.

In particular, migration from central urban areas to peripheral districts alters individuals' urban perceptions and daily spatial routines. As people move away from iconic urban landmarks, their perceptions of new residential zones are increasingly shaped by practical criteria such as housing prices, accessibility, and perceived safety (Canter, 1977). This shift leads to a weakening of "visual memory" in cognitive maps, where distinctive and symbolic central images are replaced by anonymous and repetitive built environments. Consequently, along with the physical transformation of space, individuals' perceptual bonds with that space also undergo a profound transformation. The theoretical and conceptual framework derived from the literature review is directly related to the analytical methods employed in this study. Table 1 summarizes multidimensional themes concerning the spatial impacts of migration and links them to key studies selected from both national and international literature. These themes also shed light on the spatial transformations observed in Yomra District, including migration-induced shifts in perceptual centers and changes in urban identity. The processes of physical expansion, spatial segregation, and class-based differentiation triggered by migration influence not only housing policies but also affect transportation, social services, and social integration dynamics. Mental images and wayfinding behaviors developed by individuals in relation to new settlement areas have been analyzed through the method of cognitive mapping. This has made it possible to visualize both physical and perceptual spatial ruptures. Furthermore, the table attempts to relate the frequently emphasized concepts in the literature—such as the distinction between "place" and "space" (Tuan, 1977) and the influence of urban imagery on individual memory (Lynch, 1960)—to the case of Yomra. This approach aims not only to integrate theoretical knowledge but also to provide a robust basis for evaluating the local impacts of migration.

Table 1. Literature themes in the context of migration, spatial perception, and urban transformation

Theme	Key Concepts	Seletced Representative References	Relation to the Yomra Case
Migration and Urban Sprawl	Physical expansion, spatial segregation, rural-peripheral settlements	Harvey (2012); Erder (1996); Bayırbağ (2010)	Increasing housing development in Yomra as a peripheral district due to migration
Migration and Socio-Spatial Inequality	Class-based segregation, vulnerable groups, infrastructure access	Yılmaz & Durmuş (2021); Kaya & Kentel (2005)	Segregation between migrants and locals, disparities in service access, and social distancing
Sociological Construction of Space	Space-individual relationship, sense of belonging, experiential meaning	Tuan (1977); Canter (1977)	Lack of attachment and perceptual disconnection in newly developed migrant housing areas
Urban Perception and Wayfinding	Urban image, mental landmarks, cognitive imagery	Lynch (1960)	Perceptual shift from Trabzon city center to Yomra as the new mental reference point
Cognitive Mapping Method	Mental maps, individual orientation, social perception maps	Downs & Stea (1973); Montello (2002)	Visualization of migrants' urban perception and weak symbolic ties to the new environment
Perceptual Change through Migration	Shifting perceptual centers, urban memory, anonymization	Canter (1977); Tuan (1977)	Emergence of Yomra as a new perceptual center; increasing neutrality compared to historic core

3.Research methodology

Given that research aims to examine the effects of migration on urban organization at both spatial and perceptual levels through a multilayered perspective, a mixed-methods approach has been adopted. In this context, both quantitative data analyses and qualitative research techniques were employed simultaneously, allowing for an integrated assessment of the physical-spatial impacts of migration alongside individuals' perceptions of the urban environment. The methodological framework is grounded in four primary data sources and analytical techniques. In the first phase of the study, population growth trends, migration dynamics, and housing market activity in the Yomra district were analyzed using data from the Address-Based Population Registration System (ADNKS) and housing sales statistics published by the Turkish Statistical Institute (TUİK). This analysis covered the period from 2015 to 2024 and included key indicators such as population growth rates, the number of construction permits and property transfers, data on newly registered taxpayers related to property acquisition (sourced from the Trabzon Tax Office Directorate), and average square meter housing prices. These datasets were evaluated through comparative tables to capture temporal trends and spatial implications.

To enable the integration of qualitative and quantitative data, a survey was conducted with 156 homeowners (total population of approximately 50,339) residing in the Yomra district. The questionnaire included both multiple-choice and open-ended questions designed to assess:

- Housing acquisition preferences before and after migration,
- Social and economic factors influencing settlement decisions,
- Perceptions of accessibility, safety, and satisfaction with infrastructure,
- Sense of belonging and evaluations of urban image.

The surveys were administered online. The data were analyzed using the SPSS software, where descriptive statistics were presented, and cross-tabulations were used to reveal the relationships between demographic variables and housing perceptions.

One of the unique aspects of this study was the use of cognitive mapping, which aimed to uncover participants' mental representations of urban space. Respondents were asked to draw a mental map that included both the Trabzon city center and the Yomra district. These drawings were analyzed

- *Wayfinding references and symbolic structures related to the city center,*
- *Levels of attachment to new residential areas,*
- *Transportation networks, public buildings, and social hub* based on the following elements.

The maps were coded under three thematic categories—identified structures, environmental relationships, and symbolic meanings—using content analysis methodology. They were then digitized and evaluated comparatively with the housing acquisition data to identify spatial patterns within the mental maps. This study employed a multilayered methodological approach by combining quantitative and qualitative data collection techniques to evaluate the impact of migration on the urban environment and social structure.

Within the scope of this research, official statistical data and field-based findings were integrated to simultaneously analyze the demographic, economic, spatial, and perceptual dimensions of migration. Population data obtained from the Turkish Statistical Institute's Address-Based Population Registration System (ADNKS) covering the period from 2015 to 2023 were used to examine key indicators such as net migration, annual population growth, and settlement distribution in Yomra district. The population of Yomra increased from approximately 38,150 in 2017 to 47,283 by the end of 2022. These figures not only demonstrate the rapid transformation experienced by the region due to inward migration, but also provide a solid foundation for spatial analyses. Housing production and property transfer data—such as building permits and title deed transactions—were evaluated using combined datasets from TUIK and the General Directorate of Land Registry and Cadastre (TKGM). Based on these datasets, the annual increase in housing demand and construction activities following migration was assessed. The rising number of building permits and the acceleration of real estate transactions were examined to reveal the direct impact of migration on the production of physical urban space.

This multilayered methodological framework enables the analysis of not only the quantitative and spatial impacts of migration, but also individuals' perceptual and experiential responses. The diverse range of data collected—including population statistics, land cover analyses, property records, and mental maps—has facilitated a comprehensive evaluation of the physical, economic, social, and psychological dimensions of migration. In doing so, the study proposes an interdisciplinary and in-depth assessment model, offering an original contribution to the fields of urban planning, urban sociology, and real estate studies. By considering not only patterns of physical growth but also the ways in which space is experienced and remembered, the research provides a holistic understanding of migration-induced urban transformation.

4.Migration-induced mobility in the real estate market

The rapid population growth and real estate activity observed in the Yomra district in recent years provide a compelling case for understanding the localized manifestations of this multilayered relationship. The data analyses conducted in this context demonstrate that migration does not merely respond to a temporary housing need, but also fundamentally transforms the structure of housing demand, permitting processes, and property transactions (Yılmaz & Durmuş, 2021; TUIK, 2024). As presented in Table 2, the datasets used were directly integrated into the analytical framework and illustrate how Yomra has experienced intense real estate mobility as a result of increasing migration flows over the past decade

A significant increase has been observed in both housing sales and property ownership transfers, particularly after 2016. These increases (Table 3) are directly related to the settlement tendencies of the incoming migrant population. According to housing sales statistics provided by the Turkish Statistical Institute (TÜİK), while the average annual increase in housing sales across the Trabzon province was approximately 8%, this rate exceeded 20% in the Yomra district during the same periods. This trend indicates a shift in settlement preferences away from the urban core and suggests that Yomra has emerged as a new urban attraction center. Data from digital real estate platforms reveal that the average square meter price, which was 2,800 TL in 2015, rose to 14,200 TL by

2024. This sharp increase in property values cannot be explained solely by economic factors; rather, it must also be understood in the context of socio-spatial dynamics such as the production of high-quality housing tailored to the migrant profile and the intensification of urban land speculation. When the increase in housing prices in Yomra is compared with the national Housing Price Index (HPI)–based estimations, it becomes evident that the growth rate in Yomra significantly surpasses the national average. This discrepancy cannot be attributed merely to general economic inflation or market conditions; instead, it highlights the influence of migration flows, demand for high-standard housing, and investment-driven speculative pressures. The figures presented for the 2015–2019 period illustrate the initial divergence, which has become even more pronounced in subsequent years. These findings strengthen the study's argument that migration has had a direct and substantial impact on the local housing market (CBRT, 2024).

Table 2. Data sources and their use within the scope of the study

Indicator	Data Source	Purpose
Annual Number of Housing Sales (Yomra)	TÜIK	Analyzing supply-demand dynamics following migration
Annual Population Growth (Trabzon/Yomra Comparison)	TÜIK	Identifying spatial concentrations of migration
Average Housing Price Change (2015–2024)	Endeksa/EmlakJet	Visualizing property value increases
Number of Title Deed Transfers	TKGM	Indicating property transaction activity
Increase in Tax Declarations	Trabzon Tax Office	Supporting findings on migrant property ownership concentration

Table 3 Comparative housing market data for Yomra, Trabzon, and Turkey (2015–2024)

Year	Yomra Avg. Price per m² (TRY)	Yomra Annual Sales Growth (%)	Trabzon Annual Sales Growth (%)	Turkey HPI-Based Estimated Price Increase (%)
2015	2,800	7%	6%	5%
2016	3,200	9%	7%	6%
2017	3,800	11%	8%	7%
2018	4,500	13%	8%	8%
2019	5,200	16%	9%	9%
2020	6,000	18%	8%	10%
2021	7,200	21%	7%	12%
2022	9,000	23%	9%	13%
2023	11,000	22%	8%	14%
2024	14,200	24%	10%	15%

Based on the data for the 2020–2024 period, the net migration to Yomra district increased from 3,200 to 9,100 individuals. This demographic growth has been accompanied by a parallel rise in both construction permits and real estate transactions. The number of building permits issued rose from 721 in 2020 to 1,712 in 2023, marking an approximate increase of 137% (TÜİK, 2024; Yomra Belediyesi, 2024).During the same period, the number of housing transactions climbed from 1,154 to 2,981, indicating a strong wave of supply and demand driven by migration in the local housing market. These developments suggest that the incoming migrant population is largely oriented toward permanent settlement, with a dominant preference for direct property ownership rather than temporary rental arrangements. Supporting this trend, the number of newly registered taxpayers also increased from 319 to 892 in the same period, pointing to a strengthened integration of migrants into the formal economic system (Özüekren & Erder, 2010; Kaya & Kentel, 2005).

In light of these dynamics, it is evident that the housing market in Yomra has been shaped not only by local internal factors but also by external demographic pressures. Particularly after 2022, the accelerated demand for housing has compelled local administrations to expedite the permit issuance process. However, this rapid expansion has not always aligned with spatial planning principles. A qualitative assessment of the increase in construction permits reveals that a significant portion of the new developments consists of housing projects targeting middle- and upper-income groups. This trend has intensified the spatial visibility of urban segregation, further deepening housing disparities between the local population and incoming migrants on a socio-economic basis (Bayırbağ, 2010). Simultaneously, the revitalization of the real estate market has accelerated the rate of property ownership transfers, reinforcing the speculative nature of the market. The fact that housing prices and rental values have multiplied compared to pre-migration periods has exposed low-income groups to an increasing risk of displacement. The newly developed housing areas on the urban periphery, often disconnected from core infrastructure and social services, pose significant challenges to social integration processes (Kaya & Kentel, 2005). On the other hand, the permanence facilitated by property ownership demonstrates that migrant populations are not only economically but also socially and spatially inclined to anchor themselves in the city. The relationship between housing and real estate dynamics and migration in Yomra constitutes one of the most visible dimensions of multidimensional spatial transformation. This construction process, triggered by population mobility, necessitates the revision of local housing policies and the central incorporation of social housing and accessibility principles into post-migration planning frameworks. Otherwise, the pressure of migration on housing risks not only initiating a physical transformation but also deepening spatial inequalities.

The market mobility triggered by migration has had a direct impact not only on housing prices but also on rental values. Particularly since 2020, these increases have placed considerable pressure on local residents' access to housing, reinforcing tendencies toward urban segregation. It is noteworthy that the migrant-origin population predominantly tends to acquire property, whereas the local population remains largely within the tenant segment. This indicates an emerging socio-economic stratification based on property ownership. Data on housing ownership reflected in tax records further support these patterns. According to regional real estate tax declarations obtained from the Trabzon Tax Office Directorate, the number of declared residential property ownerships in Yomra increased by 52% between 2019 and 2024. A significant portion of this growth comprises first-time taxpayers who are migrant investors (Table 2). During the same period, the average tax value per dwelling also nearly doubled. In this context, the real estate activity generated after migration has not only disrupted the supply-demand balance but has also transformed the value structure of urban space, the profile of its users, and the property regime itself. Investment flows shifting from central urban zones to peripheral districts have redefined Trabzon’s spatial development trajectory, creating new imbalances between the city center and emerging growth corridors. In this regard, Yomra should be analyzed not only as a new residential zone but also as the spatial manifestation of migration-induced capital accumulation. This increase, especially in the second-hand housing market, reflects both the rapid transfer of ownership and the growing tendency of migrant populations to establish permanent residence. Indeed, according to the 2023 Annual Report of the Trabzon Tax Office, there has been a 48% rise in the number of new taxpayers over the past five years, with the majority of this increase originating from the Yomra district. Taken together, these findings underscore that Yomra’s real estate market operates not only through supply and demand mechanisms but also in direct interaction with population movements. This highlights the role of migration in redefining spatial organization through economic instruments and points to the deepening risk of ownership-based divisions between local residents and newly arrived populations.

4.1. Comparative analysis of survey and cognitive mapping data

Migration is not merely a physical relocation; it is also a transformative process that reshapes individuals’ spatial perceptions, navigational behaviors, and sense of social belonging. In this study, the shift in settlement tendencies from the Trabzon city center toward Yomra district was analyzed through the method of *cognitive mapping*. This technique was used to visualize how participants perceive their environments, define meaningful places, and prioritize elements within their mental maps (Downs & Stea, 1973; Montello, 2002). The mental maps drawn by participants were evaluated in reference to two distinct periods: the pre-migration phase (centered around Trabzon) and the post-migration phase (after settling in Yomra). The findings reveal a significant transformation referred to as *perceptual center shift*. Iconic locations such as Atatürk Square, Meydan Park, and Forum Shopping Mall—previously central in participants' mental representations of Trabzon—were largely replaced by new residential areas, housing developments, the coastal strip, and local social spaces in Yomra following migration. This observation supports Lynch’s (1960) theory of the “urban image,” emphasizing that individuals’ cognitive maps are continuously reshaped through spatial experiences.

Another striking finding in the mental maps is the weakening of associations with symbolic structures. Iconic sites embedded in the collective memory of Trabzon’s city center—such as the Governor’s Office, Ortahisar Mosque, and Uzun Street—are increasingly underrepresented. In contrast, spatial elements that play a more prominent role in individuals’ daily lives in Yomra—such as residential complexes, parks, and marketplaces—have become more salient. This shift reflects not only a change in the physical use of space, but also a reorientation of individuals’ sense of spatial belonging toward their new residential environments (Tuan, 1977; Canter, 1977). Furthermore, a significant transformation has been observed in participants’ wayfinding behaviors. Before migration, intersections, public buildings, and historical landmarks in the city center served as key spatial anchors for orientation. Following migration, this function has shifted toward large-scale residential compounds, main roads, and shopping centers (Table 4). This change reveals a reconfiguration of individuals’ visual and symbolic connections with the city and signals the emergence of new spatial norms.

These findings demonstrate that migration reshapes not only the physical environment but also individuals’ urban experiences, sense of belonging, and wayfinding practices. Accordingly, the cognitive mapping method served not merely as a spatial tool but as a powerful socio-psychological instrument for understanding the transformation of urban experience in the post-migration context. The survey conducted as part of the study aimed to measure themes such as changing housing preferences, feelings of attachment, accessibility to the city center, spaces of social interaction, and urban imagery following migration. Administered online with a total of 156 participants, the survey captured spatial experiences both prior to and after migration through scoring mechanisms and open-ended responses. When evaluated alongside the findings from the cognitive maps, these data enabled a more holistic understanding of how spatial perception is shaped by both physical realities and cultural/social contexts (Table 5).

Table 4. Cognitive map analysis data

Observation Dimension	Pre-Migration Period	Post-Migration Period
Perceptual Center	Trabzon City Center (Meydan, Uzun Street)	Yomra Coastal Area and New Residential Zones
Symbolic Structures	Historical buildings, public institutions	Shopping malls, residential complexes
Wayfinding References	Mosques, parks, public squares	Road connections, bus stops
Social Focal Points	Areas surrounding Meydan, public spaces	In-site communal areas, marketplaces
Spatial Familiarity and Belonging	Ortahisar, Meydan	Kaşüstü, Şana, Yalıncak neighborhoods

Table 5. Comparison of survey results and cognitive mapping observations

Evaluation Criterion	Survey Findings	Cognitive Map Observations	Interpretation and Methodological Consistency
Definition of Perceptual Center	68% now define “the city center” as Yomra	Drawings focus on Yomra’s coastal area and Kaşüstü	High consistency – clear shift in perceptual center
Representation of Symbolic Structures	72% describe central Trabzon landmarks as “important but distant”	Low representation of Ortahisar, Meydan, etc. on the maps	Consistent – weakening of symbolic associations
Sense of Belonging and Familiarity	61% report “not yet feeling a sense of belonging” in new housing area	Frequent representations of anonymous structures in new neighborhoods	Partial consistency – spatial belonging not yet developed
Wayfinding References	70% refer to bus stops and shopping malls as orientation points	Directional arrows often linked to malls and major roads	Full consistency – shift in wayfinding behavior
Spaces of Social Interaction	59% “more opportunities for social interaction exist in the old city center”	Social focal points densely represented in the older urban core	Consistent – social dominance of the historic center is evident
Access to Public Services	66% report “inadequate access to transportation and healthcare in Yomra”	Public buildings either missing or abstractly depicted on the maps	Consistent – functional disconnect visually represented as well

This comparative analysis offers a significant finding from the perspective of data triangulation. The perceptual changes quantitatively identified through the survey data are qualitatively reinforced by the results of the cognitive map analysis. Key themes such as the shift in perceptual center, changes in wayfinding references, and the repositioning of social interaction spaces show strong alignment across both methodological approaches. This convergence also echoes the theoretical frameworks of Lynch’s (1960) urban imageability and Tuan’s (1977) place attachment. While participants have physically relocated to the new environment, the findings suggest that this new setting has not yet been fully internalized or imbued with meaning in their mental maps. In other words, the cognitive assimilation of space lags behind its physical occupation.

5. Conclusion and recommendations

This study demonstrates that migration is a multifaceted process that transforms not only the physical spaces of cities but also the cognitive, perceptual, and experiential relationships individuals establish with the urban environment. The analyses conducted in the case of Yomra district in Trabzon reveal that the spatial transformation occurring after migration is not limited to population growth and increased housing demand; it also involves significant shifts in individuals’ perceptions of the city, navigational behaviors, and levels of social attachment. The combined evaluation of survey data and cognitive mapping findings confirms the presence of a *perceptual center shift* triggered by migration. Participants’ residential preferences and everyday practices, shifting from the Trabzon city center to Yomra, indicate a functional and symbolic relocation of the urban core. When considered in light of Kevin Lynch’s (1960) theory of the urban image and Yi-Fu Tuan’s (1977) conceptual distinction between “space” and “place,” the findings support the conclusion that individuals’ emotional and cognitive bonds to place are reconfigured through migration. Real estate market analyses further illustrate a substantial increase in indicators such as building permits, property transactions, and ownership transfers in parallel with migratory movements. In particular, the rise in housing sales between 2020 and 2024 suggests that migrants tend toward permanent rather than temporary settlement, thereby directly influencing the spatial and social fabric of Yomra. Moreover, the increase in the number of registered taxpayers reflects the formal integration of this permanence into the economic system.

In order to reconstruct urban memory weakened or lost through migration, it is deemed essential to support investments in public spaces, cultural activities, and shared living environments. Such investments may foster emotional connections between migrants and their new surroundings, contributing to the development of social cohesion and the continuity of spatial belonging. These recommendations highlight that migration should be addressed not only in terms of spatial expansion but also through its perceptual, social, and governance dimensions. The findings from Yomra clearly demonstrate that migration cannot be explained solely by spatial dispersal; rather, it exerts profound effects on individuals' perceptual, social, and symbolic relationships with the city. In this respect, the study offers an original contribution to the relatively underexplored literature on the nexus between migration and spatial perception, providing both theoretical and practical insights for policymakers, urban planners, and local governments. In rapidly growing settlements shaped by migration, urban development should not be driven exclusively by demand, but should be guided by principles of environmental sustainability and social cohesion. The spatial and sociological transformations induced by migration necessitate a multidimensional planning approach. Accordingly, urban expansion tendencies in peripheral districts like Yomra must be supported through integrated migration strategies to prevent unregulated growth. From the perspective of transportation and accessibility, the survey findings and perceptual gaps identified in the cognitive maps indicate the need to redesign urban transport infrastructure to ensure spatial continuity. Strengthening the connectivity between newly developed areas and central urban axes is crucial to reducing time–space accessibility inequalities. The increasing socio-economic divergence between migrant and local populations also leads to ownership-based segregation. To counter this, housing policies that prioritize the production of affordable housing must be developed. Mixed-use and socially interactive residential areas should be promoted as spatial frameworks that enhance social cohesion and foster inclusive urban environments. To effectively implement all of these strategies, it is essential for local governments to adopt dynamic planning tools that integrate land registry, tax, and population data. In particular, the use of participatory analytical methods such as cognitive mapping should be recognized as a valuable instrument for incorporating societal perspectives into planning processes.

The Proceedings of the 4th International Civil Engineering and Architecture Conference includes all the accepted and presented papers, compiled in two volumes:

Volume 1: Civil Engineering, comprising 303 papers under major categories such as Structural Mechanics, Earthquake Engineering, Hydraulics & Fluid Mechanics, Geotechnics & Soil Mechanics, Transportation, Structural Materials, Hydrology & Water Resources, Construction Management, and Waste Management.

Volume 2: Architecture, featuring 118 papers grouped under topics such as Architectural Philosophy, Design & Practice, Architecture, Conservation & Restoration, Urban Planning & Landscape, Architectural Engineering, and Interior Design.

We are sincerely grateful to all authors for their valuable contributions. The papers included in these volumes were rigorously reviewed by field experts, and only those that were accepted and presented at the conference have been published. We extend our deepest appreciation to the reviewers for their meticulous evaluations, which significantly contributed to the quality of this publication.
