TABLE OF CONTENTS

PREFACE

The 4th International Civil Engineering & Architecture Conference (ICEARC'25) aimed to bring together academics, researchers, and practitioners in the fields of civil engineering and architecture from across the globe. Held in Trabzon, Türkiye on May 17–19, 2025, the conference served as a dynamic platform to review recent achievements, share emerging developments, and address both current and future challenges in these disciplines.
ICEARC'25 has once again demonstrated its truly international character, drawing over **500 participants from 33 countries**. The conference hosted **421 research presentations** delivered in **59 parallel sessions**, and provided participants with excellent networking and collaboration opportunities. In addition to the technical sessions, **four dedicated workshops**—focusing on contemporary themes such as sustainable buildings, hybrid structures, and advanced materials—offered attendees practical insights and knowledge exchange in specialized areas.
The **Proceedings of the 4th International Civil Engineering and Architecture Conference** includes all the accepted and presented papers, compiled in two volumes:

- **Volume 1: Civil Engineering**, comprising 303 papers under major categories such as Structural Mechanics, Earthquake Engineering, Hydraulics & Fluid Mechanics, Geotechnics & Soil Mechanics, Transportation, Structural Materials, Hydrology & Water Resources, Construction Management, and Waste Management.
- **Volume 2: Architecture**, featuring 118 papers grouped under topics such as Architectural Philosophy, Design & Practice, Architecture, Conservation & Restoration, Urban Planning & Landscape, Architectural Engineering, and Interior Design.

We are sincerely grateful to all authors for their valuable contributions. The papers included in these volumes were rigorously reviewed by field experts, and only those that were accepted and presented at the conference have been published. We extend our deepest appreciation to the reviewers for their meticulous evaluations, which significantly contributed to the quality of this publication.
We would also like to express our gratitude for the institutional support provided by **Karadeniz Technical University** and **the Chamber of Civil Engineers (Trabzon Branch)** of the **Union of Chambers of Turkish Engineers and Architects**. We sincerely thank our sponsors:

- **Platinum Sponsor:** Usta Grup
- **Gold Sponsors:** Cengiz İnşaat, Türen İnşaat, Odaş
- **Silver Sponsors:** Es Denizcilik, KCT Yol Yapı İnşaat
- **Bronze Sponsors:** Inosel, YaşarTek, AKM Yapı

Our special thanks go to the **Mayor of Trabzon Metropolitan Municipality**, **Mayor of Ortahisar Municipality**, and **Mayor of Yomra Municipality** for their valuable support.
We also acknowledge the outstanding efforts of the organizing committee, the student volunteers, and all the moderators who chaired our sessions with professionalism and dedication. Their contributions were instrumental in the success of ICEARC'25.
Finally, the conference concluded with a memorable **social tour to the iconic Sümela Monastery and Uzun Göl**, offering participants a taste of the region's rich cultural and natural heritage.
We look forward to welcoming you again at **ICEARC'27**.

The analysis of usage metal powder waste as cement substitute in concrete

Ebru Güzel Carlıoğlu*[1], Mehmet Serkan Yatağan[1]

[1] İstanbul Technical University, Faculty of Architecture, 34367 İstanbul, Türkiye

Abstract.
Purpose: The importance of a sustainable waste management approach is increasingly growing in order to protect natural resources and reduce waste. The limited nature of natural resources has brought forth the alternative of using recycling practices, particularly as a potential source of raw materials in the construction industry. The usage of metal powder waste in the construction sector not only ensures the safe disposal of waste but also reduces the consumption of raw materials and energy. In this way, environmental problems are prevented and economic benefits are achieved in terms of costs.
Study design/methodology/approach: In this study, metal powder waste materials have been investigated as substitute materials for cement to reduce the negative environmental impacts occurring during the cement production phase. Three different metal powder wastes, considered to improve the life cycle of concrete, have been used as cement substitute materials. The effects of boron oxide, aluminum oxide, and zinc oxide powder wastes, usage in varying proportions as metal powder waste, on the physical and mechanical properties of concrete have been experimentally investigated in a laboratory environment and how these materials alter the performance of concrete has been observed.
Findings: Based on the results obtained depending on the type and proportion of the metal powder waste used, it has been observed that alternative sources can be utilized as cement substitute materials, and these alternative sources can enhance the life cycle assessment of concrete.
Originality/value: By using metal production waste dust as recycling material, natural resources can be protected and alternative materials that can provide economic benefits can be developed.

Keywords: Waste material; Metal waste; Life cycle assessment; Sustainability; Concrete; Cement; Substitute materials.

1.Introduction

The long-standing need for urbanization throughout human history has brought with it the issue of depleting natural resources. As a lasting solution to this problem, the concept of sustainability has come to the forefront.

Sustainability can be defined as a form of development that allows current resources to be utilized without harming them, ensuring their availability for future generations. It is well known today that natural resources are rapidly depleting, and it is becoming increasingly difficult to compensate for this loss. In this context, the understanding of environmental sustainability has gained significant importance. Sustainability, while crucial in many fields, holds particular importance in the construction sector.

Following the Industrial Revolution, rapidly growing populations in urban areas have made it necessary for urban planning to align with sustainability principles. This has introduced various criteria into design processes. Examples include ecological transportation alternatives, wastewater treatment and reuse, rainwater harvesting for reuse, and the use of environmentally friendly local materials. A major reason for the rapid deterioration of ecosystems today is the production and use of synthetic materials not found in nature, which cause significant environmental damage during their lifecycle. This demonstrates that ecological design cannot be considered independently of material selection (Aytıs & Polatkan, 2010).

Concrete, the most commonly used building material in the world, is preferred in sustainable design due to its durability, longevity, local availability, thermal mass capacity, low toxic gas emissions as a finished product, recyclability, lack of contribution to the urban heat island effect, versatility, and aesthetic appeal (Tuğrul & Sev, 2015).

*Corresponding author, E-mail: carlioglu22@itu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_047

At the same time, concrete constitutes the largest share of construction and demolition waste in the construction industry. Most aggregates and the cement produced are used in concrete. By its nature, cement is an energy-intensive material that emits significant amounts of CO_2. Aggregate extraction depletes soil and involves heavy transportation processes. It is estimated that approximately 8% of global CO_2 emissions result from concrete production. It is clear that the production and use of concrete have a considerable environmental impact. The construction industry plays a decisive role in the environmental effects—both positive and negative—and the concept of sustainability, a multidimensional goal in the concrete industry, requires a range of approaches (Arıoğlu et al., 2004).

The careful and intelligent use of concrete can provide environmental benefits. By utilizing cement-reducing materials, proper mix ratios, and recycled or waste materials, concrete can be made both sustainable and durable (Arıoğlu et al., 2004).

In this study, in order to reduce the amount of cement used in concrete production and to develop a sustainable alternative material, the use of metal powders—industrial by-products—as a cement substitute was investigated. Mechanical and physical tests were carried out on three different types of concrete produced with metal waste powders, and the impact of these powders on concrete performance was evaluated.

2. Methodology

In order to determine whether aluminum oxide, zinc oxide, and colemanite powders—used as industrial waste—possess pozzolanic properties, preliminary tests were conducted on these metal waste powders. Based on the results of these preliminary tests, the material characteristics and concrete mix ratios were established. Four different cement replacement ratios were determined: 10%, 20%, 40%, and 50%. Including the control sample, a total of four different types of concrete were produced. These concrete types are: control concrete, aluminum oxide-replaced concrete, zinc oxide-replaced concrete, and colemanite-replaced concrete.

2.1 . Materials

2.1.1 . Cement

In the experimental study, CEM I 42.5R type cement, produced in accordance with the TS EN 197-1 standard, was used. Consistency determination, setting time determination, and specific gravity tests were conducted in accordance with the relevant standards.

2.1.2 . Aggregate

In the experimental study, specific gravity, moisture content determination, water absorption, and sieve analysis tests were performed on the aggregates in accordance with TS EN 1097-6 and TS EN 933-1 standards, respectively (Fig. 1). Based on these test results, the amount of material passing through each sieve and the fineness modulus of the aggregates were evaluated.

The fineness modulus is a numerical value that provides information about the granulometric composition of an aggregate. It is calculated by subtracting the cumulative percentage retained on each sieve from 100, summing these values, and dividing the total by 100 (Özkul et al., 1999). The granulometry of the aggregate blends used in the concrete was selected to fall between the A and C curves, as specified in the TS 802 “Concrete Mix Design Calculation Principles” standard (Fig. 2).

Fig. 1. Specific gravity and sieve analysis of aggregates

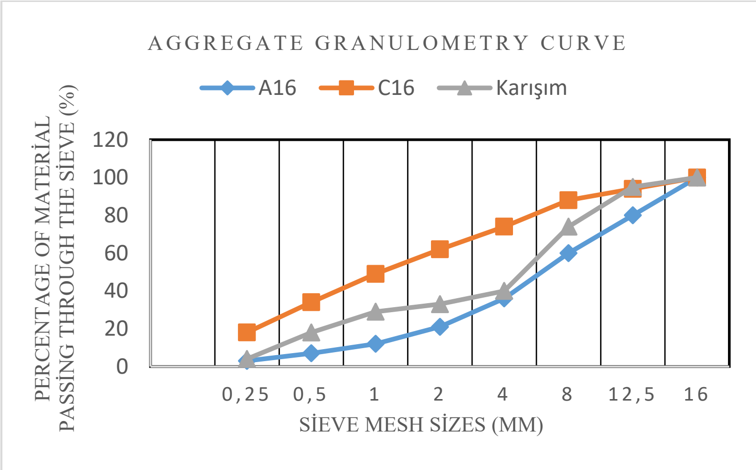

Fig. 2. Aggregate granulometry curve.

2.1.3 . Metal Production Waste Powders

In the study, aluminum oxide, zinc oxide, and colemanite products, which are metal production waste, were used in powder form. Preliminary tests were conducted to investigate the specific gravities and pozzolanic activities of these materials.

The pozzolanic activity test was carried out according to the TS 25 standard. According to the standard, the 7-day compressive strength of the produced samples should be at least 4 N/mm². The produced samples were kept for 24 hours at a room temperature of 23±2°C, covered with a glass plate. After 24 hours, without removing the molds, the samples were further kept in an oven at 55±2°C for 6 days. The samples were then left in the room for 4 hours until they reached room temperature (Fig. 3). Once the samples reached room temperature, compressive and bending strength tests were conducted using a Form-Test Seidner brand test device with a 200 kN capacity (Fig. 4).

Fig. 3. Samples kept in molds and removed from molds in the pozzolanic activity test.

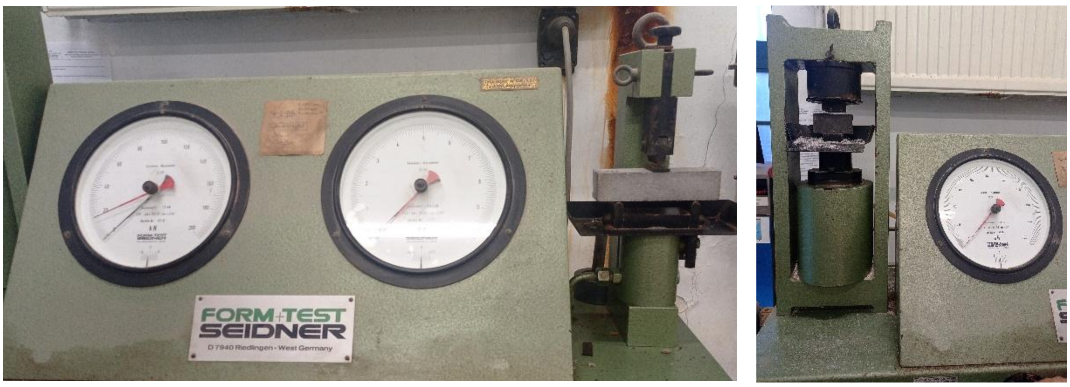

Fig. 4. Flexural strength tests conducted to determine pozzolanic properties.

2.2 . Methods

2.2.1 . Mechanical tests

The load-bearing properties of construction materials are determined based on their mechanical properties. In the study, bending tensile, compressive, and static elasticity tests were conducted to measure the mechanical properties of the different types of concrete samples produced. In these tests, the static elasticity modulus was applied on the 28th day of curing, while the bending tensile and compressive tests were performed on the 7th, 28th, and 90th days of curing.

2.2.1.1. Flexural Strength Test

For the determination of flexural strength (Rf), prism-shaped samples with dimensions of 4x4x16 cm were prepared in accordance with the standard and tested using a 100 kN capacity universal testing machine, in compliance with the TS EN 12390-5 standard (Fig. 5). The measurement of the square cross-section of the prismatic samples (b) was taken, and the distance between supports (l) was recorded. The sample was placed between the supports and broken by applying a load at the midpoint of the sample. The load value (Ff) was recorded in Newtons. The flexural strength was calculated using Equation 1.

$$\mathrm{Rf} = \frac{1{,}5 \text{ x } \mathrm{Ff} \text{ x } \mathrm{l}}{\mathrm{b}^3} \tag{1}$$

Fig. 5. 100 kN capacity testing machine used for the flexural strength test.

2.2.1.2. Compressive Test

The prismatic samples with dimensions of 4x4x16 cm, broken during the flexural test, were also tested for compressive strength (Rc) using a 100 kN capacity universal testing machine, in accordance with the TS EN 12390-3 standard (Fig. 6). The failure load (Fc) was recorded in Newtons and was calculated using Equation 2.

$$\mathrm{Rc} = \frac{\mathrm{Fc}}{\mathrm{b}^2} \tag{2}$$

Fig. 6. 100 kN capacity testing machine used for the compressive strength test.

2.2.1.3. Static Elasticity Modulus Test

Cylinder samples with dimensions of 7.5x15 cm were produced from all concrete mixes, and deformation tests were conducted. For the static elasticity modulus (Es), the samples cured for 28 days at a temperature of 20±1°C were fixed within a frame (Fig. 7). An extensometer with a precision of 0.01 mm was placed on the frame. The force (F) values corresponding to the deformation (Dl) under load were recorded using a universal testing machine.

In the stress (σ)-deformation (ε) graphs, the initial tangent of the curve, where stress and deformation are linear, was used. The slope of the tangent in this region was calculated using the least squares method. Stress, strain, and elasticity modulus were calculated using Equation 3, Equation 4, and Equation 5.

$$\sigma = \frac{\mathrm{F}}{\mathrm{A}} \tag{3}$$

$$\varepsilon = \frac{\Delta l}{\mathrm{lo} - \Delta l} \tag{4}$$

$$\mathrm{Es} = \frac{\sigma}{\varepsilon} \tag{5}$$

Fig. 7. Static elasticity modulus test setup.

2.2.2. Physical tests

As part of the physical tests, capillary water absorption, weight-based water absorption, and apparent porosity tests were conducted on the concrete samples at the 28th and 90th days of curing.

2.2.2.1. Capillary Test

The capillarity coefficient (N) was determined in accordance with the BSI Standards Publications 2011b standard, for samples that were dried at a temperature of 70±5 °C and then cooled to room temperature (23±2 °C). Prismatic samples, for which the contact surface area (As) was measured, were placed in the experimental setup under laboratory conditions, with their dry weight (mdry,s) and contact time (tso) recorded. The samples were positioned in such a way that the determined surface would be in contact with water (Fig. 8). Subsequently, at specified time intervals, the surface water on the contact area was wiped off, and weight changes (mso,s) were monitored. The values obtained from these measurements were used to calculate using Equation 6.

$$N = \frac{\text{mso,s} - \text{mdry,s}}{\text{As}\sqrt{\text{tso}}} x10^{-6} \quad (6)$$

Fig. 8. Capillary water absorption test setup.

2.2.2.2. Apparent Porosity and Water Absorption by Weight Test
Apparent porosity (Sh) is the ratio of the void volume of the material to its apparent volume. It was calculated by dividing the difference between the material's saturated weight (ms) and its dry weight (md) by the difference between the material's saturated weight (ms) and its weight in water (mh), as given in Equation 7.

The weight-based water absorption (Sk) ratio was calculated by dividing the difference between the material's saturated weight (ms) and dry weight (md) by the dry weight (md), as shown in Equation 8. Measurements were taken using an experimental setup constructed in accordance with the BSI Standards Publications 2006 standard (Fig. 9).

$$\text{Sh} = \frac{ms - md}{\text{ms} - \text{mh}} x\ 100 \quad (7)$$

$$Sk = \frac{ms - md}{md} x\ 100 \quad (8)$$

Fig. 9. Water absorption by weight and visible porosity test setup.

3. Result and discussion

3.1. Mechanical tests results

3.1.1. Compressive strength and flexural strength of concrete

Compressive and flexural strength tests were conducted on the 7th, 28th, and 90th days, and the values from the tests are presented in the graphs (Fig. 10, Fig. 11).

If we assume that the strength of the concrete mixes on the 7th day provides information about early strength, we observe that the concrete with colemanite substitution has the earliest strength, followed by the aluminum oxide and zinc oxide substituted concretes in sequence.

Considering the compressive and flexural strength values of all concrete types, it is observed that the AL%20 sample from the aluminum oxide substituted concretes has the highest value on the 90th day, the Ç%40 sample from the zinc oxide substituted concretes has the highest value on the 28th day, and the KL%10 sample from the colemanite substituted concretes has the highest value on the 90th day. Furthermore, the sample closest to the control sample is the KL%10.

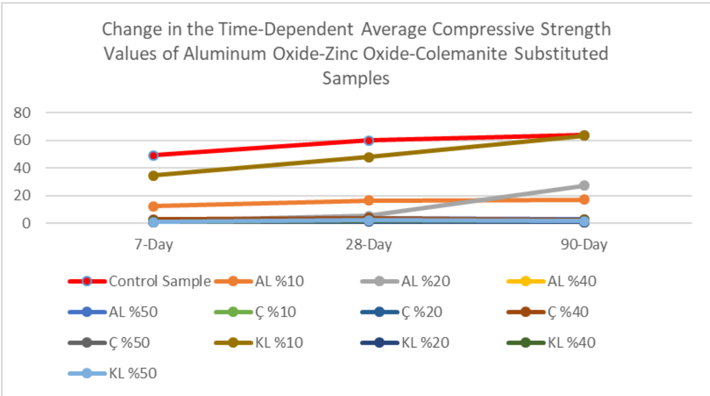

Fig. 10. Compressive strength variation graph of Aluminum Oxide-Zinc Oxide-Colemanite substituted samples.

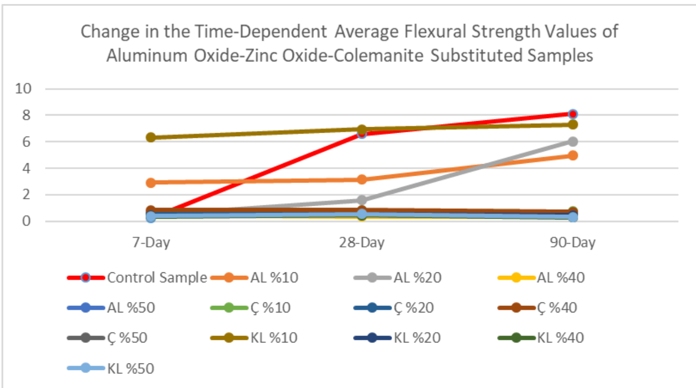

Fig. 11. Flexural strength variation graph of Aluminum Oxide-Zinc Oxide-Colemanite substituted samples.

3.1.2. Static Elasticity Modulus of concrete

Cylinder samples with dimensions of 7.5x15 cm were produced from all concrete mixes, and a deformation test was performed on the 28th day of curing.

When the stress-strain measurements were plotted on a graph, the highest values, as shown in the graph, were recorded for the colemanite substituted samples, followed by the aluminum oxide substituted samples, and the zinc oxide substituted samples (Fig. 12). The KL%10 sample achieved the highest value and was the closest to the control concrete.

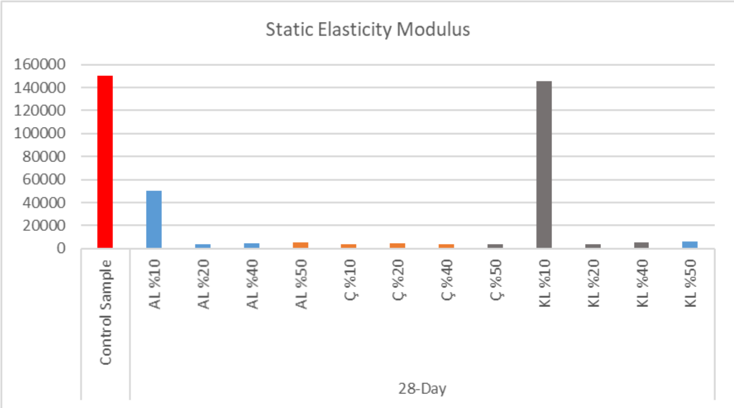

Fig. 12. Elastic modulus values of Aluminum Oxide-Zinc Oxide-Colemanite substituted samples.

3.2. Physical tests results

3.2.1. Capillary, Apparent Porosity and Water Absorption by Weight of concretes

When the results of capillary water absorption, water absorption, and apparent porosity were examined, it was observed that as the substitution ratio increased in all samples, the capillarity coefficient also increased, as shown in Fig. 13.

The increase in the capillarity coefficient, which is related to the material's pore structure, indicates that as the substitution ratio in the material increases, the pore ratio in the samples also increases..

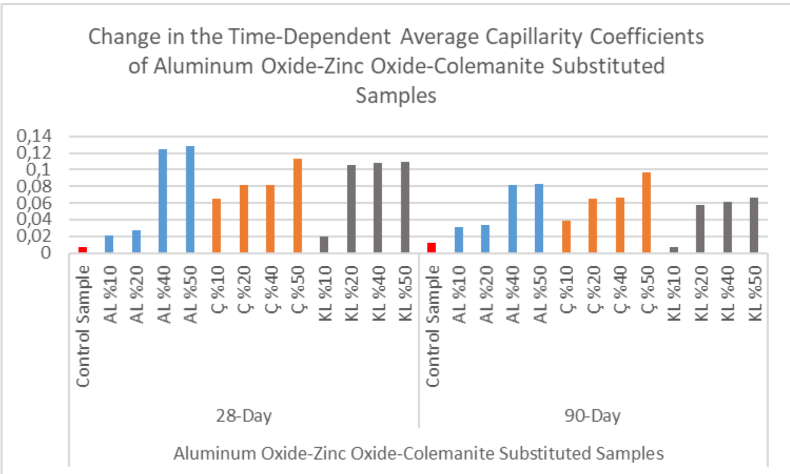

Fig. 13. The change in the average capillarity coefficients of Aluminum Oxide-Zinc Oxide-Colemanite substituted samples.

In the samples, a decrease in capillarity coefficients over time is observed. This decrease is attributed to the fact that, at the end of hydration, each component of the cement creates different hydration products (C-S-H, Calcium-Silica-Hydrate), which fill the voids in the concrete. Additionally, it is believed that the metal waste powders added as substitutes increase the impermeability of the concrete. These reactions are thought to prevent the formation of capillary pore spaces within the concrete, and as a result, the capillary water absorption is lower over time, as shown in Fig. 14 and Fig. 15.

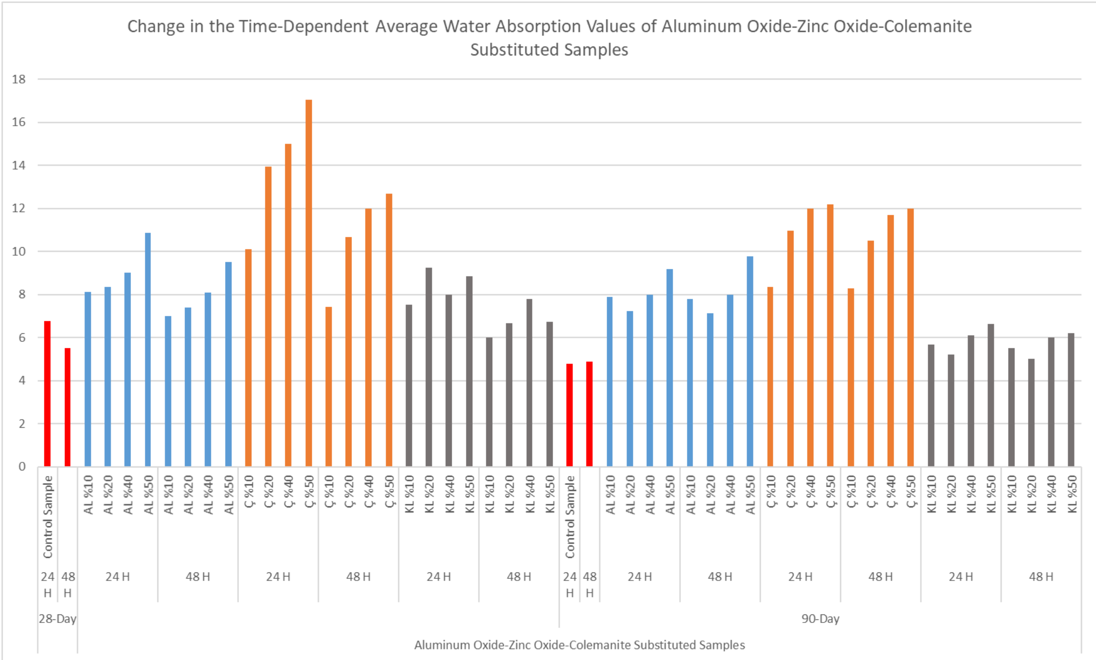

Fig. 14. The change in the average water absorption values of the samples with aluminum oxide-zinc oxide-colemanite substitution.

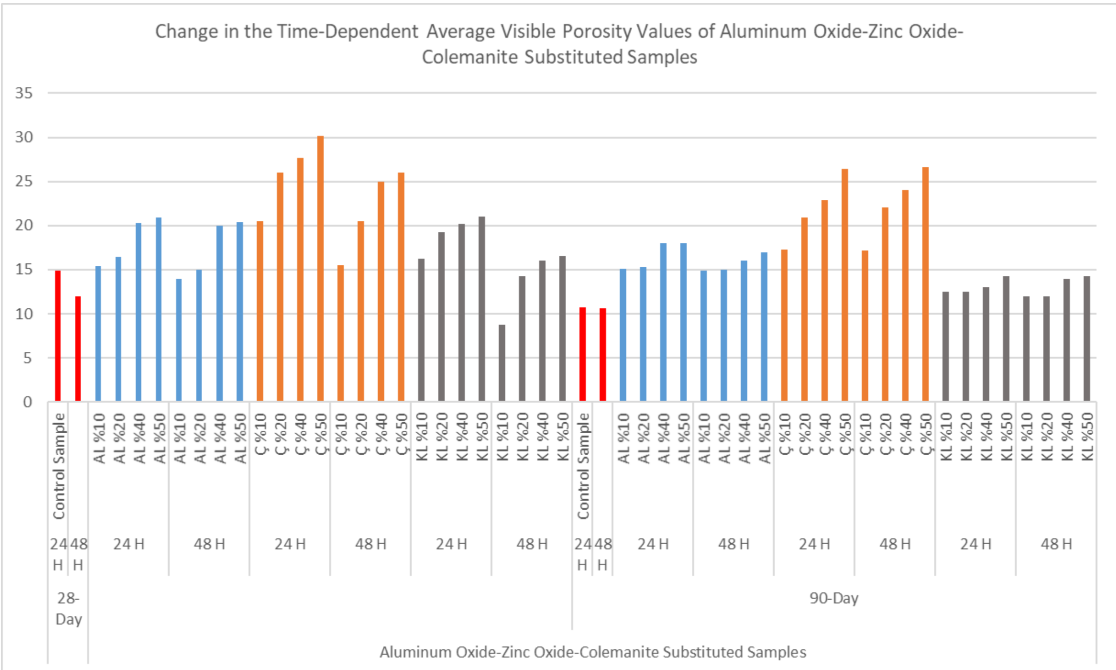

Fig. 15. The change in the average visible porosity values of the samples with aluminum oxide-zinc oxide-colemanite substitution.

4. Conclusions

In this study, the importance of sustainability through the reuse of recycled materials is emphasized. In this context, aluminum oxide, zinc oxide, and colemanite substituted concretes were produced to investigate the effect of using metal powders, which are production waste, as cement substitutes on the physical and mechanical properties of concrete. The waste metal powders used in the production of these concretes were substituted for cement in different proportions, and the effect of various metal powders and their proportions on the durability and strength properties of concrete was examined.

- When examining the experiments conducted to investigate the physical properties, it is understood that the samples with 10% KL substitution improved the physical properties of the concrete.
- When examining the experiments conducted to investigate the mechanical properties, it is observed that the samples with 10% KL substitution have values similar to or close to the control samples.
- As the substitution ratio of metal waste powders increases, a decrease in mechanical strength is observed.
- When the experimental data is examined, it is considered that concretes with colemanite and aluminum oxide substitution could be suitable for use as a load-bearing material according to TS 500 standards. However, other samples that do not fall under the load-bearing class, considering their physical and mechanical properties, might be suitable for use as cement substitutes in plaster and mortar production.
- The use of metal production waste powders as recycled materials can conserve natural resources and provide economic benefits.

Enhancing thermal comfort and energy-saving potential of the buildings with multiple-layered phase change material

Doğukan K. Yemenici*[1], Kübra E. Barış[1]

[1] *Kocaeli University, Department of Architecture and Design, 41310 Kocaeli, Türkiye*

Abstract. The increasing population, rising living standards, and growing use of indoor spaces have significantly increased energy demand in the construction sector. This situation highlights the need for innovative building envelope design to reduce energy consumption and promote environmental sustainability. In this context, phase change materials (PCM), known for their high thermal energy storage capacity, emerge as an environmentally friendly solution. Key factors affecting the thermal comfort and energy consumption of buildings include the type, thickness, melting temperature, and number of layers of PCM. Although most of the research is focused on the use of single-layered PCM in exterior wall design, research on multiple-layered PCMs is quite scarce. Thus, the current study aims to assess the use of multiple-layered PCM in the exterior wall design of an educational building located in different climate zones of Türkiye. Simulations were conducted to evaluate the impact of multiple-layered PCM and PCM-thermal insulation (TI) combinations on thermal comfort, energy-savings, and construction costs during both summer and winter periods. Istanbul and Erzurum were chosen to represent temperate-humid and cold climates, respectively. Simulation results revealed that wall sections combining PCM and TI had higher thermal performance and energy-savings compared to those with only PCM. Multiple-layered PCM provided better thermal comfort with lower energy requirements for summer and winter periods, compared to single-layered PCM. Wall sections with multiple-layered PCM (3 PCM layers, each 30 mm) and TI (30 mm) could achieve energy savings of up to 3.93% in heating energy consumption and 2.77% in cooling energy consumption, compared to single-layered PCM.

Keywords: Multiple-layered phase change material; Thermal insulation; Heating and cooling; Thermal comfort; Energy-saving

1. Introduction

In Türkiye, approximately 33% of the total energy consumption occurs in the residential sector. Therefore, the development of technologies that enhance energy efficiency in residential buildings is of great importance (Terhan, 2021). Energy efficiency refers to the reduction of energy consumption without compromising the level of comfort. Considering the correlation between energy consumption and the level of development, energy efficiency is not only a key component of environmental sustainability but also a critical factor in economic development (Terhan et al., 2023).

The building envelope, which consists of external components such as walls, roofs, and windows, is one of the primary sources of thermal energy losses. Among these, walls play a critical role in energy efficiency by accounting for approximately 25% to 30% of the total thermal energy loss (Abanda & Byers, 2016). A thermally optimized building envelope design contributes significantly to the reduction of both heating and cooling loads. In this context, one of the innovative and increasingly applied solutions in building envelope design is the integration of "thermal energy storage systems."

Phase change materials (PCM) are innovative substances employed in the thermal energy storage systems of buildings (Beltran & Martinez-Gomez, 2019). These materials transfer the stored thermal energy to the indoor environment in a controlled manner, thereby enhancing indoor thermal comfort. Consequently, they offer significant potential for reducing the heating and cooling energy demands of a building (Sivanathan et al., 2020).

Conventional thermal insulation materials (TI) enhance the thermal resistance of the building envelope by limiting heat transfer between the interior and the external environment (Al-Homoud, 2005). The combination of PCM-TI improves the overall thermal performance of buildings and enables more stable indoor thermal comfort levels (Alizadeh & Sadrameli, 2019). A review of the existing literature reveals that the majority of studies have focused on single-layered PCM applications. These studies often assess performance based on PCM with a fixed

https://doi.org/10.31462/icearc2025_a_aen_079

thickness and a single melting temperature. However, multiple-layered PCM applications offer the potential to regulate heat flow across the building envelope more effectively, significantly reducing thermal loads. Various studies have demonstrated that, depending on the thermophysical properties of the building envelope and the type, thickness, and melting temperature of the multiple-layered PCM and TI used under different climatic conditions, energy savings in heating loads of approximately 2.26–27% and in cooling loads of approximately 8.54–38% can be achieved (Arıcı et al., 2022; İlgar & Terhan, 2024; Asghari et al., 2024; Refahi et al., 2024; Rehman et al., 2021; Dardouri et al., 2023). To fill the current knowledge gap in the literature, the aim of this study is to comprehensively examine the effects of using multiple-layered PCM in the external wall design of an educational building located in two different climate region of Türkiye, in terms of energy efficiency, indoor thermal comfort, and construction cost during both summer and winter periods. Istanbul and Erzurum were selected to represent temperate-humid and cold climate zones, respectively. It is anticipated that the use of multiple-layered PCM could significantly contribute to environmental sustainability by reducing building energy consumption.

2. Methodology

2.1. Description of the Simulated Building

A basic single-story education building model (500 cm x 400 cm x 300 cm) was designed for the simulation (Fig. 1). Because the building model consisted of a single zone, there were no inner walls, and all of the exterior walls were modelled identically. The building has a terrace roof. The west wall was equipped with a wooden door measuring 90 cm wide and 220 cm high. In the current study, the south wall of the building was equipped with a window 400 cm in length and 150 cm in height. The distance between the window bottom and floor was 80 cm. The glass was an air-filled double glass with an overall heat transfer coefficient (U) of 2.8 W/m^{2}K, solar heat gain coefficient of 0.7, and visible transmittance of 0.8.

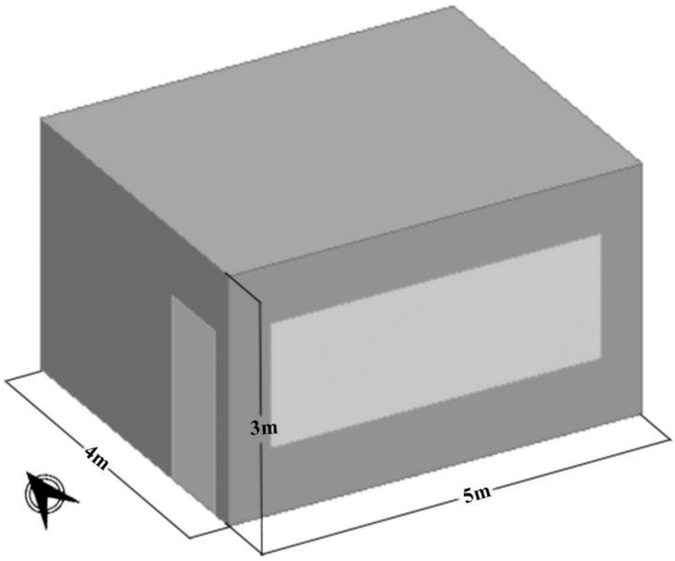

Fig. 1. Geometrical model of the education building analysed

The type and thickness of the materials in the building envelope have been designed in accordance with the thermal conductivity coefficients specified in TS 825 (2013). The details of the building envelope are provided in Table 1, and the thermophysical properties of the materials used are given in Table 2.

Table 1. Details of the building envelope layers

Building Envelope	Layers (from inside to outside)
Roof	20 mm cement-based plaster, 120 mm reinforced concrete slab, 30 mm cement screed, 50 mm thermal insulation, waterproofing, and gravel roofing
Reference wall	20 mm plaster, 30 mm PCM, 240 mm aerated autoclaved concrete and 20 mm plaster
Exterior wall with integrated thermal insulation	20 mm plaster, 30 mm PCM (up to three layers), 240 mm aerated autoclaved concrete, 30 mm TI, 20 mm plaster

Table 2. Thermophysical properties of the selected materials

Material	Density (kg/m³)	Thermal conductivity (W/mK)	Water vapor diffusion resistance (μ)
Cement-based plaster	2000	1.6	15/35
Aerated autoclaved concrete	500	0.15	5/10
Thermal insulation (Glasswool)	32	0.04	1

In this study, the PCM used was directly selected from the database of the DesignBuilder® software (BioPCM® M27/Q21). The thermophysical properties of the PCM are summarized in Table 3. Based on findings from a previous study, the optimal melting temperature of the PCM was determined to be 21 °C for winter, as lower outdoor temperatures allow for more efficient phase transition between melting and solidification, and 27 °C for summer conditions. The lowest heating and cooling energy demands were achieved when the PCM layer was placed on the interior side of the wall section and the TI layer on the exterior. The most effective configuration in terms of maintaining indoor thermal comfort and maximizing energy savings was identified as using 30 mm thick PCM and 30 mm thick TI (Yemenici & Barış, 2024). Therefore, to evaluate the effects of PCM layering on indoor thermal comfort, total energy savings, and construction costs, 30 mm thick PCM was applied on the inner side of the wall section, and 30 mm thick TI was positioned on the outer side in PCM-TI integrated wall configurations.

Table 3. Thermophysical properties of the PCM

Thermophysical properties		Values
Density (kg/m³)	Solid form	880
	Liquid form	760
Thermal conductivity (W/mK)	Solid form	0.2
	Liquid form	0.15
Specific heat (J/kgK)		2000

In this study, two different combinations of material layering have been developed. The wall containing a single-layered PCM (Fig. 2Ref) is defined as the reference wall, and its details are provided in Table 1. To determine the optimal number of PCM layers, the following approach was used:

- The PCM (up to three layers) was placed in the innermost layer of the walls
- The PCM (up to three layers) was placed in the innermost layer, and TI was placed in the outermost layer

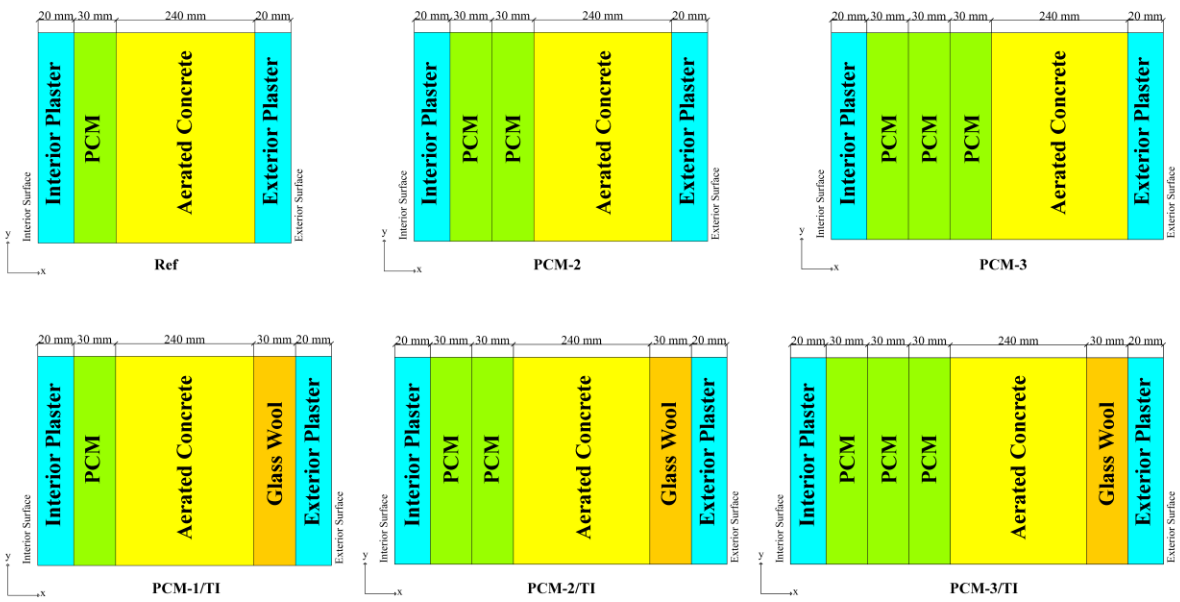

Fig. 2. Simplified drawing of wall sections simulated in the study

The wall sections were coded in [PCM-a] or [PCM-a/TI] format. PCM and TI represent phase change material and thermal insulation, respectively. "a" represents the number of layers of PCM.

2.2. Simulation Details

The analyzed building was intended for educational purposes, with working hours from 09:00 to 16:00. The building's occupancy rate was fixed at 0.55 occupants/m^2. Metabolic rates depend on the activities of the occupants in the education building. Furthermore, the use of equipment was entered into the simulation based on weekly usage rates. An illumination level of 3.4 W/m^2–100 lx of was taken into consideration, during working hours.

As an exterior temperature of 18 °C can maintain the inside at a comfortable temperature of 24 °C, hence, the heating or cooling requirements for any place are usually calculated according to this exterior baseline temperature (Menyhart & Krarti, 2017). The time-dependent variation of the outdoor temperature for the representative cities from January 20-22 and July 20-22 is shown in Fig. 3 respectively. According to this, the outdoor air temperatures in the cities located in two different climate zones are either below or above the reference temperatures. As a result, heating and cooling requirements arise to ensure sufficient thermal comfort. Since the winter and summer seasons represent the maximum heating and cooling energy requirements, respectively, the study focuses on the winter and summer periods, with the goal of reducing heating and cooling energy demand (Arumugam et al., 2022).

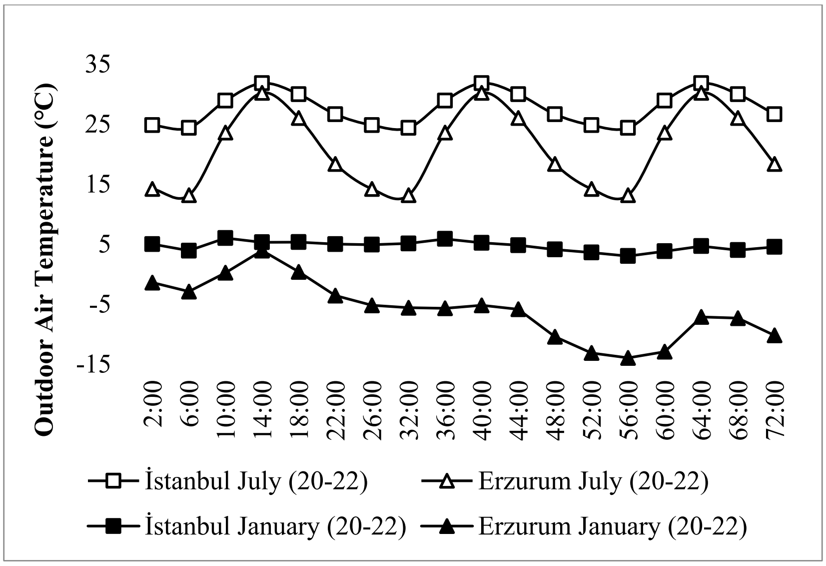

Fig. 3. The outdoor air temperature-time graph for the representative cities

The thermal comfort range was defined as 19 °C for the heating period and 26 °C for the cooling period. Accordingly, mechanical systems are activated only when the indoor temperature falls below 19 °C or exceeds 26 °C. The heating demand of the building is met through a natural gas-based system, while the cooling demand is fulfilled using an electrically powered system. All heating, cooling, and ventilation requirements are provided by mechanical systems, and the impact of natural ventilation was excluded from the simulations by setting it to "off." DesignBuilder® software was used for the simulations. To accurately simulate the phase change process of the PCM, a computational technique known as the "Finite Difference Calculation Method" was selected (U.S. Department of Energy, 2021)

The effects of multiple-layered PCM and TI integration on the thermal performance of the building envelope were assessed by considering indoor temperature reduction (ITR) values. The term "ITR" describes the decrease in the maximum interior temperature of the simulated building (with multiple-layered PCM and PCM+TI) compared with the reference building (without PCM and TI). The mechanical systems were turned off during the ITR calculation to mitigate the risk of changing the thermal performance of the building envelope.

The effects of the multiple-layered PCM and TI on the energy performance of buildings were determined by considering the annual energy savings. The annual energy savings is the amount of energy saved when PCM and TI are incorporated into a building envelope. The annual energy saving, as a ratio (ESR), was calculated to represent the percentage of energy saved by incorporating the PCM and TI, according to Equation (1):

$$ESR = \frac{\text{EC (without PCM / TI)} - \text{EC (with PCM / TI)}}{\text{EC (without PCM / TI)}} \text{ x } 100\ (\%) \tag{1}$$

Where EC is energy consumption (kWh). The ESR and EC values were determined when the mechanical system was active between 07:00 and 24:00 with 100% efficiency and was inactive between 00:00 and 07:00.

The economic viability of wall sections incorporating PCM-TI combinations, designed for different climatic zones of Türkiye, was assessed by considering two key indicators: energy cost savings (ECS) and payback period (PP). Initially, ECS was calculated in accordance with Equation (2) (M'hamdi et al., 2022):

$$ECS = (\mathrm{ES_{summer}} * \mathrm{EC}) + (\mathrm{ES_{winter}} * \mathrm{NC}) \tag{2}$$

ES_{summer} and ES_{winter} (kWh) represent the difference between the annual total cooling and heating energy consumption of the building with simulated alternative wall sections compared to that of the reference wall section. EC denotes the electricity cost, while NC symbolizes the natural gas cost. According to the Turkish Statistical Institute (TÜİK, 2022), the annual average electricity cost in Türkiye is 139.1 kuruş/kWh, and the natural gas cost is 29.5 kuruş/m³.

PP (year) obtained from different PCM-TI combinations in the simulated buildings was calculated according to Equation (3):

$$PP = \frac{[(\mathrm{C_{PCM}} * \mathrm{V_{PCM}}) + (\mathrm{I_{PCM}} * \mathrm{W_{PCM}})] + [(\mathrm{C_{TI}} * \mathrm{V_{TI}}) + (\mathrm{I_{TI}} * \mathrm{W_{TI}})]}{\mathrm{ECS}} \tag{3}$$

C_{PCM} and V_{PCM} represent the cost (TL/kg) and volume (m³) of the PCM, respectively, while I_{PCM} indicates the installation cost (TL/day) and W_{PCM} denotes the number of workers required for PCM installation (Table 4). Similarly, C_{TI}, V_{TI}, I_{TI}, and W_{TI} refer to the cost, volume, installation cost, and number of workers required for the installation of the TI material, respectively. During the calculation of installation costs, it was assumed that the reference building with dimensions of 500x400x300 cm, can be completed in one working day by two workers, whereas the building with integrated PCM-TI requires two working days in total, requiring each worker to work one full day.

Table 4. Parameters used in ECS and PP calculations

Parameters	Values
PCM Cost (TL/kg)	30 mm: 68.82
TI (glass wool) Cost (TL/kg)	30 mm: 84.00
PCM-TI Volume (m^3)	30 mm: 1.3806
PCM-TI Area (m^2)	46.02
PCM Production Facility	Kocaeli (Coral)
TI Production Facility	Adana (İzocam)
Daily Wage of a Worker (TL/gün)	2500

2.3. Climate Conditions

In this study, Istanbul, representing the temperate-humid climate characteristics, and Erzurum, representing the cold climate region of Türkiye, were selected. Hourly environmental conditions, such as temperature, solar radiation, atmospheric humidity, and wind speed, are available in the DesignBuilder® software database. These data were validated by comparing them with the data provided by the Turkish State Meteorological Service (İl ve İlçeler İstatistikleri, 2024).

Table 5. Solar radiation intensities and sunshine durations in selected cities

	Months												kWh/ m^2-year	Altitude	Sunshine (h/day)
Cities	1	2	3	4	5	6	7	8	9	10	11	12			
İstanbul	41	56	95	129	166	180	184	161	127	83	50	36	1389	40	5.9
Erzurum	70	91	132	138	162	181	193	174	142	103	68	56	1511	1890	6.7

The solar radiation intensities and sunshine duration data for the selected cities were obtained from the Türkiye Solar Atlas (Türkiye Güneşlenme Potansiyeli Atlası, 2010), which was prepared by the Meteorological Service of Türkiye (Table 5).

Istanbul represents the 2nd (temperate-humid) climatic region and is under the influence of the Mediterranean, Marmara, and Black Sea climates. In Istanbul, summer is hot and dry, and winter is warm and rainy. The annual average temperature is 16.4 ºC, and the average number of rainy days is 116.5. In addition, strong winds are effective during certain periods in Istanbul (İl ve İlçeler İstatistikleri, 2024). The annual total solar radiation intensity is 1389 kWh/m^2, and the average daily sunshine duration is 5.9 hours (Türkiye Güneşlenme Potansiyeli Atlası, 2010).

Erzurum is located in the 5th climate region and has the coldest climate conditions in Türkiye. Summer is warm and dry; winter is very cold and snowy; and spring is rainy. The lowest average temperature is -20 ºC. Snowfall usually starts in October and continues until late April. The annual average temperature is 5.8 ºC, and the average number of rainy days is 122.1. Harsh climatic conditions are further exacerbated by winds (İl ve İlçeler İstatistikleri, 2024). The annual total solar radiation intensity is 1511 kWh/m^2, and the average daily sunshine duration is 6.7 hours (Türkiye Güneşlenme Potansiyeli Atlası, 2010).

3. Results and Discussion

3.1. Effects of PCM Layers on the Thermal Performance of the Building Envelope

Fig. 4 shows the indoor temperature reduction for three peak days in January and July, to determine the effect of the number of PCM layers on the thermal performance of building envelopes with integrated PCM and PCM-TI.

According to Fig. 4a and 4b, the highest indoor temperatures in both climate regions were observed between 14:00-18:00, while the lowest indoor temperatures were recorded at 06:00. According to Fig. 4c and 4d, the highest indoor temperatures across all climate regions were detected between 14:00-16:00. For the three peak days in January, the highest indoor temperature of the reference building was recorded in Istanbul (13.40 ºC). During the midday hours, when solar radiation is at its peak, the indoor temperatures of reference buildings were lower than those of buildings with integrated PCM. On the same dates, the lowest indoor temperatures of the reference buildings during the night were 5.12 ºC in Istanbul and -7.06 ºC in Erzurum. For the three peak days in July, the highest indoor temperature in the reference building was recorded in Istanbul at 38.86 ºC. During the night, the indoor temperatures of reference buildings with single-layered PCM were lower than those of buildings with multiple-layered PCM, for the three peak days in January, while they were higher for the three peak days in July. In other words, the building envelope with the most significant temperature fluctuations throughout the day was the reference wall section with single-layered PCM.

The integration of multiple-layered PCM in the interior region and TI in the exterior region of the reference building's wall section results in a decrease in indoor temperature reduction (ITR). In other words, multiple-layered PCM prevents sudden temperature changes in the external environment from affecting the indoor environment, allowing users to feel thermally more comfortable indoors. The multiple-layered PCM and TI in the building envelope prevent sudden temperature fluctuations in the external environment from impacting the indoor environment, enabling users to feel thermally comfortable indoors.

During the midday hours, when the highest outdoor temperatures are experienced during both winter and summer, integrating a three-layered PCM into the inner section of the building envelope and TI into the outer section (PCM-3/TI) provided a higher percentage of ITR compared to the reference wall and sections with only multi-layered PCM in all climate regions. In the winter period, the three-layered PCM provided an ITR of 0.38 ºC in Istanbul and 0.33 ºC in Erzurum, and adding TI to these sections in the outer region resulted in higher ITR values (0.51 ºC and 0.49 ºC, respectively).

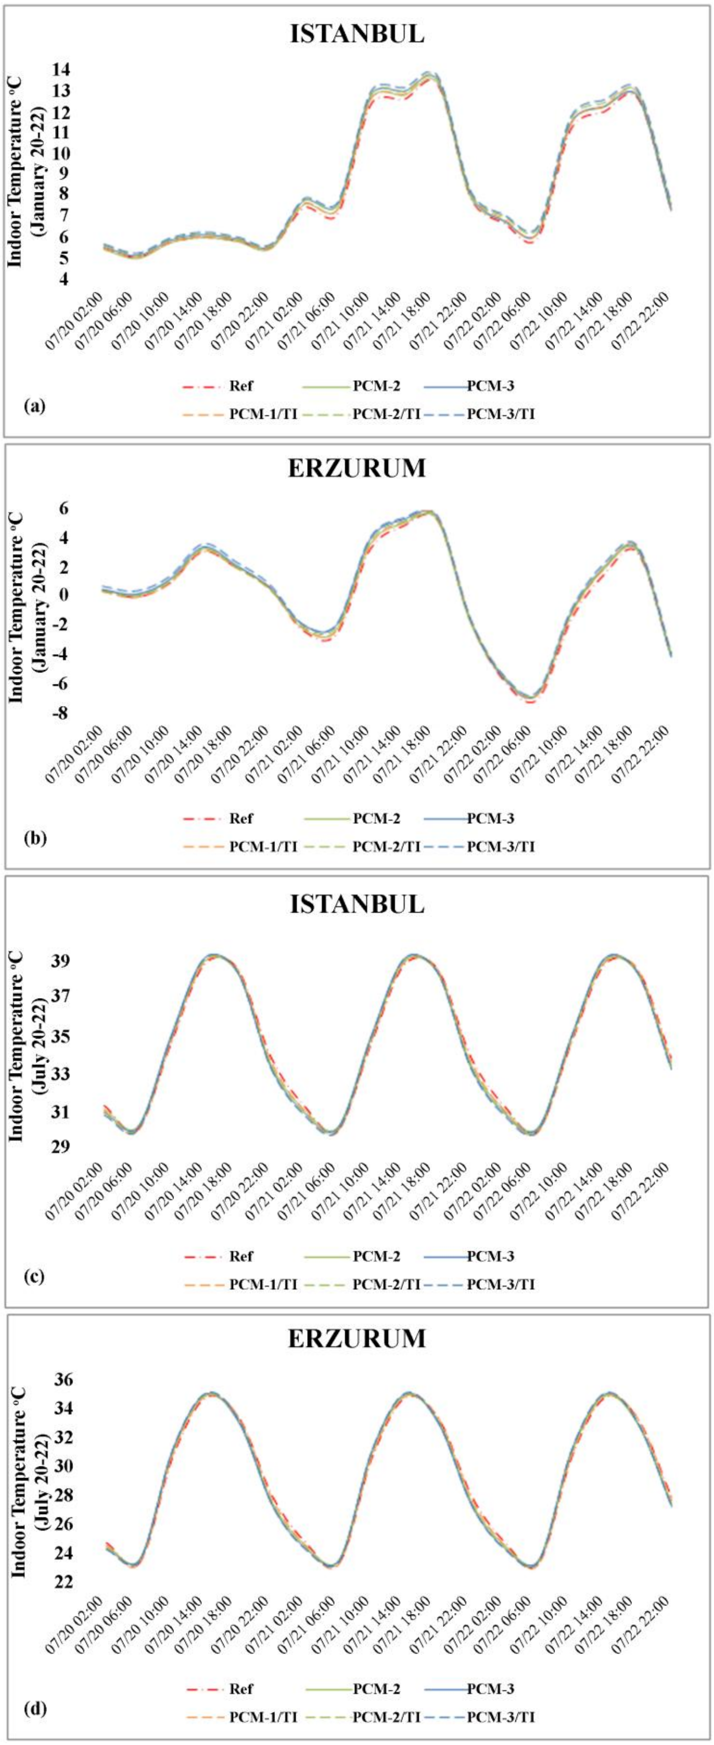

Fig. 4. The reference, indoor temperature reduction for three peak days in January and July of buildings with PCM and PCM-TI integrated: (a) Istanbul (January 20-22); (b) Erzurum (January 20-22); (c) Istanbul (July 20-22); (d) Erzurum (July 20-22)

In the summer period, increasing the number of PCM layers also increased the ITR. When TI was integrated, increasing the number of PCM layers resulted in a more effective ITR, similar to the effect observed in buildings with PCM integration. When the number of PCM layers was increased to three (PCM-3), it provided an ITR of 0.56 ºC in Istanbul and 0.64 ºC in Erzurum compared to the reference building. With the integration of TI (PCM-3/TI), a constant ITR was obtained in Erzurum, while a higher ITR value of 0.60 ºC was achieved in Istanbul.

The higher ITR values obtained in both the PCM-a and PCM-a/TI integrated wall sections, compared to the reference building, can be explained by Fourier's Law. According to Fourier's Law, integrating materials with low thermal conductivity into the building envelope prevents heat from transferring from the more intense environment to the less intense one, thereby increasing the thermal resistance of the building envelope and enabling the maintenance of comfort conditions indoors (Garrido et al., 2001). However, the ITR values obtained in the PCM-a section are lower than the ITR values achieved in the PCM-a/TI section in both climate regions.

In conclusion, increasing the number of PCM layers significantly contributes to the improvement of thermal comfort by reducing ITR. The integration of multiple-layered PCM into the building envelope helps stabilize indoor conditions by balancing external temperature variations. This is particularly effective in climates where temperature reduction during the day is significant. In winter, it prevents sudden indoor cooling, thus reducing heating demand, while in summer, it mitigates overheating, thereby reducing cooling loads. The integration of TI into the building envelope ensures the controlled release of heat stored by the PCM, further diminishing the impact of sudden temperature changes on indoor conditions. In this context, the results obtained in this study indicate that increasing the number of PCM layers directly affects ITR, and, when used in conjunction with TI, this effect is further enhanced.

In this study, the ideal section for winter and summer periods was identified to be the three-layered PCM in the PCM-a/TI wall section, providing the highest thermal comfort. Literature studies have identified the ideal sections for wall configurations containing PCM in the inner and outer regions and TI in the outer region as follows: two-layered PCM for Kocaeli (Türkiye) (Arıcı et al., 2022), three-layered PCM for the inner region in İzmir (Türkiye) (Ilgar & Terhan, 2024), and two-layered PCM for both inner and outer regions in Kansas City (USA) (Asghari et al., 2024). Indeed, these findings align with the data presented in the literature.

3.2. Effects of PCM Layer on the Energy Savings of the Building Envelope

Fig. 5 shows the annual total heating and cooling energy consumption for buildings with PCM and those with PCM-IY integrated walls during the winter and summer periods.

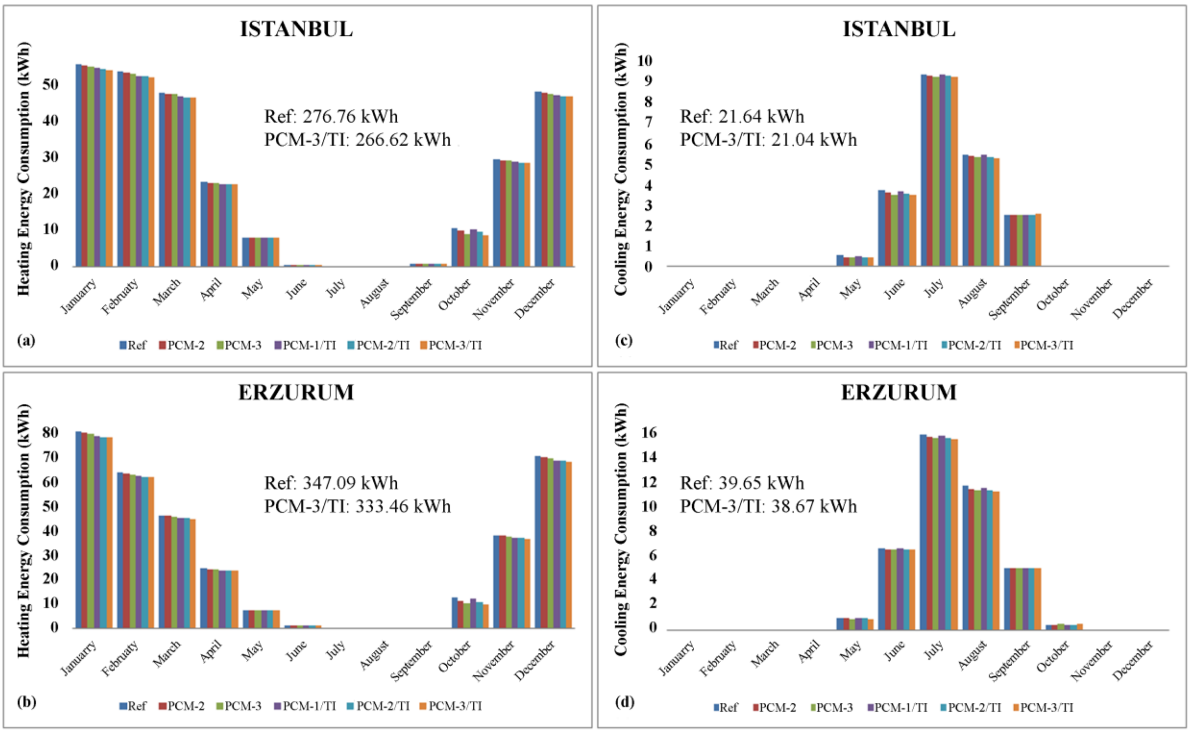

Fig. 5. The reference, total heating and cooling energy consumption of buildings with PCM and PCM-TI integrated walls: (a) Istanbul (Heating); (b) Erzurum (Heating); (c) Istanbul (Cooling); (d) Erzurum (Cooling)

In Istanbul, during the winter period, the annual total heating energy consumption of the reference building is 276.76 kWh. With the PCM-3 wall section, this consumption decreases to 271.81 kWh, and with the integration of PCM-3/TI, it further decreases to 266.62 kWh. In Erzurum, the annual total heating energy consumption of the reference building is 347.09 kWh. The use of PCM-3 in the wall section reduces this to 340.44 kWh. With the integration of TI in this wall section, the annual total heating energy consumption is determined to be 333.46 kWh. Based on these findings, it can be stated that integrating multiple-layered PCM and TI together in the wall sections yields positive results in terms of heating energy savings during the winter period (Fig. 5a, Fig. 5b).

According to Fig. (5c and 5d), in Istanbul, during the summer period, the annual total cooling energy consumption of the reference building is 21.64 kWh. With the integration of PCM-3, this energy consumption decreases to 21.13 kWh. With the integration of TI in this wall section, the annual total cooling energy consumption is determined to be 21.04 kWh. In Erzurum, a cold climate region, the annual total cooling energy requirement is 39.65 kWh, reduced to 38.89 and 38.67 kWh with the use of PCM-3 and PCM-3/TI, respectively. A higher annual total cooling energy consumption is calculated in Erzurum, compared to Istanbul. This indicates that the average air temperature of the region is not the only significant parameter affecting heating and cooling energy consumption in buildings. Typically, global solar radiation intensity increases as the altitude of a region rises (Qu et al., 2021). The solar radiation intensity for the representative cities is obtained from the Türkiye Solar Potential Atlas prepared by the Turkish Meteorological Service (Türkiye Güneşlenme Potansiyeli Atlası, 2010). Table 5 shows that solar radiation intensity increases gradually with altitude in Istanbul and Erzurum. The altitudes of Istanbul and Erzurum are 40 m and 1890 m, respectively. Due to the higher altitude in Erzurum, greater solar radiation intensity results in more heating of the building envelope during midday, thus allowing the PCM to store more energy and increasing the cooling load. The solar radiation intensities in Istanbul and Erzurum are 1389 KWh/m² and 1493 KWh/m², respectively. Therefore, the total cooling energy consumption for the building may be higher. It can be concluded that when designing passive buildings using PCM technology, it is important not to rely solely on climate classification, but also to consider other geographical factors such as altitude and solar radiation intensity.

During the winter period, the highest energy savings were achieved in the wall section, containing three-layered PCM in the inner region and TI in the outer region, with the (PCM-3/TI) having values of 3.66% in Istanbul and 3.93% in Erzurum. Similarly, during the summer period, the highest energy savings were also obtained with the PCM-3/TI wall section, achieving 2.77% in Istanbul and 2.47% in Erzurum. Based on all these findings, it has been determined that the combined use of three-layered PCM in the inner region and TI in the outer region offers advantages. These advantages include annual heating and cooling energy savings compared to the reference building with single-layered PCM.

3.3. Economic Findings

Fig. 6 shows the calculated values of the key economic parameters such as ECS and PP in determining the economic effectiveness of building envelopes with PCM and PCM-TI combinations.

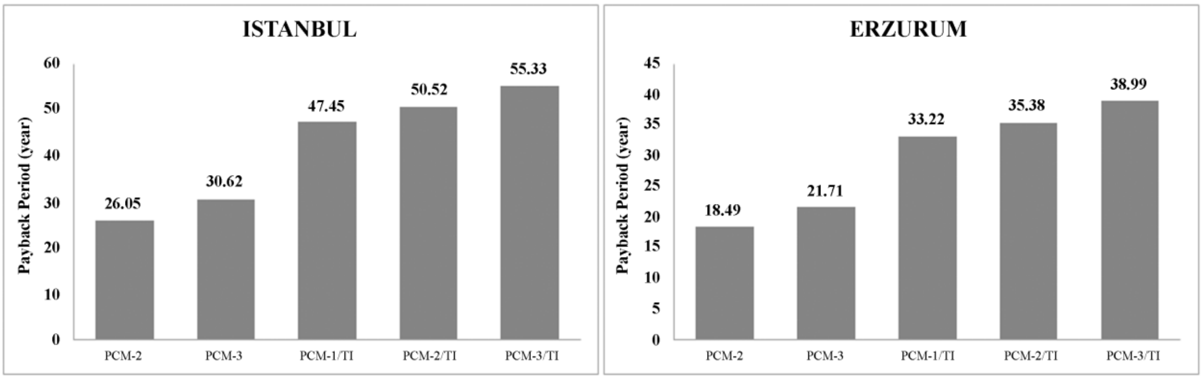

Fig. 6. Payback periods according to climate zones

Istanbul's temperate humid climate conditions result in buildings being exposed to both heating and cooling loads (İl ve İlçeler İstatistikleri, 2024). Therefore, the use of PCM-TI combinations to enhance the energy efficiency of the building envelope is of great importance. When only multiple-layered PCM is used in Istanbul (PCM-2, PCM-3), the PP is determined as 26.05 years and 30.62 years, respectively. Even without TI integrated, these relatively long PP are primarily due to the temperate and humid climate characteristics of Istanbul, which limit the thermal effectiveness of PCM, and the cost of the materials used in the building envelope, which extends the PP relative to the energy savings achieved. The use of PCM-TI further increases the PP. The PCM-3/TI combination, which provides the best thermal performance for both the heating and cooling seasons, results in a PP of 55.33 years.

Erzurum, located in the fifth-degree climate zone, is one of the coldest cities in Türkiye; and the long and snowy winter months significantly increase the heating demand (İl ve İlçeler İstatistikleri, 2024). In buildings with wall sections containing only multiple-layered PCM (PCM-2, PCM-3), the PP are calculated as 18.49 years and 21.71 years, respectively. The PCM-3/TI combination, which provides optimal thermal performance for both the heating and cooling seasons, results in a PP of 38.99 years.

The effect of the increase in the number of PCM layers on the PP results in a rise in investment costs, and limited savings beyond a certain point. The longer PP for PCM-3 compared to PCM-2 in both climate zones indicates that the contribution of each additional layer to thermal performance continues to diminish, and an optimal cost-effectiveness limit can be reached.

Moreover, while the use of PCM in conjunction with TI improves thermal performance in both Istanbul and Erzurum, it further extends the PP. The calculated PP of 55.33 years (Istanbul) and 38.99 years (Erzurum) for the PCM-3/TI combination highlights the need for careful optimization of integrated solutions in terms of cost-effectiveness. Consequently, the increase in the number of PCM layers contributes to energy performance, although it requires a cost-benefit balance at different scales for each climate zone. As is well known, according to the Turkish Building Earthquake Regulation (2018), the economic lifespan of buildings is generally considered to be 50 years (Türkiye Bina Deprem Yönetmeliği, 2018). Since the PP obtained in this study is calculated as less than 50 years for all the scenarios examined, the combined use of PCM-TI in the same wall section can be considered an economically viable solution. The PP values for the PCM-3/TI combination, which provides the best thermal performance for both heating and cooling periods, are 55.33 years for Istanbul and 38.99 years for Erzurum. While the result for Istanbul is on the borderline in terms of economic sustainability when compared to the building's lifespan, it is evident that this integration is more advantageous in colder climate regions such as Erzurum.

4. Conclusions

The possibilities of using multiple-layered PCM to improve the thermal performance of an educational building and reduce annual heating and cooling energy consumption have been investigated. The results obtained from the studies conducted within this scope are as follows:

- In wall sections where both PCM and TI are used, not only climate classification but also other geographical factors such as altitude and solar radiation intensity should be considered. Although the average air temperatures in Erzurum are lower than in Istanbul, the solar radiation intensity is higher due to the city's higher altitude. This results in an increased heat gain in the building envelope during midday hours, leading to higher cooling energy consumption.
- During the winter period, using a wall envelope with three-layered 30 mm PCM (with a melting temperature of 21 ºC) on the interior and 30 mm TI on the exterior results in energy savings during the summer period, using three-layered 30 mm PCM (with a melting temperature of 27 ºC) on the interior and 30 mm TI on the exterior (PCM-3/TI) results in energy savings of 2.47-3.93% compared to the use of single-layered PCM (Ref).
- The combinations of PCM-TI, as well as the increase in the number of PCM layers, are the primary factors that increase the PP. However, considering the high thermal comfort provided by the combination of multiple-layered PCM and TI for both heating and cooling periods; along with the reduced ITR throughout the day; and higher total heating and cooling energy savings, the use of this combination is beneficial.
- The PP values obtained by increasing the number of PCM layers being shorter than the typical building economic lifespan of 50 years, demonstrate that the combination of multiple-layered PCM and TI offers a viable and cost-effective solution. However, the calculation of the PP for the three-layered PCM and TI combination (PCM-3/TI) as 55.33 years in Istanbul indicates that this integration does not provide the same economic advantage for all climate regions. This situation arises from the temperate and humid climate conditions in Istanbul, which limit the thermal efficiency of PCM, and the cost of the materials used in the building envelope, which extends the PP comparison to the energy savings achieved. However, in Erzurum, the PP (18.49-38.99 years) being shorter than the building's economic lifespan suggests that increasing the number of PCM layers improves the ITR and enhances the thermal efficiency of the building envelope that by providing energy savings.

The impact of plan configurations and design decisions in healthcare facilities on wind resilience of roofs

Hazal Koç*[1], Altuğ Kasalı[1], Uğur Demir[1]

[1] Izmir Institute of Technology, Faculty of Architecture, Department of Architecture, Izmir, Türkiye

Abstract. This study aims to evaluate how architectural design decisions affect wind-induced pressures and the material fragility of roof coverings. The analysis considers various plan configurations with different building aspect ratios. It aims to quantify the extent to which design models and stereotypical design approaches in healthcare facility design influence the fragility of roof coverings. For this purpose, three inpatient unit layouts—single corridor, racetrack, and compact square—were examined, each characterized by distinct building aspect ratios. These layouts were analyzed across six building height categories (low, medium, and high-rise), four roof types (flat, single slope, double slope, and hipped), and for roof types where slopes are available, roof slopes of 5°, 30°, and 60°, in alignment with EN1991-1 standards. The research reveals that architectural design decisions have a significant impact on wind-induced pressures, especially in critical roof zones. Hipped roofs with 30° slope gave the best pressure and fragility results, while flat roofs and those with 5° slope exhibited more fragility. It is evident that Terrain Category 0, most critical wind conditions, produces the maximum wind load, thus emphasizing the integral design requirement under such conditions. The present study offers a novel systematic method that binds a wide range of architectural parameters and performance metrics into a cohesive calculation framework. This methodology effectively links design decisions to wind-resilience outcomes and presents rapid calculation models to performance-based design principles. As a result, this study brings actionable insights for architects toward optimizing the design process for resilience and performance.

Keywords: Fragility assessment; Healthcare facility design; Performance-based design; Roof covering; Wind performance

1. Introduction

The set of architectural decisions such as layout characteristics, facade design, building geometry, roof type, context, corner modifications, and building orientation are considered as determinants for wind exposure (Davenport, 1971; Hoxey et al., 1993; Kwok, 1998; Merrick & Bitsuamlak, 2009; Nagar et al., 2020). In the case of healthcare facilities, wind pressures can have significant consequences, as these structures often have many windows, higher walls, and other features that can make them vulnerable to wind damage. The inefficient choice of geometries in design can lead to higher construction costs for buildings if the wind exposure is not considered carefully. Like most buildings, healthcare facilities are bluff body objects in wind dynamics studies. Air flowing around and over these bluff bodies usually creates turbulent wake zones behind them. One of the most sensitive elements in this context is the roof, often subject to significant uplift forces and pressure fluctuations. Understanding how design configurations affect wind-induced pressures is crucial to optimize building performance and reduce material fragility.

Wind-induced loading conditions present additional importance in healthcare facilities because these buildings must be able to bear up to extreme weather conditions and maintain their structural and operational integrity to ensure the safety of patients, staff, and visitors (Chand & Loosemore, 2015; Ceferino et al., 2020). This necessity underlines the need for additional considerations in the case of healthcare facilities. Additionally, healthcare facilities are obligated to meet additional regulations and they are subjected to more rigid rules. Design decisions made to meet these regulations and rules appear as phenomena that influence the shape of hospital morphology (Guerrero et al., 2022). Accordingly, these regulations, which cannot be ignored when making design decisions, should also be among the factors affecting morphology.

Within the context of this study, the term "morphology," refers to the overall mass of healthcare facilities. Therefore, the roof of the structure, which holds great importance in terms of wind pressures, is one of the leading research topics in this framework. In this manner, healthcare facilities present a unique opportunity wherethe

*Corresponding author, E-mail: hazalkoc@iyte.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_105

design of inpatient floors are considered as critical in shaping the overall morphology of hospital buildings. Compared to other components such as emergency departments or outpatient clinics, inpatient units necessitate a lower level of connectivity to main entrances and exits. Therefore, they are more likely to be positioned at higher levels where wind forces are more effective. Thus, a thorough understanding of design decisions and their influence on the wind forces and chosen roof material is crucial.

To achieve this objective, this study aims to examine the impact of design decisions in inpatient units on building zones vulnerable to wind forces, with a particular focus on roofs. Three frequently repeating layout types for inpatient units, namely single corridor, racetrack and compact square (Kobus et al., 2008) were identified for further investigation. Each type represents a different layout configuration within the inpatient care units which indicates a different behavioral setting. These hypothetical hospital floor types have provided basic analytical units to be studied in the calculations. Furthermore, the study employs the widely accepted wind calculation protocol, EN1991-1, and calculates wind pressure acting on different zones suggested by the same methodology. Therefore, 14.400 hypotectical scenarios were calculated considering various cases. To handle this process a Java code was created by the authors. The calculations and building matrix are explained in the method chapter in detail.

By simulating how different architectural configurations influence wind pressures, particularly on roof zones, this approach allows for a comprehensive analysis of how morphology-related design decisions affect the structural resilience and material fragility of healthcare facility roofs. Therefore, the central research question this study addresses is: How do architectural design decisions influence wind-induced pressures and the material fragility of roof coverings in healthcare facility inpatient units?

2. Methods

The main objective was to establish a basis for comparability and ensure that various plan types serve as representative models for typical inpatient floor layouts. To achieve this comparability, the structural axis spacing, room type, and auxiliary spaces were kept unchanged. These fixed features were integrated into these generic layouts while remaining faithful to their working principles. To obtain some of the data needed for calculating wind loads, additional data for these plan diagrams had to be provided. Although all these plan types - single corridor, racetrack, and compact square (Table 1) - are variations of the rectangular form, they propose different aspect ratios. Accordingly, the prominent phenomenon to be questioned here is the relationship of architectural decisions arising from the functioning schemes of these space examples with similar capacities with structural loads. The study considers the wind load and examines its relationship in more detail.

Table 1. Plan Schemes

Plan Type	Scheme
Single Corridor	Racetrack	Compact Square	

* Blue indicates circulation zones. Red denotes service areas, including nurse stations, support rooms, elevator lobbies, and main stairs, classified as service due to their role in staff circulation.

In order to calculate wind loads, the protocol necessitated additional data including window sizes, building dimensions, roof type, and certain environmental parameters. The generic plan types have been developed in detail to cover the necessary data for these floor types by using the repeating layout components (Table 2). Data such as environmental factors, building height, and roof type were obtained by making separate calculations for each possibility, providing the necessary details for these plan schemes. In order to track this multivariate process efficiently, a six-digit code system was developed also in order to express the characteristics of the buildings. Each digit was assigned with a changing variable and used these building definitions as descriptors to introduce these buildings to the Java program that has been created. Each hypothetical building has a unique code, which represents the characteristics of the building proposed by each letter. The code is designated as idjkpz, with the number corresponding to each digit. The key is as follows: i (floor plan type), d (building direction) j (building height), k (roof type), p (roof pitch) and z (exposure category). For example, building 1x52a1 indicates a 15-story, that has a mono pitched roof with 5° pitch and has a single corridor plan type with the x direction and is in the Terrain Category IV as specified by EN1991-1.

A series of calculations by varying the height factor to establish the level of influence the height factor has been conducted. These buildings were classified as low-rise, mid-rise, utand high-rise. Moreover, two examples from each category were implemented. Buildings with 3 and 4 floors are categorized as low-rise, buildings with 6 and 9 floors as mid-rise, and buildings with 15 and 20 floors as high-rise (Table 3). The roof types specified in the roof type table (Table 4) are specified as defined by EN1991-1. Each hipped roof type's calculations involve three scenarios with 5°, 30°, and 60° roof slopes. The *p* input in the building code is the letters: "*a"* for 5°, *"b"* for 30°, and *"c"* for 60°. The building codes have no *p* input for the flat roof type. For the hypothetical calculations with flat roof type, it is assumed that these buildings have parapet walls with a height of 0.025 of the building height. As environmental conditions 5 terrain categories were employed. The *z* input in the building code implies these terrain categories where 1 is "Terrain Category 0", 2 is "Terrain Category I", 3 is "Terrain Category II", 4 is "Terrain Category III", 5 is "Terrain Category IV".

Table 2. Plan Type Specifications

Geometry Code (I)	Inpatient Unit Layout Type	Number of Patients	Aspect Ratio	Area (m²)	Number of NS	Area-patient ratio
(I=1)	Single Corridor	72 (36*2)	4,09	1.805	1	25
(I=2)	Racetrack	66 (33*2)	2,56	1.941	2	30
(I=3)	Compact Square	56 (28*2)	1,00	1.537	1	27

Table 3. Building Height Codes

Height Code (J)	**Floor Number**
(J=1)	3
(J=2)	4
(J=3)	6
(J=4)	9
(J=5)	15
(J=6)	20

Table 4. Roof Type Codes

Roof Code (K)	**Roof Type**
(K=1)	Flat Roof
(K=2)	Monopitch Roof
(K=3)	Duopitch Roof
(K=4)	Hipped Roof

In summary, the study aims to address the need of comprehensive investigation of the effects of design decisions. These decisions, which are interdisciplinary in nature, determines the extend of wind forces and material responses. Thus the study illustrates the mentioned effects through hypothetical cases. It employes the commonly used EN1991-1 as calculation method and uses its environment and roof definitions as building morphology alternatives. By standardizing key layout components while varying critical parameters such as height, roof configuration, orientation and environmental exposure, the study ensures comparability between different design scenarios. The use of a structured coding system facilitates efficient data tracking and simulation in the Java-based computational tool, enabling high-volume, detailed analysis on 14,400 hypothetical cases. This robust approach paves the way for meaningful insights into the interaction between hospital morphology and structural vulnerability to wind forces, thus providing valuable guidance to the design of resilient healthcare infrastructure. The study also emphasizes the need for interdisciplinary approaches in designing complex buildings such as hospitals.

3. Results and Discussion

Within EN1991-1, many roof types, namely flat, mono-pitched, duo-pitched, hipped, and multi-span, have been examined. Accordingly, four widely used types of roofs were included in the analysis; flat, mono-pitched, mono-pitched, duo-pitched, and hipped roofs (Table 5). In EN1991-1 depending on the types of these roof types, different zoning is used, and different coefficients are given for different roof slopes. Furthermore, the most critical and excessive loads on the roof occur at the corners on the side of the wind, defined as the F zone by EN1991-1. Accordingly, the F zone, which is typical for each roof type and has a critical value, is analyzed. The forces that occur in this region are generally suction forces. Therefore, the analysis of these zones and the wind forces is essential for the roof covering and joint detail choices (Lee et al., 2013).

Table 5. Roof types and loading directions

Roof Type	Direction x	Direction y
Flat Roof		Monopitched Roof		Duopitched Roof		Hipped Roof		
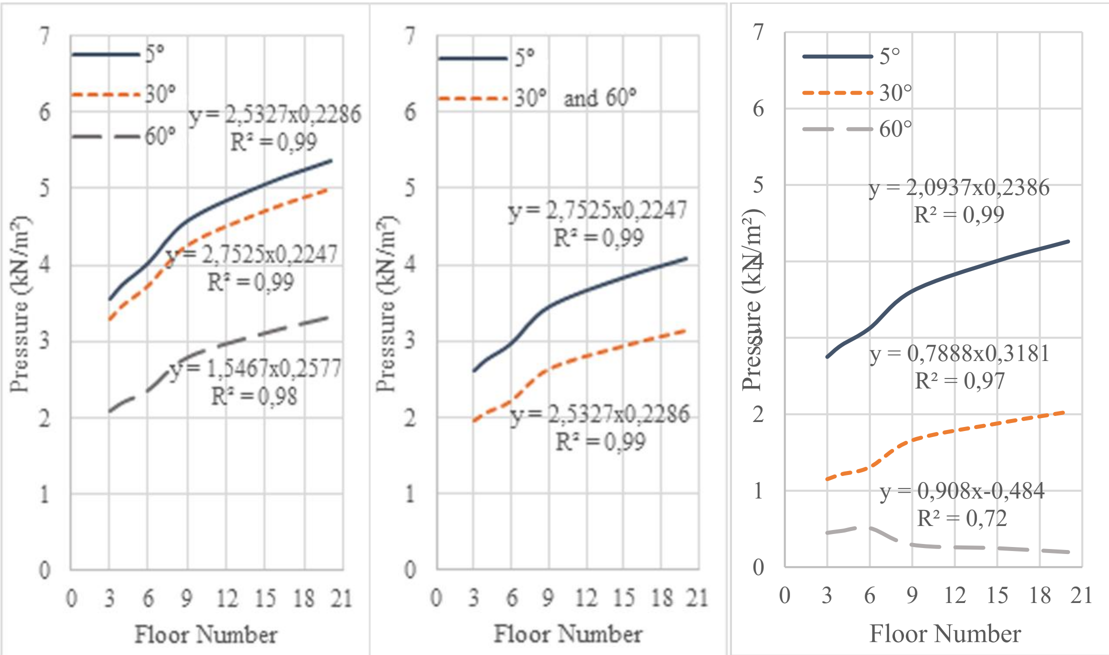
Variation of wind velocity pressure against number of floors is shown in Fig. 1. As illustrated in Fig. 1, the hipped roof configuration consistently results in the most favorable, lowest, pressure values among the various roof types examined. The information presented in Fig. 1 pertains to Building Type 1x (Single corridor), characterized by a lateral dimension of 86×21 meters. Furthermore, the dataset presupposes that the structure is located in an area categorized as Terrain Category 0, encompassing maximum wind pressure values. It is imperative to highlight that within the scope of the investigation focusing on various roof types and inclinations pertinent to the specified region, it was determined that exclusively the hipped roof variant, identified as 4c, exhibiting a slope of 60 degrees, yielded positive pressure values. In addition, the same values were obtained for the building types, with the height and aspect values determined for the roof types with 30 and 60-degree slopes for the roof model 3 (duopitched roof), which were defined as duo pitched by EN1991-1.



a) b) c)

Fig. 1. Number of floors vs. peak wind velocity pressure at Zone F for a) mono pitched roof b) duo pitched roof c) hipped roof

More information on the behavior of roof type 2c (double pitched roofs with 60° slope) is shown in Fig. 2. These graphs show how the wind pressure changes along the number of storeys for different exposure directions. The graph on the left (1x, 2x, 3x) shows the pressure values when the wind approaches from the x direction of the building, while the graph on the right (1y, 2y, 3y) represents the y direction. Pressure increases with height in all exposure scenarios, albeit at different rates. In particular, exposure in the y-direction generally yields higher pressure coefficients, with the 2y curve reaching the highest peak pressure (~4.6 kN/m²). This is due to the fact that in the plan types provided, the side of the y-type perpendicularly affected by the wind corresponds to the long side of the rectangular shape. The most conservative scenario, 2y, should be considered critical in structural design as it emphasizes the sensitivity of steeply pitched double-pitched roofs to high wind forces, especially from certain directions. This behavior reinforces the importance of analyzing the directional wind effect and slope interaction when applying vulnerability assessments for roof design.

Moreover, damage to the building envelope can lead to adverse events later on when these areas are exposed to wind pressures or water-borne damage due to the loss of integrity of the building elements (Boughton et al., 2011). In this sense, fragility analyses were conducted to assess more deeply the implications of this review for the architect as design inputs. Fragility is defined as the probability of exceeding a specific state of damage (Abdelhady et al., 2022). Therefore, fragility curves are tools used to assess the risk of exceeding a certain damage or a limit. These fragility curves are used to determine the probability of exceeding limit values set by different parameters. They can be used as auxiliary tools in the design phase. One of the steps required for this assessment is to determine the limits that will be examined for the probability of exceedance, which are referred to as damage states. Accordingly, fragility curves can determine damage probabilities at the level of individual elements (Gavanski et al., 2014) and within a broader systemic framework (Dong & Li, 2016).

In this study, fragility curves were developed to understand the link between roof selection and damage probability. In this context, analyses for each roof type were used. These analyses were performed for the F zone, which is subjected to the highest pressures. Since the main purpose of the brittleness analysis is to understand the effect of roof morphology, the analysis is based on the fracture limit of a single material. The sandwich panel was chosen as the material for the roof covering, and the fragility analysis of this specific material is detailed in Fig. 3-4. The breaking point of this material was taken as 3.25 kPa (Abdelhady et al., 2022) and analyzed separately for each roof type and slope. In light of the results, as seen in Fig. 3-4, it is observed that in cases where the roof slope is 5 degrees, regardless of the roof type, the material fragility exhibits similar vulnerabilities to the flat roof. The structures featuring hipped roofs exhibit minimal material fragility. Furthermore, within the range of slopes assessed, it was determined that roofs possessing a 30-degree incline demonstrated the most reduced fragility indices. Since the wind pressure coefficients of the roof types Monopitch and Duopitch in two different directions are highly different, only the data in the critical direction is used for the fragility analysis.

The calculation of roof loads within EN1991-1 follows a similar method to the calculation of wind loads acting on facades. According to this method, the calculated wind pressure value is multiplied by coefficients provided by the code. When these coefficients are analyzed, in most cases, the most critical loading occurs at the corners (zone F) (Alrawashdeh & Stathopoulos, 2015). However, in duopitched roof, at a slope of 30 degrees, the pressure at Zone G is higher than at Zone F. Furthermore, for pressures at Zone F in duopitched roofs and hipped roofs "wind forces in this region changes rapidly between positive and negative values on the windward face at pitch angle of +5° to +45°" as stated in EN1991-1. Therefore, for this region, in some cases, both negative and positive pressure coefficients provided by EN1991-1.

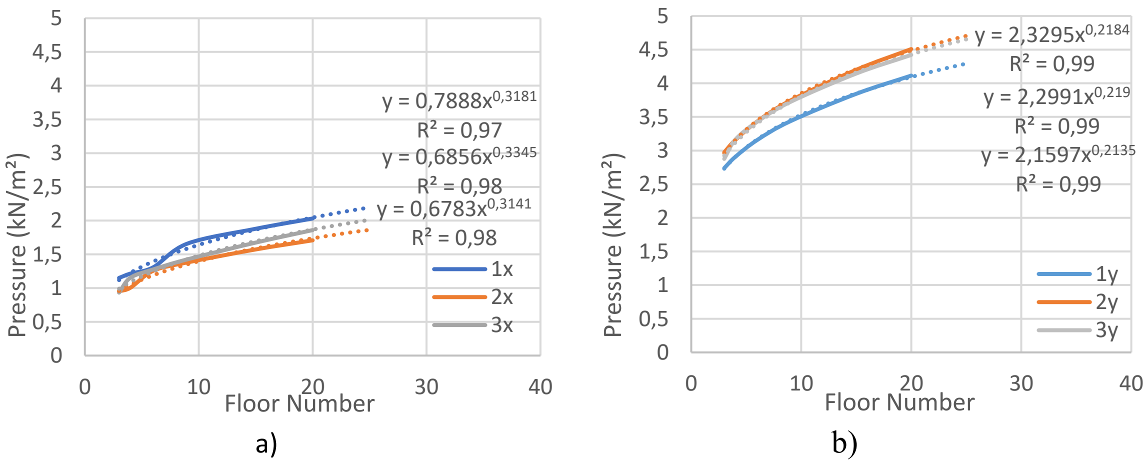


Fig. 2. Plan type analyses for duopitched roof with 60º slope (2c) a) direction x b) direction y

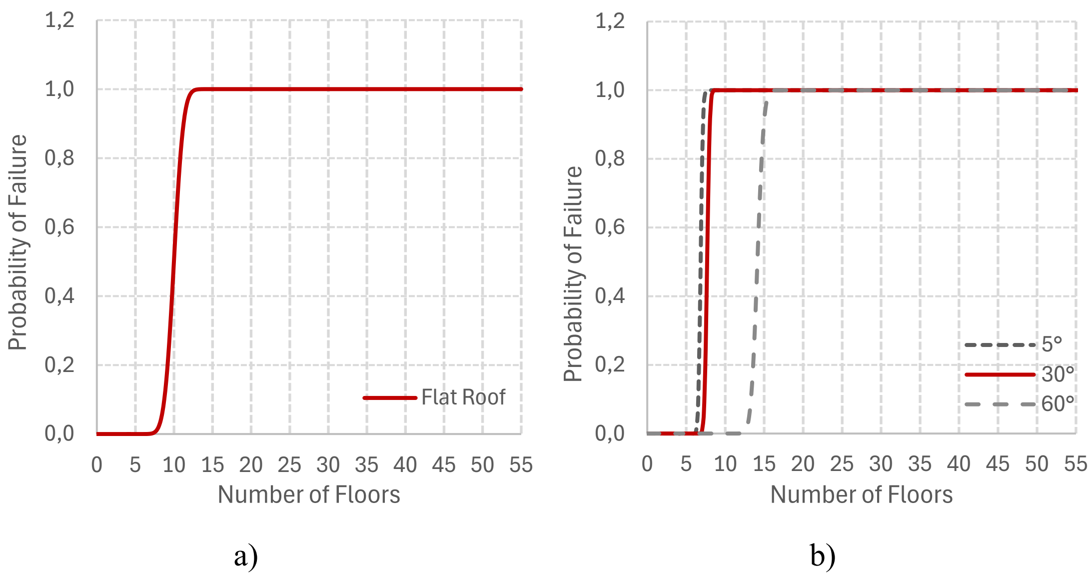

Fig. 3. Roof fragility curves a) Flat roof, b) Monopitch roof

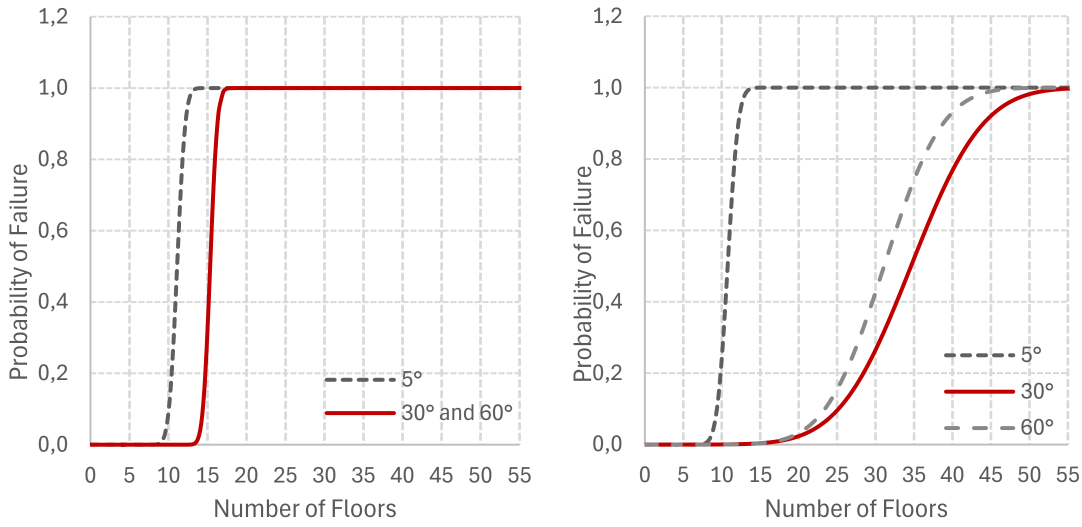

c) d)

Fig. 3. Roof fragility curves c) Duopitch roof, d) Hipped roof

Based on the analysis conducted within the framework of this study, it was determined that among the various roof configurations evaluated, the monopitched roof configuration exhibited the highest-pressure values across all the slopes analyzed. In the fragility analysis, when the F region is examined in terms of material failure, it is seen that roofs with 5° slope exhibit similar material behavior to flat roofs regardless of roof type. A key finding from the analysis is that the pressure coefficients for roofs, as outlined in EN1991-1, display higher values for roofs with a 5° slope in comparison to those with different slopes. This distinction highlights the critical need to factor in slope variations when conducting structural analysis and design of roofing systems to guarantee their stability under diverse environmental loads.

Furthermore, our fragility analysis revealed notable differences in how monopitched and duopitched roofs respond to wind forces coming from two directions. Specifically, for monopitched roofs, the wind impacting perpendicularly to the higher side of the roof results in elevated pressure values in Zone F. Conversely, when the wind impacts the lower side, the pressure decreases. It's important to note that during the evaluation of these pressure values, the selection of materials was based on the most severe loading conditions encountered.

Consequently, the highest-pressure values were incorporated into the fragility analysis. As a result, when constructing the fragility curves for both monopitch and duopitch roofs, the analysis focused on wind load data impacting the structure from a singular orientation. On the other hand, for hipped and flat roofs, the analysis accounted for both orientations due to their similar response patterns to wind forces from any direction. This approach revealed that, for hipped roofs, the same materials require a significantly greater building height to reach failure, highlighting the importance of considering roof type and orientation in structural design and analysis.

4. Conclusions

This study investigated the influence of architectural design decisions—roof type, slope, and building height—on wind-induced pressures and the resulting material fragility in the roof of inpatient blocks within healthcare falcilities. Through a comprehensive simulation of 14,400 hypothetical scenarios based on EN1991-1 standards, the results highlight the structural implications of design morphology under extreme environmental conditions. The following conclusions can be drawn from the analyses.

- Roofs with a 5° slope exhibit behaviorsimilar to flat roofs under wind pressure, resulting in higher fragility levels compared to steeper slopes.
- Monopitch roofs are the most vulnerable, in the direction where they don't present slope, consistently generating the highest wind pressure values across all slopes, making them the least favorable option from a structural and economic standpoint.
- Hipped roofs offer superior resilience, requiring substantially greater building heights to reach failure thresholds, especially under Zone F pressures.
- 30° slopes emerged as the most efficient configuration, showing the lowest probability of material failure and the most favorable performance under wind loading.

These findings underscore the necessity of integrating wind-performance criteria early in the architectural design process. In healthcare settings—where structural robustness directly impacts operational continuity—designers must consider the relationship between roof configuration and wind-induced fragility to create safer, more resilient buildings.

Evaluation of the effects of building form on the wind performance of structures

Merve Çoban Çınar*[1], Esra Bostancıoğlu[1]

[1] Istanbul Kultur University, Institute Of Gradute Education, Department of Architecture, 34158 İstanbul, Türkiye

Abstract.The increased use of fossil fuels has led to the depletion of these resources, environmental issues, and concerns over energy security, which have forced countries to turn to renewable energy sources. Many countries are accelerating this transition by increasing investments in renewable energy, with infrastructures like solar panels and wind turbines. With the advancement of turbine technology, integrated micro-turbines in buildings have become a subject of great interest in international literature today.
This study will conduct a literature review and evaluation of building configurations for the integration of wind turbines in order to improve the wind energy performance of the turbines. In the context of the relationship between wind turbines and building form, the effects of factors such as building height, aspect ratio, floor plan, and distance between buildings on wind speed and wind direction will be investigated. Since building form is a crucial design criterion that significantly affects electricity generation in wind turbine integration, an analysis focusing on building configurations for micro wind turbine integration will be conducted.
The data obtained from the evaluation will be used to create a design guide for generating wind energy through building configurations with wind turbine integration. It is believed that the results of this study will contribute to the successful and sustainable implementation of such projects, representing an important step toward the emergence of energy-independent buildings.

Keywords: Energy Production, Wind Turbine, Sustainable Buildings, Wind Flow, Building Form.

1. Introduction:

The use of fossil fuels significantly contributes to environmental pollution and carbon emissions, exacerbating global warming. In contrast, renewable energy, particularly wind energy, presents a promising solution to both the energy crisis and global warming. Buildings, as major consumers of energy, play a pivotal role in global warming. In 2019, buildings accounted for 35% of global energy consumption and 38% of global carbon emissions. To address rising energy demands, it is essential to prioritize renewable energy sources.

In Turkey, rapid urbanization has led to increased energy consumption, largely dependent on fossil fuels, thereby intensifying environmental pollution. Renewable energy, particularly wind energy, is viewed as a viable solution to mitigate these challenges. This research investigates the potential of buildings to generate energy from wind, aligning with the United Nations Sustainable Development Goals (SDGs), including affordable and clean energy, sustainable cities and communities, and climate action.

As part of its sustainability efforts, Turkey has introduced regulations mandating Net Zero Energy Buildings (NZEBs) to generate at least 10% of their energy needs from renewable sources starting in 2023 (The Ministry of Environment, Urbanization, and Climate Change introduced new provisions in the Official Gazette No. 31755). These regulations aim to promote energy-efficient buildings and sustainable construction practices.

The potential for increasing electricity generation through wind energy is considerable, particularly in areas with high wind energy potential. In regions such as the Aegean and Marmara, wind turbines are already deployed in wind farms independent of buildings. These farms, typically situated in rural areas, produce energy using turbines separate from buildings. However, given that wind energy potential increases at higher altitudes, integrating wind turbines into densely built urban areas could significantly enhance energy production, benefiting both the economy and environmental health of the country.

In urban settings, decentralized energy production using various renewable sources has the potential to meet part of the growing energy demand, helping address energy crises and mitigate climate change (Ayhan & Sağlam, 2012). In response to these needs, literature studies have examined wind flow analyses, building forms, and

*Corresponding author, E-mail: mmervecoban@gmail.com

https://doi.org/10.31462/icearc2025_a_aen_116

configurations within urban environments, with various trials and calculations conducted. Identifying optimal locations within and around buildings to efficiently harness wind energy is a critical step in integrating wind turbines into buildings.

Ilgın and Günel (2021) proposed a typological classification for wind energy integration in existing and planned buildings, presenting comprehensive and consistent strategies for architectural integration. Furthermore, Ilgın and Günel (2021), highlight the growing trend of incorporating wind energy into building designs, especially in high-rise structures globally. Their research suggests that in the near future, architects will design buildings capable of generating sufficient energy to meet urban energy needs, with wind turbines becoming an integral part of every building, particularly in high-rise contexts. They argue that interdisciplinary collaboration between architects and engineers is essential to combine renewable energy use, building function, and architectural design processes to foster innovative solutions. Ilgın and Günel (2021) also note a lack of research on the relationship between building form and wind energy utilization, particularly regarding the application of advanced micro turbines in new buildings in Turkey. This research seeks to fill this gap by developing a design approach for integrating micro turbines into building forms, facilitating the application of NZEB principles in new constructions.

Micro wind turbines, which are smaller and more suitable for residential areas, offer a feasible alternative to large-scale turbines, minimizing noise and light pollution. Previous studies have identified key design factors such as environmental conditions, building structure, and turbine specifications that can optimize energy production in wind turbine-integrated buildings.

In areas with wind potential, buildings can be integrated with micro turbines, enabling them to generate the energy they consume from wind. This approach will reduce dependence on fossil fuels. Traditionally, turbines have been installed in rural areas; however, thanks to technological advancements, they can now be mounted on buildings, thus optimizing energy production and addressing issues such as energy storage in recent studies.

In this study, a literature review will be conducted to examine the effects of building form on wind performance, and changes in building form that increase wind potential will be analyzed to determine building form alternatives. Thus, the integration of micro turbines can be optimized, maximizing the amount of energy produced. This research envisions a future where buildings become primary sources of energy.

2. Methodology

The primary objective of this study is to integrate micro wind turbines into buildings and enhance the existing wind energy potential through optimized building design, aiming to generate more energy than the building consumes. By establishing a relationship between the integration of micro wind turbines and building form, the goal is to achieve efficient energy production by optimizing the building's design. As an initial step, the research envisions buildings as primary sources of energy.

To achieve this, a comprehensive literature review will be conducted to examine existing studies on turbine integration into buildings and the impact of building forms on enhancing wind potential. From the review, design criteria will be identified, particularly focusing on how different building forms influence wind speed, wind direction, and subsequently, the efficiency of electricity production through wind turbine integration.

The data derived from the literature will be evaluated to identify key variables that improve wind performance in the context of building design. Specific building forms will be analyzed to determine their potential to optimize wind energy production. The findings will be used to propose formal design strategies for buildings capable of generating energy through wind energy, marking the first step towards creating self-sufficient, energy-generating buildings. The workflow of the study is illustrated in Fig. 1.

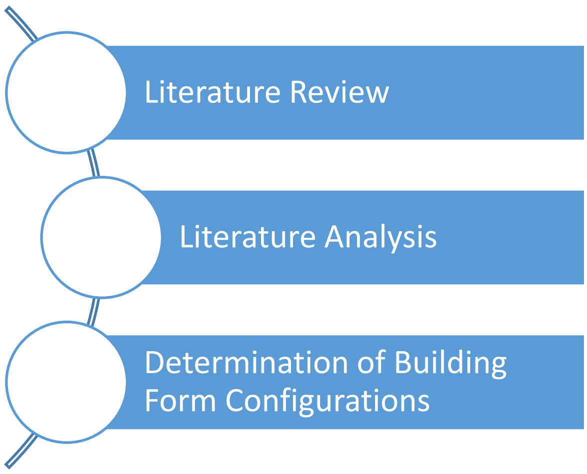

Fig. 1. Workflow of the study

3. Findings:
In accordance with the steps outlined in the "Methodology" section, the findings are presented under three distinct subheadings.

3.1 Literature Review
The foundational use of wind turbines in tall buildings is rooted in early wind analyses aimed at reducing structural vibrations in high-rise building designs. Initially, wind analyses focused primarily on designing building shapes that minimized structural vibrations. As turbine technology advanced, the integration of turbines into buildings became more common, and the potential for turbines to enhance wind energy production in tall buildings gained increasing significance. The first buildings to incorporate wind turbines for renewable energy generation were tall structures. This shift led to studies that not only explored the relationship between wind analyses and building form but also sought to optimize energy production through turbine integration.

The evolution of wind turbine technology, coupled with the rising demand for sustainable energy due to global population growth, has contributed to the widespread adoption of turbines. This trend supports their use at both urban and building scales, particularly in cities where energy consumption continues to rise. In urban environments, decentralized energy production—leveraging a variety of energy sources—holds the potential to meet a portion of the increasing energy demand while addressing energy crises and mitigating climate change (Ayhan & Sağlam, 2012). In response to these challenges, a body of literature has focused on wind flow analyses, building forms, and configurations within urban fabrics, examining the suitability of various locations within and around buildings to harness wind energy efficiently.

The height of the building is a key criterion in many of these studies. For example, Al Quran (2016) analyzed two different building heights, comparing them to the average surrounding height in various neighborhoods of Montreal. Balduzzi et al. (2012) adopted an average building height of 13.6 meters in their study of London's urban environment. Similarly, Shiraz et al. (2020) analyzed various alternatives in Montreal, considering the average height of buildings in selected neighborhoods. In areas where the tallest building stood at 44 meters, they opted for a 30-meter structure, while in a neighborhood with a 200-meter tall building, they selected a 140-meter building. Furthermore, Lu and Sun (2014) conducted computational fluid dynamics (CFD) simulations to explore the feasibility of using wind energy in Hong Kong's high-rise buildings, concluding that the substantial building heights and their clustering effects made wind energy usage theoretically promising.

Wang et al. (2015) investigated the impact of various aspect ratios and building heights on wind speed and wind energy density. Their study found that buildings with smaller plan areas—those with shorter lengths or narrower widths—generally had higher wind energy densities compared to larger buildings. However, they cautioned that the total amount of energy produced and the economic feasibility should also be considered in practical applications.(Fig. 2.)

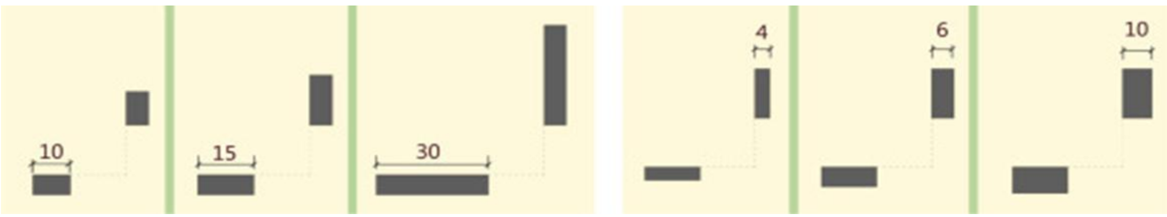

Fig. 2. Building Ratio (Wang et al, 2015)

Building corner modifications have been found to significantly enhance the aerodynamic performance of tall structures. Zhou et al. (2017) conducted CFD simulations to assess wind flow around low-rise buildings with different geometries to identify the optimal building form. Their study, which considered four building shapes—cuboid diffuser, cylinder diffuser, semi-cylinder diffuser, and composite prism diffuser—demonstrated that the composite prism diffuser, characterized by a rectangular prism with chamfered edges, outperformed the other shapes by maintaining more stable wind speeds across various heights. The study further optimized the building's geometry, determining that the ideal aspect ratio was 10x4, with a chamfer radius of 0.6 meters yielding the best results in terms of wind speed.(Fig.3)

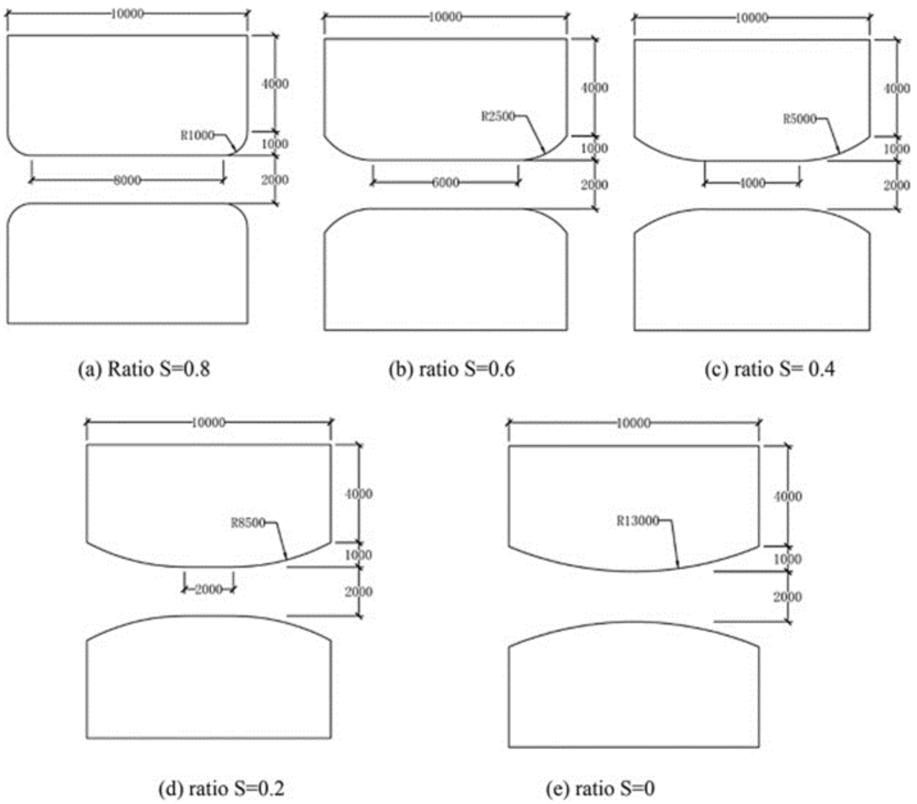

Fig.3. Building Corner Modifications (Zhou, 2017)

Similarly, Kono and Kogaki (2012) used Large Eddy Simulation (LES) to analyze wind flow around a rectangular, isolated prism-shaped building. Their findings revealed that wind power density was higher at the upper edge of the roof, influenced by wind direction, and that the velocity profile exhibited less variation. In another LES study, they examined the effects of wind direction and horizontal aspect ratio on the wind flow pattern of high-rise cuboid buildings.

Numerous studies have confirmed that corner modifications can reduce wind resistance and the wind-induced response in wind-resistant tall buildings (Xie, 2014; Thordal et al., 2020; Gu and Quan, 2004). The effects of different corner shapes—such as chamfered, recessed, fluted, and rounded corners—on wind pressure distribution across building surfaces have been extensively investigated through wind tunnel experiments (Li et al., 2018; Kawai, 1998; Kwok, 1988; Tamura and Miyagi, 1999; Carassale et al., 2014) and computational fluid dynamics (CFD) simulations (Thordal et al., 2020; Elshaer et al., 2016, 2017; Tamura et al., 1998; Bernardini et al., 2015; Alminhana et al., 2018; Juan et al., 2021c).(Fig 4.)

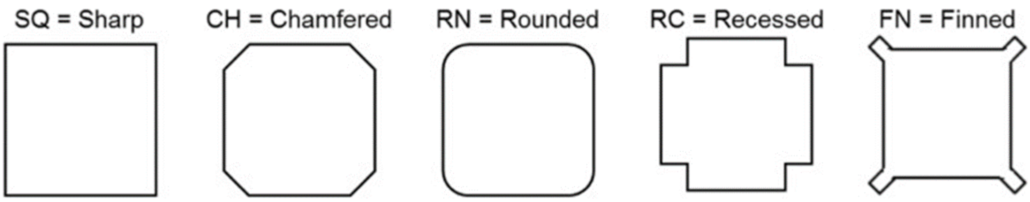

Fig.4. Different Corner Shapes for Buildings (Juan, 2024).

In a more recent study, Juan et al. (2024) conducted CFD analyses on various corner configurations, emphasizing the importance of incorporating aerodynamic principles into early-stage building design to optimize wind energy performance. They found that rounded corners can increase power density while reducing turbulence, thus improving the performance of rooftop turbines. Moreover, longer chamfer lengths and larger corner radii further enhanced wind flow, supporting more efficient energy generation. The study also highlighted the potential for vertical-axis wind turbines (VAWTs) to be strategically placed in the corridors between buildings with rounded edges, presenting new opportunities for wind energy generation. This body of research underscores the importance of considering corner geometry and prevailing wind conditions in the design of sustainable and energy-efficient urban environments.

3.2 Literature Analysis

The increasing global population and growing demand for sustainable energy have accelerated the development and integration of wind turbine technologies at both urban and building scales (Ayhan & Sağlam, 2012). In urban environments, where energy consumption continues to rise, on-site decentralized energy production holds significant potential for mitigating the effects of energy crises and climate change. In this context, various studies have investigated the relationship between building form and wind flow characteristics, emphasizing the importance of considering aerodynamic behavior in the early stages of architectural design.

3.2.1 Building Height and Wind Energy Utilization

Since wind speed generally increases with altitude, building height is considered a critical parameter for the effective use of wind turbines. Several studies have evaluated wind energy potential by analyzing different building heights in various urban morphologies. For instance, Al Quran (2016) examined two different building heights across various neighborhoods in Montreal, using the average surrounding building height as a reference. Similarly, Shiraz et al. (2022) selected 30 m and 140 m buildings for their analyses in areas where the tallest buildings were 44 m and 200 m, respectively. Lu and Sun (2014), through CFD simulations conducted in Hong Kong, demonstrated that high-rise buildings possess significant potential for wind energy generation due to their elevation and the wind concentration effects caused by surrounding structures.

3.2.2 Plan Ratio and Energy Density

The geometry of the building footprint, particularly its plan ratio and base area, also plays a vital role in determining wind energy density. Wang et al. (2015) found that buildings with smaller plan areas (e.g., narrow or short facades) tend to exhibit higher wind energy density. However, they also emphasized that total energy output and economic feasibility must be considered alongside wind density in real-world applications.

3.2.3 Corner Modifications and Aerodynamic Performance

Corner design is a key factor in improving a building's aerodynamic performance, influencing both wind-induced loads and the efficiency of wind turbines. Zhou et al. (2017) conducted CFD simulations on four different low-rise building forms and identified the chamfered rectangular prism (composite prism diffuser) as the most effective shape for maintaining stable and enhanced wind speed. Their findings also showed that a chamfer radius of 0.6 meters yielded optimal wind conditions.

Similarly, studies by Kono and Kogaki (2012) using Large Eddy Simulations (LES) revealed that wind power density was highest along the upper roof edges, depending on wind direction, making these zones suitable for turbine placement. More recently, Juan et al. (2024) emphasized through CFD analyses that rounded corners help reduce turbulence while increasing power density, leading to improved rooftop turbine performance. The study also highlighted the potential of vertical-axis wind turbines (VAWTs) placed between rounded-edge buildings, offering new opportunities for efficient turbine integration.

3.2.4 Wind Direction and Urban Layout

The alignment of buildings with prevailing wind directions and their spatial configuration within the urban context also significantly influence wind energy performance. The Venturi effect, often occurring between closely spaced tall buildings, can increase wind speed and enhance turbine efficiency (Lu & Sun, 2014). Therefore, building form must be considered not only at the individual scale but also in relation to its environmental context.

Based on the findings of the literature review, several key factors influencing wind potential at the building scale have been identified. Building height plays a significant role in wind energy production, while the plan ratio (width-to-length) affects the density of energy capture. Additionally, corner modifications contribute to aerodynamic performance, enhancing or reducing airflow efficiency around the structure. Furthermore, the orientation and spatial positioning of buildings within urban settlements have been shown to influence local wind speeds, thereby affecting the overall effectiveness of wind energy systems integrated into the built environment (Fig. 5).

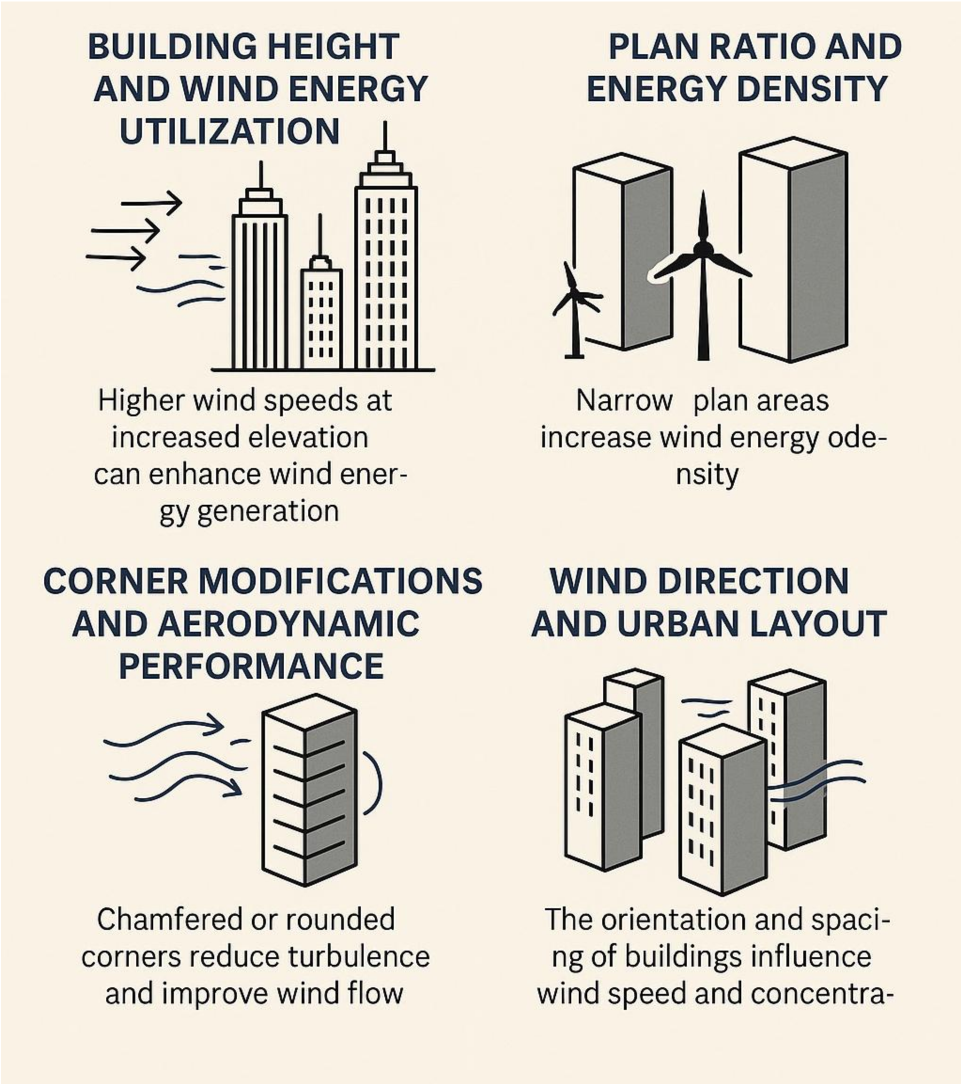

Fig.5. An Evaluation of the Impact of Building Form on Wind Potential: A Literature-Based Review

3.3. Determination of Building Form Configurations

In the literature-based study, the evaluation of the impact of building form on wind potential revealed that building height affects wind energy utilization, plan ratio influences energy density, corner modifications affect aerodynamic performance, and wind direction has an impact on urban settlements. Design decisions outside urban settlements are made at the building scale and influence architects' design choices. In the integration of microturbines, identifying the area on the building surface with the highest wind potential is important for increasing the amount of energy generated. Therefore, this study aims to identify building configurations that enhance wind potential in order to improve the energy performance of buildings utilizing wind energy. Based on previous research in the literature, alternative building forms have been proposed at the building scale by considering the form factors that influence wind potential, such as building plan aspect ratio (width/length), building height, and corner modifications (Fig. 6).

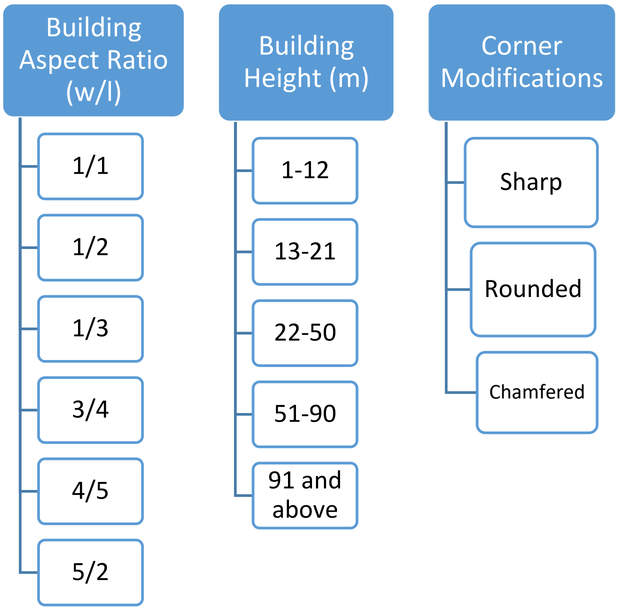

Fig.6. Form-Related Factors Affecting Wind Potential at the Building Scale and Alternative Building Configurations

4. Conclusions

This study has demonstrated that the integration of wind turbines into building designs, particularly when optimized, can significantly enhance energy production. The growing global emphasis on mitigating climate change and reducing carbon emissions underscores the increasing importance of renewable energy solutions, especially within urban environments. In this context, the incorporation of wind turbines into high-rise buildings represents a promising approach to addressing energy demands while minimizing environmental impacts.

The literature review and subsequent analysis reveal that several factors, including building height, shape, and wind flow dynamics, are critical in determining the efficiency of wind turbine integration. Taller buildings, in particular, benefit from stronger wind currents at higher altitudes, which are crucial for maximizing energy production. Additionally, modifications to building shapes—especially at the corners—can substantially improve wind speed and turbine performance. Chamfered and rounded corners, for example, reduce the area that is unsuitable for turbine placement, thus providing more available space for energy generation.

This research also highlights the potential of integrating micro wind turbines into buildings as a means of reducing reliance on fossil fuels and achieving Net-Zero Energy Buildings (NZEBs). Investigating the effects of building form on wind performance is essential for designing more energy-efficient and sustainable structures. Furthermore, the study underscores the importance of interdisciplinary collaboration, emphasizing that cooperation among engineers, architects, and renewable energy experts is essential to the successful development of integrated energy solutions.

In conclusion, the integration of wind turbines into buildings—especially through the use of micro turbines and optimized building designs—offers substantial potential to increase energy production and reduce environmental impacts. Future research should focus on developing advanced design strategies to enhance turbine integration within urban environments and various architectural forms. This approach represents a significant step toward achieving sustainable energy production and reducing the ecological footprint of urban development.

Balancing daylight performance and user comfort through pleated folding square façade modules

Ecenur Kizilorenli*[1], Ahmet V. Orhon[2]

[1] Dokuz Eylul University, Graduate School of Natural and Applied Sciences, Department of Architecture, 35160 İzmir, Türkiye
[2] Dokuz Eylul University, Faculty of Architecture, Department of Architecture, 35390 İzmir, Türkiye

Abstract. Increasing energy efficiency and interior comfort, which are sustainable architectural design goals, gains a new dimension with the integration of movable facade systems. The developed facade systems offer the opportunity to increase the efficiency of natural daylight while minimizing unwanted exposure and overheating. In this context, this study focuses on a movable facade system consisting of square modules and investigates the potential of these systems to optimize daylight performance. In the research, a foldable movement mechanism is proposed by using square modules, dividing these modules into sub-triangles and allowing each triangle to exhibit a folding movement within itself. The dimensions, opening angles and movement dynamics of each module, which are activated by the sub-triangles and can be folded and opened without affecting each other's movement, were defined and simulated in detail. After the efficiency of the system was predicted, the system's limitations were evaluated by proposing a folding system with a prototype. Along with the data obtained from the prototype, metrics such as sDA (Spatial Daylight Autonomy), ASE (Annual Sunlight Exposure) and UDI (Useful Daylight Illuminance) were examined in the simulations using Rhinoceros, Grasshopper, Honeybee, Ladybug and Octopus. The results show that the foldable square modules is effective in exposure control with low ASE values and also provides a successful solution in meeting sDA and UDI targets. The study aims to provide a framework for the potential applications of the square module geometry while emphasizing the importance of movable facade systems in sustainable building design.

1. Introduction

Daylight plays a critical role in sustainable building design because it not only reduces reliance on artificial lighting but also enhances the visual and psychological well-being of occupants (Garcia-Fernandez and Omar, 2023). However, excessive or poorly managed daylight can lead to discomfort, exposure, and increased cooling loads (Pauley, 2004; Wu et al., 2019; Kangazian & Pavazavi, 2023). In parallel, the search for sustainable architectural solutions has become a central focus due to the need to increase energy efficiency, improve indoor environmental quality and reduce the carbon footprint of buildings (Alassaf, 2024; Ma et al., 2023). Among the various strategies used, the integration of movable façade systems has emerged as a promising approach to optimize daylight use while reducing issues such as exposure and solar heat gain (Banihasemi et al., 2015; Hosseini et al., 2019). In particular, movable facades offer flexibility to adapt to changing environmental conditions, improving both daylight performance and user comfort (Hasselaar, 2006; van Hooff et al., 2014; Soudian & Berardi, 2021; Gonçalvez et al., 2024). As seen in the literature, the increasing use of geometric modules offers the opportunity to create complex and movable shading patterns, providing effective control over daylight and solar heat gain (Dastoum et al., 2024). These studies often employ key metrics such as Spatial Daylight Autonomy (sDA), Annual Sunlight Exposure (ASE) and Useful Daylight Illuminance (UDI) are used when evaluating the daylight performance of the proposed and implemented systems.

In these studies in the literature (Neşeliler et al., 2025; Talaei and Sangin, 2024; Kim et al., 2024; Sönmez and Kunduracı, 2021), Spatial Daylight Autonomy (sDA), which is also included in LEED v4.1, in the evaluation of the daylight performance of the proposed and implemented systems, measures the percentage of an area that receives at least 300 lux of daylight in at least 50% of the occupied hours per year; for compliance, at least 40% corresponds to 1 point, 55% to 2 points and 75% to 3 points, Annual Sunlight Exposure (ASE) which can be considered as a complement to the sDA metric, assesses the percentage of a space that experiences illuminance

---

https://doi.org/10.31462/icearc2025_a_aen_120

levels above 1000 lux for more than 250 occupied hours per year, with less than 10% being the recommended threshold to avoid excessive glare and overheating, and Useful Daylight Illuminance (UDI) divides daylight levels into three ranges: below 100 lux (insufficient daylight), between 100-2000 lux (optimal daylight) and above 2000 lux (excessive daylight that can cause glare and thermal discomfort). A well-balanced daylight strategy typically aims to maximize the percentage of time in the 100-2000 lux range, targeting at least 50% of occupied hours (Nabil & Mardaljevic, 2005; Berardi & Anaraki, 2015; Dabe & Adane, 2018; LEED, 2025). These metrics collectively assess the system's ability to enhance daylight availability while mitigating glare and overheating, contributing to both occupant comfort and energy efficiency.

The development and validation of movable façade systems aimed at improving interior daylight performance require a rigorous iterative process that combines computational tools and physical prototyping. Simulations conducted using Rhinoceros, Grasshopper, Honeybee, and Ladybug allow rapid exploration of design parameters such as module geometry, folding angles, and material properties while predicting performance outcomes under a variety of environmental conditions (Toutou et al., 2018). In addition to these stages, physical prototyping, an artifact that approximates a feature (or multiple features) of a product, service or system (Wood et al., 2001), remains important for testing real-world functionality, assessing mechanical durability and improving user interaction. By combining digital and physical testing, this dual approach ensures that theoretical optimizations align with practical applicability, encouraging both high-performance and constructible innovations.

This study investigates the potential of a movable façade system consisting of square modules that use a folding motion to control daylight penetration and distribution. A foldable and movable façade system consisting of square modules divided into smaller sub-triangles, each of which can move independently, is proposed. This design allows for a folding movement where each module can adjust its orientation and opening angle without interfering with adjacent modules. Rhinoceros, Grasshopper, Honeybee and Ladybug computational tools are used to simulate and analyze the daylight performance of the proposed system. Through detailed modeling and simulation, the research first examines the base case scenario, which is a generic office proposed within the scope of the study, and then investigates the relationship between the geometric configuration of the square modules, the movement dynamics and the resulting daylight conditions. In parallel with this process, a prototype of a single module within the multiplied square modules was developed to understand the mobility and limitations of the module through physical modeling and revisions to this model. The combined use of prototypes and simulations allows the system to be evaluated not only theoretically but also in practical conditions. This two-way approach aims to increase the chances of providing an efficient solution.

The findings aim to demonstrate the effectiveness of foldable modules in meeting the exposure control and daylight performance targets of the interior. The analysis of different configurations within the system was completed by evaluating the previously determined metrics. The aim is to obtain multiple configurations where these metrics exceed thresholds. This supports the concept of movement of the system while also offering the user different usage alternatives in different periods. This study aims to contribute to the growing body of knowledge on movable façade systems by examining the intersection of geometry, movement and daylight performance.

2. Method of the Study

The study is based on 3 main stages, each of which has subcategories (Fig. 1). The first stage was determined as designing a façade system by proposing square folding façade modules using Rhinoceros and Grasshopper and applying this system to a generic space. After the system was implemented, Honeybee and Ladybug were used in addition to Rhinoceros and Grasshopper in order to make initial observations regarding the efficiency of the system. At this stage, the number of parameters was intentionally limited to be detailed in later stages. The second main stage is related to determining the movement constraints of the system designed with one and two-dimensional elements in order to perform the initial simulations and to have an idea about the efficiency of the system and the arrangements regarding the effect of these constraints on the daylight performance of the system. In order to observe these constraints and to examine the folding movement of the system in real life, the scope of this stage a 3D model was created regarding the movement of the module by modeling a triangular section inside the square module in 3D. After this prototype was produced, movement constraints were determined on the model printed with a 3D printer. Thus, the first and second stages were combined, and the simulation was revised by revising the parametric model and the number of parameters. The final stage aims to optimize the use of daylight in the interior space by using Octopus to ensure user comfort through the separate movement of each element of the revised system.

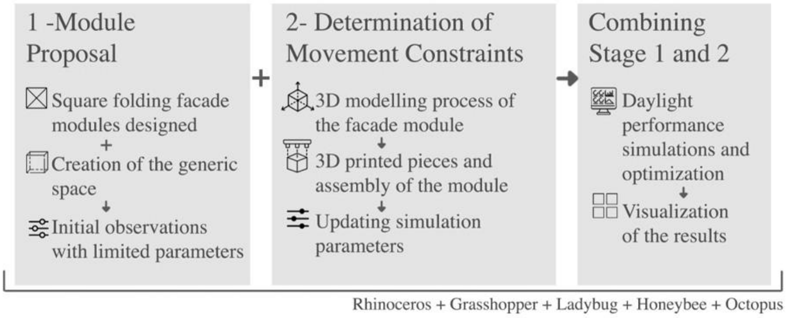

Fig. 1. Stages of the Study

2.1. Module Proposal and Initial Daylight Performance Results

In Phase 1, two stages were carried out simultaneously. While a generic space was defined, the modules forming the façade system were also suggested.

As the first stage, a generic space with a glazed south façade was modelled using Rhinoceros, providing a context for testing and iterating the proposed modules. For this, a standard office area was defined, and a parametric model was created. The depth of the proposed office structure was defined as 5.5 meters, the façade width as 7.2 meters and the height as 3.85 meters. Each surface was defined as different layers within itself, and different material values were provided (Table 1) with Grasshopper and Honeybee according to LEED v4.1 standarts (LEED, 2025). The south facade of this office building was defined as a glass facade and the ratio of the glass surface to the wall on the 7.2mx3.85m facade was determined as 75.7% with the glass portion measuring 7mx3m. According to LEED v4.1, the ceiling was defined to have a reflectance value of 80%, the wall 50% and the floor 20%.

In order to evaluate the interior daylight performance in the base scenario, i.e. without a façade system, an analysis grid was defined at 0.6 m intervals at ground level and 0.76 m above the floor. This grid was used to assess sDA, ASE, and UDI values at each stage.

In parallel with this process, a module creation was developed based on square geometry to create the façade system. This square geometry was divided into sub-sections and a module exhibiting a folding movement was produced (Fig. 2). In the production phase of this module, the edge midpoints and corner points of each triangle were defined. By combining these points, a total of eight right triangles were obtained in the square. The 45-degree angle of these triangles corresponding to the center of the square was divided into 4 equal angles and 4 more sub-triangles were defined. These sub-triangles formed the panels that would exhibit a folding movement. A parametric model was then constructed in which the folding movement was achieved by moving each right edge of each triangle toward its hypotenuse.

After these two stages were completed, modules were deployed on the façade, with a total of 21 modules used. In addition to the full modules, half modules can also be proposed depending on the facade length and width. The movement angles of the modules were defined in 5-degree increments to reduce simulation time.

Table 1. Simulation Parameters

Location	İzmir, Türkiye	Window Transmittance	40%
Orientation	South	Work Plane Height	0.76m
Office Dimensions	H: 3.85m W: 7.2m L: 3.5m	Simulation Grid Spacing	0.6m
Window Dimension	H: 3m W:7m	Parameters	Folding angles (x*5)
Reflectance Values	Ceiling: 80% Floor: 20% Walls: 50% Façade Elements: 40%	Objectives	sDA, ASE, UDI

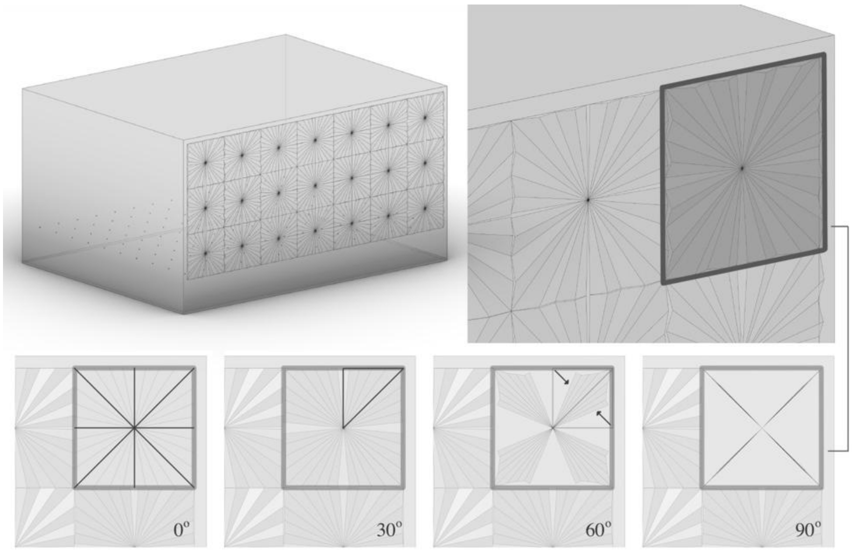

Fig. 2. Generation and Arrangement of Modules

Before testing the prototype of the model, the daylight performance of the proposed interior space and the initial evaluation of the system were conducted. In the base case without the façade system, the results were: sDA 100%, ASE 88.57%, and UDI 41.04%.

Following this stage, the system was applied to the façade. Prior to detailed analysis, a preliminary test was conducted in which all panels moved simultaneously at 10-degree and multiple-angle intervals, providing initial performance predictions.

Table 2. Initial Daylight Performance Analysis

Angle	sDA	ASE	UDI
0	0	0	71
10	0.01	0	64
20	10	0	46
30	43	16	36
40	67	31	31
50	94	47	29
60	100	56	28
70	100	64	27
80	100	72	26
90	100	75	26

*All values are in percentages

This analysis reveals that configurations where all modules are positioned at 30 and 40 degrees have a high probability of producing efficient results in terms of sDA (Spatial Daylight Autonomy), ASE (Annual Sunlight Exposure) and UDI (Useful Daylight Illuminance) measurements. Within the scope of this analysis, it was predicted that by varying the module angles exhibiting total movement with individual movements in other stages, it would provide an advantage in terms of comfort by ensuring the optimal use of natural light in the interior while also balancing excessive sunlight exposure. These positive results proved the reliability and effectiveness of the configuration determined at this stage of the design, and formed a basis for the transition to the next stages of the study. Therefore, physical module production was carried out after this step.

2.2. Modelling and Prototyping Process

After the possible efficiency of the system was predicted, the prototyping phase was initiated. This stage, composed of interrelated steps involving iterative feedback, focused on one of the eight identical triangles within the square module. Initially, the folding mechanism was designed to operate by sliding the ends of the panels along a rail. However, this method did not enable a uniform folding motion; instead, it merely gathered the panels. As a result, this approach—tested using A4 paper and cardboard—was not implemented further.

As the next stage, a scissor system was proposed so that each panel could be folded at an equal angle. However, the problem here was that the panels could not be attached to the scissor system due to the change in the distance from the center and the diameter lengths in the scissor system.

As the last stage, one of the joints was planned to move in a guide (Fig. 3). This configuration successfully enabled uniform panel movement, achieving the desired folding motion. Thus, the targeted behavior was realized by the end of the third prototype iteration (Fig. 4).

The components of the modules—including nuts and bolts, panels, elements of the scissor mechanism, and connecting parts—were produced using a 3D printer. Hinges were modeled for the panel edges that are adjacent and designed to rotate; however, paper tape was used to allow quick and flexible movement testing. The parts were printed using a Bamboo Lab A1 3D printer with PLA+ filament, 1.75 mm in diameter.

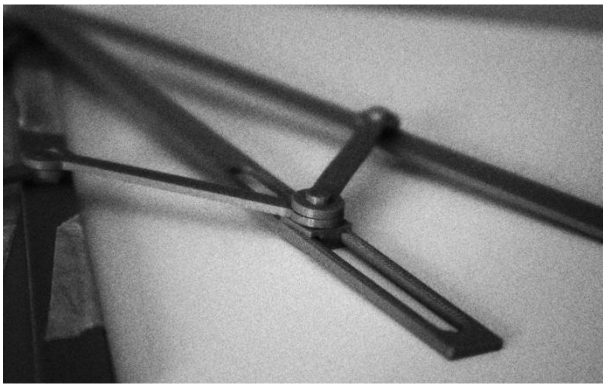

Fig. 3. Sliding Joint Detail

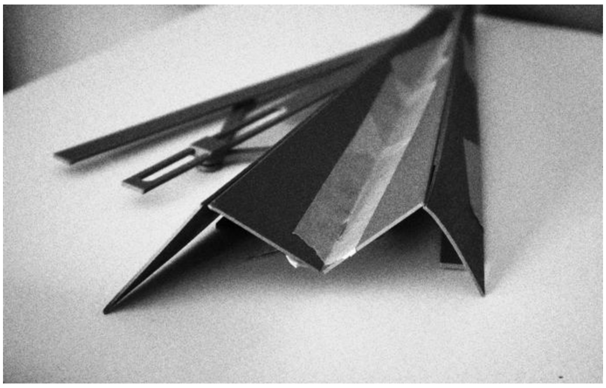

Fig. 4. General View of the System and Panel Plates

During the movement of the module, the sliding joint shifts position and supports the panels to remain fixed. However, a key limitation of the study is that when scaled with the computational model, the material thickness and the connection parts of the scissor system can close up to 80 degrees instead of 90 degrees as targeted.

Two important information obtained at this stage is the ability of the panels to provide equal folding and the closing angle. These inputs were collected to be used in the next stage and the simulation parameters were updated according to this information.

3.3 Daylight Performance Analysis Based on the Physical Model

The movement angles of the panels were updated in the slider in the Grasshopper interface to increase by 5 and multiples between 0-80. The material and permeability values were kept the same for consistency with the first simulation. Since the parameters were updated at this stage, unlike the first simulation, panel ID numbers were assigned to the 21 modules on the façade, and each was moved with different sliders (Fig. 5). Thus, each module can move at different angles within itself, thus supporting the formation of configurations aimed to provide alternatives to the user. For this reason, since the possibilities of each panel at 5-degree positions between 0-80 cannot be tested one by one, the Octopus plugin was included in the Rhinoceros, Grasshopper, Ladybug and Honeybee plugins at this stage. Thus, simulations were performed by defining each panel angle as a parameter and sDA, ASE and UDI values as objectives. Optimization was started with the population size 55 and max generation 15 values. In order to be able to examine all the configurations in the table later, all sliders and result information were recorded with the Data Recorder component.

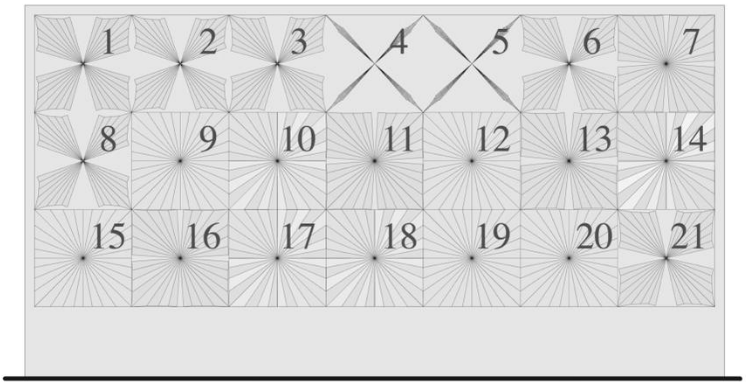

Fig. 5. Module IDs

As a result of the optimization, more than 800 configurations were obtained. All values were compiled into a table and organized. First of all, configurations with sDA values below 40% and ASE values above 10% were eliminated. The results were ranked by writing a formula that kept the weight and importance of all metrics equal. The ten most efficient configurations and the results obtained are given in Table 3.

Table 3. Selected Configurations and Results

Results			Module IDs																				
sDA	ASE	UDI	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21

*sDA, ASE and UDI values are in percentages

From the obtained results, the first configuration was visualized and detailed. The obtained results were sDA value 90%, ASE value 9.3% and UDI value 65.5%. This proves that efficient configurations can be obtained even though the system has limitations.

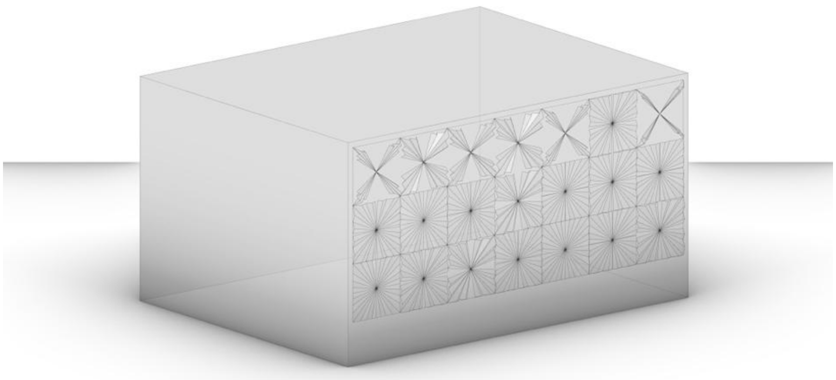

Fig. 5. Selected Optimal Configuration

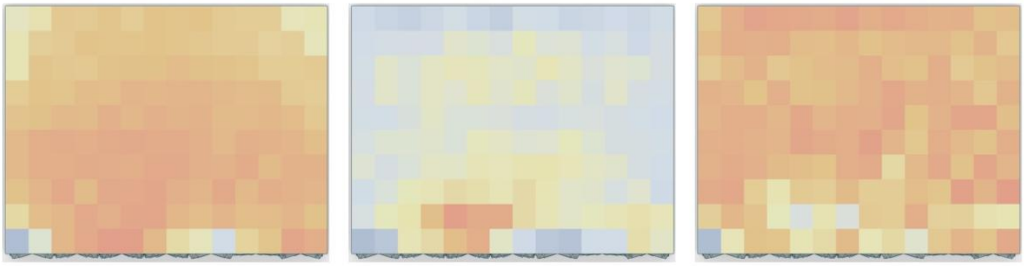

Fig. 5. Selected Configuration and Daylight Performance Results

4. Conclusion

This study focuses on the potential of movable façade systems in line with the goal of improving indoor environmental quality, at a time when sustainable architectural solutions are increasingly gaining importance in today's design approaches. In particular, the effect of a movable façade system consisting of square modules and controlling daylight penetration with a folding movement on optimizing indoor daylight performance was evaluated in detail. The study was carried out by combining methods, using digital simulations and physical prototype production. In this process, the key metrics sDA (Spatial Daylight Autonomy), ASE (Annual Sunlight Exposure) and UDI (Useful Daylight Illuminance), which are also included in LEED v4.1 standards, were used to evaluate the daylight performance of the proposed system. The base case scenario revealed that there were excessive sunlight exposure problem in the indoor space, which once again emphasized the necessity of a movable façade system. By defining certain stages, the simulations were updated after testing how the proposed system would work in a real-life scenario. Different configurations of 21 modules were examined with the individual movement of each module. The most efficient configuration obtained stood out with sDA 90%, ASE 9.3% and UDI 65.5% values. These results proved that the system can offer highly efficient configurations despite the specified limitations and can effectively control exposure problem while using daylight at an optimal level in the interior.

In general, this study has revealed the potential of movable facade systems to improve daylight performance and increase user comfort; it has examined the relationship between geometry, movement and daylight performance. The proposed system has provided flexibility by offering users various configuration alternatives in different usage periods and environmental conditions. In addition, this two-way approach combining digital simulations and physical prototyping has enabled this study to harmonize theoretical optimizations with practical applicability.

The impact of thermal insulation on energy savings and thermal comfort: a study in multi-story residential buildings

Özlem Aydın*[1], Tuğba Uncuoğlu[1]

[1] *Karadeniz Technical University, Department of* Architecture*, 61080 Trabzon, Türkiye*

Abstract. Energy-efficient building design is achievable by thoughtfully evaluating and cohesively integrating the most suitable values for various variables. Energy-efficient building design is possible by considering the most appropriate values for many variables and bringing them together harmoniously. In our country, especially with the entry into force of the Energy Efficiency Law, studies carried out for efficient energy use have become even more important. In this context, a rapid increase has been observed in external insulation applications, especially in buildings, for increasing energy performance and saving energy. While external insulation applications provide energy savings, they are also effective in improving the user's thermal comfort conditions.
Studies, particularly those addressing heating energy demands during cold periods, prominently focus on ensuring thermal comfort and enhancing energy conservation in buildings. This study evaluates user behaviors related to energy consumption, measures taken, and satisfaction levels in achieving the desired thermal comfort in indoor environments during cold seasons. The primary aim is to emphasize the significance of external insulation applications as a key strategy for energy savings in residential buildings. In this context, a survey was conducted in two apartment buildings within a multi-story residential complex to assess the impact of two different wall constructions' insulation performance on thermal comfort satisfaction. The survey results indicate that external insulation applications positively influence energy savings and enhance users' thermal comfort satisfaction. The findings demonstrate that effective insulation practices reduce building energy consumption and contribute significantly to the national economy.

Keywords: Energy efficiency, Energy efficient retrofit, Thermal insulation, Thermal comfort.

1. Introduction

While the energy demand is constantly increasing globally, the depletion of fossil fuel reserves raises serious concerns about possible future energy supply problems. Although this situation can be solved in the short term by finding new energy sources and making them sustainable, another solution is to reduce the consumption momentum and use the existing energy more efficiently. In this context, it is a fact that has been revealed by scientific studies that significant energy savings can be achieved by improving energy performance in the building sector. When it comes to the evaluation of building performance, the criteria on which the energy efficiency of the building will be determined should be defined by standards, and the application conditions should be explained by guidelines. Within the framework of the concept of energy-efficient building, each country has standards, regulations, and policies developed within its local conditions. Building energy regulations and standards help to realize the potential for energy conservation in buildings and to increase the demand for energy-efficient design in buildings. This also forms a basis for the development of energy-efficient policies (Harputlugil, 2013). In Türkiye, legal regulations regarding energy efficiency have gained momentum within the framework of the harmonization process with the European Union. In this context, the Energy Efficiency Law was adopted in 2007, creating a legal basis for energy saving. In line with the law, the Energy Performance in Buildings Regulation, which entered into force in 2010, aimed to increase energy efficiency in buildings and made it mandatory to issue energy identity certificates for all existing and new buildings. In addition, the TS 825 "Thermal Insulation Rules in Buildings" standard, which determines the technical principles regarding thermal insulation in buildings, was made mandatory in 2000, thus increasing the importance of thermal insulation.

In residential buildings, significant heat losses occur during the winter months, and substantial heat gains are observed in the summer. However, both contractors and building occupants typically overlook these issues, focusing primarily on the aesthetic and visual appeal of the building. As a result, during the construction phase, the selection of inappropriate building materials and the failure to implement essential applications can have negative environmental impacts, leading to increased energy consumption over the lifespan of the building. In this context, despite the high energy consumption, the building sector holds the greatest potential for energy and emission savings compared to other sectors (Fig. 1). Given the high potential for low-cost energy savings within the building sector, it has emerged as a priority area for energy efficiency (Mıhlayanlar & Meral, 2023).

The building envelope plays a crucial role in meeting the basic needs of the user, as well as contributing to energy conservation, air quality, and mitigating global warming. However, additional artificial energy systems are often required to control climatic effects during certain times of the year. In contemporary settings, the depletion of energy resources, which serve as inputs for these systems, and the corresponding increase in costs, have made the efficient use and conservation of energy imperative.

When analyzing energy consumption patterns in buildings, it is observed that 65% of the energy is used for heating, cooling, and ventilation, 20% for lighting, and 15% for other systems (URL-1), (Fig. 2). The construction sector, accounting for 33% of total energy consumption, holds significant potential for energy savings. The sector's high energy consumption highlights the increasing importance of insulation in energy conservation efforts. Therefore, in modern buildings designed with an emphasis on conscious energy use and equipped with suitable materials and architectural details, effective solution proposals should be developed by considering the alignment of the final products with energy policies, within the context of the owner-designer-contractor-user relationships.

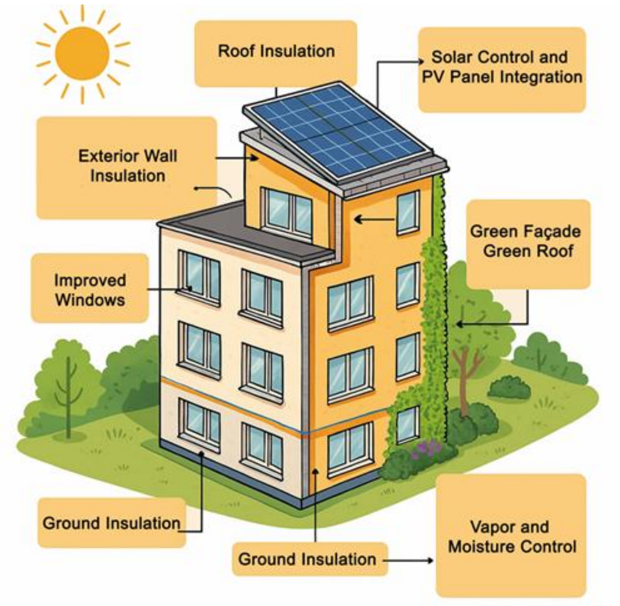

Fig. 1. Energy saving potential in buildings

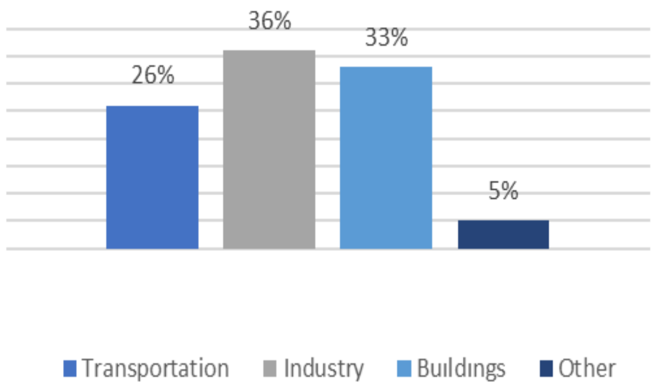

Fig. 2. Total Energy Consumption Rates in Türkiye, (URL-1)

To achieve energy conservation in buildings, it is essential to provide the desired indoor climate with minimal fuel consumption. At this point, thermal insulation is the most critical building requirement that minimizes fuel consumption while simultaneously ensuring indoor climatic comfort. Thermal insulation should be implemented to extend the lifespan of the building, to provide users with comfortable and healthy spaces, to save on heating and cooling costs during the building's use, and to achieve the same level of energy efficiency. Furthermore, thermal insulation enables occupants to experience desired thermal comfort in spaces while using less energy. In cases where the necessary thermal insulation is not applied or is applied incompletely, the comfort temperature of the indoor environment will never reach the desired level. As a result, inappropriate air currents arise within the interior, which reduces the comfort level of the space. By applying appropriate insulation, the surface temperature of the interior walls is increased, and optimal environmental conditions are established. Through the conscious decisions made by architects during the design phase, buildings' dependency on non-renewable energy sources can be reduced, and economic losses and potential negative environmental impacts can be significantly mitigated (Canan & Bakır, 2003). Considering the energy challenges faced by our country, insulating the building envelope has become inevitable for consuming less energy and providing thermal comfort within interior spaces. In recent years, building envelope insulation has emerged as a crucial component of the construction sector to minimize energy consumption (Aydın, 2011).

1.1 Energy-Efficient Retrofitting in Buildings

In recent years, increasing awareness of environmental sustainability along with increasing energy costs necessitates the development of more conscious, holistic, and systematic approaches to increase energy efficiency in buildings. In this context, improving the energy performance of buildings not only contributes to reducing energy costs but also has great importance in terms of reducing greenhouse gas emissions and minimizing environmental impacts.

Energy-efficient renovation in existing buildings is expressed in the literature with terms such as "energy efficient retrofitting," "reinforcement," and "efficiency renovation." In this process, a detailed analysis of the current condition of the building should be carried out through on-site inspection, observation, and calculations. Packages containing appropriate combinations of retrofit measures should be determined, tested, and their effectiveness should be compared to decide on the most suitable options (Atmaca & Yılmaz, (2019); Liu vd., (2020); Ma vd., (2012); Mıhlayanlar & Meral, (2023). Evaluations based on criteria such as sustainability, life cycle, and cost-effectiveness are of critical importance in this selection process. In addition, building typology, climate conditions, building envelope features, mechanical systems, lighting, and renewable energy integration should be addressed with an integrated approach to making buildings energy efficient.

Table 1. Energy-efficient retrofit recommendations for buildings (ÇŞB, 2015)

External Wall Insulation	• It is recommended to insulate the exterior with materials such as XPS / EPS, which have a low thermal conductivity coefficient.	
Solar Control	• Passive solar gain is provided on the south facade, while external sunshade systems are recommended on the west and east facades. • Reflective film or Low-E glass can be used on the windows.	
Green Facade and Roof (Advanced Application)	• Green facade elements or roof gardens are recommended to reduce energy loads.	

Table 1 continued

Solar Energy Systems (PV Panel Application)	• Part of the building's electricity needs can be met with solar panels placed on the roof. A sloping position on the south facade is recommended.	
Roof Insulation	• Thermal insulation should be made on the roof with materials such as rock wool or glass wool, at least 10 cm thick. • Reflective surface coatings should be added to the insulation on flat roofs.	
Ground Floor	• Thermal insulation should be applied to the floors that come into contact with the ground, and details that will reduce sound and heat transfer should be considered in the flooring between floors	
Improvement of Window and Door Systems	• Existing single-glazed joinery should be replaced with heat-insulated double or triple-glazed systems. • Thermally broken aluminum or wooden joinery is recommended instead of PVC. • Window seals should be renewed to ensure sealing.	
Air Tightness	• Air leakage should be prevented with sealing tapes and filling materials at the building shell joints, window, and door connections.	

2. Method

Efforts to ensure thermal comfort and enhance energy conservation in buildings primarily focus on heating energy consumption during cold periods. This study evaluates user behaviors related to energy consumption, the measures they adopt, and their satisfaction levels in achieving the desired thermal comfort in indoor environments during cold seasons. The significance of external insulation applications, implemented to improve energy efficiency in residential buildings, is emphasized as a key aspect of this research.

The study area consists of 12-story residential buildings (Fig. 3). When the two residential buildings were first built, the insulation applied was double-wall thermal insulation. In one of the two blocks, external insulation was applied 3 years ago to save energy, considering the increasing energy costs. The research methodology involved a systematic sampling approach and a survey administered to a selected group of residents. The sample group was determined based on specific criteria, focusing on the thermal comfort satisfaction of individuals living in the two buildings. While one building retained only cavity wall insulation, the other had an additional layer of external insulation applied to the same wall construction. The primary aim of the study was to assess the impact of these two different wall constructions on insulation performance and thermal comfort satisfaction.

Fig. 3. Insulated and uninsulated residential buildings

The survey, distributed to residents of the selected buildings, covered various topics, including perceptions of thermal comfort, satisfaction with energy consumption, and the impact of insulation applications. The survey forms were distributed to apartments on the ground and standard floors of the buildings. Particular attention was given to selecting participants who had lived in their apartments for at least two years. This criterion ensured that respondents were familiar with their living environment and had experienced at least two heating seasons, enabling them to provide more informed answers. In total, 36 participants were surveyed.

The survey aimed to analyze four main factors to evaluate the impact of external insulation on comfort:

- Economic satisfaction,
- Comfort satisfaction,
- Priorities in heating.

The survey responses collected from the building residents were subjected to statistical analyses, and the findings were evaluated and interpreted based on the results.

3. Findings

This study aimed to assess the impact of thermal comfort conditions on user satisfaction in both insulated and uninsulated buildings. To achieve this, survey results collected from users were analyzed and presented as percentages and graphical representations using the Excel program. The data obtained were interpreted to provide a detailed examination of user satisfaction and preferences.

According to the survey results, 66% of the participants identified as female, while 33% identified as male. In terms of age distribution, 8% of participants were in the 20-29 age range, 19% in the 30-39 age range, 36% in the 40-49 age range, 8% in the 50-59 age range, and 28% were aged 60 years or older. Regarding educational attainment, 5% of participants reported being literate, 11% were primary school graduates, 25% were high school graduates, and 58% were university graduates. In the evaluation of participants' employment status, it was found that 36% were unemployed, 50% were employed, and 13% were retired. Regarding the duration of residence, 19% had lived in their current residence for 1-4 years, 19% for 5-9 years, and 61% for 10-14 years.

In the assessment of sunlight exposure in the residences, 66% of participants reported that their homes receive sunlight, 5% stated that their homes do not, and 28% indicated that their homes partially receive sunlight. Overall, a large portion of the participants have residences that benefit from sunlight, but there may be a need to increase access to sunlight for more buildings and residential areas.

In the evaluation of heating system satisfaction, 73% of participants residing in insulated buildings reported being satisfied with the current heating system, 20% indicated being mostly satisfied, and 7% expressed moderate satisfaction. In the evaluation of users residing in uninsulated buildings, 38% reported being satisfied, 33% expressed being mostly satisfied, 10% indicated moderate satisfaction, 10% noted slight satisfaction, and 10% stated that they were not satisfied. (Fig. 4). The findings show that users living in insulated buildings generally have higher satisfaction levels in terms of thermal comfort.

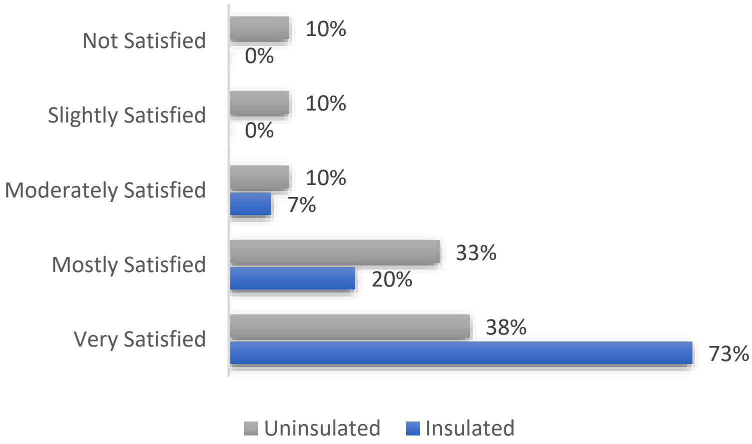

Fig. 4. Satisfaction level with the heating system

In the survey, participants were asked, "Do you use additional heating devices (electric heater, stove, air conditioner, electric radiator, etc.)?" Among users residing in insulated buildings, 20% responded affirmatively, while 80% indicated that they do not use additional heating devices. In contrast, all users living in uninsulated buildings (100%) reported that they do not use additional heating devices. This finding suggests that thermal comfort can generally be achieved in insulated buildings without the need for supplementary heating devices, whereas the need for such support appears to be absent in uninsulated buildings.

Participants who answered "yes" to the question "Do you use additional heating devices?" were further inquired about the circumstances under which these devices were used. Forty percent of the participants reported using additional heating devices when the weather was colder than seasonal norms, 20% used them during the evening hours, and 40% used them both when the weather was colder than seasonal norms and during the evening hours. These data suggest that the use of additional heating devices is influenced by both weather conditions and specific times of day.

Participants' behaviors regarding the use of combi boilers were assessed through a multiple-choice question. Among participants residing in insulated buildings, 40% indicated that they use the combi boiler at the same level during both day and night, while 30% stated that they use it at different levels during the day and night. In contrast, among participants living in uninsulated buildings, 31% reported using the combi boiler at the same level throughout the day and night, and 27% reported using it at different levels depending on the time of day (Fig. 5). These findings suggest that combi boiler usage habits may vary based on the insulation status of the building.

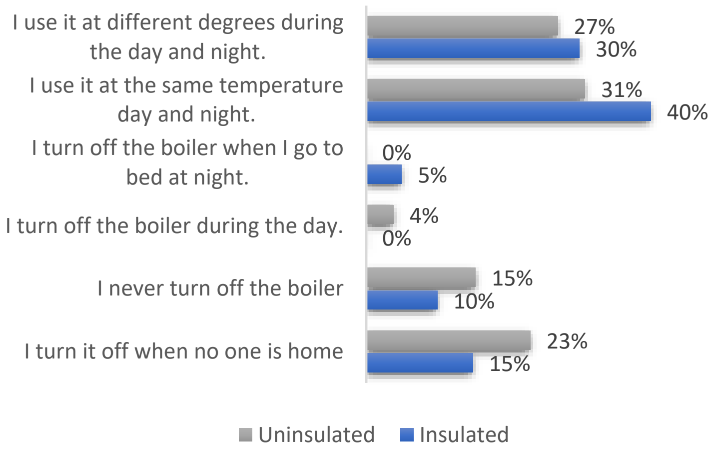

Fig. 5. Combi boiler usage behavior

Participants were asked whether they used room thermostats or thermostatic valves. Among those residing in insulated buildings, 80% reported not using such devices, while all participants (100%) living in uninsulated buildings stated that they did not use them. This indicates that the use of room thermostats or thermostatic valves is not common in either type of building.

Participants were also asked about the factors they prioritize when using combi boilers. Among users living in insulated buildings, 47% indicated that "heating satisfaction" was their primary concern, 27% prioritized "economy," and 27% prioritized "children." In contrast, 57% of users in uninsulated buildings identified "heating satisfaction" as their main priority, 29% prioritized "economy," and 14% prioritized "children." These findings suggest that the insulation status of the building can influence users' priorities when using combi boilers (Fig. 6).

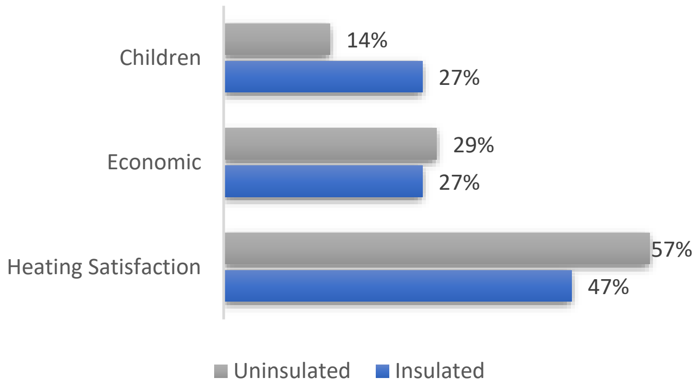

Fig. 6. Priority of combi boiler usage

The relationship between the amount of money spent on heating and participants' heating satisfaction was assessed. Among users living in insulated buildings, 33% responded, "I spend little, I get very warm," while 38% of users residing in uninsulated buildings responded, "I spend a lot, I get moderately warm" (Fig. 7). These findings indicate that insulation has a positive impact on the relationship between energy expenditure and heating satisfaction.

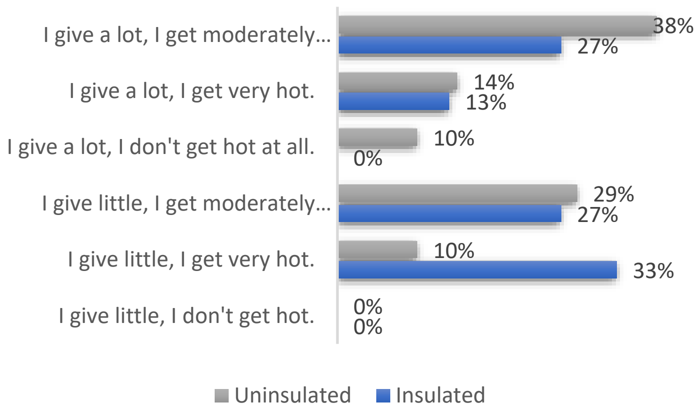

Fig.7. Economic contentment

Survey participants were asked whether the radiators in their homes were turned on. The majority of participants reported that the radiators were generally on; however, 22% indicated that the radiators in their bedrooms were turned off (Fig. 8). This suggests that some users have made adjustments that may limit thermal comfort in specific areas of their homes.

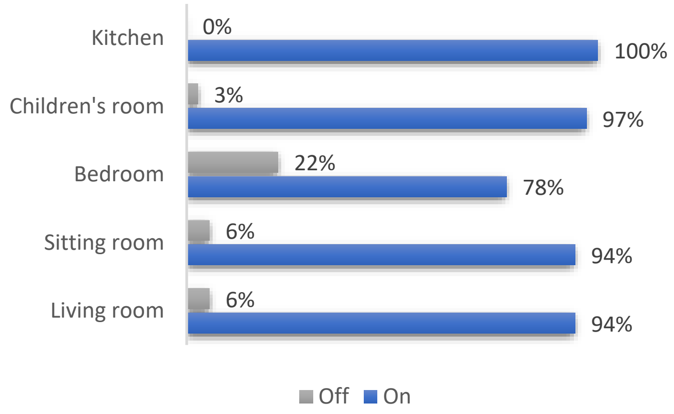

Fig. 8. Whether the front of the heaters is turned on or off

The survey inquired whether participants had made any modifications to the dimensions of their radiators, to which all participants in both building types responded "no." Additionally, the status of thermal insulation implementation was assessed. Among participants living in insulated buildings, 40% reported having installed thermal insulation, while 14% of those in uninsulated buildings indicated that they had done so. Furthermore, 19% of participants in uninsulated buildings expressed that they were considering implementing thermal insulation (Fig. 9). These findings suggest that individuals residing in uninsulated buildings exhibit lower levels of awareness or application of insulation measures.

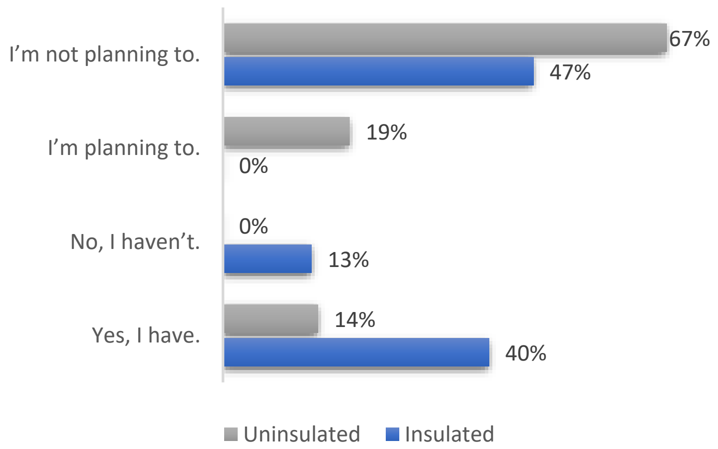

Fig. 9. Supplementary thermal insulation

Survey participants were asked about their current insulation practices. Among those residing in insulated buildings, 86% reported insulating the exterior, while 14% insulated the balcony door. In contrast, 33% of participants living in uninsulated buildings indicated that they had insulated the exterior walls, window sashes, and balcony doors.

Among users considering additional insulation in uninsulated buildings, 50% planned to insulate the exterior walls, 10% intended to insulate the windows, and 20% aimed to insulate the balcony door (Fig. 10). These findings suggest that there is both awareness and a growing trend of insulation application in uninsulated buildings.

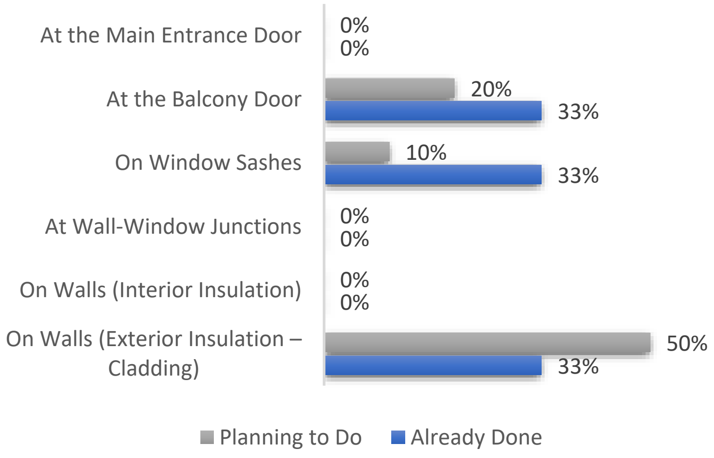

Fig. 10. Supplementary thermal insulation in uninsulated buildings

The satisfaction levels of survey participants regarding the heating conditions in their homes were assessed. Among those living in insulated buildings, 67% reported being satisfied with the heating conditions, 27% were mostly satisfied, and 7% were moderately satisfied. In contrast, among participants residing in uninsulated buildings, 33% reported being mostly satisfied, 29% were satisfied, 24% were moderately satisfied, 10% were not satisfied, and 5% were slightly satisfied (Fig. 11). These results indicate that users living in insulated buildings have a higher level of satisfaction with their heating conditions.

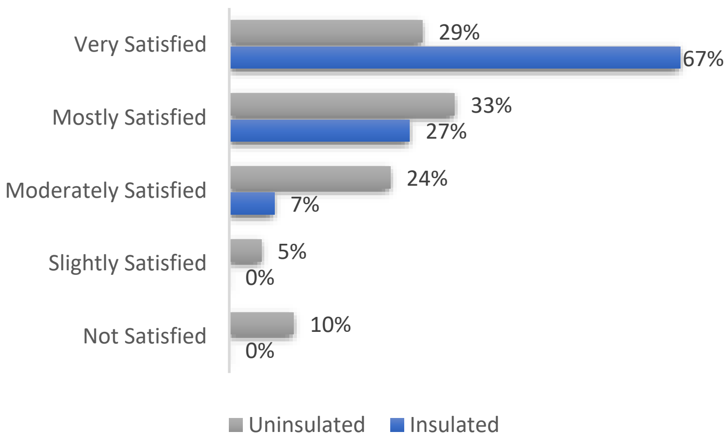

Fig. 11. Heating satisfaction

Finally, participants residing in externally insulated buildings were asked, "Did your natural gas bill decrease after the external insulation application?" To this, 27% of the participants responded "yes," 20% answered "no," and 53% indicated "partially." However, the majority of users reported that they were unable to observe a reduction in their bills due to the increase in energy prices.

4. Discussion

In this study, conducted in a multi-storey residential complex in Trabzon province with varying external wall constructions, the evaluation of users' thermal comfort and economic satisfaction levels led to the following findings:

• It was observed that a significant majority of users in the building with external insulation were satisfied with the heating system, in contrast to users in the other buildings.

• Although additional heating devices were used in the insulated building, participants reported using them when the weather was colder than seasonal norms, during seasonal transition periods, and in the evening hours. It is hypothesized that users residing in uninsulated buildings avoid using additional heating devices due to concerns about the potential increase in their natural gas bills.

• It was observed that the majority of users in both insulated and uninsulated buildings utilize the combi boiler at equal levels during the day and night. This behavior is believed to be motivated by users in insulated buildings who prefer consistent use, either to avoid the increased energy consumption associated with frequently turning the combi boiler on and off or to maintain a constant indoor temperature. In uninsulated buildings, this pattern is thought to stem from the desire to prevent discomfort caused by rapid drops in ambient temperature, in addition to the reasons mentioned above.

• When participants were asked about the use of room thermostats or thermostatic valves, it was found that 80% of users in insulated buildings and all users in uninsulated buildings did not use such equipment. This suggests that users may lack awareness of these control systems, which are designed to enhance energy efficiency, or do not possess sufficient knowledge regarding their functions and benefits.

• An analysis of the relationship between heating costs and heating satisfaction revealed that in uninsulated buildings, heating costs are high while the heating level remains moderate. In contrast, in the insulated building, heating costs are low and heating satisfaction is high. These findings indicate that heat losses are significant in uninsulated buildings, leading to economic strain and discomfort for users. At the same time, insulation directly contributes to improved energy efficiency and greater heating satisfaction.

• It was found that the vast majority of users living in uninsulated buildings do not implement any insulation measures, and most do not plan to consider such measures in the future. Among the few who contemplated additional insulation, the focus was primarily on insulating the external walls and balcony doors. This situation is believed to be related to users' reluctance to assume the additional financial burden associated with insulation.

• In the priority assessments, it was observed that most users in both building types prioritized thermal comfort satisfaction. Specifically, 67% of users in insulated buildings reported being satisfied with their heating, while 33% of users in uninsulated buildings expressed being mostly satisfied.

5. Conclusions

These results show that insulated buildings offer advantages in terms of thermal comfort and energy efficiency. Considering the positive effects of external thermal insulation on user satisfaction in the existing multi-story residential block, a series of suggestions have been developed for energy-efficient improvement studies. First of all, it has been observed that external thermal insulation application increases the thermal comfort and economic satisfaction of users. In this context, external facade insulation should be encouraged in uninsulated buildings, aiming to reduce energy losses and increase user satisfaction. It is important to raise users' awareness about the energy-saving and long-term economic advantages of insulation applications. For this purpose, awareness about insulation can be increased by organizing training programs and encouraging users to make such investments. In addition, introducing incentive mechanisms such as state support, tax reductions, or low-interest loans to reduce insulation costs will make insulation more accessible.

Investigation the effect of kinetic shading elements on reducing cooling loads

Esra Kaplan*[1], Figen Beyhan[1]

[1] Gazi University, Architecture Faculty,Department of Architecture, 06570, Ankara,Türkiye

Abstract. Today, the energy used for heating, cooling, and lighting in buildings constitutes the majority of a building's total energy consumption. Especially since the 2000s, architects have focused on the design of shading elements to provide the optimum values required for the thermal and visual comfort of indoor spaces. Kinetic shading elements have been considered the most effective solution within the scope of this study, as they can be designed according to the climatic conditions of the building's environment and can be quickly controlled through today's technological simulation tools to evaluate how they respond to variable parameters. Evaluating the purpose of using kinetic shading elements and their suitability according to variable parameters in the design process is highly important in terms of the performance of the design. Therefore, in this study, design parameters, dependent and independent variables affecting the design, design tools, methods used for optimization, and the results of numerous studies conducted in recent years for different purposes have been examined. As a result, based on the evaluations of the reviewed studies, this study has identified the design criteria and their importance that designers should pay attention to in the design process of kinetic shading elements. It is observed that the outcomes obtained from the examined studies achieve optimum values in line with their objectives through kinetic shading elements. In this way, the discipline of architecture contributes to the ongoing energy crisis today by reducing the energy consumption of buildings.

Keywords: Kinetic Shading Elements, Parametric Design, Cooling Loads of Buildings, Sustanibility.

1. Introduction

Today, factors such as population growth, industrialization, and the rapid advancement of technology lead to the depletion of renewable energy sources, global warming, and an energy crisis. The energy crisis and climate change, which have recently become major concerns for many countries, are foreseen to cause climatic and societal problems such as the depletion of natural resources, an increase in natural disasters, and water scarcity. Therefore, most countries, especially in Europe, have made decisions in various agreements and conferences to control and reduce energy consumption in order to overcome the energy crisis (Ortega Pastor et al., 2024). Some of these decisions include various restrictions related to the construction sector, which accounts for approximately 40% of global energy consumption, according to global data (International Energy Agency, 2023; European Commission, 2021). To reduce the energy used in buildings, it has been suggested—and incorporated into regulations—that climate-responsive, energy-efficient building designs and innovative design approaches be utilized.

According to the 2024 reports of the International Energy Agency (IEA), a significant portion of the energy consumed in buildings stems from heating and cooling systems. The energy spent to ensure indoor comfort in buildings constitutes approximately 50–70% of total consumption. Additionally, 30% of the total energy used in buildings contributes to global final energy consumption, which in turn accounts for 26% of energy-related global emissions. Cooling systems, in particular, are causing a significant increase in electricity demand due to rising income levels and climate change, especially in developing countries. The IEA projects that by 2030, energy consumption from air conditioning and appliances in buildings will increase by 35% (IEA, 2024; IIR, 2024). For this reason, architects, due to their responsibilities toward the physical environment, are expected to evaluate the energy use of the buildings they design and to adopt climate-focused design approaches. Within the scope of this study, in consideration of the projected increase in global temperatures in the future, the importance of shading elements that contribute to building energy efficiency and reduce the need for cooling energy will be explained and evaluated with references from the literature to support their development.

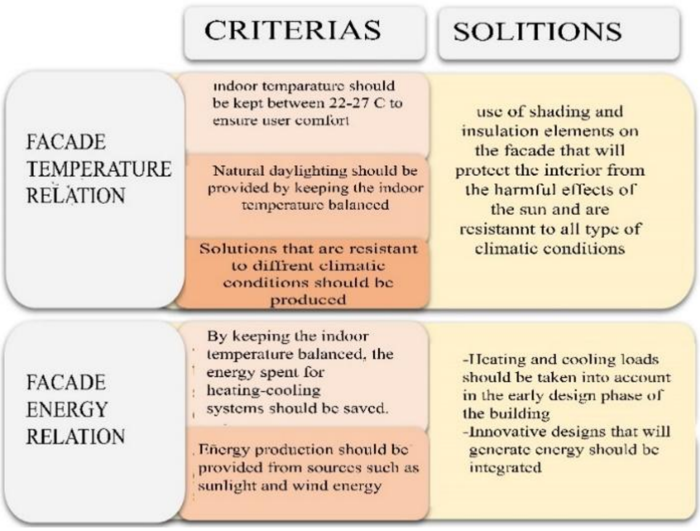

Fig. 1. The Relationship Between Façade, Temperature, and Energy, and Its Solutions
(Adapted from Esgil, M., and Yamaçlı, R., 2023)

The effective control of heating and cooling energy in buildings largely depends on the performance of the building envelope (walls, roof, windows, and floors), as it is in direct contact with the external environment. The purpose of the building envelope is to act as a barrier between the indoor and outdoor environments, ensuring indoor comfort (Gür, 2007). A well-designed building envelope significantly reduces energy demand by minimizing the effects of external conditions on the interior. Heat loss and gain, insulation quality, air tightness level, and the effectiveness of window and shading systems are directly affected by factors such as these, which in turn reduces the load on HVAC systems. Therefore, the energy-efficient design of the building facade is very important to achieve low carbon targets and sustainable building strategies (Ascione et al., 2016). In conclusion, to understand the importance of the building facade, which directly affects indoor comfort in a sustainable environment, it is necessary to understand how temperature and energy are related to the facade. Fig. 1 explains the relationships between the building envelope, energy, and temperature.

The building envelope emphasizes the importance of comprehensively considering thermal and visual comfort between energy and temperature.As a result, the design of the building envelope is extremely important in terms of contributing to the sustainability of both the user and the physical environment. Rising global temperatures due to climate change have increased the need for cooling energy use of buildings, especially in warmer climate zones. It shows, trategies to improve energy efficiency in the building sector need to be revisited and improved. Therefore, the effective use of shading materials within passive design strategies plays an important role in modern building design in terms of both energy savings and thermal comfort. Controlled management of solar radiation not only reduces dependence on mechanical systems, but also reduces carbon emissions and reduces the need for cooling energy of buildings (Olgyay, 2015).

According to these data, researchers have investigated the design of shading elements to reduce the cooling energy demand of buildings, especially those located in hot climate zones. This study reviews and evaluates recent research on methods tools for shading element design performance parameters.

2. Design Parameters of Shading Elements in Hot Climate Regions

Shading element design can take form according to design parameters such as the function of the building, its location, climatic conditions, design expectations such as lighting, heating and cooling for the needs. For this reason, in order to design a shading element, the purpose should be clearly defined before the study. The performance criteria of a shading element design are generally shown in Table.1. as building energy performance, thermal comfort, visual comfort, lifetime and cost, aesthetic requirements (Özyer, 2017, Koç, 2019, Erkan 2024). Since this study evaluates shading elements in terms of building energy use and indoor comfort, it will focus on building energy performance, thermal comfort and visual comfort parameters.

Table 1. Expected Performance Criteria of Shading Elements (Erkan, 2024)

Building Energy Performance	Cooling Energy Consumption Heating Energy Consumption Lighting Energy Consumption Ventilation Energy Domestic hot water systems
Thermal Comfort	Temperature Humidity Air Velocity
Visual Comfort	Glare Control Adequate Illumination Level Uniform Daylight Distribution
Service Life And Cost	Low Initial Construction Cost Long Service Life Material Recyclability High Durability (Minimum Maintenance And Repair Needs)
Aesthetic Requirements	Visual Connection With The Outdoor Environment Privacy Contribution To The Building Façade

According to the factors shown in the table, cooling, heating, lighting, energy consumption within the building energy performance parameter, temperature, humidity, glare control, adequate illumination level within the thermal comfort parameter, homogeneous daylight distribution within the visual comfort parameter, interior lighting according to the data obtained from the literature, energies criteria have played an important role in the selection of studies to be evaluated within the scope of this study as they directly affect user comfort and building energy consumption.

When determining appropriate parameters for shading element design, sometimes favorable conditions can turn unfavorable.For example, shading elements block solar radiation from entering indoor spaces, especially during the summer months.This results in less energy consumption for cooling.However, they may consume more heating energy than heating energy because they can block useful solar radiation in the winter months.Similarly, shading elements can consume more electricity by blocking sunlight.This can lead to more energy waste in efforts to reduce the building's energy consumption.As a result, when designing shading, it is important to consider the connection between lighting, heating, and cooling (Özyer, 2017).

To design shading elements, it is essential to first know the desired comfort level in indoor spaces.The presence of daylight should be well defined for indoor comfort.Therefore, it is necessary to examine the Daylight Assessment Criteria to evaluate the performance of the shading element during the preliminary design phase. Daylight availability (daylight availability-DA) is a fundamental metric that measures the adequacy of natural lighting in the interior spaces of a building.There are two main classes of this evaluation: static and dynamic.Using local climate data, dynamic or climate-based metrics evaluate annual performance.In this case, Daylight Autonomy (DA) refers to the percentage of time a space is illuminated solely by daylight. Daylight Illuminance (UDI) categorizes lighting levels in the range of 100 to 2000 lux as useful.

Additionally, a metric known as Spatial Daylight Autonomy (sDA) measures whether a specific area is adequately illuminated by daylight.This measurement indicates whether a certain percentage of the floor area exceeds a specific lighting level (e.g., 300 lux) during the analysis period (Illuminating Engineering Society, 2012).Direct sunlight exposure (ASE) is used to evaluate visual comfort (Yıldırım et al., 2024; Meek & Van Den Wymelenberg 2014).

Other metrics used for daylight visual comfort were created to measure the glare problem. Daylight Glare Probability (DGP) is a metric that estimates the probability of a user being affected by glare and is based on subjective experience (Wienold & Christoffersen, 2006). This metric is used to assess visual comfort and takes into account the level of brightness, the position of light sources and visual contrast. Glare is considered to be very uncomfortable if the DGP value is 45% and above, uncomfortable in the range of 40-45%, perceptible in the range of 35-40%, and imperceptible below 35% (Wienold, 2007)(Fig.2). These criteria play a significant role particularly within the scope of sustainable building certification systems (such as LEED v4, BREEAM, CASBEE, etc.) and lighting comfort, in ensuring visual comfort in indoor spaces and optimizing energy performance.

Glare	Daylight
Daylight Glare Index (DGI)	Daylight Autonomy (DA)
Visual Comfort Probability (VCP)	Continuous Daylight Autonomy
British Glare index (BGI or BRS)	Useful Daylight Illuminance (UDI)
Daylight Glare Probability (DGP)	Spatial Daylight Autonomy (SDA)
Simplified discomfort glare probability (DGPs)	Annual Sunlight Exposure (ASE)
CIE Glare Index (CGI)	Daylight Factor (DF)
Unified Glare Rating (UGR)	Mean Illuminance (MI)
j- Index	Vertical eye illuminance (E_v)

Fig. 2. Parameters of Evulate Glare and Dayligthing (Valtibar etal., 2018)

A sustainability-focused design is essential to achieve an ideal balance between natural lighting and thermal comfort in indoor environments. After determining the dynamic daylight evaluation metrics aligned with the intended purpose, it is necessary to decide on the method by which these metrics will be measured. From past to present, the direction and intensity of solar radiation falling on the shading element, and the location of the design on the façade, involve many variables. To achieve this goal, various daylight measurement methods have been used over time, including solar path analysis, light and thermal impact assessments, computer-aided simulations, physical modeling, heliodon testing, and on-site measurements (Yıldırım et al., 2024).

Table 2. Methods for Measuring Natural Daylight Usable in the Design of Shading Elements (Yıldırım et al., 2024)

In the Design Process		In the Usage Process
Pre-Design Phase	Detailed Design Phase	On-Site Physical Measurement High Dynamic Range Imaging
- Sun Path Analysis - Mass Modeling - Shading Calculation	- Computer Simulation - Heliodon Analysis with Physical Scale Model	

According to the information obtained from the literature, solar path analysis and computer simulations are the most commonly used techniques in this study. Solar path analysis allows designers to measure the angle and intensity of sunlight reaching a building at a specific location throughout the year, enabling them to monitor how solar radiation affects the design process. Polar or cylindrical projections show the sun's position in the sky. These diagrams show the trajectory of the sun in two dimensions, both over the course of a day and a year. This helps architects study the effects of the sun (Bodart & Cauwerts, 2017) (Fig. 3).

Computer simulations are an effective tool for analyzing a space's daylight performance under different sky conditions throughout the year. The geographical location of the space, CIE sky models, and specific date-time data are used to conduct these simulations. After determining the illumination levels on the working plane, static metrics such as Daylight Factor (DF) and dynamic metrics such as Useful Daylight Illuminance (UDI), Daylight Glare Probability (DGP), and Daylight Autonomy (DA) are evaluated.Moreover, it has been observed that climate-based dynamic measurement methods are more widely used in recent research (Oral, 2023).

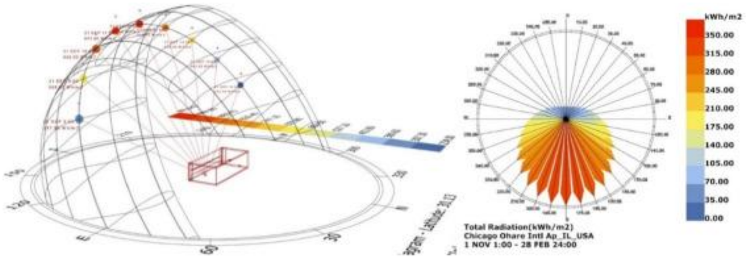

Fig.3 An Example of Solar Path Analysis (Eltaweel, A., & Yuehong, S. U., 2017)

In order for the shading element form to be created, after determining the performance parameter, daylight evaluation criteria, and daylight performance measurement method, it is necessary to go through the decision-making stage to determine the form, orientation, and movement of the shading element. The type, size, and inclination of shading elements play an important role in controlling solar radiation; fixed and movable systems offer different advantages (Tzempelikos, A., & Athienitis, A. K., 2007). Shading elements are divided into two categories according to their form: fixed and movable. Due to the variability of the parameters effective in the design of shading elements throughout the year, month, and day, maximum benefit can be achieved by designing the elements to be movable according to the purpose and desired evaluation metrics. Movable shading elements offer the possibility of optimizing both cooling and heating energy consumption by opening and closing according to the changing needs throughout the year. In addition, while fixed horizontal shading elements block solar radiation coming at steep angles more effectively than vertical shading elements, lattice-type shading systems, which are a combination of both types, provide higher efficiency in reducing cooling energy consumption by blocking low-angle radiation at different times of the day (Koç, 2019). In Table 3, shading elements are classified according to their forms.

Table 3. Classification of Shading Elements by Form (Özyer, 2017)

Classification by Form			
Fixed Shading Elements		**Movable Shading Elements**	
Horizontal Shading Elements	Vertical Shading Elements	Horizontal Shading Elements	Vertical Shading Elements
Hybrid (Louver-Box) Shading Elements	Parallel Plate Shading Elements	Awning Shading Elements	Venetian Blind Shading Elements
		Kinetic Shading Elements	

Among movable shading elements, kinetic shading elements are designs that have the ability to change certain functions, properties, or behaviors in response to changing performance requirements and variable boundary conditions over time, and this flexibility is used with the aim of continuously improving overall building performance. Kinetic shading elements include building components that differ in terms of materials, components, and systems. They have the potential to reduce energy consumption while enhancing indoor comfort (Attia et al., 2020). Therefore, when designed in conjunction with today's design technologies, they are more efficient than other fixed and movable shading elements, as they provide ease of design and enable monitoring of the desired comfort level.

3. Kinetic Shading Element Design

Kinetic shading elements are systems that can automatically change their shapes, orientations, openings, and positions in facade design in response to environmental variables such as temperature, humidity, and wind. The ideal lighting level and thermal comfort for indoor spaces are achieved by these systems by controlling thermal gains and making the best use of daylight. Kinetic facades enhance indoor comfort and increase the energy efficiency of building designs because they operate in an environmentally conscious manner (Güncü, A. and Kurunç, A., 2013).Today, in recent studies conducted with technological developments, parametric design is used when designing kinetic shading elements. Parametric design allows for easy modification of a large number of parameters in a digital environment and simultaneous testing of elements with simulation tools (Razzaghmanesh, 2015). Therefore, it is important to use parametric design tools in the design of kinetic shading elements to respond to today's variable weather conditions.

Parametric design allows different ideas to be developed quickly and effectively during the design and production stages. This method gives the designer the opportunity to evaluate different scenarios and manage decision-making processes flexibly. Parametric modeling enables the design to be continuously reviewed, evaluated and updated. This flexibility makes it easier to find various design options (Engin, 2022).

This research categorizes two main parametric design processes known as genetic algorithm-based systems and rule-based design systems. Rule-based systems, also called shape grammar-based design systems, guide the design process through predefined geometric and logical rules. Creative solutions such as origami patterns or traditional or cultural motifs can be used in trial-and-error based evaluation systems (Belek and Yamaç 2023). Genetic algorithms can develop and optimize various design options using evolutionary approaches inspired by nature. Efforts to find the best design are related to gene transfer, mutation rules, and reproduction.Variation generation has the ability to solve complex surfaces and geometric challenges (Radwan, Osama, 2016). By using one of these two methods, designers can manage the process dynamically and flexibly and define a specific target parameter (Alafandy & Kazzaz, 2018).

Compared to traditional architectural modeling, parametric design provides a faster and more efficient process. Changes made in traditional design often take a long time and require remodelling, but in parametric design, the design can be easily modified. This method defines the relationships between elements, and these relationships shape the design. Parametric tools provide flexible and adaptive solutions, especially for complex facade issues in architecture. Hybrid platforms that combine features such as modeling, simulation, and evaluation are typically these types of tools. It is very important to choose the right method or tools to achieve the correct design outcome. Nowadays, parametric design tools are used to easily design the variables of kinetic shading elements (Panya et al., 2020)(Fig.4).

	Geometry and Data Modeling	Energy and Thermal Simulation, Climate Analysis	Daylighting Simulation	Computational Fluid Dynamic Simulation
Main Scope	Create geometrical and data model that support simulation	Predict the impact of architectural design in energy consumption and emissions	Anticipate natural light quality and visual comfort as a function of a space's geometry and material surfaces	Model airflows inside and outside the buildings, predict comfort

Design Development	Revit, Archicad	OpenStudio, EnergyPlus, DesignBuilder, IES-VE, eQuest, TRNSYS	3Ds Max, Radiance, Daysim, DIVA	Fluent, Virtual Wind
Parametric Design	Grasshopper, Dynamo	JePlus, JePlus EA	Grasshopper and various plug-ins	

Fig.4 Parametric Design Tools and Their Functions in Architecture (Panya et al., 2020)

For example, the Grasshopper plugin designed for Rhinoceros software, especially when used with the Ladybug tool, is one of the most frequently used tools in the field of parametric design. Grasshopper is an algorithmic modeling platform that structures the design process through a network and graphically represents the relationships between dependent parameters. This structure allows designers to monitor the parametric relationship network they create and take the steps they desire. Simulation-based tools accelerate the design process and enable the evaluation of system performance and the comparative analysis of various designs. Therefore, solutions with the best performance criteria can be easily obtained. However, there is no single tool that can be applied to every design problem. As a result, the context of the design, the expected performance output, and user requirements should determine the appropriate software and simulation tools. In this context, the tools used in the parametric design process are shown in Fig.5 the example flowchart below.

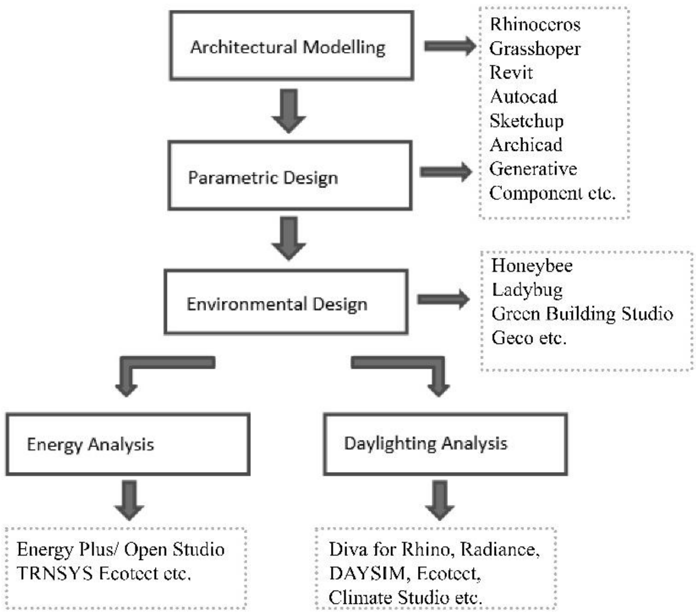

Fig.5 Systematic Diagram of Tools Used in the Parametric Design Process (Adapted from Seyrek et al., 2021)

Studies in the literature reveal that the design of kinetic shading elements plays a critical role in solutions aimed at reducing the cooling energy demand of building envelopes, especially in hot climate regions. In this context, daylight metrics, temporal variables, and user comfort parameters should be evaluated together during the design process. Due to the multivariable nature of the issue, it has been demonstrated that the use of parametric modeling and simulation-based methods is necessary in the design of kinetic shading elements.

The optimization process for determining the performance of kinetic facade systems includes a performance-oriented phase that evaluates the parametric model-based design under climatic conditions. The design models developed in this process are analyzed using climate-based simulation tools such as Ladybug, HoneyBee, EnergyPlus, Radiance, Daysim, and ClimateStudio (Panya et al., 2020; Seyrek et al., 2021). Based on the obtained data, variations are generated through different configurations of the kinetic facade system, and these variations are comparatively evaluated within the scope of the performance-based optimization process. In this way, through the holistic interpretation of simulation and analysis outputs, the extent to which the design criteria contribute to the targeted functionality and energy efficiency level is determined. Therefore, parametric design methods and tools are the most beneficial design approach in the design of shading elements intended to reduce cooling energy demand. Within the scope of this study, recent kinetic shading element studies have been evaluated in terms of expected performance criteria, forms, dependent and independent variables affecting the design, and the optimization references targeted for the efficiency of these variables.

4. Material and Metot

In this study, kinetic shading element studies developed in recent years with different performance expectations were compiled using data obtained from the literature. These studies were examined in terms of their design purposes, parametric design tools and methods, dependent and independent variables, optimization methods, and references. The responses of the variables dependent on the design objectives to the independent variables affecting the form were observed, and whether a relationship existed between them was evaluated. For example, in the study by Kim, D. H., et al., the impact of movable shading systems to optimize daylight was investigated. Shading elements were evaluated in terms of daylight performance metrics such as SDA, ASE, UDI, and LUX, considering independent variables like geometric types, dimensions, rotation angles, opening and closing rates, and presence or absence. The data-based method proposed using a Genetic Optimization algorithm produced results that met LEED v4.1 standards, indicating the successful development of the kinetic shading element. The values analyzed in the table were evaluated specifically for each study, and their explanations are noted below the Table.4.

T: Time, BL: Building Location, SOD: Shading Element Opening/Closing State, SEM: Shading Element Movement (R: Rotation, SL: Sliding, FL: Folding), STT: Shading Element Material Transmittance, SSE: Size Of Shading Element, SPP: Shading Element Material Properties (C: Color, N: Number), SD: Shading Element Depth, SS: Shading Element Size, SE: Shading Element Existence, SG: Shading Element Geometry, FL: Façade Location, DSF: Distance from Structure Façade, UL: User Location, VC: Visual Comfort, TC: Thermal Comfort, ES: Energy Saving, EG: Energy Gain

According to the table, it is observed that the kinetic shading element studies reviewed from the literature have utilized parametric design tools for real-time simulations based on the expected performance, and have successfully provided benefits in accordance with relevant performance optimization references. Moreover, in recent shading element design studies, it is seen that studies with different performance goals employed different independent variables, while those with common objectives tended to use shared independent variables in their design processes. This suggests that a useful relationship can be established between dependent and independent variables.From the literature, if more studies are added to the table and common goals are found to be linked to similar independent variables, it may be possible to develop multiple methods for designing kinetic shading elements based on data gathered from the literature. However, it is considered that more studies need to be evaluated in order to establish these methods.

5.Conclusion

Kinetic shading elements have the ability to instantly respond to climatic conditions and user demands. Within the scope of this study, in order to reduce the cooling energy demand of buildings in hot climates (which is considered the main problem) and to bring indoor comfort to the optimum level in line with the desired goals, kinetic shading elements must be designed by considering multiple parameters. In this study, the reviewed recent examples are responsive kinetic façade designs that provide dynamic responses to environmental effects, adapt to varying environmental conditions, and thus increase indoor comfort while reducing energy consumption. These design approaches play a significant role in enhancing energy efficiency and advancing sustainable architecture. Based on the examples examined and the data obtained from the literature within this study, the necessary parameters for designing a shading element have been compiled and presented in the table below.

Table 5. Required Parameters for Kinetic Shading Element Design

Factors Directly Influencing The **Design** Of The **Shading Element**		**Environmental Properties Independent** Of The **Shading Element**	
Form - Vertical Louver -Horizontal Louver - Hybrid Design -Space Frame, Etc.	Design Performance Goal - Visual Comfort - Thermal Comfort - Energy Saving, Etc.	Building Location And Climate Characteristics	- Building Type (Office, School, Hospital, Etc.) - Number Of Occupants
Parametric Design Method And Tool - Shape Grammar-Based Design - Genetic Algorithm-Based Design	Daylight Performance Criteria And Method - ASE - Sda - DGP - EUI, Etc.	Position Of The Shading Element On The Building Façade (North, South etc.)	- User's Position İnside The Space - HVAC System - Window-To-Wall Ratio (WWR)

Table 5. continued

Movement Of The Shading Element - Rotation - Folding - Sliding, Etc.	**Material Properties** **- Material (Wood, Metal, Plastic, Etc.)** **- Transparency Ratio** **- Color** **- Reflectance Ratio** **- Quantity**	**- Material Properties İn The Environment (İnterior-Exterior Wall, Floor, Ceiling)** **- Thickness** **- Conductivity** **- Thermal Absorptivity** **- U, R Values** **- Reflectance Value, Etc.**
Optimization Method And Tool - Pareto Front - NSGA II, Etc. Simulation Tools (Galapagos, Honeybee, Etc.)	- Distance From The Building Façade - Shading Element Depth - Scale (Size) Of The Element - If Louvered, Open-Close Ratios - Inclination Angles Of The Shading Element, Etc.	- Outdoor Relative Humidity - If Present, Artificial Lighting in The İnterior - Solar Radiation

The Table 5 above serves as a roadmap for researchers who wants to design kinetic shading elements and need the necessary parameters. Since the factors listed in the table are based on research and data from the literature, studies that were not considered and the factors of specific designs have not been included; therefore, additions can be made to the factors in the table. However, in general, these are the relevant parameters. As technological developments advance and different design methods emerge, the table will need to be updated. The study shows that the design of kinetic shading elements makes a significant contribution in the context of the building sector, which is currently responsible for a share of energy consumption, and is expected to become even more important in the coming years to help mitigate global climate crises. The study has revealed the importance of well-designed kinetic shading elements in reducing the energy buildings spend on cooling loads.

Investigation of the steel material used in the structural system of alvar aalto's buildings: the case of villa mairea

Şevin Yavuz*[1], Yeşim Kamile Aktuğlu[1]

[1]*Dokuz Eylül University, Department of Architecture, 35000 İzmir, Türkiye*

Abstract. Steel is an important building material in the field of architecture and has many advantages. It is durable, lightweight, fast to produce, reusable and long-lasting. Most importantly, it is cheap and can be used in large shapes. These extreme features led Alvar Aalto to turn to steel. Alvar Aalto is one of the most important modernist architects of the 20th century. He made great contributions to Finnish architecture. It generally deals with the use of natural materials, organic functions, and human-centered designs. However, as Aalto's career progressed and he explored new materials and technologies, he began to incorporate steel into his designs. It has built composite buildings with steel and other building materials in its structures. Alvar Aalto's use of steel combined with other materials allowed him to create balanced and aesthetic projects. He was able to use steel successfully in every aspect of his designs, which he generally used to ensure the continuity of glass and to design wide openings. From the smallest to the largest structure, the use of steel is an ongoing practice. The steel he uses in every field can be seen sometimes in his accessories and sometimes in his furniture. Although the steels used in their structures are not clearly visible, it can be understood when looking at the drawing techniques in the project. In the case of Villa Mairea, he used steel without hiding it and integrated it with other building materials. Among the features of steel material in Villa Mairea, especially its structural feature has been utilized.

Keywords: Alvar Aalto; Steel; Structural System; Building Material; Villa Mairea

1. Introduction

In the first half of the 20th century, steel emerged as a transformative material in architectural structural systems. Modernist pioneers such as Le Corbusier and Mies van der Rohe employed steel not only as a technical innovation but also as a medium for aesthetic expression. However, Alvar Aalto developed a distinctive approach that sought to integrate modern technology with the humanistic and cultural dimensions of architectural design (Frampton, 1995; Pelkonen, 2009).

Villa Mairea serves as a compelling example of Aalto's unique interpretation of steel usage. The building is noteworthy not only for its incorporation of modern materials, but also for the way these materials are transformed to evoke a humane and nature-oriented architectural atmosphere (Schildt, 1994; Siren, 2013).

2. Villa Mairea (1938-1941)

Villa Mairea was commissioned by Harry and Maire Gullichsen, leading figures of the A. Ahlström company, and constructed within the Noormarkku ironworks estate (Alvar Aalto Foundation, n.d.).

The exterior elevations feature a combination of materials: segments of untreated Finnish pine and timber, alongside fine stone slabs and roughcast plaster. At the main entrance, a row of columns composed of unstripped saplings supports a free-form canopy. From the entrance hall, a short flight of steps leads to the living room, where an irregularly shaped staircase encircled by asymmetrical wooden posts ascends to the upper floor (Fig. 1). A portion of the outer wall is designed with a sliding system that allows for the complete opening of the house to the garden.

The dining room window faces an internal courtyard, while a rear door opens to a covered passage leading to the sauna. The kitchens are adjacent to the dining room, and behind them are rooms designated for the household staff. A secondary staircase connects the kitchen to the children's playroom, the breakfast room, and the guest wing. The upper floor also includes the family bedrooms and Maire Gullichsen's painting studio (Alvar Aalto Foundation, n.d.).

Fig. 1. A photograph illustrating the interior of Villa Mairea, featuring the steel columns and the wooden staircase detail.

3. The Role of Steel in the Structural System of Villa Mairea

The structural system of Villa Mairea is hybrid in nature, incorporating reinforced concrete elements, steel columns, and wooden beams. This combination ensures both structural stability and spatial flexibility (Docomomo Suomi/Finland, n.d.).

Although wood dominates the material palette, steel columns are visibly present and architecturally significant. As illustrated in the floor plan (Fig. 1), the steel elements are distributed throughout the structure, exemplifying a dispersed load-bearing system (AACDAS, 2015).

In the main hall and entrance area, the circular-section steel columns enable broader spans and a more fluid spatial configuration (Poole, 2017).

Rather than being arranged in a strict grid, these columns are positioned in a seemingly random rhythm reminiscent of trees in a natural forest. This strategy transforms the structural system into an integral component not only of the building's physical framework, but also of its spatial and emotional experience (Siren, 2013).

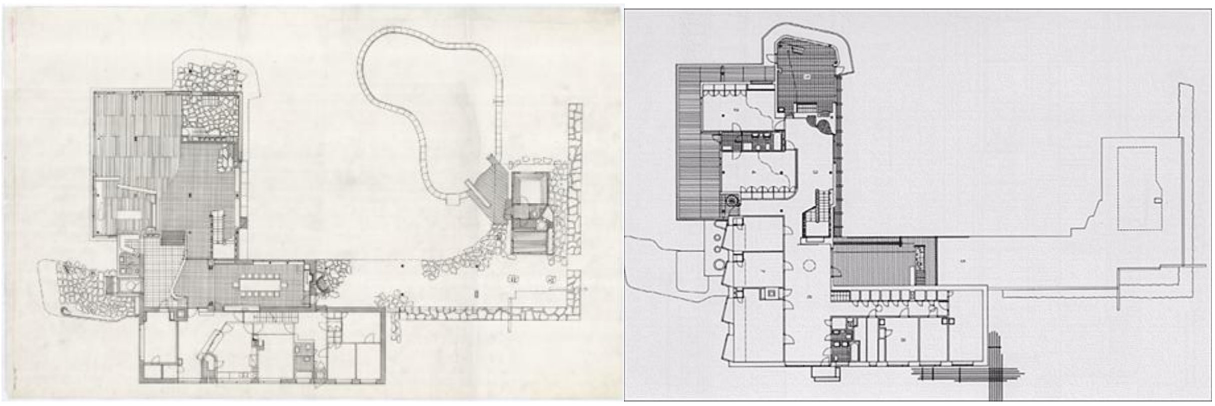

Fig. 2. A photograph showing the ground floor and first floor plans of Villa Mairea.

The steel columns have been treated with various cladding techniques; some are coated with glossy black paint, while others are wrapped in rattan or birch bark strips (Fig. 3) (Schildt, 1998). Through these interventions, the columns acquire a visual and tactile resemblance to tree trunks in nature, effectively softening the industrial character of the steel.

Fig. 3. A photograph depicting the columns in Villa Mairea that are painted in glossy black and wrapped with rattan or birch bark strips.

Steel also plays a crucial role in the main staircase system. The steel beams that serve as the primary load-bearing elements are concealed within wooden cladding, thereby ensuring structural integrity while maintaining a sense of visual lightness and natural material expression (Boelkins, 2017). The structural framework of the staircase is resolved through steel without being exposed, allowing the supporting elements to fulfill their function without imposing a visible presence on the user (Fig. 4).

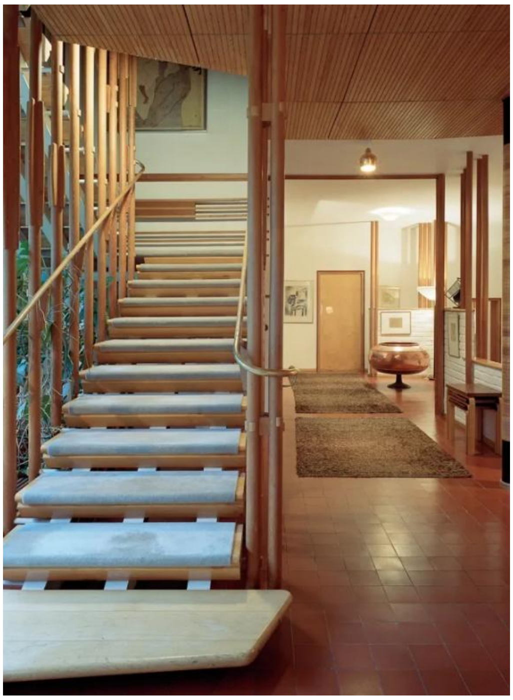

Fig. 4. A photograph of the main staircase of Villa Mairea.

The canopy structure located at the entrance is supported by slender, white-painted steel columns (Fig. 5). These columns are designed with minimal cross-sections, relying on the inherent strength of steel for load transfer. The curvilinear reinforced concrete canopy they support serves not only as a protective element but also as a symbolic gesture of welcome at the threshold (Angela Adams, n.d.). The entrance door itself is clad with vertical wooden slats and integrated into a steel frame for structural support and visual coherence.

Fig. 5. A photograph of the entrance canopy of Villa Mairea, supported by white-painted steel columns.

Steel also plays a significant structural role in the upper-floor terrace located at the rear façade of the building. A slender steel beam supports the roof covering, transferring its load to a concrete beam, which in turn conveys the load to the ground via a steel column. This system demonstrates the functional contribution of steel in terms of spanning capacity as well as maintaining spatial continuity within the architectural composition (AACDAS, 2015).

In the examples discussed above, steel performs critical tasks from a building physics perspective while simultaneously enhancing the aesthetic and experiential qualities of the structure through its integration with other materials.

Fig. 6. A photograph of the steel column located on the terrace of Villa Mairea.

4. The Use of Steel, Wood, and Concrete

In Villa Mairea, Aalto never employed steel as an isolated material. Rather, it is consistently placed in dialogue with local and natural materials such as wood, stone, and brick (Pelkonen, 2009).

For instance, while the canopy at the entrance is supported by white-painted steel columns, the adjacent sauna area draws on traditional Finnish architecture by utilizing roughly hewn timber logs as load-bearing elements (Angela Adams, n.d.). This juxtaposition highlights the building's technical and cultural diversity.

A similar approach is observed on the upper terrace. In the roof system, wooden cladding is supported by steel beams, which in turn are anchored to reinforced concrete load-bearing elements. This configuration ensures a balanced distribution of structural loads and contributes to architectural coherence (AACDAS, 2015).

In Villa Mairea, steel is not merely employed for structural necessity; it is seamlessly integrated with other surfaces and formal elements to enrich the spatial atmosphere (Poole, 2017; Siren, 2013). This demonstrates that steel is regarded not only as a technical component but also as an experiential element within the design process.

5. Comparative Analysis: Villa Mairea and Contemporary Modernist Buildings

The significance of steel in Villa Mairea becomes clearer when compared to contemporary modernist works. In Le Corbusier's Villa Savoye (1931) or Mies van der Rohe's Barcelona Pavilion (1929), steel and reinforced concrete are openly expressed, with the structural system forming a direct extension of architectural aesthetics

(Frampton, 1995). In these examples, steel columns are typically left exposed, allowing the structural reality of the building to align with its architectural language.

In contrast, Alvar Aalto's approach in Villa Mairea reflects a more holistic and intuitive design philosophy. Steel is treated not merely as a technical material but as an element intertwined with nature, human experience, and local culture (Pelkonen, 2009). The steel columns in Villa Mairea are designed not only as load-bearing components but also as elements that evoke the impression of a forested landscape within the interior space (Siren, 2013).

Unlike Mies van der Rohe's minimalism, Aalto enriches the steel elements through material layering. For example, in Villa Mairea, steel columns are wrapped with rattan or birch strips, enabling them to blend with the natural environment. Thus, they become not only structural supports but also aesthetic components of the spatial narrative (Schildt, 1998).

In Aalto's design, steel is not arranged in a rigid grid system but rather dispersed irregularly, mimicking the random distribution of trees in nature. This approach introduces a spatial rhythm that is both visual and emotional (Poole, 2017). In doing so, it presents an organic and human-centered design language that contrasts sharply with the systematic and repetitive logic of high modernism.

Ultimately, Aalto's use of steel in Villa Mairea deviates from the strictly technical approaches of his contemporaries. Here, steel is not just a structural material but a creative and atmospheric element within the architectural composition.

6. The Use of Steel in Aalto's Later Works

Villa Mairea can be regarded as one of the initial milestones in Alvar Aalto's architectural engagement with steel. Following this project, Aalto continued to employ steel in both structural and architectural roles across various scales and building typologies. This continuity indicates that steel became a permanent part of his design vocabulary—not merely as a material, but as a conceptual tool.

The Finnish Pavilion for the 1939 New York World's Fair stands as another notable example of Aalto's approach to steel. Constructed using a lightweight steel frame, the pavilion not only achieved structural efficiency but also allowed for large interior spans suited to exhibition functions (Weston, 1995). The transference of Villa Mairea's design logic to this context further reinforces steel's role in Aalto's evolving architectural language.

Similarly, the Seinäjoki Civic Centre (1958–1968) exemplifies the continuity of this approach. In this complex, steel and reinforced concrete are used in tandem—particularly in large-span public spaces where steel becomes an integral component of the structural system (Weston, 1995). This reveals how Aalto's method of material hybridity extended into larger-scale public architecture.

Aalto's evolving use of steel provides a compelling example of how the relationship between material and space can be reimagined in architecture. The principles developed in Villa Mairea were carried forward and further elaborated in his later works, both technically and aesthetically.

7. Conclusions

Alvar Aalto's treatment of steel in Villa Mairea stands as a significant example in modern architectural history, not only from a technical standpoint but also as a design philosophy. He used steel not merely as a load-bearing component but as an integral part of the architectural narrative. Combined with reinforced concrete and timber, steel contributed to a hybrid structural system that enabled wide spans and supported spatial continuity.

The steel columns in Villa Mairea functioned not only structurally but also compositionally—evoking a forest-like ambiance in the interior. Through surface treatments such as paint, rattan wrapping, and birch cladding, the industrial identity of steel was softened to create a more tactile and sensory aesthetic. These choices reflect Aalto's commitment to integrating technical materials into a human-centered architectural language.

This distinctive approach continued in his subsequent works. In both the Finnish Pavilion (1939) and the Seinäjoki Civic Centre (1958–1968), steel was employed to achieve structural spans, spatial flexibility, and a sense of architectural lightness. Aalto's consistent use of steel across different scales illustrates how it can function not only within an engineering context but also as a cultural and aesthetic medium.

In conclusion, Villa Mairea exemplifies a holistic architectural approach in which steel is considered not just for its structural capacity but for its symbolic, spatial, and experiential dimensions. Through this work, Aalto developed a unique interpretation of steel that foregrounds the material's multifaceted role in architectural design—offering a lasting source of inspiration for contemporary practice.

Abstract. Most of the thermal discomfort in the Mediterranean urban areas arises from the Urban Heat Island (UHI) effect. As the sun shines almost vertically down on top of the cities, geometrically speaking, the roofs and open terraces are the areas that are exposed to direct solar radiation during the day. If minimization of UHI is the concern, the solution is mostly in the roof tiles and floor tiles covering terraces. If some of this solar radiation can be reflected back to the sky, then UHI can be mitigated. In this study, preliminary results of a project aimed at developing new engobe and glazes on roof and floor tiles are presented. A traditional and commercial floor tile body is chosen to act as the substrate on which the glaze layer is to be coated. Glazes are made by using commercial frits modified in house by adding various oxides to render the coated tiles more reflective especially in the Near Infrared (NIR) region of the solar radiation spectrum. Different pigments are tested to observe their effects on NIR reflection ability. Preliminary results have shown that at least 60% reduction in NIR reflection has been achieved. That means more than half of the solar energy is reflected which means significant reductions in accumulation of heat on roofs and hence in the local area.

Keywords: Cool roof; Urban heat island; Reflective surface coating; Roof tile; Ceramic

1. Introduction

The Urban Heat Island (UHI) is defined as an urban area with higher temperatures than rural areas due to human activities (IEA, 2023; Turhan et al., 2023). Climate change significantly contributes to the intensification of the UHI effect in cities. This leads to increased heat waves and energy consumption in cities during summer, and adverse impacts on public health. As global temperatures rise and extreme weather events become more frequent, climate change further exacerbates the UHI effect (Zhao et al., 2021).

Considering that cities are responsible for approximately 66% of total global energy consumption (Batista et al., 2023), it is important to mitigate the impact of UHI on energy consumption to achieve sustainability goals. Similarly, buildings account for 35% of global energy consumption. Therefore, the impact of UHI on the energy performance of buildings needs to be investigated in detail (Romano, 2021). The literature suggests strategies to reduce the UHI effect to achieve energy savings in buildings. Examples of these strategies include the use of high-reflectivity materials on building surfaces and pavements (Jige et al., 2021; Sedaghat, 2022; Batista et al., 2023), increasing green spaces (Aleksandrowicz et al., 2017), and green roof/green wall applications. Among these strategies, reflective surfaces benefit from industrial processes already used to produce traditional building materials. The manufacturing of reflective ceramic roof tiles is an excellent example of this approach since 25-35% of heat gain in buildings occurs through roof surfaces (Fig. 1) (Hydrosol, 2023).

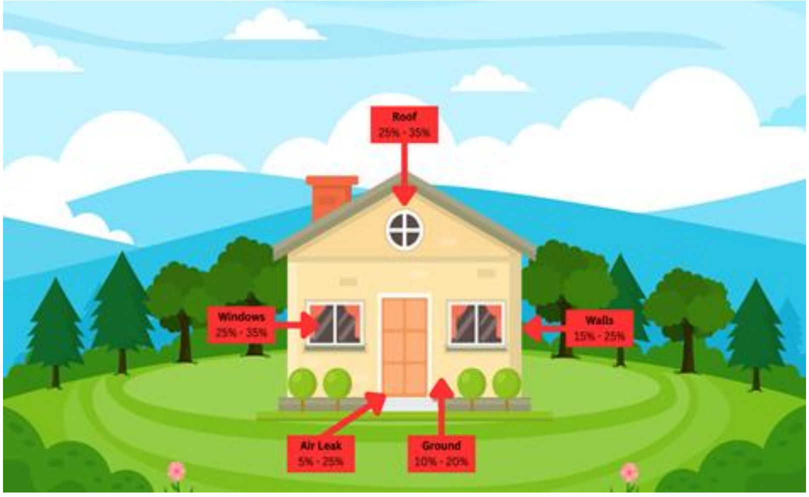

Fig. 1. Distribution of heat gain in buildings (Hydrosol, 2023).

Solar radiation is composed of rays of different wavelengths like gamma rays, x-rays, UV, visible, infrared, etc. As far as the cool roof concept is concerned, the purpose is to reflect as much as possible any part of this radiation from the roofs. Visible light (400 to 700 nm of wavelength) contains 43% of the power in the air-mass, 52% in Near Infrared (NIR) range (700-2500 nm) and 5% ultraviolet (UV) radiation according to ASTM G173-03 (ASTM, 2003). When the surface of the roof tile is completely white, solar-opaque and smooth, NIR reflectance is about 85% (Levinson et.al., 2007). This is the ideal roofing surface but is not desirable for obvious reasons that during sunny days the glare from roofs gives discomfort to people in the cities. Hence, there is an effort in the literature to produce NIR-reflective surfaces that are non-white (Brady et.al., 1992). This can be achieved by forming a coating with high NIR reflectance.

This study focuses on the production of ceramic roof tiles using two distinct approaches: (i) surface modification through the application of reflective coatings (Castellani et al., 2017; Morini et al., 2018) or (ii) modification of the components forming the ceramic tile to give them reflective properties (Ferrari et al., 2013; Ferrari et al., 2014; Governatori et al., 2021). For example, Castellani et al. (2017) developed retro-reflective (RR) coloured ceramic tiles by applying a UV-resistant, transparent paint containing clear solid barium titanate glass microspheres, which increased the reflection of grey (2.6%) and brown (5.1%) tiles. Similarly, Morini et al. (2018) increased the global reflection of a light brown ceramic tile from 30% to 39% by coating it with the same UV-resistant, transparent paint containing RR clear solid titanate microspheres. On the other hand, Governatori et al. (2021) base the development of reflective building surfaces on the modification of the frits and glazes used in ceramic tile products (Ferrari et al., 2013; Ferrari et al., 2014). Revel at al. (2014) developed cool coloured ceramic tiles, acrylic paints and bituminous membranes and tested on the facades of test buildings in Madrid-Spain.

This study proposes the development of novel reflective-glazed tiles to be used on roofs specifically targeting UHI issues in urban areas. Conventional red roof tiles are traditionally made from impure earthenware terracotta compositions which are mostly produced with little control of chemical composition in moderate technology kilns at around 980°C. In addition, the experimental reproducibility in this study would have been poor if terracotta bodies were used. Therefore, in this study, modern floor tiles are chosen as the substrate or the base layer on which to coat the glaze layer a few hundred μm thick. The choice of floor tiles as the substrate is based on the fact that such materials are produced on a mass scale in large quantities, their chemical compositions, physical properties like particle size, surface area before sintering are all well controlled on an industrial scale. So, selection of floor tiles helped eliminate unnecessary loss of resources during the experimental part of the study. Once the proper glaze formulation with maximum reflectivity is developed it is easy to transfer the glaze to a lower melting conventional terracotta roof tile. A local industrial floor tile manufacturer (Seramiksan A.Ş., Turgutlu, Manisa) provided the floor tile body powder in granule form with about 250 μm average diameter. Engobe and frit were also provided by the same company as well as other producers.

2. Materials and Methods

The experimental work followed two main routes: (a) glaze coating composition optimization and (b) scale up of tiles to be used in an experimental roof set-up (1 m^2 area) for thermal performance analysis. In this study, the results of the first part are presented. The work is on-going, and further progress will be reported elsewhere. The flow chart followed in the study is given in Fig. 2. As can be seen in Fig. 2, floor tile granules are compressed in a uniaxial hydraulic press at about 100 MPa to obtain cylindrical pellets of 20 mm diameter and 2 mm height.

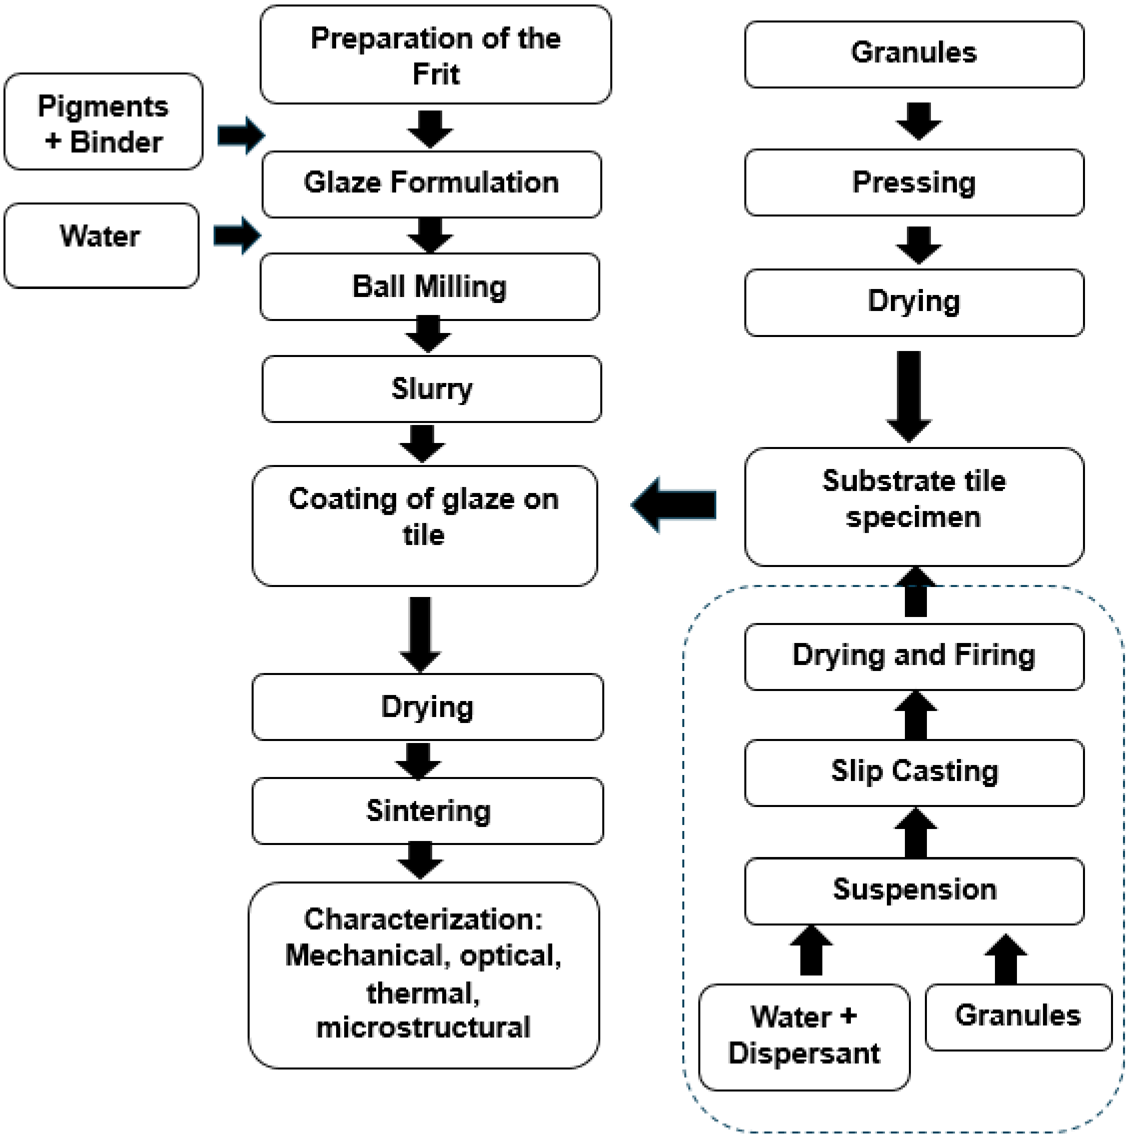

Fig. 2. Flow chart followed during the study.

As these pellets contained about 5% moisture they could be coated with the engobe and glaze layers and sintered safely without worrying about the possibility of drying cracks much. But without a low temperature sintering (bisque-firing) they would not be able to stay in one piece during handling for coating. Consequently, they were all bisque-fired at 800°C for 10 min to impart sufficient strength for handling in the following stages of processing.

Separately, suspensions were prepared for both the glaze (frit + pigment) and the engobe. The glaze suspension was made using 97% frit and 3% pigment oxide mixture. The frit was an industrially used composition provided in pre-melted glass form which was ground to pass completely through a 150 µm (less than 150 µm) particle size. Bisque-fired pellets were dipped by hand in engobe, frit or pigment suspensions sequentially based on the order listed in Table 1. Some samples were coated by frit without an engobe layer. The latter is designed to act as an intermediate layer to hide the darker color of the body and to balance differences in thermal expansion coefficients of the frit and the body.

After coating the bisque-fired body specimens with different layers of different materials (engobe and/or frit), drying was done in an oven at 110°C overnight before sintering at 1200°C for 30 min in line with the industrial practice. All samples showed a good level of attachment to the base layer with pore-free glassy surface. A glaze needs to be protective and water-tight, so maturation of glaze is important and is achieved in this study for all samples. The reflectivity measurements were conducted using a Perkin Elmer Lambda 950 Spectrophotometer. In these measurements, the reflectance in the Near Infrared (NIR) range (i.e. between 700 and 2100 nm) is important and needs to be maximized to obtain sufficient solar reflectance by the glazed surface to be developed in this study (Ferrari et al., 2016). Any radiation outside this range was considered outside the scope of this study as it would be economically/practically prohibitive to try to reflect UV/Visible radiation. Usually, a porcelain floor tile with a white surface offers about 60% reflectivity in this NIR range but cannot be used on roofs or terraces as the white colors gives discomfort for people in the sunny urban areas.

Table 1. Experimental test conditions.

Sample code	Body	Engobe	Frit Code	Pigment	Average NIR Reflectivity (%)
FT*	FT	-	-	-	15
EP*	FT	EP	-	-	36
29	FT	EP	TRS-13	G3*	65
30	FT	EP	TRS-14	G3	58
33	FT	-	5061	G3	54
37	FT	EP	5061	G3	60
40	FT	-	TRS-13	G3	41
42	FT	EP	TRS-13	G1*	58
49	FT	EP	TRS-13	R3*	32
50	FT	EP	TRS-13	Y3*	42

*FT: Floor tile layer; EP: Engobed pellet; G3: Third green pigment; G1: First green pigment; R3: Third red pigment; Y3: Third yellow pigment

3. Results and Discussion

Samples obtained from experiments are shown in Fig.s 3-6. Adhesion of the glaze and engobe to the body was successful in all samples (Fig. 3). All three layers were pore-free and dense. There were no cracks between the different layers. Engobe layer was lighter colored and glassy while the body was less vitrified (glassy). Glaze and engobe layer thicknesses were each about 400 µm.

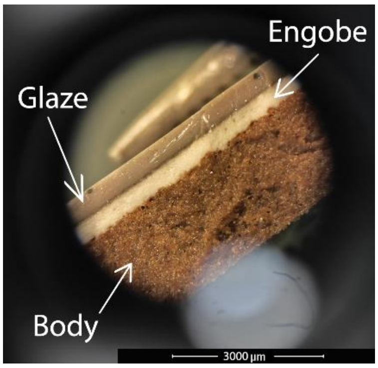

Fig. 3. Cross sectional image of sample 29 in optical microscope. G: Glaze, E: Engobe, B: Body.

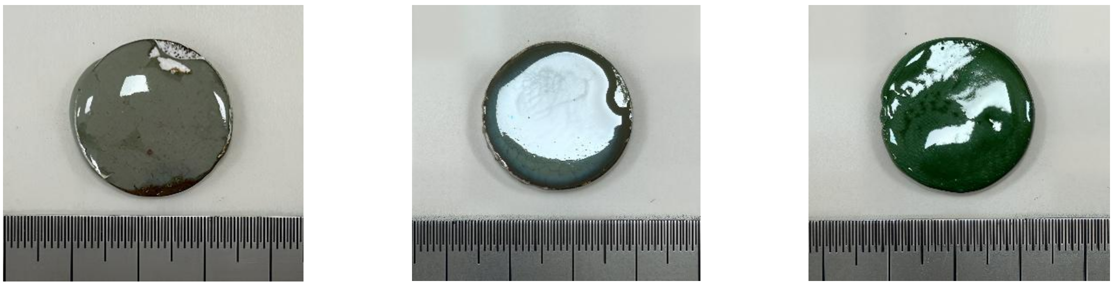

Sample: 29 Sample: 30 Sample: 33

Fig. 4. Samples 29, 30 and 33.

Fig. 5. Samples 37, 42 and 49.

Sample: FT Sample: EP Sample: 50

Fig. 6. Samples FT, EP and 50.

Reflectivity measurements of the samples are shown in Fig.s 7 to 11. In Fig. 7, the reflectivities of the base body layer (FT), the engobe (EP) and glaze (frit + pigment) layers are shown. Considering that the base layer had about 15% reflectivity, the effect of the engobe layer can be clearly seen to make a remarkable effect on reflectivity (36%). When the glaze layer is applied on the engobed layer further significant improvements could be achieved. Sample 29 with only a small amount of chromium as pigment showed significant increases in reflectivity well in excess of 65%. This sample provided the authors with a high amount of confidence in achieving high reflectivity without going ”white” which is undesirable due to sun-glare effects. Therefore, the key in achieving high reflectivity was to avoid using white color Ferrari et al., (2016). Sample 29 had a green color which should be acceptable as a roof cover material. This is up to the final users's decisions.

The effect of the presence of an engobe layer was investigated in samples 29-40 and 33-37. Samples 33 and 40 had no engobe layer but they were coated by a glaze layer. Samples 29 and 37, however, had all the layers coated sequentially. The purpose was to test whether the presence of the engobe layer would make much difference. It was found that the engobe layer was quite effective in providing higher reflectance as shown in Fig.s 8 and 9.
The effect of the type of frit was investigated in samples 29, 30 and 37 which contained different industrial frits. The results are shown in Fig. 10 where sample 29 was found to be most effective in providing the highest reflectivity. This sample contained the frit coded “TRS-13” which is selected as the frit to be used in the rest of the experimental program.

Once it was decided that the engobe layer was useful and the best frit was TRS-13, the study was directed toward studying different pigment types. As there are several different pigments available in the market, the selection of pigment was restricted to only four colors: green, red, yellow and black. The measurements for the samples with black pigment was not ready to report here so these results will be reported elsewhere. Fig. 11 shows the results from samples 29, 42, 49 and 50 which contained green, another green, red and yellow pigments. As can be seen in Fig. 11, the green pigment was found to be most effective in providing the highest reflectance values (around 65%). The study is ongoing, and other pigments are investigated to further maximize reflectivities.

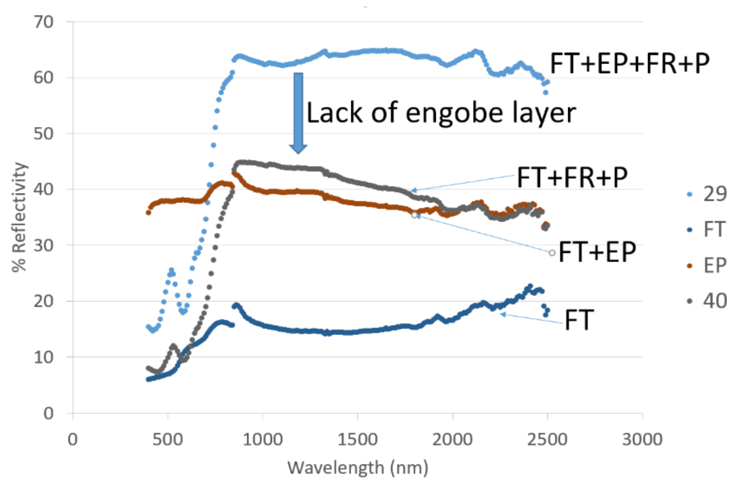

Fig. 8. The results of reflectivity measurements of samples FT, EP, 29 and 40.

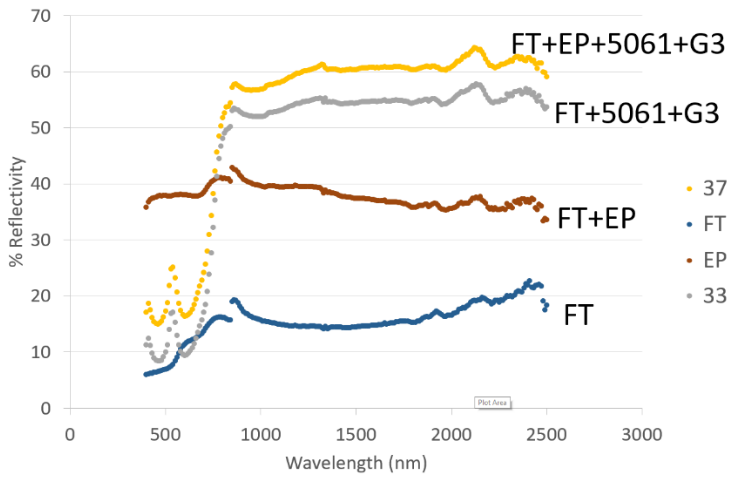

Fig. 9. The results of reflectivity measurements of samples FT, EP, 33 and 37.

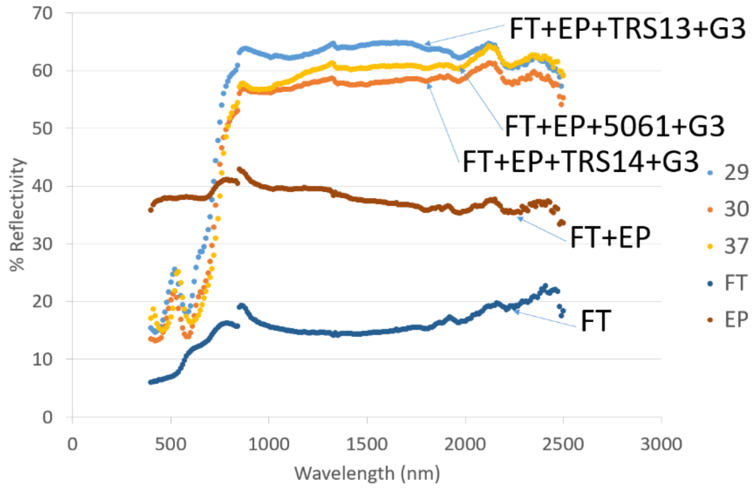

Fig. 10. The results of reflectivity measurements of samples FT, EP, 29, 30 and 37. Three different frits are compared. The best one was the frit TRS-13 that was used in sample 29.

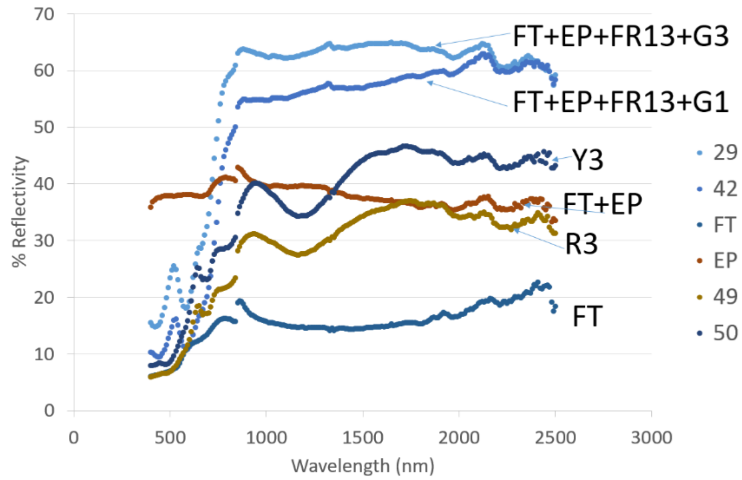

Fig. 11. The results of reflectivity measurements of samples FT, EP, 29, 42, 49 and 37. Different pigments are compared. The most effective pigment was chromium containing G3.

4. Conclusions

Laboratory work involving floor tile pellets coated with engobe and glaze layers proved to be successful in obtaining glaze coatings that provided high reflectivity in the NIR spectrum of solar radiation. Tile samples produced in this study were free from pores, cracks, air bubbles and were composed of different body, engobe and glaze layer combinations that were well-bonded to each other. Solar reflectivity measurement results were promising in that the continuation of the work will involve scale up which means to produce larger tiles to cover experimental roofs. The research effort is already ongoing to analyze thermal effects of the new tiles which eventually are planned to lead to minimization of UHI effects.

- Tile samples were successfully coated with engobe and glaze layers using different pigments.
- Engobe layer proved to be effective in increasing reflectivity in the NIR range which is beneficial in mitigating UHI effects.
- Among the different frits, TRS-13 was found to be most effective in providing the highest reflectivity.
- Chromium containing pigment was the most effective in providing high reflectivity while red and yellow pigments were poor in that regard.

Acknowledgments

The research described in this paper was financially supported by the İYTE-AUDP Project under the grant number 2023IYTE-2-0021. Authors would like to thank Metin Özbekler, Duygu Günay and Atilla Balaban for their help during experiments. Special thanks to Seramiksan A.Ş. and Bien Seramik A.Ş. for providing raw materials. The consultations with Murat Ataman and Engin Akgün are also highly appreciated.

Evaluating risks in the 3D concrete printing process: 5x5 matrix approach

Şeyma Gebel*[1], Berru İzel Gökgöz[2], Zeynep Yeşim İlerisoy[1]

[1] Gazi University, Faculty of Architecture, Department of Architecture, Ankara, Türkiye
[2] Ostim Technical University, Department of Interior Architecture and Environmental Design, Ankara, Türkiye

Abstract. Three-dimensional printing technology offers important advantages such as increasing production speed, reducing material waste, and design flexibility in the construction industry. However, due to its developing structure, this innovative method's applicability brings various risk factors. This study used the 5x5 risk assessment matrix method to identify and evaluate potential risks that may arise in the 3d concrete printing process. Based on the data obtained from the literature, 17 basic risk factors were analysed according to likelihood (L) and severity (S) levels and risk scores were determined. According to the findings, 1 of the 17 risk factors (nozzle characteristics) was 'unacceptable', 11 (motion control, open exposure duration, cybersecurity risks, wall joint detail and design, lack of knowledge and experience, inadequate safety measures, lack of skilled labor, inadequate setting time, insufficient extrudability, Inadequate infill density) were 'high risk', 1 (complex working environment) was 'medium risk' and the remaining 4 (wind, temperature, relative humidity, radiation and chemical material) are classified in the 'low risk' category. In this context, it is pointed out that risk assessment is necessary in multifaceted and interdisciplinary issues such as printing material properties, environmental status, construction site, design decisions, safety and printer property parameters. For this reason, it is thought that the development of integrated risk assessment models covering many different areas, such as not only occupational health and safety, but also structural integrity, production efficiency, cyber security and environmental impacts, will increase the applicability and efficiency of the technology. In this direction, studies based on comparative analysis of applications carried out under different conditions can contribute to developing academic literature in the field by increasing the knowledge of additive manufacturing technology.

Keywords: 3D concrete printing; Risk analysis; Additive manufacturing technology; 5x5 Matrix method; Risk assessment

1. Introduction

Three-dimensional printing (3DP) technology stands out as a revolutionary innovation in the construction industry and enables the construction of structures and elements based on the principle of additive manufacturing. This technology enables the integration of computer-aided design (CAD) and robotic systems to create structures by extruding materials such as concrete layer by layer using specially designed large-scale three-dimensional printers. Unlike traditional moulded concrete pouring methods, this process, which is based on the principle of moldless production, offers many important advantages such as less human intervention, minimum material waste and shortening of construction time. In addition, it increases design flexibility by allowing the production of customised architectural forms with structures with complex geometry. Due to its important advantages, it is also applied in many industrial areas today (Tay et al., 2016; Wu et al., 2016).

Despite the significant advantages and promising potential of 3D printing in the construction industry, several uncertainties and risks regarding the viability of this technology still remain. 3D printers are automated and mechanical systems with inherent risks; therefore, various factors such as downtime and maintenance costs should be carefully analyzed for their impact on the overall risk level of the 3D printing process (Ahmed et al., 2025). Although many studies to date have addressed the risks in construction projects, there is limited research in the literature to comprehensively examine the risks that 3D concrete printing technology may pose in construction projects. The application of new technologies brings with it additional risks that are unique compared to traditional methods. The main objective of this study is to identify and systematically evaluate the new risks that this technology may cause in 3D concrete printing projects in the construction industry using the 5x5 Matrix method.

*Corresponding author, E-mail: seyma.gebel@gazi.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_208

In this study, the applicability of 3d concrete printing technology, which is becoming increasingly widespread in the construction industry, is addressed from a risk management perspective. The objective is to identify, analyse, and evaluate process-specific potential hazards in a systematic manner.

In this context, various risk dimensions, including worker safety, structural performance, and production efficiency, were assessed using a 5x5 risk matrix approach. This assessment proposes preventive strategies to support integrating safe and sustainable technology into construction practices. The study identifies 17 key risk factors associated with 3d printing in construction and comprehensively evaluates the applied methodology and its outcomes.

2. Methodology

Risk assessment results play a critical role in minimising the risks of accidents and deaths by prioritising the work and maintaining the operational flow. The 5x5 Matrix method offers a more reliable and objective evaluation process by minimising the margin of error in risk rankings thanks to its complete numerical data. Unlike traditional construction methods, the increasing prevalence of three-dimensional concrete printing technology, especially in the construction sector, brings new and hard-to-predict risks. In this context, the method determined within the scope of the study stands out as an effective assessment tool in terms of identifying, sequencing and controlling the risks related to issues such as operational, technical and occupational health that may arise in three-dimensional concrete printing processes. It is thought that it is a suitable method for the scope of this study in terms of allowing the evaluation of new and uncertain risks that three-dimensional printing technology may pose in construction projects with a quantitative, systematic and prioritisation-based approach.

Within the scope of this study, the definitions and steps for the 5x5 Matrix risk assessment method will be detailed, and then calculations will be made with the risk factors determined by the data obtained from the literature within the scope of the subject. Fig. 1 shows the flowchart of the research.

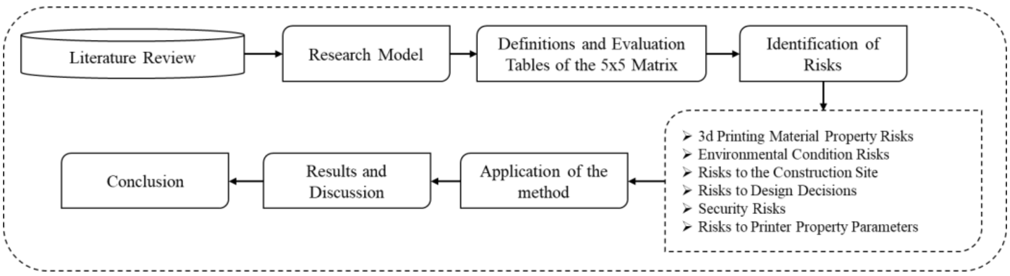

Fig. 1. Flowchart of the study

2.1. 5x5 Matrix risk assessment method

The construction industry is an area where risk management is vital due to its high potential for hazards. Especially in terms of occupational health and safety, it is necessary to identify, analyse and control possible risks in advance. The 5x5 risk assessment matrix, one of the methods used in this framework, enables the hazards encountered in the sector to be examined with a systematic and holistic approach.

The 5x5 Matrix is a practical risk assessment method used especially in analysing cause-effect relationships. With this method, first of all, it is ensured that the probability of occurrence of an event and the effect it will have if it occurs are graded and quantitatively measured (Özkılıç, 2005). The risk score is obtained from the product of likelihood and severity (degree of harm) and is written in its place in the table (Equation 1). Reviewing the literature shows that the definitions of risk, severity, and likelihood are largely framed in the context of occupational health and safety (Aker, 2020; Gur et al., 2021; Öztürk & Şimşek, 2020). This limited approach to various risk assessments prevents accurate and clear assessments. The relevant tables are given in Tables 1 and 2.

$$\text{Risk Score (RS)} = \text{Likelihood (L)} \times \text{Severity (S)} \tag{1}$$

Table 1. Severity values in the event of an incident (Özkılıç, 2005)

Event	Violence	Severity Value
In the event of multiple deaths or permanent incapacity for work	5	Very serious
In case of major injury or occupational disease	4	Serious
In case of injuries requiring rest	3	Middle
In case of minor injuries requiring first aid (no loss of work)	2	Light
In case of accidents that require only simple first aid without loss of work	1	Very Light

Table 2. 5x5 Matrix Probability Value (Bekdemir, 2019)

Frequency	Likelihood	Likelihood value
Once a year	Too small	1
Quarterly	Small	2
Once a month	Middle	3
Weekly	High	4
Everyday	Very high	5

Table 1 refers to the severity values in case of an event, Table 2 refers to the 5x5 Matrix likelihood value, and Table 4 refers to the risk score matrix. According to this table, risk is grouped into four groups: 'low, medium, high and unacceptable' risk. The data obtained from Tables 1 and 2 are recorded in the analysis table in line with the matrix-based risk assessment approach (Table 4), and the necessary improvement measures are applied according to the action steps specified in Table 5, starting with the one with the highest risk score. After the relevant measures are implemented, each risk factor should be re-evaluated, the current risk score should be determined, and the evaluation form should be prepared accordingly. It should be restructured.

Due to the unique nature of these applications, the literature has shown that definitions and evaluation parameters (Ball & Watt, 2013; Duijm, 2015; IEC/ISO, 2009; Jensen et al., 2022) state that it needs to be restructured to align with the objectives of the study. In this regard, the evaluation team, experienced in the 3d concrete printing process, developed the scale presented in Table 3 to fit the content of the study. Calculations were made accordingly.

Table 3. Severity values in the case of events that can occur in the 3d concrete printing process

Event	Severity	Severity Value
There is complete failure in the 3d concrete printing process. The system stops due to the failure of critical components. The manufactured elements are completely dysfunctional. There are serious delays in project delivery. It is necessary to redo the production.	5	Very serious
The elements produced are technically unacceptable. Requires reproduction. Loss of material and time occurs. Delays occur in delivery dates. The efficiency of the production process is significantly reduced.	4	Serious
There are quality problems in the printed elements, but they are not out of use. Partial rework or correction may be required. There is a limited impact in terms of cost and time. There may be short-term disruptions in operational flow.	3	Middle
There is a small level of aesthetic or functional deterioration in the product. The part is available. The process continues, but there may be minimal loss of productivity. Additional costs are non-existent or negligible.	2	Light
The process was completed without any problems. The final product is technically and aesthetically acceptable. There is no negativity in time, cost and quality parameters.	1	Very Light

Table 4. Risk Score (Rating) Matrix (Özkılıç, 2005)

OxS	Violence				
Probability	1	2	3	4	5
1	Low (1)	Low (2)	Low (3)	Low (4)	Low (5)
2	Low (2)	Low (4)	Low (6)	Medium (8)	Medium (10)
3	Low (3)	Low (6)	Medium (9)	Medium (12)	High (15)
4	Low (4)	Medium (8)	Medium (12)	High (16)	High (20)
5	Low (5)	Medium (10)	High (15)	High (20)	Unacceptable (25)

Table 5. Admissibility Values of the 5x5 Method Risk Result

Risk Value	Assessment	Risk Assessment Result (Action)
Unacceptable Risk	(25)	Work should not be started until the identified risk is reduced to an acceptable level; if there is an ongoing activity, it should be stopped immediately. The activity must be prevented if it is impossible to reduce the risk despite the measures taken.

Tablo 5 continued.

High	(15,16,20)	Work should not be started until the identified risk is reduced, and if there is an ongoing activity, it should be stopped immediately. If the risk is related to the continuation of the business, urgent measures should be taken, and as a result of these measures, the continuation of the activity should be decided.
Medium	(8,9,10,12)	Activities should be initiated to reduce the identified risks. Risk mitigation measures may take time.
Low	(2,3,4,5,6)	Additional control processes may not be needed to eliminate the identified risks. However, existing controls should be maintained, and it should be ensured that these controls are maintained
Negligible risk	Negligible	In order to eliminate the identified risks, it may not be necessary to plan control processes and keep records of the activities to be performed.

3. Risk identification

Construction risk management is a structured management process that includes the systematic identification and analysis of uncertainties that may be encountered throughout the life cycle of a construction project and the development of appropriate response strategies to these risks; It is a structured management process whose purpose is to eliminate, reduce or control risks and to achieve project goals safely and effectively (Wang et al., 2004; Ahmed et al., 2025). Risk analyses predict the consequences that may arise if the project does not progress according to plan. No matter how advanced analytical techniques are, the correct interpretation of data depends on expertise. Evaluations with systematic analyses instead of heuristic approaches offer a clearer, more reliable view of risks (Uğur, 2006).

Risk management in construction projects is a systematic and structured approach that aims not to eliminate all risks, but to prioritize and manage the most important and effective ones. There is a certain level of risk inherent in every project; Some of these risks are acceptable as they are associated with the potential returns of the project. However, at an early stage, identifying and effectively controlling the risks that pose a direct threat, such as the project's duration, cost and quality, is critical. In this context, a successful risk management process depends on technical analysis and the organisation's continuous and proactive approach to risks. Such a risk management approach is important in applying technology safely, efficiently, and sustainably, especially in areas such as 3d concrete printing technology, where rapidly developing and innovative applications occur.

Geometric decisions made during the design phase in 3d printing technologies directly shape the success and risk level of the production process (Takva et al., 2024; Gebel et al., 2024). For this reason, it is important to integrate architectural design parameters into risk assessment processes to implement the technology in a safer and more efficient way. This section explains the multifaceted risks of 3d printing by grouping them into 6 main categories. Table 6 provides detailed information on the definitions and references of these risks encountered in construction projects. A total of 17 risk factors were identified within the scope of this study.

- 3d Printing Material Property Risks: These are the material properties related to the physical and mechanical properties of the material used in the 3d printing process. Using different materials or mixing ratios of the components in the studied material properties specific to the concrete material is effective in the final 3d printed product.
- Environmental Condition Risks: These include various external factors that affect the 3d printing process, such as temperature, humidity, wind, etc., so that other parameters work effectively. The print environment directly or indirectly affects the final product.
- Risks to the Construction Site: It refers to potential hazards that may threaten safety, accessibility and operational integrity in relation to the physical environment, equipment, workforce and processes in the area where 3d concrete printing technology is used.
- Risks to Design Decisions: It covers the characteristics of the final product produced with a 3d printer. In the final product, static factors are important, including the structure's geometry, size, and complexity.
- Security Risks: Cybersecurity risks in 3d printing refer to situations where digital design data and production processes are compromised by unauthorised access, data integrity is compromised, or interference with the system's operation.
- Risks to Printer Property Parameters: These are the printer features that depend on the structural features of the 3d printer. The change in printer types changes the efficiency of the printing process, its cost, and the production process. At this point, the printer's features are very important in the 3dp process.

The concepts of risk and danger are explained in the literature. Risk is the possibility of loss, injury, or other harmful consequences resulting from the hazard. On the other hand, danger is the potential for harm or damage in the workplace or may come from outside, affecting the employee or the workplace (Aker, 2020). The definitions in Table 7 are discussed within this framework.

Table 6. Risks of 3D printing in construction projects

Main title	N	Risk	Definition	Reference
3D Printing Material Property Risks	1	Inadequate infill density	In 3D printing, fill density refers to the amount of material used to fill the internal structure of the printed product. The high fill density means that there will be fewer gaps within the structural elements. This can make the structure more robust and resistant to impacts. Depending on the application and the desired properties of the structure, the most common fill densities range from 10% to 50%.	Lyu et al, 2021 Qaidi et al, 2022 Ćwikła et al, 2017 Gosselin et al, 2016 Karalia et al, 2021
	2	Insufficient extrudability	It is the ability to continuously squeeze concrete out of the nozzle, and this property depends on the fluidity. If concrete is not fluid, it cannot be extruded; if it cannot be extruded, it cannot be printed.	Malaeb et al, 2019
	3	Inadequate Setting Time	It is the time until the concrete is completely solidified.	Günzel, 2021 Lyu et al, 2021 Özalp and Yılmaz, 2020
Environmental Status Risks	4	Relative Humidity	In outdoor printing processes, adjustments to the mixing ratios of concrete materials are required according to current temperature and humidity levels to optimise printability and extrudability parameters.	Diggs-McGee et al, 2019 Ma et al.,2022 Moelich et al, 2022
	5	Temperature	Evaporation of moisture from pressurised concrete can inhibit the hydration of cement and affect the development of mechanical properties; temperature and wind, on the other hand, affect the behaviour of concrete printing materials.	Diggs-McGee et al, 2019 Ma et al.,2022
	6	Wind	Low humidity and high wind speeds can exacerbate surface moisture evaporation in concrete printing, potentially leading to filament cracking.	Ma et al.,2022 Moelich et al, 2022
	7	Radiation & Chemical Material	Exposure to ultraviolet radiation and chemicals can compromise the structural integrity of concrete products, highlighting the need for regulations tailored to environmental factors to ensure the product's durability.	Pacewicz et al, 2018 Siddika et al, 2020
Risks to the Construction Site	8	Lack of skilled labour	New technologies used in the construction industry pose a significant challenge due to limited access to a qualified and experienced workforce, especially in countries where these methods have not yet become widespread.	(Hwang et al., 2017)
	9	Complex working environment	The overall complexity of the workspace and the different levels of access can create a challenging working environment for robots.	(Ahmed et al., 2025)
	10	Inadequate safety measures	Operational hazards caused by electrical and mechanical causes can lead to injuries, considered the most serious industrial accidents.	(Ahmed et al., 2025)
Risks to Design Decisions	11	Wall Design	Wall design consists of fill density and wall combination. In construction projects where 3D concrete printers are used, the design of the wall to be printed plays an important role in the printing process. In this process, the material properties, geometry and design of the wall type to be printed affect the print quality, durability and cost of the final product.	Gosselin et al., 2016 Khan et al, 2021 Martínez-Rocamora et al, 2020 Žujović et al, 2022 Lim, 2023
	12	Wall joint detail	The wall connection affects the strength, durability, and overall performance of the structure. Form corner joints can be created at different angles for aesthetic concerns, costs, durability performance and functional features. Angled corner joints are generally simpler and less costly, increasing the rigidity of the structure.	Lim, 2023 Marais et al, 2021 Suntharalingam et al, 2021 Wang et al, 2020

Table 6 continued.

Main title	N	Risk	Definition	Reference
Risks to Design Decisions	13	Lack of knowledge and experience	Lack of knowledge and experience on the subject can cause structural errors and serious risks in occupational health and safety. For example, due to the inability to determine the optimum distance between the nozzle tip and the base level, unsuccessful/defective products may occur in varying geometries.	Jo et al., (2020)
Security Risks	14	Cyber Security Risks	The fact that 3d printers work with CAD files increases cybersecurity risks, such as unauthorised access to the system and unauthorised modification of the parameters of the printing process.	(Ahmed et al., 2025), (Zeltmann et al., 2016)
Risks to Printer Property Parameters	15	Open exposure duration	Open exposure duration refers to when cement or similar materials can flow through the printer nozzle without clogging. Continuous operation of the printer causes its hardware to heat up due to heat dissipation and friction, which affects the uptime.	Jo et al., 2020 Mueller et al., 2015
	16	Nozzle Features	It includes parameters such as the speed of movement of the nozzle, the size of the nozzle's tip and the nozzle's height. Nozzle characteristics are important in optimising print quality and making printing more efficient.	Blank et al, 2016 Jo et al, 2020 Lyu et al, 2021 Tay et al., 2016
	17	Motion control	It determines the movement of the nozzle and how the material is layered to create the object to be 3d printed. Motion control ensures that printers operate correctly and, as a result, improves production quality. It also improves energy efficiency by helping to manage printer movement more efficiently.	Blank et al, 2016 Lyu et al, 2021 Zhao et al, 2019

4. Results and Discussion

In this study, 17 different risk factors that may be encountered during the application process of 3d concrete printing technology in the construction sector were defined, and the risk score (RS= LxS) was calculated for each of them based on the likelihood (L) and severity (S) values. The scores obtained are given in Table 7. Fig. 2 provides a visualisation of these risk scores. Accordingly, the risks were evaluated in four categories: unacceptable, high, medium and low. Risk scores were analysed according to a scale ranging from 1 to 25 within the framework of this method. According to the findings, 1 of the 17 risk factors was classified as 'unacceptable', 11 as 'high risk', 1 as 'medium risk' and 4 as 'low risk'.

The only parameter with an unacceptable level of risk is 'nozzle characteristics'. This situation shows that the elements that directly affect the printability and structural integrity of the product can pose a threat that can lead to serious consequences. In particular, the fact that nozzle properties can directly cause production defects can create serious operational risks that may result in material deformation, loss of time and material damage.

It is seen that the risks that may occur in the high-risk group for 'motion control, open exposure duration, cybersecurity risks, wall connection and design' are of critical importance. Inadequacies in the motion control system affect production precision, causing structural imbalances, which in turn affect the mass manufacturability process. The risks to wall design and connection reveal the sensitivity of the relationship between digital modelling and material behaviour in the 3d printing process, and reveal the necessity of considering design processes, engineering controls and connection details with a holistic approach. Although cybersecurity risks are often overlooked in digital manufacturing processes, they are critical, especially in CAD-based automation systems such as 3d concrete printing. Unauthorized modification of system data or vulnerability to external interference of print parameters can lead to serious manufacturing defects and structural security vulnerabilities. This situation shows that cybersecurity has become an important component of the IT and construction industries. These risks are followed by 'lack of knowledge and experience, inadequate safety measures, lack of skilled workforce, inadequate setting time, insufficient extrudability and inadequate infill density'. Risks related to a lack of knowledge and experience increase the potential for wrong decision-making in the process, which can threaten both production efficiency and occupational health and safety.

The 'complex working environment', which is evaluated in the medium risk group, and the physical complexity in the environments/sites where 3d concrete printing is applied, make the effectiveness of robotic systems difficult.

Although environmental factors such as 'wind, temperature, relative humidity', which are classified as low risk, do not directly affect the success of the printing process, there is the potential for the risk level to increase over time if neglected. Therefore, these risks need to be managed through periodic monitoring and control mechanisms.

As a result, the analysis revealed that although 3d concrete printing has important opportunities for the construction industry, it contains multidimensional and technology-specific risks. Unlike traditional construction risks, the risks in this technology can be various sources, such as a lack of knowledge and experience about technology, software, and environmental ffactors. For this reason, in the risk management process, occupational health and safety and interdisciplinary elements such as cyber security, structural design, production continuity and efficiency should be evaluated holistically.

Table 7. 3D concrete printing process risk assessment results

No	Main Topics	Danger	Risk	L	S	Risk Score
1	3d Printing Material Property Risks	Inadequate infill density	Mechanical weakness, mass manufacturability problem, loss of time and money	4	4	16
2	3d Printing Material Property Risks	Insufficient extrudability	Printing failure, loss of time and money	4	4	16
3	3d Printing Material Property Risks	Inadequate setting time	Mass manufacturability problem, printing failure, loss of time and money	4	4	16
4	Environmental Status Risks	Relative humidity	Material deformation, loss of time and material	2	2	4
5	Environmental Status Risks	Temperature	Thermal expansion/cracking, material deformation, time and material loss	2	2	4
6	Environmental Status Risks	Wind	Material drying instability, material deformation, time and material loss	2	2	4
7	Environmental Status Risks	Radiation and chemical exposure	Health problem, material deformation, time and material loss	1	4	4
8	Risks to the Construction Site	Lack of skilled labour	Incorrect/incomplete operation, operational disruption, time and financial loss	5	3	15
9	Risks to the Construction Site	Complex working environment	Collision, imcorrect/incomplete operation, operational disruption, injury or death, property loss	4	3	12
10	Risks to the Construction Site	Inadequate safety measures	Injury or death, loss of property	4	4	16
11	Risks to Design Decisions	Wall design	Structural imbalance, constructability problem, mass manufacturability problem, time and material loss	5	4	20
12	Risks to Design Decisions	Wall joint detail	Structural imbalance, constructability problem, mass manufacturability problem, time and material loss	5	4	20
13	Risks to Design Decisions	Lack of knowledge and experience	Wrong decision-making, incorrect operation, operational disruption, time and financial loss	4	4	16
14	Security Risks	Cybersecurity risks	Data loss, security vulnerability, incorrect transaction applications, loss of time and money	4	5	20
15	Risks to Printer Property Parameters	Open time (or open exposure duration)	Mass manufacturability problem, mechanical problems, material deformation, time and material loss	5	4	20
16	Risks to Printer Property Parameters	Nozzle characteristics	Clogging, uneven flow, mass manufacturability problem, mechanical problems, material deformation, time and material loss	5	5	25

Table 7 continued.

No	Main Topics	Danger	Risk	L	S	Risk Score
17	Risks to Printer Property Parameters	Motion control	Mass manufacturability problem, mechanical problems, material deformation, time and material loss	5	4	20

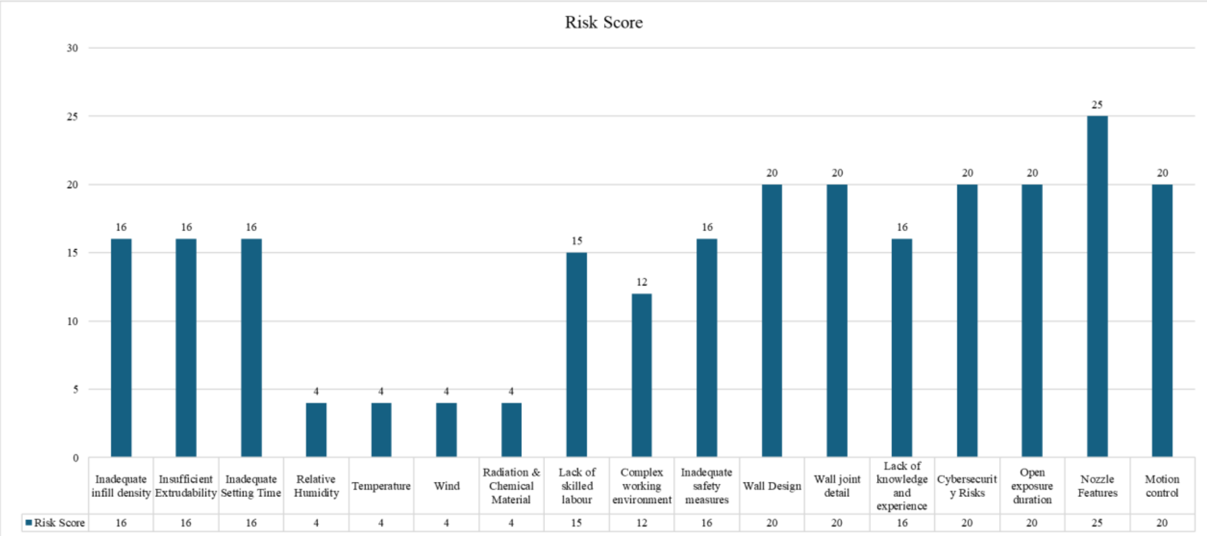

Fig. 2. Risk score table

5. Conclusion

3d printing technology greatly transforms the construction industry with its many advantages, such as cost, speed and design flexibility. Thanks to advances in this technology, producing environmentally sustainable and cost-effective structures with complex geometries that are difficult to construct with traditional methods is becoming possible. It is expected that in the future, this technology will become fully widespread and one of the mainstream construction methods. However, there are issues that need to be addressed in many areas, from materials science to building regulations. In addition to this situation, when we look at the applications of 3d printing technology in the construction sector, it is seen that despite its structural and production advantages, it also has multifaceted risks. Within the scope of this study, the 5x5 risk assessment matrix method, which is used to systematically identify and prioritise risks, allows the objective analysis of 17 basic risk factors specific to this technology. The findings point to the necessity of risk assessment on multifaceted and interdisciplinary issues such as printing material properties, environmental status, construction site, design decisions, safety and printer feature parameters. Therefore, for 3d printing technology to be applied safely and efficiently in the field, it is recommended to go beyond the traditional occupational health and safety framework and adopt an integrated risk management approach.

Developing risk management capacity and raising awareness in this field in construction projects where 3d printing technology is applied is important in preventing possible project failures. On the other hand, it is thought that this situation may also be beneficial in ensuring the sustainability of sectoral transformation. At this point, studies on risk assessment are considered necessary for the efficient, safe and widespread adoption of new technologies.

Future studies should address the potential risks that 3d printing technology may encounter in different construction applications with a more comprehensive and multidisciplinary approach. In this context, it is thought that the development of integrated risk assessment models covering many different areas, such as occupational health and safety, structural integrity, production efficiency, cyber security and environmental impacts, will increase the applicability and efficiency of the technology. In addition, it is thought that it may be possible to increase the accuracy and effectiveness of existing risk analysis methods in decision-making processes through experimental research and risk modelling supported by field data. On the other hand, the development of the subject in the international literature can be supported by increasing the sharing of information on additive manufacturing technology with studies in which the applications carried out under different conditions are discussed comparatively.

Evaluation of energy-efficient passive design parameters in traditional Ayvalık houses

Sümeyye Sena Bastem*[1], Gül Koçlar Oral[1]

[1] *Istanbul Technical University, Department of Architecture, 34437 Istanbul, Türkiye*

Abstract. Since the 1970s, important steps have been taken to prevent climate change and reduce the effects of global warming on a global scale. In this context, the construction sector, which has a large share in energy use and carbon emissions, is also taking precautions and developing strategies. To promote sustainability on a global scale, various initiatives have been introduced to enhance the energy efficiency of both new and existing buildings. Considering that energy-efficient design parameters are also adopted in traditional structures, examining the construction techniques of these structures and applying them to current structures can significantly contribute to reducing energy consumption and carbon emissions.
Within the scope of the study, Traditional Ayvalık houses, which are preserved close to their original state and are still in use in Ayvalık, which is registered as a historical and natural site, were examined. Ayvalık district, located in the west of Turkey, is located in the temperate climate zone according to the TS825 standard. This study aims to examine the energy-efficient passive design parameters adopted in Traditional Ayvalık houses and to reveal the energy efficiency potential of these structures. Energy efficient passive design parameters were evaluated and explained in terms of settlement and orientation, building form, material use and construction techniques. Data collection, archive work, in-situ observation and physical examination methods were used in these evaluations. As a result of the study, passive design parameters adopted in traditional Ayvalık houses were presented. In addition, the advantages of using these parameters for new structures in similar climate zones were explained. Future studies that can be done to develop the study are listed.

Keywords: Sustainability; Energy efficient design; Passive design parameters; Traditional houses; Ayvalık houses.

1. Introduction

Industrialisation and population growth bring about important innovations in the construction sector in areas such as construction systems, material diversity, production, and planning. These innovations provide time, labour, and cost savings while causing an increase in energy consumption and carbon emissions. According to current data, approximately 40% of global energy consumption and one-third of carbon emissions originate from the building sector. To ensure sustainability on a global scale, energy-efficient approaches need to be implemented in new and existing structures. Therefore, considering that energy-efficient design parameters are adopted in traditional structures, examining the construction techniques of these structures and applying them to existing and current structures will contribute to reducing energy consumption and carbon emissions.

Historical buildings were constructed using energy-efficient systems that incorporated locally sourced materials and were specifically designed to respond to prevailing climatic conditions. A systematic analysis of these vernacular design approaches and their integration with contemporary technologies can provide insights for enhancing the energy performance of modern buildings.

This study examines Ayvalık houses, located in a temperate humid climate zone and registered as a historical and natural conservation site. Ayvalık, which began to develop in the mid-18th century, functioned as a port city predominantly inhabited by Greeks until the population exchange in the early 20th century. The density of registered heritage buildings, the use of local materials and the housing texture compatible with the climate make this region a unique case study in terms of energy efficiency.

In the literature review, it was found that studies were conducted in the field of architectural design and restoration regarding Ayvalık houses, examining plan typologies (Hayta, 2011; Tibet, 2013; Özker, 2020), façade features (Akın, 2015; Şaşkın, 2020) and façade elements (Efe, 2020). Additionally, studies have been conducted to document and analyse registered structures in the restoration area (Yıldırım Gönül, 2004; Uztuğ, 2006; Asımgil,

* Corresponding author, E-mail: ozdemirsu18@cde.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_209

2013; Çamkaya, 2023). However, it has been determined that there is no comprehensive study focusing on the energy efficiency of traditional Ayvalık houses built in their original texture and harmony with the climate. Although studies have been conducted on energy efficiency in traditional structures located in different climate zones, it is remarkable that no such study has been conducted in Ayvalık houses. In this context, the study aims to analyse the passive design principles adopted in traditional Ayvalık houses, to identify applicable variables for designing climate-responsive buildings, and to reveal the energy efficiency potential of these vernacular structures. In line with this goal, traditional stone houses located in the moderately humid climate region were analysed with data collection, archive work, on site observation and physical examination methods. The buildings were evaluated based on passive design criteria, including site layout and orientation, building form, spatial organisation, building envelope design, and material usage. Based on the findings, the passive energy efficiency strategies observed in traditional Ayvalık houses are presented, and their potential integration into contemporary architectural design processes is discussed.

2. Methodology

In this study, the field research method, a qualitative research approach, was employed. Ayvalık district was selected as the case study area in line with the research objectives. The high density of historical structures in Ayvalık, the fact that the structures are largely registered and preserved in a way close to their original state, were effective in this selection. Traditional Ayvalık houses built at different scales, with similar features and in harmony with the local climate, were examined within the scope of the study.

Data collection was carried out through archival and document analysis, on-site observations, and physical assessments. Historical data, architectural plans, registration documents, and previous restoration records were examined through archival and document review. Through on-site observations and physical assessments, façade characteristics, spatial organisations, structural elements, building materials, and their relationship with the surrounding environment were systematically examined and documented.

The data obtained were analysed within the framework of energy-efficient passive design principles. The buildings were evaluated according to criteria such as settlement layout and orientation, building form, spatial organisation, building envelope characteristics, material use, and construction techniques. As a result of the evaluation, it is aimed that the energy-efficient passive design strategies adopted in traditional Ayvalık houses will both contribute to the restoration processes of the structures and guide the designs of new houses to be built in similar climate regions.

This paper constitutes the initial phase of a long-term research study. The data collected in this phase will be used to assess the energy performance and carbon emissions of Ayvalık houses. Following the current condition analysis, improvement scenarios based on existing usage patterns will be developed, and the integration of active energy systems will be explored. Both passive and active design strategies will be assessed across various scenarios, and benefit analyses will be conducted to identify optimal solutions. Improvement strategies applied to different building typologies will be supported through deep learning algorithms. As a result, an energy-efficient decision support system will be developed to guide the restoration and adaptive reuse of traditional buildings. All phases of the study are illustrated in Fig. 1., with the current phases addressed in this paper highlighted.

2.1. Case Study

Ayvalık district of Balıkesir is located in the south of Edremit Gulf, opposite the island of Midilli, between bays and gulfs. The settlement is concentrated in low-slope coastal areas, while its surroundings are characterized by gently elevated hilly terrain. According to the TS 825:2024 standard titled Thermal Insulation Rules for Buildings, Ayvalık is located within the 3rd-degree day zone and is classified as a temperate climate zone (Fig.2.).

Following the migration of the Greek population in the 18th century, Ayvalık emerged as a significant commercial center. This period of development was also evident in the city's architectural development (Ozker, 2020), marked by an increase in religious buildings, educational institutions, and examples of civil architecture. The increasing population and urban expansion, particularly from the mid-1950s onward, further accelerated Ayvalık's development. To control urban growth and protect the existing architectural character, the High Council of Immovable Monuments and Antiquities declared Ayvalık a historical and natural conservation area in 1976 (ÇEKÜL Foundation, 2014).

Within the scope of this study, traditional houses located in the city center of Ayvalık—structures that have largely retained their original architectural features—were selected for analysis. The selection criteria included the registration status of the buildings, the preservation of original materials and structural characteristics, representation of different plan typologies, and their continued functional use today

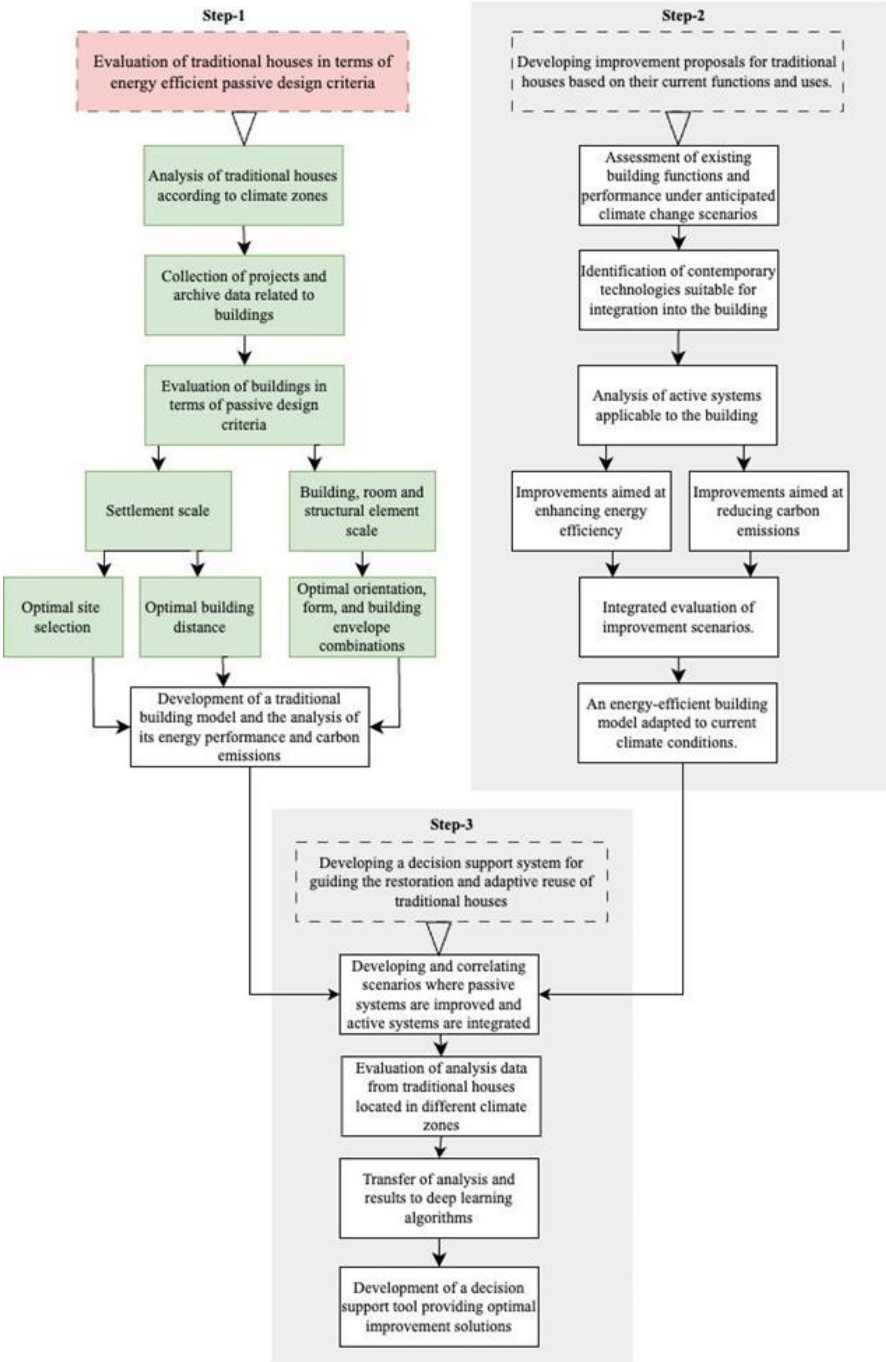

Fig. 1. Schematic representation of the study

2.2. Traditional Ayvalık Houses

Traditional Ayvalık houses, which played a significant role in shaping the historical urban pattern, are still in use today and meet a significant portion of the city's residential needs. These houses, typically arranged in a contiguous row typology, are characterized by their street-facing entrances and stone masonry construction, rising up to three stories, and they have back courtyards. Constructed by Greek craftsmen, these houses generally feature workshop or commercial spaces on the ground floor, while residential areas are located on the upper floors. One of the most distinctive architectural features inherited from the Greek period is the entrance design: doors are recessed within niches or iwans, opening directly to the street and typically accessed via two or three steps (Akın, 2015).

The spatial organisation of the streets and the layout of the dwellings reflect the prominence of neighbourhood interactions. Architectural elements such as bay windows 'cumba', balcony, and terrace projections contribute not only to social engagement between neighbours but also to natural ventilation and interior comfort. These characteristics feature the multifunctionality of Ayvalık houses, which historically served both residential and productive purposes while fostering social ties within the community.

Fig. 2. Degree day regions map of Turkey (TS 825:2024)

3. Passive Design Strategies in Traditional Ayvalık Houses

Under this heading, traditional Ayvalık houses were systematically examined with reference to energy-efficient passive design criteria. The analysis focused on parameters such as settlement area and building orientation, building form, spatial organization, building envelope, and material selection. This analysis sought to identify the relationship between the traditional housing fabric and energy-efficient principles.

3.1. Settlement Area and Orientation

The settlement of Ayvalık is concentrated along the coastline, in low-sloping areas. According to TS 825, Ayvalık is located within the third-degree day zone and classified as a temperate humid climate region. The dominant wind direction in the region is from the northeast. These northeasterly winds enhance thermal comfort during the summer months by providing a cooling effect. In addition, local breezes—such as the "meltem" winds caused by land-sea temperature differentials— contribute to the region's climatic comfort.

Fig. 3. The street pattern of traditional Ayvalık houses (Personal archive, 2015)

Fig. 4. Building heights and street widths (Personal archive, 2024)

The city's grid plan offers several environmental advantages, such as benefiting from the dominant winds and increasing sea access. Fig. 3 shows the grid system, the positioning of the buildings relative to the sea and the building blocks. Streets are narrow, effectively channelling airflow from the sea inland. Buildings are arranged close to one another, providing mutual shading and promoting air circulation.

This settlement organisation supports passive energy strategies by facilitating natural ventilation, providing solar control and contributing to thermal comfort at both the building and urban scales (Fig. 4). In this context, the settlement pattern and orientation of structures in Ayvalık exemplify climate-responsive urban design principles that are inherent in traditional settlements.

3.2. Building Form
Traditional Ayvalık houses are generally arranged in a contiguous layout, with their entrances positioned according to the street. These buildings are typically constructed with a maximum of three stories, adopting a typology characterised by 'cumba' and back courtyards, and are built using local stone materials. These houses are generally rectangular in plan and feature two façades—one facing the street and the other facing the back courtyard or garden. Windows and openings placed in alignment across opposing façades facilitate cross ventilation, thereby enhancing natural airflow and mitigating interior humidity. Architectural features such as balconies, terraces, overhangs, and notably bay windows of varying dimensions are prevalent. These elements not only foster social interaction within the urban pattern but also serve essential passive energy functions, including shading and ventilation. The overall architectural approach demonstrates an adaptive response to the temperate humid climatic conditions of the region while accommodating the socio-cultural practices of its inhabitants. As such, traditional Ayvalık houses exemplify vernacular architecture that successfully integrates user comfort with passive energy efficiency strategies.

3.3. Spatial Organisation
Traditional Ayvalık houses are typically two- or three-story structures, with one or two levels constructed above the ground floor. Based on their floor area, these houses can be classified into three categories: 40–50 m², 80–90 m², and over 120 m². One of the most distinctive architectural features inherited from the Greek influence is the design of the entrances—positioned within niches and iwans, opening directly onto the street, and accessed via two to three steps (Akın, 2009).

The ground floors are designed independently from the upper floors in terms of both function and spatial organization. The plan scheme is formed according to the formation of spaces on the upper floors and functional diversity on the ground floors. While the upper levels accommodate residential functions, ground floors were traditionally allocated for commercial or service-related uses, such as workshops, ateliers, or storage spaces. The absence of residential functions on the ground floor is due to its design for commercial activities.

In some cases, ground floors also include courtyards; however, due to the compact and contiguous building layout, courtyards are not present in every house (Yıldırım Gönül, 2004). Given that all traditional Ayvalık houses have a street-facing orientation, access to these courtyards is generally provided through the house.

Living areas are typically located on the first floor (Yıldırım Gönül, 2004). This floor, which is accessed via stairs leading from the ground level, typically contains two or three rooms. In accordance with traditional housing typology, there is no distinct room designated exclusively for the kitchen; instead, the kitchen is often integrated into the main living area. Many houses also feature internal doorways connecting adjacent rooms, facilitating movement and interaction between spaces.

Sleeping areas are usually situated on the second floor, which often includes enclosed projections such as bay windows that extend toward the street (Yıldırım Gönül, 2004). These architectural elements provide several advantages, including spatial expansion, enhanced views, and improved natural ventilation. At the same time, terraces are frequently used on this floor.

Fig. 5. Spatial organisation according to floor plans in Ayvalık houses Plan drawings (Ozker, 2020)

3.4. Building Envelope

The building envelope—including the roof, walls, floor, windows, and doors—constitutes the surface controlling heat transfer between indoor and outdoor environments. The thermal transmission occurring through these components influences both indoor air temperature and interior surface temperatures.

3.4.1 Walls

The ground-floor exterior walls of traditional Ayvalık houses are composed of load-bearing masonry stone walls, approximately 60–70 cm thick. The most commonly used material on this floor is a natural, volcanic-origin stone locally known as “sarımsak taşı” (sarımsak stone). In buildings where this material was not employed, rubble stone walls were constructed instead. Typically, walls were built with stone up to the level required to support wooden beams, while the uppermost courses were completed using brick (Efe, 2019).

In structures utilizing sarımsak stone, the exterior surfaces were often left unplastered and unpainted in order to preserve the natural appearance of the stone. In contrast, the rubble stone walls were generally plastered and painted on the exterior surfaces. On the upper floors, the material composition of the exterior walls changes. In some buildings, stone was continued through the first and second floors (Fig.6; a,b,c); however, in most cases—especially in projecting sections such as overhangs—the Bağdadi construction system was applied (Fig.6. d,e). Bağdadi walls were formed by filling a timber frame with brick infill and then plastering the surface (Efe, 2019; Çamkaya, 2023). Fig. 6 illustrates the exterior wall layers observed in traditional Ayvalık houses.

There is also observe variation in the interior wall construction depending on the floor level and construction period. On the ground floor, earlier examples often used the Bağdadi system for partition walls, whereas in later periods, the use of stone or solid brick became more widespread (Uztuğ, 2006). On the upper floors, interior partitions were typically constructed using the Bağdadi technique, with wall thicknesses ranging from 12 to 15 cm. Regardless of the material used, all interior wall surfaces were plastered to achieve a smooth surface.

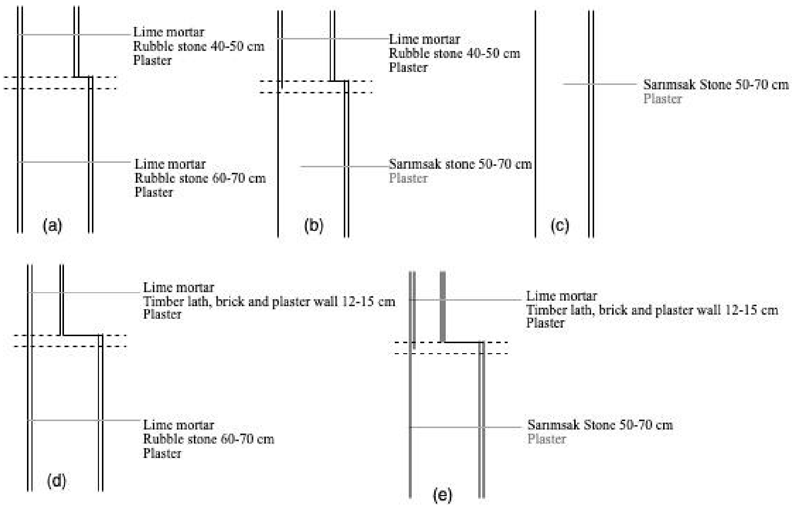

Fig. 6. Layers of walls in traditional Ayvalık houses (Created by the author)

3.4.2 Windows and Doors

In traditional Ayvalık houses, doors and windows are designed in response to climatic conditions. To address the challenges of the temperate humid climate, and to ensure adequate daylight and natural ventilation within the interior, window openings were designed to be relatively large, and storey heights were left high. These design strategies facilitated both air circulation and the entry of sufficient heat and light into the indoor environment (Akın, 2015).

Analysis of the size and positioning of the windows reveals that, on the ground floors, only small openings are typically placed on the street-facing façades. Also, small ventilation openings are located above the entrance doors. Ground-floor spaces are equipped with smaller windows compared to the upper floors, generally measuring approximately 70–80 cm in width and 130–140 cm in height (Çamkaya, 2023). By contrast, the upper-floor windows were designed in larger dimensions, ranging between 80–100 cm in width and 150–180 cm in height, with aspect ratios varying between 1:1.5 and 1:2 (Çamkaya, 2023). These wide upper-floor windows enhance ventilation during summer months and optimize solar heat and light gain in winter due to lower solar angles. Fig. 7 illustrates the ground-floor openings, the rectangular windows on the first and second floors, and the shutter serving as solar shading devices.

Windows and doors feature timber frames with single glazing. This system contributes positively to passive indoor climate regulation due to the limited occurrence of thermal bridging. In three-story buildings, timber shutters installed on the top-floor windows serve to control direct solar radiation and reduce indoor heat gain. Doors are generally situated within recessed iwans and are constructed as double-leaf timber joinery. Their dimensions range from 100 to 250 cm in width and from 220 to 350 cm in height (Efe, 2019).

Fig. 7. Building facades (Personal archive, 2024)

3.4.3 Roof

In traditional Ayvalık houses, the roof system consists of gable or hipped roofs constructed with wooden structural frameworks and covered with alaturka tiles (traditional material) (Uztuğ, 2006). The form of the roofs is significantly influenced by the contiguous row-house typology. The parapet walls separating the roofs of adjacent buildings were generally constructed using solid bricks (harman tuğlası) (Çamkaya, 2023). These elements served not only as a fire safety measure but also as a means of defining spatial boundaries between roofs. The use of alaturka tiles was particularly suited to the local climate. The air gaps between the overlapping tiles contributed both to waterproofing and to passive ventilation. The structural framework of the roofs consists of timber elements from locally sourced materials. The roof spaces formed by sloped roofs play a passive climatic role by reducing thermal load on upper floors during summer and minimizing heat loss in winter.

Additionally, the roofs were designed to collect rainwater. Rainwater collected on the roof is channeled through pipes 'künk' to cisterns located either on the ground floor or within the courtyard (Çamkaya, 2023). These cisterns store rainwater collected during the wet season, meeting household water needs throughout the year. Moreover, the thermal mass of the water within the cisterns contributes to maintaining indoor thermal comfort, helping keep interiors cool in summer and warm in winter (Efe, 2019).

3.5. Materials

In traditional Ayvalık houses, locally sourced and natural materials—primarily various timber species and volcanic stones from the region—were used extensively. Among these, a volcanic-origin stone known colloquially as sarımsak stone is particularly prominent (Efe, 2019). This stone was used both as a load-bearing material in wall construction and as a decorative element around building corners, window, and door frames. In addition to sarımsak stone, rubble stones were frequently used in masonry walls. In the construction of bay-windowed exterior walls and interior partition walls, a timber-frame (Bağdadi) system with brick infill (harman tuğlası) was commonly employed. The interior components of the buildings were also predominantly crafted from timber. Stairs, built-in cabinets (yüklük), closets, door and window frames, and shutters were all made from timber (Çamkaya, 2023). The primary load-bearing floor beams were also wooden—typically made from cypress—and measured approximately 25–30 cm in width. In addition to the main structural materials, natural binders such as earth mortar, lime mortar, and clay were used both as binding agents in masonry and as plaster coatings.

Furthermore, wrought iron elements (ferforje) are commonly observed on building façades. Although originally installed for security purposes, their fine craftsmanship elevated them into significant aesthetic features, particularly when used on doors, windows, bay windows (cumba), and balcony railings.

4. Results

The study systematically presents the energy-efficient design strategies in traditional Ayvalık houses. The passive design criteria identified in these structures are compiled and summarised in a schematic table (Fig. 8).

Settlement Area		In temperate humid climate regions, settlements are typically located on sloped terrains. However, in Ayvalık houses, the settlement is situated on flat coastal land. This configuration has been shaped by the topographical characteristics of Ayvalık and the socio-cultural needs of its users.
Distance between Buildings	 (Moutsopoulos, 1974)	In the traditional houses of Ayvalık, narrow streets were designed to obstacles to solar irradiation, thereby creating shaded outdoor spaces. Additionally, these narrow street patterns facilitated the channelling and velocity of wind flow, contributing to improved microclimatic comfort within the urban fabric.
Building Form		In temperate humid climate regions, typically characterised by expansive surfaces oriented toward prevailing winds and featuring rectangular or irregular plan forms. Traditional Ayvalık houses, however, are arranged in rows with openings predominantly located on their narrow façades. Architectural elements such as 'cumba' and balconies provide natural air flow to the structure.
Natural Ventilation		To reduce the adverse effects of humidity in traditional Ayvalık houses, natural ventilation strategies were employed. Large, opposing windows were incorporated to facilitate cross-ventilation, while architectural elements such as 'cumba' and balconies enhanced airflow by directing prevailing winds into the interior spaces. The roofs were designed with a pitched form and covered with clay tiles, which contributed to passive ventilation through the air gaps between the tiles.
Building Envelop		The structural components of traditional Ayvalık houses are composed of natural materials, and their combination in forming the building envelope is well-adapted to the local climatic conditions. In ground flooring, the use of stone walls and enhanced structural durability contributes to thermal comfort by maintaining interior coolness. In some cases, 'baghdadi' (timber frame infill) wall systems were utilised on upper floors and stone walls were applied in some buildings. The materials used for roofing and window openings were also found to be compatible with the region's climatic requirements.
Sunlight Control		Traditional Ayvalık houses benefit from controlled solar irradiation due to the narrow layout of their streets. Additionally, timber shading elements have been incorporated into some buildings to prevent direct sunlight from entering interior living spaces.
Water Management	 A view of the pipes coming from the roof on the wall.	In traditional Ayvalık houses, rainwater is collected and stored by transferring it to cisterns located on the ground floor or in the atrium with pipes.
Fire Safety		Due to the row-house configuration of traditional Ayvalık houses, brick firewalls are constructed between adjacent units to enhance fire safety and prevent the spread of fire between structures.

Fig.8. Passive design features of traditional Ayvalık houses

5. Conclusions

The spatial organization, material usage, and construction techniques of traditional houses are shaped by the geographic characteristics, climate conditions, and socio-cultural structure of their respective regions. In this context, traditional Ayvalık houses exemplify climate-responsive architecture, where passive design principles have enabled the construction of environmentally adapted buildings that enhance user comfort.

This study presents a systematic evaluation of traditional Ayvalık houses in terms of energy-efficient passive design criteria. The assessment framework includes settlement area, building orientation, building form, spatial organization, building envelope, and material usage. The analysis revealed that narrow streets were deliberately formed to benefit from natural ventilation and limit solar radiation. Building orientation was aligned with prevailing wind and sunlight conditions. The rectangular building forms reflect adaptation to the temperate humid climate. Moreover, overhangs and cumba elements were observed to reduce the impact of high humidity. An examination of plan typologies indicates a frequent use of open spaces such as courtyards, balconies, and terraces. The functional organization typically places workspaces on the ground floor, living areas on the first floor, and bedrooms on the second floor. While this arrangement is largely driven by social customs, locating living spaces on the middle floor also contributes positively to thermal comfort.

The evaluation of the building envelope shows that wall layers are designed to suitable climatic conditions and minimize heating and cooling loads. The size and placement of window openings promote natural airflow, while pitched roofs provide summer cooling and reduce heat loss in winter. The use of local and natural materials is crucial for minimizing carbon emissions. Stone masonry on the ground floor enhances structural stability, regulates humidity, and contributes to thermal comfort. The upper floors often employ the Bağdadi wall system, which reduces structural weight and supports natural ventilation and humidity control. Timber-framed windows and floor systems offer low thermal conductivity and partial permeability, enhancing both insulation and ventilation.

The study demonstrates that traditional Ayvalık houses with passive design principles reflect an inherently energy-efficient design approach. However, contemporary architectural practices often fail to integrate such climate- and environment-sensitive parameters. Incorporating the passive strategies used in traditional Ayvalık houses into modern design processes offers valuable opportunities to improve energy efficiency and reduce carbon emissions. Decisions at the settlement scale that enable natural ventilation, choices related to building form, material selection, and the layered structure of the building envelope can play a significant role in reducing heating and cooling demands. In particular, designing climate-adaptive building envelopes can substantially enhance overall energy performance.

This study provides a systematic evaluation of energy-efficient passive design strategies in traditional Ayvalık houses. Investigating these buildings, many of which are registered and well-preserved, establishes a foundation for future research in the field of energy performance in vernacular architecture. Moreover, the study offers passive design recommendations that can inform both the evaluation of traditional buildings in similar climate zones and the enhancement of energy efficiency in contemporary building design.

To expand and improve upon this research, the following future work is proposed:

- Experimental studies can be conducted to determine the physical properties of the traditional materials used in Ayvalık houses. These studies can generate reference data for use in building energy simulations by identifying the materials' optical and thermophysical properties.
- While this study has compiled the passive design principles observed in traditional Ayvalık houses, further work can investigate the integration of passive and active systems based on current building functions and usage needs.
- Energy-efficient retrofit scenarios developed for traditional houses can be supported and promoted in restoration and implementation processes.
- Carbon emission analyses can be conducted on traditional buildings in use, with improvement proposals developed to reduce emissions.
- Simulation-based studies can explore how energy-efficient approaches derived from traditional houses can be adapted to contemporary buildings.
- The potential performance of traditional buildings under future climate change scenarios can be analyzed, and climate adaptation strategies can be developed accordingly.

In conclusion, this study on the energy efficiency of traditional houses provides a reference not only for researchers in building physics but also for those working in restoration, materials science, architectural design, and practice.

Abstract. Tiny houses have emerged as a potential, environmentally friendly housing solution to mitigate the unsustainable impacts of the residential sector. Their popularity has increased significantly, especially during the COVID-19 pandemic. With their growing appeal, the building performance, sustainability, and circularity of various materials in tiny houses are worth to be search. This study focuses on the performance characteristics of the most commonly used architectural materials in tiny house models, steel and timber, to assess the relations with CO_2 emission, energy use, and circularity. A prototype tiny house, located in a temperate climate zone (Mersin, Turkiye), is modelled in Autodesk Revit using steel and timber material configurations for walls, floors, and ceilings. The energy consumption and carbon emission of these two cases are analyzed using Autodesk Insight in conjunction with Revit software. For the circularity evaluation of the cases, the Material Circularity Indicator (MCI) tool is used. The findings reveal that using timber for wall, floor, and ceiling elements in tiny houses has better embodied carbon emissions than steel. The embodied carbon emissions of a steel-based tiny house exceed those of a timber-based counterpart by 30%. However, from the circularity perspective, steel has a higher circularity index with an 82% ratio than timber with 52%. Consequently, the environmentally friendly buildings are not only related to carbon emissions or energy consumption but also related to waste disposal reduction and, accordingly, circularity.

Keywords: Tiny houses; Circularity; Carbon emission; Energy use; MCI.

1. Introduction

In the late 1990s in the United States, due to housing affordability issues and a desire to live more sustainably, the tiny house movement emerged by building very small homes (Shearer et al., 2018). The idea behind this movement is mainly to cope with economic challenges and to reduce the consumption of natural resources to be sustainable and energy efficient (Saleem et al., 2021). The 'tiny house' or 'tiny home' is defined as a small dwelling unit less than 37 m^2 that is either permanent or relocatable by the 2018 International Residential Code (IRC) (Kuittinen et al., 2023). A typical tiny house layout features a compact kitchen, a bathroom, a combined living and working area, and a sleeping space, with very limited storage capacity. Vaulted ceilings are often used to maximize vertical space, and sleeping lofts are commonly incorporated into the design (Mukhopadhyay, 2020).

There are many benefits to living in a tiny house and reducing the size of the living space. One of the biggest benefits of living in a tiny house is the reduction of the carbon footprint (Wu and Hyatt, 2016). Although in Boeckermann et al.'s (2019) questionnaire study, the most distinct reason to live in a tiny house is seen as affordability, the environmental impact of tiny houses is another important key driver (Kuittinen et al., 2023).

Buildings consume over 40% of global energy, generate 36% of all carbon dioxide (CO_2) emissions, and 28% of greenhouse gas emissions (Rauf et al., 2022). Even though significant improvements in energy efficiency have been achieved in recent decades, population growth (supposed to grow by 29% until 2050) and the increasing need for residential areas cause a rise in energy demand (Crawford and Stephan, 2020). The energy demand and greenhouse gas emissions are influentially related and so, high energy use causes unfavorable environmental impacts (Jin and Kim, 2018; Sabobeh et al., 2024). In this regard, the studies (Carlin, 2014; Kilman, 2016; Crawford and Stephan, 2020; Sabobeh et al., 2024) claim that tiny houses reduce the material demands, create a lower environmental impact in terms of resources and production process. Unlike traditional residences, tiny houses consume less energy for heating, cooling, and lighting. Yet, the selection of the building materials plays a crucial role in evaluating a buildings' environmental impacts (Dipasquale et al., 2025). In other words, the materials

* Corresponding author, E-mail: damlanurilipinar@karabuk.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_210

used in the design of tiny houses affect the carbon emissions and energy use. Commonly used material for these houses is wood. However, owing to some advantages like being lighter, fire-resistant, etc., steel is also used for the tiny houses.

Among sustainability approaches, circular economy (CE) has attracted great attention in recent years and this interest has significantly influenced design processes, especially with circularity-focused approaches (Ruiz-Pastor et al.,2024). The primary goal of evaluating the circularity of products is to aid decision-making by offering insights regarding the products and their life stages (Bragança et al., 2010). Additionally, the assessment needs to be coherent, comprehensive, and objective (Mesa et al., 2018; Ruiz-Pastor et al.,2024). The primary additive of the circular economy is made "sustainability more likely" by separating economic development and resource consumption (van den Berg, 2019). On one hand, adopting circular economy (CE) practices is increasingly recognized as contributing to sustainable development goals (Schroeder et al., 2019). On the other hand, circular economy and sustainable development are not systematically synonymous because the recycling process can create new challenges for overall environmental impacts, while it is one of the main opportunities in circularity. However, to understand the relation of circularity and sustainability still needs further research (Schroeder et al., 2019).

In this regard, the aim of this study is to investigate the triple relation between carbon emissions, energy use, and circularity through a tiny house. The objectives of the research are (i) to compare the carbon emission and used energy intensity differences of timber and steel wall, floor, and ceiling elements in tiny houses, (ii) to calculate the circularity index of timber and steel materials wall, floor, and ceiling elements in tiny houses, and (iii) search the environmental impacts of CE work toward sustainability.

2. Materials and Method

In this research, a tiny house with two alternatives, timber-based and steel-based, is modelled in Autodesk Revit as a case study. The tiny house has a floor area of 18,85 m^2 and a loft area of 4,5 m^2, including open living space with a kitchenette, a bathroom, and a loft that serves as a sleeping space, and a closet. The height of the highest point of the house is 4.20 meters, and the height of the lowest point is 2.70 meters. The plan layout and 3D view of the tiny house are illustrated in Fig. 1. The first alternative model is built from wood and has a wooden joist for the floor and ceiling. The wall frames are created with C16 timber stud (75x125 mm) and covered with wood-based MDF material. The second alternative model is made from steel material. For ceiling and floor elements are designed with steel joists. The wall frames are formed with steel studs and covered with gypsum board. The material details in two alternatives are seen in Fig. 2.

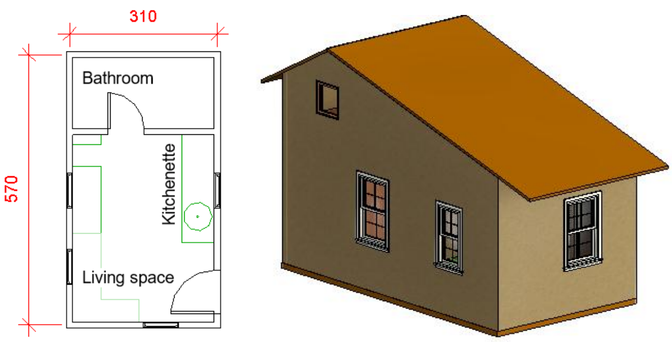

Fig. 1. Tiny house case study floor plan and 3D view

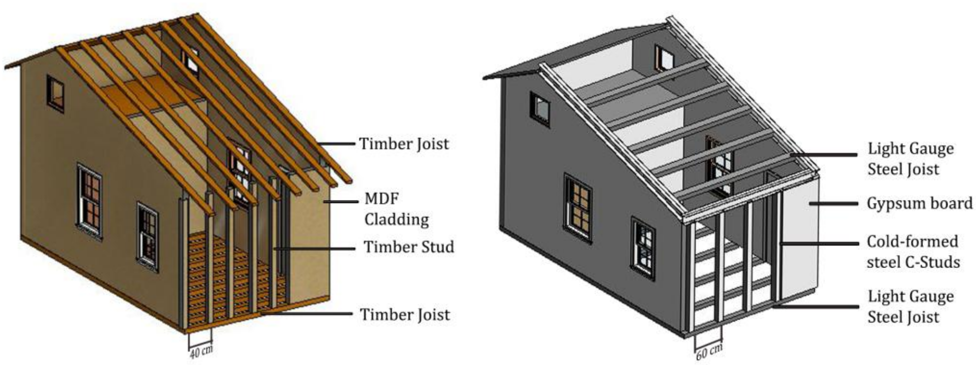

Fig. 2. Two alternatives with timber and steel material-based tiny houses

In the light of the scope of the study, the embodied carbon, operational carbon, energy used and circularity ratios for timber and steel tiny houses are calculated. In light of the scope of the study, the embodied carbon, operational carbon, energy used, and circularity ratios for timber and steel tiny houses are calculated. The tools used are explained in the following sections.

2.1. Carbon Emissions and Energy Use Intensity Calculations in Next Gen Insight

Assessing the carbon impacts of timber and steel tiny houses, two alternatives are simulated by utilizing Autodesk Insight. The scope of Insight covers the envelope and interiors subset of architectural elements based on the data included in the Energy Analytical Model. Therefore, the walls, ceiling, and floor elements are the focus of this research. Moreover, embodied carbon emission calculation in Insight comprises only the manufacturing stage (A1-A3) while the operational carbon emissions include operational energy (B6). Hence, the embodied carbon in this study refers only to the manufacturing stage, and operational carbon represents the operational energy phase.

Insight is a cloud-based tool that connects with Revit, providing users with flexible dashboards, an intuitive interface, and an easy analysis approach. The interface of Insight makes it more practical to explore, visualize, and compare carbon analysis results. It relies on Revit's Energy Analytical Model as its foundation for Operational (OC) and Embodied Carbon (EC) analysis. Insight uses the stored data in Revit, like building envelope performance, material specifications, etc., and more to illustrate the relation between carbon impacts and energy offsets (Insight Product Team, 2024).

The Revit Energy Analytical Model offers a reliable foundation for evaluating both Embodied and Operational carbon analyses. The Embodied Carbon analysis in Insight leverages data from Building Transparency's EC3 database regarding material Embodied Carbon and provides the option to modify these defaults or incorporate specific EC definitions. For Operational Carbon, Insight uses EnergyPlus, an extensively used open-source simulation engine for energy analyses. This engine is developed by the US Department of Energy (DOE), managed by the National Renewable Energy Laboratory (NREL), and applied worldwide for dynamic energy simulations (Insight Product Team, 2024).

2.2. Circularity Calculations in Material Circularity Indicator (MCI) Tool

For the evaluation of the circularity indexes of timber and steel tiny houses, Material Circularity Indicator (MCI) tool is used in this study. The Material Circularity Indicator (MCI) is a free Excel tool that measures the circularity of a product's material flow. The MCI is one of the circularity metrics that meets the guidelines of the new ISO 59020 standard for 'Circularity Metrics'. Circularity metrics provide a superior assessment compared to solely depending on recycling rates, as they encompass all methods of attaining circularity, including consumption avoidance, durability enhancement, reuse, remanufacturing, bio-based products, and composting.

The MCI tool can be used to evaluate and compare the 'circularity' scores of individual goods and product portfolios. The MCI quantifies the circularity of a product, namely the extent to which it has separated from the use of non-renewable resources and the generation of unrecoverable trash. The calculator assesses a product's circularity using the modified 2024 MCI methodology, delivering a score ranging from 0 to 100%. A score of 0 implies a standard linear model based on consumption and disposal. A 100% score, on the other hand, represents a fully circular strategy in which the product avoids the use of nonrenewable resources and eliminates waste entirely (URL-1, 2025).

3. Results and Discussion

In this section, the quantitative results are generated and interpreted to assess the sustainable performance of products from a circularity perspective. First, the carbon footprints of tiny houses are calculated in Insight. Second, the circularity ratio of them is computed. Finally, the results are compared and used to try to solve the relationship between carbon emissions and circularity.

As a first step of the study, carbon emission calculations are carried out. Before simulating the carbon emissions in Insight, some necessary parameters should be specified in the energy settings in the Revit interface because Insight uses data in the energy analytical model. Under the advanced energy setting tab in Revit, building function is selected as single house, building operating schedule is set 24/7, HVAC system is arranged Central VAV, HW Heat, Chiller 5.96 COP, Boilers 84.5 eff. The geographic location of the project should also be clarified before the analysis. In this study, Mersin is selected as the location of the tiny houses. Then, an analytical model is generated and uploaded to the Insight. The model is analysed in the cloud for key sustainability and performance aspects of the houses. The results are seen in the cloud web page. The outputs from the analysis are shown comparatively for timber and steel tiny houses in Fig. 3.

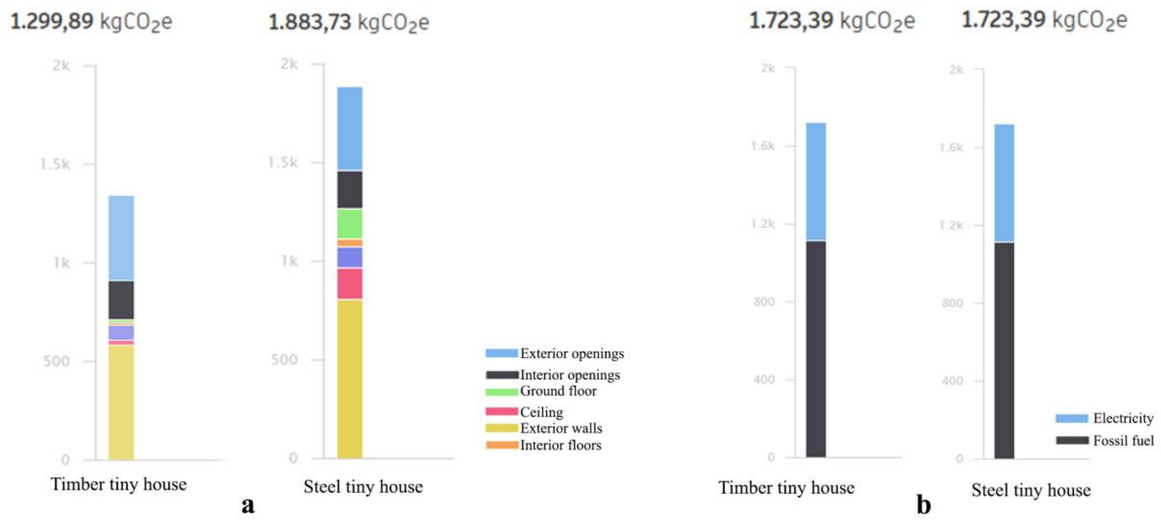

Fig. 3. (**a**) Embodied carbon emissions and (**b**) operational carbon emissions of timber and steel tiny houses

According to the calculation results, timber-based tiny house has lower embodied carbon emission with 1299,89 kgCO2e, while steel-based tiny house has 1883,72 kgCO2e embodied carbon emission. The operational energy of tiny represents their total energy demand to operate building systems, determined through analysis of fossil fuel types and electricity data. Therefore, operational energy is not related to the type of materials used for the building elements. Thus, the operational energy of the two alternatives, which are exactly the same each other except for building materials, is observed to have the same value. Accordingly, annual energy use intensity, an indicator of the energy efficiency of a building's design and/or operations, should be the same for the two alternatives. The energy consumption of these houses is 274,79 kWh/m², which represents the amount of total energy used in one year divided by the building area. When considering the amount of energy for individual heating is 311 kWh/m2 in Turkey's capital Ankara (Ucal and Günay, 2021), the energy use of tiny houses for heating, cooling, and electricity is considered reasonable.

The second step of the study is getting the circularity ratios of the two alternatives. For the calculation, selected material types and their used amounts are taken into consideration. The quantity and mass of each component are specified. The source of the materials for each component is added under the resource inflow. In this tool, the source of the materials can be chosen as virgin, recycled, remanufactured, or reused. In this study, the source of each material is designated as virgin. Besides, it is indicated how many functional units the components deliver over their life versus the industry average. Here, the industry average is '1' while the steel elements are defined as '6', and timber elements are '2'. Then, for the circularity calculation, the end-of-use conditions of each product should be clarified. For the steel alternative, resource outflow is defined as reuse, and for the timber alternative, it is defined as recycling. According to these inputs, the calculator tool gives the circularity results seen in Table 1. This table includes inputs provided by users and outputs, highlighted in the table, generated by the calculator tool. The tool gives the circularity index result between 0 and 1, circularity index percentage between 0% and 100%, also produces circular mass and linear mass results.

Table 1. Circularity results of timber and steel tiny houses generated in MCI tool

	Component Name	Mass Each	Quantity	Resource Inflows			Utility Unit		Utility Function	Resource Outflows				Comprised of				Circular Mass	Linear Mass
		Kilograms		Material Type	Source	Utility Based on	U	U(av)		Collection Rate	Destination	(0-1) MCI	% MCI	Raw material Decoupling	Waste Decoupling	Enhanced Utility	Circularity Gap	kg	kg
STEEL TINY HOUSE	Cold Formed Steel C-stud	3,78	30	Steel	Virgin	Utility	6	1	6	100%	Reuse	0,93	91,7%	0%	50%	41,70%	8,3%	98,82	8,98

TIMBER TINY HOUSE	Timber Stud Wall Frame	1027,18	1	Timber	Virgin	Utility	2	1	2	100%	Recycle	0,57	52,50%	0%	5%	47,50%	47,5%	539,27	487,91
	Timber Floor Joist	397,82	1	Timber	Virgin	Utility	2	1	2	100%	Recycle	0,57	52,50%	0%	5%	47,50%	47,5%	208,86	188,96
	Timber Ceiling Joist	477,36	1	Timber	Virgin	Utility	2	1	2	100%	Recycle	0,57	52,50%	0%	5%	47,50%	47,5%	250,61	226,75
	Internal MDF Cladding	6,7	50	MDF	Virgin	Utility	2	1	2	100%	Recycle	0,55	50%	0%	0%	50%	50%	167,5	167,5
	External MDF Cladding	6,7	50	MDF	Virgin	Utility	2	1	2	100%	Recycle	0,55	50%	0%	0%	50%	50%	167,5	167,5

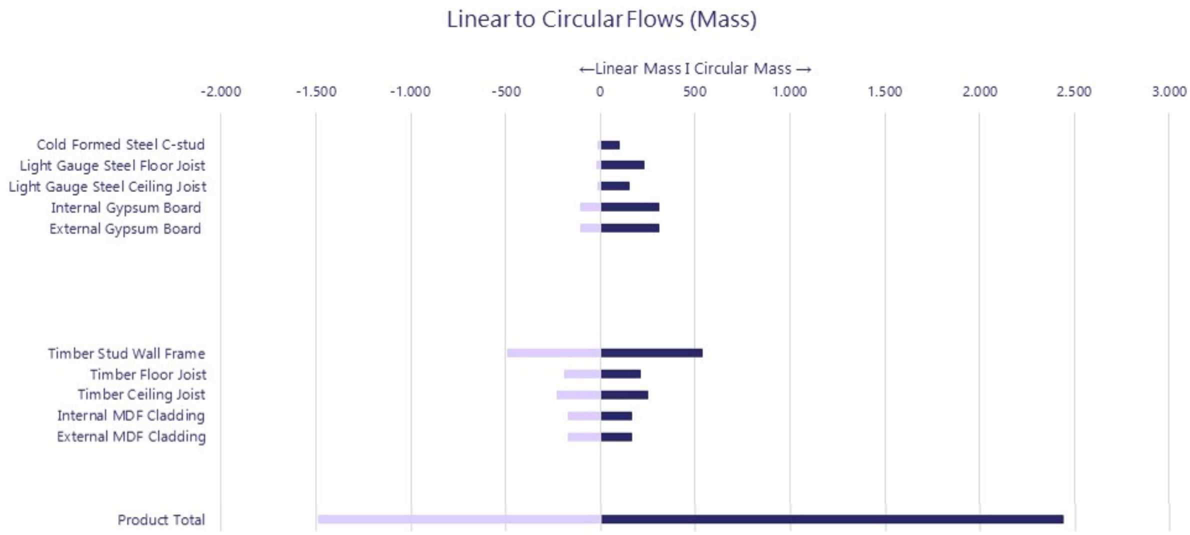

Fig. 4. Circular and linear mass distribution of the component, illustrating the proportion of mass considered circular based on total mass and circularity percentage

The circularity results demonstrated that the steel material tends to be more circular than timber. When compared to the linear and circular mass of the two alternatives, parallel to the circularity ratio, the circular mass of steel is higher than timber, as shown in Fig. 4. The circularity ratio strongly depends on the utility factors in the calculation. In the MCI tool, utility can also be chosen as lifetime, mass, lifetime &mass, utility &mass. In this study, it is defined as utility. Additionally, destination decisions, like reuse, recycle, compost, landfill, etc., and their rates affect the result of circularity. In this study, the destination decision for steel elements is defined as reuse with 100%, while for timber, it is recycling with 100%. In this regard, while steel is compared to timber, steel's strength-to-weight ratio is up to seven times greater, reducing the load on foundations. This efficiency leads to faster, more cost-effective construction. Steel can be reused repeatedly without losing integrity, and it is easy to disassemble steel frames. It is resistant to moisture-related problems and so does not require maintenance in a short period (Hradil et al., 2014).

As a result of the calculations, the circularity ratio of the steel tiny house is 81,5%, and the circularity ratio of the timber tiny house is 51,8%. From the perspective of the embodied carbon emissions releases, the timber tiny house has 30% less carbon emissions than the steel tiny house. At this point, only circularity or embodied carbon emission is not enough to say that one of the tiny steel or timber houses is the best option. The following Fig. (Fig. 5) provided by the MCI calculator helps to define components that you may want to prioritise for enhanced circularity due to their environmental footprint. Thus, the relation between circularity and carbon footprint can be interpreted.

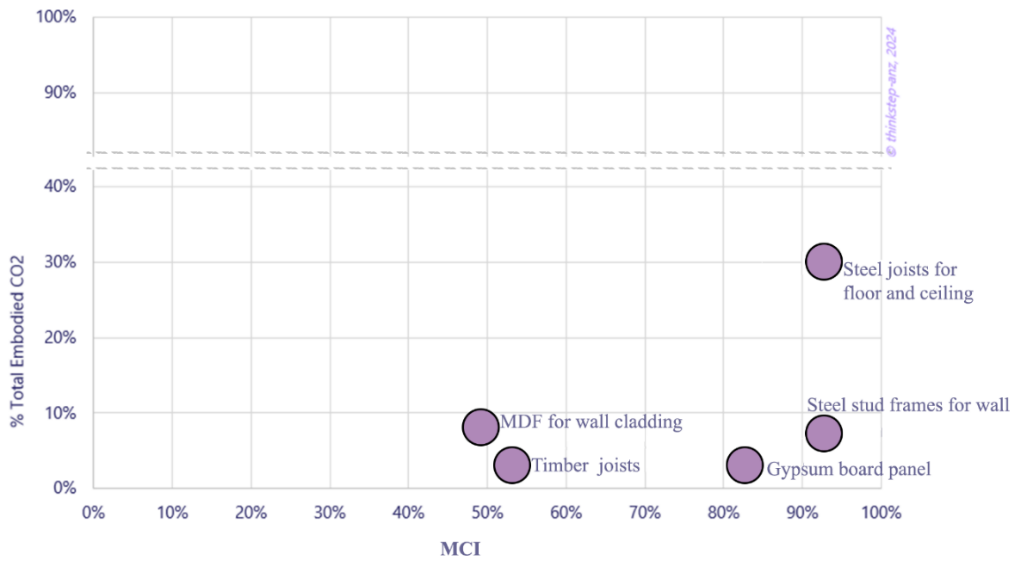

Fig. 5. % Circularity vs % Embodied CO_2 for timber and steel elements

4. Conclusions

Tiny houses are defined as affordable and environmentally friendly alternatives for the built environment, but the variety of materials used to produce these houses creates confusion and uncertainty. Although the dominant materials are seen as timber in the industry, steel also has a high usage ratio for the modular and tiny houses sector. In this regard, this study investigates the carbon footprint and circularity relations from the perspective of the environmental impact through a timber and steel tiny houses case project.

When the calculation results are evaluated directly, the embodied carbon of a tiny steel house is 30% more than tiny timber house. As a rapid evaluation, timber can be thought of as more logical to use for the sustainability goals. On the other hand, when examining the circularity results, the circularity ratio of the elements of the steel tiny house is 82%, while the circularity of the timber alternative is 52%. Moreover, considering the reuse potential of steel frames, steel can be evaluated as a more sustainable alternative than a timber house due to the reduction of waste generation and decrease in the use of raw materials. Consequently, sustainability has many inflows, and they show that there are additional factors for industry and owners to evaluate the environmental impacts of the housing design. As a result, this study does not provide a certain decision for the selection of material for tiny houses, as it can not be said that a timber tiny house or a steel tiny house is a preferable option for sustainable design. The embodied carbon of the steel tiny house is higher than timber, but maybe the environmental impact of the steel option can be balanced with the reuse of 5 or 6 times in its lifecycle. Ultimately, a truly comprehensive life cycle assessment should adopt a holistic perspective—one that not only considers the material production phase but also evaluates the potential for reuse, multiple life cycles, and recyclability beyond the initial end-of-life. Such an approach is essential for accurately assessing the long-term environmental performance of all types of buildings.

A limitation of this study can be specified that the operational carbon emission amounts and energy intensity used in the two alternatives are the same. For this reason, the operational energy cannot be an active input for the assessment of the environmental impacts of steel and timber tiny houses.

Abstract.
Today's environmental problems and limited natural resources have led the building sector to adopt more sustainable approaches. Sustainable buildings reduce energy and resource use, minimize environmental impacts and provide healthy living spaces for users. These buildings provide both environmental and economic benefits.

For this reason, it is of great importance to adopt sustainability principles in the building sector. Sustainability in the building industry can be achieved by selceting the right building materials and documenting them with green building certificates. By determining the criteria for the selection of building materials, it is possible to create user and environmentally friendly, long-lasting buildings. Buildings are certified and scored in many categories by green building certification systems. When these elements are considered together, it becomes possible to produce environmentally sensitive and efficient buildings.

In this study, the Haut Amsterdam building, which is certified as a green building and produced in line with sustainability targets, was examined in terms of its architecture, sustainable features and building material selection. It is aimed to evaluate the contribution of life cycle planning in the building and the use of building information modeling, and to evaluate the wood composite and aluminium materials used within the framework of building material selection criteria.

Keywords: Building Material Selection, Green Building Certification Systems, Building Life Cycle Assessment, Sustainability, Timber-Concrete Composite.

---

1. Introduction

Today, sustainability-oriented approaches in the building industry have gained great importance both environmentally and functionally. Achieving sustainability goals in the building industry requires a holistic approach to building material selection criteria and green building certification systems. While the selection of the right building materials ensures that buildings have long-lasting, functional, environmentally friendly and economical features, the compliance of the selected materials with sustainability standards is documented through green building certificates. Green building certification systems aim to reduce the environmental impact of buildings based on criteria such as energy efficiency, material recycling and waste management. The integration of building material selection and green building certificates contributes to supporting building production processes that minimize environmental impacts and provide social benefits in the long term.

The choice of building material in buildings directly affects the building, the user and the environment. When making a choice, building materials should be selected that will increase building/user comfort, have a long service life, contribute to energy efficiency, are functional, can be integrated with the design and do not adversely affect human health and the environment with their life cycle (Sahlol et al., 2021). For this reason, it is aimed to select the most suitable option by creating various criteria in the selection of building materials, filtering and comparing according to the desired features.

The aim of this study is to determine the criteria to be considered in the selection of building materials in line with the principles of sustainable building design and to evaluate the building materials used in line with these criteria. In this context, the original materials used in the "Haut Amsterdam" building were evaluated and compared with common alternative building materials that can perform the same function within the scope of fire resistance, sound insulation, harmlessness to the environment and health, lightness, aesthetics, sustainability, ease of installation, long life and recyclability criteria. The evaluation of building materials was carried out using three

https://doi.org/10.31462/icearc2025_a_aen_274

different methods within the scope of Multi Criteria Decision Making- Line Graph Comparison method, Arıoğlu method and TOPSIS multi-criteria decision making method.

2. Building Material Selection Methods

The selection of building materials is a complex process that requires consideration of numerous criteria, including sustainability, cost, durability, and environmental impacts. To ensure that this process is managed in a systematic and objective manner, various selection methods have been developed. Some or all of these methods may be used (Balanlı, 1997). Some of these methods are summarized below.

The "Multiplicative Scheme" method proposed by Olssan and Perning enables the comparison of building materials evaluated from technical, structural, and economic perspectives and the elimination of options. In this method, each material type is scored using a multiplication factor based on its ability to meet the defined criteria, thereby supporting the selection process (Balanlı, 1997).

The "Hillerborg" is a method of analyzing products according to performance criteria and determining the most suitable option in terms of cost and quality. In this method, building material properties are defined and weighted. The quality values and costs of the options are calculated, and the data obtained is evaluated to determine the most suitable option (Balanlı, 1997).

The "Arıoğlu" method is a systematic, step-by-step decision-making method that manages the building material selection process. In this method, the following are determined in order: system level of expansion, environmental factors, functional requirements, objectives and constraints, material properties, and criteria. Options are identified by organizing material information. The identified options are evaluated, compared, and selected. Finally, a suitability check is performed (Kokulu, 2016).

The Multi-Criteria Decision Making method is an analysis technique that aims to systematically determine the most beneficial decision by evaluating multiple options based on technical, economic, environmental, and social criteria. In the preliminary evaluation stages and in situations requiring quick decision-making, the "Line Graph Comparison" method can also be used to score and perform a qualitative comparison (Belton & Stewart 2002).

In a study examining the most widely used methods within multi-criteria decision-making methods in the literature, the most commonly used methods were observed to be the "Technique for Order Preference by Similarity to Ideal Solution" (TOPSIS), "VlseKriterijumska Optimizacija I Kompromisno Resenje" (Multicriteria Optimization and Compromise Solution (VIKOR)), "Analytic Hierarchy Process" (AHP), and "Complex Proportional Assessment of Alternatives Under Grey Environment" (COPRAS-G) mathematical models (Beltrán & Martínez-Gómez, 2019; Bajwa et al., 2025). The "TOPSIS" method ranks alternatives by identifying the ones closest to and farthest from the ideal solution. It is an effective method for evaluating the performance data of physical and mechanical properties of building materials. "VIKOR" aims to find compromise solutions in multi-criteria decision-making problems. When evaluating alternative building materials, it aims to produce a solution that is closest to the best but also balanced and compromising in the decision-making process. AHP ensures the hierarchical structuring of criteria and sub-criteria in the decision-making process. This method is generally used in material selection to compare alternatives by weighting criteria. "COPRAS-G" is a method integrated with gray system theory, used to evaluate material alternatives in situations where data is unclear and there is uncertainty based on estimates (e.g., environmental impact, recycling potential, etc.).

3. Material Selection Criteria Evaluated within the Scope of Green Building Certification Systems

Green building certifications are systems used to measure and improve the environmental impact of buildings. They focus on criteria such as energy efficiency, water conservation, indoor air quality, material selection, and waste management in buildings. These certifications promote the sustainability of buildings, encourage their design and operation in an environmentally conscious manner, while also aiming to contribute to user health and reduce operational costs. Building Research Establishment Environmental Assessment Method (BREEAM), Leadership in Energy and Environmental Design (LEED), and Deutsche Gesellschaft für Nachhaltiges Bauen (DGNB) are widely used green building certifications worldwide. Green building certifications also provide various criteria for material selection.

The criteria outlined in these certifications are designed to reduce a building's environmental impact and enhance user comfort. In green building certification systems, the following criteria are emphasized: preferring materials with a high recycled content, locally sourced materials, and materials with a low carbon footprint; ensuring transparency through Environmental Product Declarations (EPD) for selected building materials; selecting products with low volatile organic compound (VOC) emissions for health and safety; products that do not pose a threat to user health and are free from toxic substances, and selecting building materials that are durable, easy to maintain and repair, and have a longer lifespan, thereby reducing resource use throughout the building's life cycle, are key considerations in building material selection (Deutsche Gesellschaft für Nachhaltiges Bauen, 2018; BREEAM, 2024; U.S. Green Building Council, 2025).

The LEED system evaluates material selection under the Materials and Resources (MR) category. This category accounts for 14 points out of the total 100 points in the LEED assessment. Materials used should be selected to minimize environmental impacts. In the Materials and Resources category, points are awarded based on the LCA impact, EPD sharing, health hazard status of material components, recycled content ratio, use of local materials, and use of materials produced from renewable sources (U.S. Green Building Council, 2025).

The DGNB system evaluates materials under the “Environmental Quality” heading. This category accounts for 40% of the evaluation. The Life Cycle Assessment (LCA) impact of building materials is important. It evaluates and scores the material's resource use, recyclability, waste generation, impact on indoor air quality, and durability (Deutsche Gesellschaft für Nachhaltiges Bauen, 2018).

In the BREEAM system, the Materials category evaluates the environmental impact and resource efficiency of material selection. The Materials category, examined in five sections, evaluates and scores the LCA impact, the sustainability of the material supply chain, sustainability certifications for materials (ISO 14001, etc.), the percentage of recycled or recyclable materials used, the durability of building materials, and their impact on human health. Table 1 provides the credit scores for the Materials section (BREEAM, 2024). The BREEAM certification scheme is customized for certain countries such as the UK and the Netherlands. For example, under the BREEAM-NL certification applied in the Netherlands, buildings can earn a total of 18 credit points for materials (BREEAM-NL, 2014).

Table 1. Credit Points for BREEAM Building Material Category (BREEAM, 2024)

Criteria	Credits
01. Building life cycle assessment	7 (+3 additional credit available)
02. Environmental product declarations	1
03. Responsible sourcing of building materials	4 (+1 additional credit available)
04. Durability and flexibility	1
05. Material efficiency	1

4. Haut Amsterdam Building

Haut Amsterdam, located in Amsterdam, the Netherlands, is a sustainable building designed by Team V Architecture. The project received an award in a project competition organized in 2016, where sustainability was of great importance in the evaluation phase. Every decision made during the design process of the building has been shaped by making choices in line with the principles of sustainability to serve the residential function, maximize the use of wood, and at the same time give the building the characteristics of a high-rise building. For this purpose, both functional and environmentally appropriate design decisions have been taken. The building, which was started in 2019 and completed in 2022, is the tallest wooden building in the Netherlands and the third tallest in Europe. The 21-story building is 73.00 m high. The total building area is 14,443 m² (Pintos, 2022).

Located on the banks of the Amstel River, the building prioritizes transparency of the façade, natural light and unobstructed views, and for this reason, a load-bearing wall system was applied inside, not on the façade, and these walls also function as dividing walls between the apartments (Fig. 1). This usage also made it possible to be flexible in terms of apartment size, plan layout and façade design (Vermeulen, 2022). Within the scope of the selection criteria of the building materials to be used in the building, sustainable, high quality and functional materials were targeted. For this reason, the use of wood, which will provide a significant carbon footprint reduction compared to the use of concrete or steel structural materials in a similar structure, was considered the most appropriate option, and its use was prioritized, aiming to minimize the embedded carbon footprint in the building (Verhaegh et al., 2020). In Dutch, haut means wood. It also allows for “Haute Architecture”, a name derived from the fashion term “Haute Couture”, allowing users to actively participate in the design of their apartments and decide on the size, number of floors, layout and balcony layout (Fig. 2, Fig. 3, Fig. 4, Fig. 5, Fig. 6, Fig. 7), (Url-1, 2024).

Fig. 1. Haut Amsterdam Site Plan (Pintos, 2022).

To achieve a transparent appearance, provide natural heating through sunlight, and ensure optimal lighting, large glass facades with integrated solar panels have been designed. Solar panels have also been installed on the roof of the building. It is stated that 1,500 m² of solar panels are used on the facades and roofs (Pintos, 2022). Over 6,000 m² of corrosion-resistant anodized aluminum profiles have been used and anodized in the windows and doors of the building (Geberit TR, 2025). Additionally, the building includes sensor-controlled thermostats that detect and adjust heating and cooling, nesting boxes for birds and bats, and a rooftop garden for rainwater storage as part of its sustainability measures (Pintos, 2022). The building has achieved a BREEAM Outstanding rating with a score of 88.07% under the BREEAM-NL certification. The material score for the building is reported to be 83.33% (Fig. 8) (BREEAM-NL, 2023).

golden light publishing®

Due to Amsterdam's climate conditions, which are not suitable for the entire structure to be made of wood, the foundation, basement, and core sections of the building are constructed of concrete to provide resistance to wind and moisture, while the floors are made of Timber-Concrete Composite (TCC) and the walls are made of Cross-Laminated Timber (CLT) panels. Due to the limited space at the site and the lack of storage space, the wood-based materials such as TCC, CLT, and gululam used in the structure were pre-manufactured at a factory 200 km away and assembled at the site. The building uses 2,800 m³ of CLT, and the amount of wood used results in a 50% reduction in carbon emissions compared to other buildings, with approximately 1,800 tons of CO_2 stored. It is stated that the stored amount is equivalent to the annual CO_2 emissions of approximately 400 homes (Geberit TR, 2025).

Building Information Modeling (BIM) was used in the production process to ensure material supply, transportation, assembly, and all coordination. This enabled the entire production and building process to be planned, preventing issues such as limited space, storage, overproduction, waste generation, coordination, and communication deficiencies. It has been stated that project managers were able to view all production, planning, and building processes through BIM, enabling them to plan subsequent processes seamlessly. It has been noted that BIM provides advantages in project processes and significantly facilitates collaboration and coordination between various departments (Brüninghoff Group, 2022).

5. Examination of Sustainable Building Materials Used in the Haut Amsterdam Building

The building structure is designed to be sustainable, aiming for high quality and utilizing innovative building materials and components in material selection. Although the building's height, wide facades, and decision to use a significant amount of wood presented challenges, an integrated approach shaped the building design and production.The high material score of the building under the BREEAM-NL certification is believed to be due to factors such as the high amount of wood used in the building, the characteristics of the framing materials, the preference for solar panels in the facade and roof design, as well as the high LCA results, durability, and efficiency levels of these materials.

However, in this study, only anodized aluminum framing materials and wood-concrete composite panels were examined within the scope of sustainable building material analysis. This selection was made because these materials allow for a comprehensive evaluation in terms of both their functional and aesthetic roles in the building and the material selection criteria. Solar panels, on the other hand, were not analyzed within the framework of material selection criteria as they are considered a systemic energy production component.

The anodized aluminum framing material used in the structure are the AluBlack product from the Alumet brand. Anodizing is a transformative process that enhances aluminum's natural corrosion resistance and visual appeal through an electrochemical process. Anodized aluminum framing materials offer high solar reflectivity, ease of cleaning, the assumption that 100% of the material can be reused or recycled at the end of its life, a long service life, low carbon emissions, resistance to fire, corrosion, and scratching, and its sustainability. The product is certified to ISO 9001 QSC, ISO 14001 EMS, and Qualanod standards. (Fig. 9, Fig. 10), (Web2, 2024).

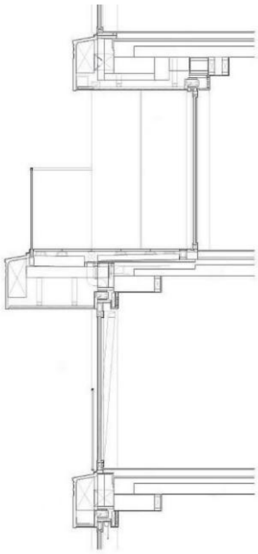

Fig. 9. System section (Url-3, 2024).

Fig. 10. Use of anodized aluminum framing material (Url-3, 2024).

The superior performance of Timber-Concrete Composite (TCC) in fire resistance and acoustic comfort compared to wood, its lower carbon footprint and higher carbon sequestration compared to concrete, its thinner and lighter weight enabling longer spans, and its modular design allowing for flexible design, and its superior performance compared to both wood and concrete under both compression and tension are the reasons why it is preferred for use in building.

TCC panel flooring used in building is obtained by combining two layers of 160 mm CLT panels and 80 mm C55/67 class concrete layers. In this system, where CLT and concrete are used together, CLT carries the tensile forces while concrete absorbs the compressive forces, thereby sharing the structural loads. TCC panel floors are prefabricated in a factory and assembled on-site. These panel floors are placed on top of CLT load-bearing walls (Verhaegh et al., 2020) (Fig. 9, Fig. 11). In areas where the floor edges are not supported by load-bearing walls, glulam (glued laminated timber) beams are used. The panel floors are installed so that the wooden surfaces are visible inside the building, ensuring an effective natural wood appearance in the structure (Brüninghoff Group, 2022; Frangi, 2022).

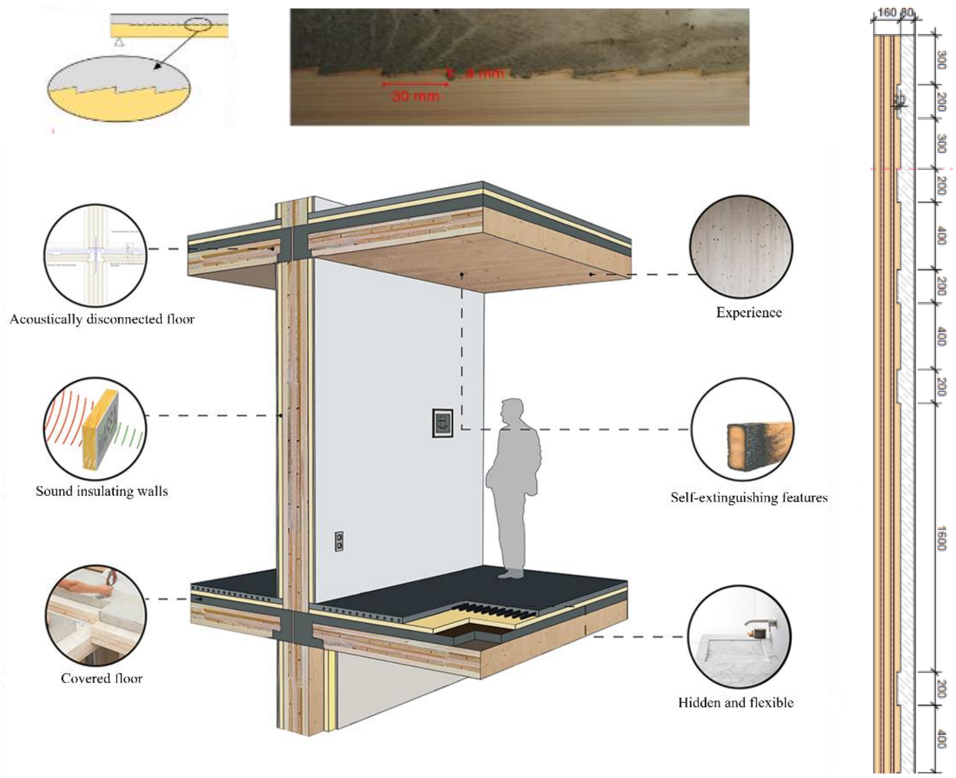

Fig. 11. Detail of TCC Flooring and CLT Wall Junction (Pintos, 2022; Brüninghoff Group, 2022; Frangi, 2022).

6. Evaluation of Building Materials Used in the Haut Amsterdam Building According to Building Material Selection Criteria

The Haut Amsterdam building scored 83.33% in the materials section of the BREEAM-NL certification. Buildings can earn a total of 18 credit points related to materials during the certification process (BREEAM-NL, 2014). Accordingly, the building earned 14.9 credit points. However, the certification system does not provide detailed information on which points were awarded.

The BREEAM-NL system evaluates the selection of building materials as follows:

- Assesses the environmental impact of materials used in the main components of the building.
- Examines whether materials are sourced from sustainable sources.
- Evaluates the lifespan and durability of materials used.
- Assesses the potential for reuse, modularity, and convertibility of the building and the materials used over time.
- Considers the recycled content ratio of materials and the use of reused building elements.
- Evaluates the amount, type, and management of waste generated.

Within the scope of the study, the anodized aluminum profiles and TCC panel flooring used in the Haut Amsterdam structure were examined in terms of sustainable building material selection criteria and evaluated by comparing them with the material score obtained by the structure under the green building certification. TCC panel flooring was compared with wood, reinforced concrete, and steel flooring, while anodized aluminum framing material was compared with aluminum, wood, and polyvinyl chloride (PVC) framing materials. Since a multi-criteria evaluation will be conducted for the assessment of building material selection methods, and weight values will be assigned equally, it was decided to use the Arıoğlu Method, Graphical Comparison Method, and TOPSIS method.

Similar to the BREEAM-NL certification system, the environmental impact, sustainability (CO_2 impact), fire resistance, sound insulation, durability, ease of application, flexibility in dimensions, recyclability, and environmental harmlessness of building materials will be evaluated. Therefore, the criteria to be compared for flooring are fire resistance, sound insulation, environmental and health safety, rigidity, weight (lightness), aesthetics, sustainability (CO_2 impact), ease of application (installation, production time), longevity/durability, and recyclability. The criteria to be compared for framing materials are fire resistance, sound insulation, environmental and health safety, weight (lightness), aesthetics, sustainability (CO_2 impact), ease of application (installation, production time), longevity/durability, and recyclability.

Within the scope of the Arıoğlu method:

- Criteria are determined.
- Each material is evaluated on a scale of 1-5 according to the defined criteria.
- The system with the highest total score is accepted as the most suitable solution. The value coefficient for each criterion will be taken as 1 (Kokulu, 2016).

Within the scope of the Multi Criteria Decision Making-Line Graph Comparison method;

- The criteria are listed on the horizontal axis.
- On the vertical axis, the scores each material receives for these criteria on a scale of 1 to 5 are marked.
- These scores are analyzed for each material, and a performance profile is created. (If a material's strengths are unbalanced, for example, very high in one criterion and very low in another, it is determined that the material is inconsistent. If a material's scores are balanced across all criteria, it is deemed to have balanced performance and is considered a suitable material).

Within the scope of the TOPSIS method;

- Alternatives are scored on a scale of 1-10 for each criterion (1 = very poor, 10 = very good).
- Criteria are normalized

$$\boldsymbol{r_{ij}} = \frac{\boldsymbol{x_{ij}}}{\sqrt{\sum_{\boldsymbol{i=1}}^{\boldsymbol{n}} \boldsymbol{x_{ij}^2}}}. \text{ (xij: alternatif i'nin kriter j için puanı)} \quad (1)$$

- The normalized matrix is multiplied by the criterion weights.

$$\boldsymbol{vij = wj \cdot rij} \text{ (Eşit ağırlıkta: tüm wj=0.1w\_j = 0.1wj=0.1)}$$

- The positive and negative ideal solutions are identified (P: the highest value in each criterion, N: the lowest value in each criterion).
- The distance from each alternative to the positive and negative ideal solutions is calculated.

$$\boldsymbol{s_i^+} = \sqrt{\sum_{\boldsymbol{j}} \left(\boldsymbol{v_{ij}} - \boldsymbol{v_j^+}\right)^2} \quad \boldsymbol{S_i^-} = \sqrt{\sum_{\boldsymbol{j}} \left(\boldsymbol{v_{ij}} - \boldsymbol{v_j^-}\right)^2}$$

(2)

- The proximity coefficient is calculated, and the resulting coefficient is taken as the TOPSIS score. The higher the score, the closer the solution is considered to the ideal solution (Chakraborty, 2022).

$$\boldsymbol{c_i} = \frac{\boldsymbol{S_i^-}}{\boldsymbol{S_i^+ + S_i^-}} \quad (3)$$

- After determining the criteria and scoring in the TOPSIS method, TOPSIS scores were calculated using TOPSIS software belonging to the "Decision Radar" web-based platform (Url-4, 2025).

Table 2 presents the evaluation of TCC, reinforced concrete, wood, and steel flooring systems according to the Arıoğlu method within the scope of the defined sustainability criteria. The flooring system material with the highest total score is "TCC" (Wood-Concrete Composite) flooring, which scored 44 points under the method. The maximum score that can be achieved under the method is 50. When the score of 44 is converted to a percentage, it results in 88%. The materials are ranked as follows: TCC first, followed by Timber, with Concrete and Steel sharing the same score.

A line graph of the flooring materials evaluated in Table 2 under the Line Graph Comparison method has been created in Table 3. According to this graph, TCC is the material with the most balanced line and the highest score. Wood stands out in terms of sustainability, aesthetics, and harmlessness, while it received low scores in fire resistance and rigidity. Reinforced concrete scored high in fire resistance and durability but low in harmlessness, aesthetics, and lightness. Steel is an effective material in terms of aesthetics and recyclability but scored low in fire resistance and sustainability.

The scoring on a scale of 1 to 10 for the flooring material selection criteria using the TOPSIS method is presented in Table 4. In the Decision Radar web-based platform, matrices were calculated by entering alternatives, criteria, and scores for each criterion for the TOPSIS score (Fig. 12). In the TOPSIS method, the most ideal selection is the option closest to 1; therefore, the most ideal flooring material option is TCC with a score of 0.80 (80%) (Table 5).

Table 2. Evaluation of Flooring Materials According to Sustainability Criterias Using The Arıoğlu Method.

Building Material	Fire Resistance	Sound Insulation	Harmlessness to Health/Environment	Rigidity	Lightness	Aesthetics	Sustainability	Ease of Application	Longevity / Durability	Recyclability	Total
TCC	4	4	5	5	3	5	5	4	5	4	44
Concrete	5	3	3	5	1	2	2	2	5	2	30
Timber	2	2	5	2	5	5	5	4	3	5	38
Steel	2	2	3	4	3	4	1	3	4	4	30

Table 6 presents the evaluation of anodized aluminum, wood, PVC, and aluminum framing materials based on the sustainability criteria defined within the Arıoğlu method. The framing material with the highest total score is anodized aluminum, which received 40 points under the method. The maximum score that can be obtained under the method is 45. When the score is converted to a percentage, it results in 88%. The material ranking is as follows: anodized aluminum, wood, aluminum, and PVC.

Within the scope of the Line Graph Comparison method, the framing materials evaluated in Table 6 have been plotted on a line graph in Table 7. According to this graph, anodized aluminum has the most balanced line compared to the other three materials, demonstrating very strong technical criteria (fire resistance, durability, recyclability) and moderate harmlessness. Wood is very strong in terms of environmental impact, health, and aesthetics but weak in terms of lightweight. PVC is high in terms of lightweight and ease of installation but receives low scores in terms of non-toxicity and service life. Aluminum is strong in terms of service life but receives low scores in terms of non-toxicity and sustainability.

Table 6. Evaluation of Framing Materials According to Sustainability Criterias Using The Arıoğlu Method.

Building Material	Fire Resistance	Sound Insulation	Harmlessness to Health/Environment	Lightness	Aesthetics	Sustainability	Ease of Application	Longevity / Durability	Recyclability	Total

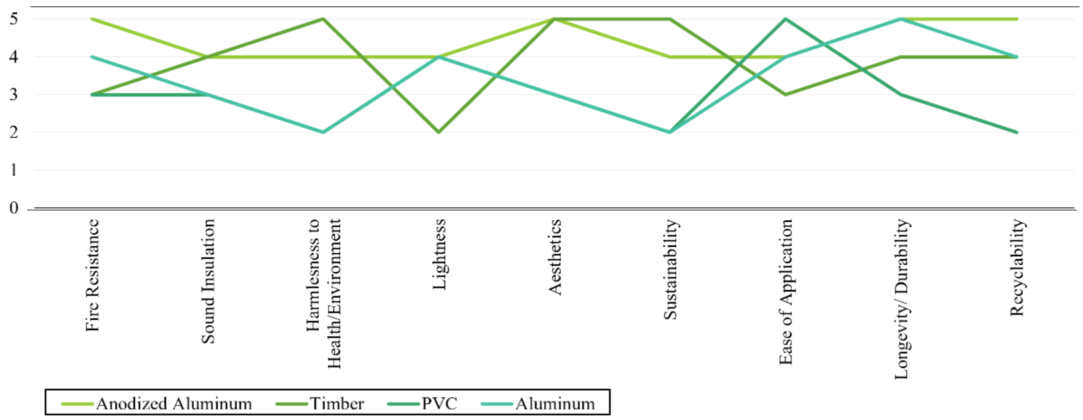
Table 7. Line Graph for Framing Materials Evaluated Within The Scope of Sustainability Criterias.



The scoring criteria for framing material selection according to the Topsis method, ranging from 1 to 10, are presented in Table 8. In the Decision Radar system, matrices were calculated by entering the alternatives, criteria, and scores assigned to each criterion for the TOPSIS score (Fig. 13). In the TOPSIS method, the most ideal selection is the option closest to 1; therefore, the most ideal framing material option is anodized aluminum with a score of 0.72 (72%) (Table 9).

7. Conclusions

The Haut Amsterdam building is a sustainable, environmentally friendly, and exemplary structure in terms of building material selection and building methods. The 83.33% score obtained in the building material usage section of the BREEAM-NL certification is a high score according to BREEAM standards. However, detailed information on each material could not be obtained.

The Timber-Concrete Composite and anodized aluminum materials were evaluated using the Line Graph Comparison, Arıoğlu, and TOPSIS methods, which enable the creation of evaluation criteria in accordance with the material section criteria of the BREEAM-NL Certification System and the subsequent evaluation of the multiple criteria using equal weight scores.

When evaluating flooring and framing materials used in the Haut Amsterdam building and their alternatives using the Line Graph Comparison method;

- TCC was found to be the most ideal among TCC, wood, concrete, and steel flooring materials.
- Anodized aluminum was found to be the most ideal among anodized aluminum, wood, PVC, and aluminum framing materials.
- The evaluation conducted within this method and the material selection made by the Haut Amsterdam building in line with its sustainability objectives were found to be compatible.

Under the Arıoğlu method, both TCC and anodized aluminum scored higher than other materials when compared. TCC scored 44 out of 50 points, while anodized aluminum scored 40 out of 45 points. When calculated as a percentage, both materials were found to be 88%. Under the multi-criteria decision-making method, the TOPSIS method was used to evaluate TCC and anodized aluminum profiles, and they were found to be the most ideal materials among the evaluated materials. The ideal ratio for TCC material is 80%, and the ratio for anodized aluminum material is 72%. Considering the lack of detailed information about all materials and the fact that the assessment was made on the basis of only two materials, the results obtained from the Line Graph Comparison method, the Arıoğlu method and the TOPSIS method were found to be consistent with the assessment of the BREEAM-NL certificate within the scope of the material criteria of the building.

In conclusion, it is considered that the Line Graph Comparison method can assist in selecting the ideal material within the scope of sustainable selection criteria, while the Arıoğlu and TOPSIS methods can help achieve results close to the evaluation and scoring methods of the BREEAM-NL certification within the scope of scoring methods.

Aknowledgement

This study was prepared within the scope of the Sustainable Building Materials course offered in the Fall Semester of the 2024-2025 Academic Year at the Department of Architecture, Graduate School, Gebze Technical University.

The magical structural system of Munich Olympic Stadium

Yesim Kamile Aktuglu*[1],

[1] *Dokuz Eylul University, Department of Architecture, 35040 Izmir, Türkiye*

Abstract. Munich Olympic Stadium is the main part of the Olympiapark Area since 1972, when the Summer Olympics took place. At that time, the structural solution of the canopy structure over the seats was really an extraordinary solution, not from architectural side but also from engineering side. Its architect, Günther Behnisch and its engineer, Frei Otto, designed a unique structure, still in service today, in 2025.The lightweight canopy structure is being carried by pilons, standing up at the back side of the seating area, all are at the different heights from the ground. Its transparent roof cover lets the structure be seen easily from everywhere.
The cables to support the cantilevered canopy structure go very far to be mounted to the ground level.
The experimental works of Otto, done before, prepared this special built product to get life.
Not only the Stadium is having a unique roof, but also all other closed spaces for different branches of the sport have special roof structures.
In the paper, it is aimed to underline the advantages of the canopy over the Stadium, constructed with structural steel and transparent cladding material, from the architectural point of view and also from the structural point of view, to call for the designs in future.

Keywords: Munich Olympic Stadium, Frei Otto, Günther Behnisch, Structural Steel, Pilons

1. Introduction

The Munich Olympic area, built in 1972, is still in service for the rescreation of the people. The transparent roof of the Stadium(Fig.1) has a very unique solution, not only in 1972, but also today(Aktuglu, and Orbay, 2024) (Aktuglu, 1999).

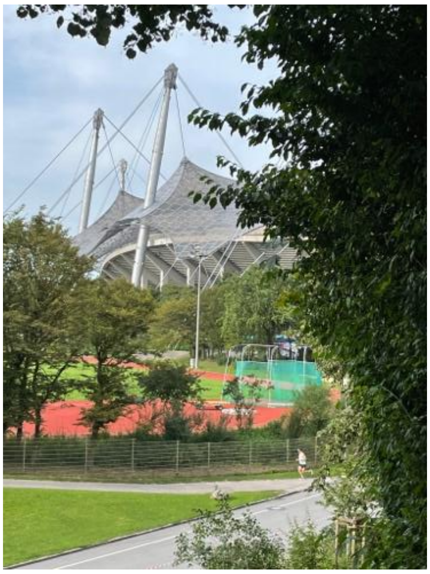

Fig. 1. The view of the Stadium from the road coming through SAP Garden (photo by B. Orbay and Y.K. Aktuglu, 09.08.2024)

*Corresponding author, E-mail: yesim.aktuglu@deu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_287

The structural solution of the seating area has its own elegant construction detailing also to let the total view of the stadium reflect the beauty of the whole structure in a very-well designed way to all. The outcomes of the partnership between architects and engineers should add the built environment a better case to attract others for the function through the Munich Olympic Stadium to Munich Olympic Area.

The design team of the roof of Munich Olympic Stadium is Behnisch and Partner, that Günter Behnisch, whose the famous works are the buildings in Munich Olympic Park (Gympel, 1996) and Frei Otto to solve the cantilevered roof, supported by cable net structures (URL-1, 2025). They have multiple saddle-shaped surfaces which are framed by edge cables. And they have suspended from masts. Pilons at the perimeter, support primary cables which in turn, they resist to interior network of interior cables and flying masts which gives the form of the structure of the roof. Roof area is 74.000m2. The width of cable net mesh i2 75*75cm. Edge cables are constructed by locked coil ropes. Guy cables are constructed by parallel strand bundles. Joints and connectors are made of cast iron. Masts/pilons are steel tubes in the form of puro. The first cover of the transparent roof was from acrylic glass which is Plexiglas. Then during the restoration of the roof in 1997, it has changed (Winney, 1998).

The innovative lightway structure of this roof solution, through imposing tensile structures for the Olympic Games here, (Fleming, 1991) also lets a whole section of the games watch with a clear view.

2. Details of the roof, call for magical structural system

The details of the roof and the stadium seating area and the connection of both of them, as seating places and roof over them, are enough good to understand the transfer of the loads from top to the ground(Fig.2.)(Fig.3.).

With the help of the novel large scale physical models, the design team could navigate to find the most suitable form for the transparent tent (Whitehead, 2022).

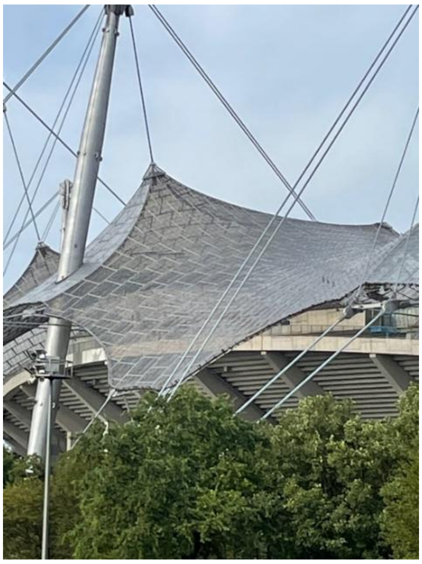

Fig. 2. The view of the whole structure with roof and the seating places (photo by B.Orbay and Y.K. Aktuglu, 09.08.2024)

Fig. 3. The view of the cables coming from masts and roof to the ground (photo by B.Orbay and Y.K. Aktuglu, 09.08.2024)

Fig. 4. The view of the end cables coming from the end of the cantilevered roof to the ground (photo by B.Orbay and Y.K. Aktuglu, 09.08.2024)

The end cables to stabilize the end of the cantilevered roof carried their loads to earth very strongly (Fig.4.). And double cables are used at the Munich Olympic Stadium (Blanc, 1993).

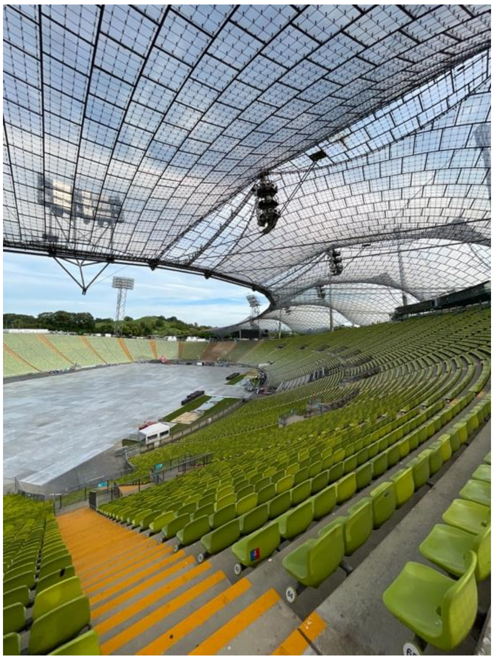

Fig. 5. The view of the transparent roof and the structure for the seating steps (photo by B.Orbay and Y.K. Aktuglu, 09.08.2024)

And the layout of seating places, together with the cantilevered transparent roof show how to have a clear view for the performances, eg sports, mucis performances, etc. which is the most important aim while designing the structure (Fig.5.).

4. Conclusions

As a conclusion, the whole structure of Munich Olympic Stadium and its cantilevered roof have lots of magical details to compose the roof and stadium itself. It is a very good case study to learn a lot about the complete cable net structure together with its steps under the roof for audience area (Fig.6.). The latest success of this landmark is that it is a very convenient structure and area for big music concerts eg. Coldplay had its concerts, on 13.08.2024, with lots of people.

What we may conclude that to have a real landmark structure as Munich Olympic Stadium, there should be a team with architects and engineers to solve the details, will stand more than 50 years, since 1972. The sustainability of this area and the cantilevered roof structure and the stadium comes automatically through its perfectly designed project, will lead to all of us, who will design the world through architecture and engineering of buildings and structures.

Multipurpose structures which are resilient, sustainable and with aesthetic properties is a stark reminder of how cities must work. An open area which can be used 365 days a year, suitable for any number of event types (even can used in natural disasters), which is also considered as a landmark is what every city needs to attract more attention. As its utilization rate grows, the structure’s lifetime value increases. Basically every city is better off with architecturally pleasing and functional structures, rather than just functional structures. The way Munich Olympic Stadium is a pristine example of enhancing cities with better design, better sustainability and better functionality. Even religious sites can be made more appealing and functional with such design and engineering.

Just for illustration purposes, such structures can be redesigned to go along with the local design patterns and serve as functional units. Regardless of the current need, below is an imaginary figure of a structure added as an extra attraction for Kayabaşı Yaylası in Akçaabat, Trabzon.

Fig. 6. A ChatGPT imagined implementation as an extra attraction for Kayabaşı Yaylası in Akçaabat, Trabzon.

Fig. 7. The whole view of the cantilevered roof and seats under the roof (photo by B.Orbay and Y.K. Aktuglu, 09.08.2024)

The main aim of this paper whose title as “The magical structural system of Munich Olympic Stadium” is to let architects and engineers remember to use cable net structures to span large meters without any obstacle in the space as a magical design, letting the roof fly in new stadiums, concert halls, airport buildings, and also residences, in not only urban area but also in everywhere of the world. For its form is very flexible, and also it is very light to construct, this cable net structure will add lots of advantage to the construction budget towards in a more positive way.

During the passing years, it will be very beneficial to visit this kind of unique landmarks from time to time, to investigate about what is changing in the structural details, due to the time.

Acknowledgments

The research described in this paper was supported by Dr.Industrial Engineer Berk Orbay, to be an engineer guide for the area of Munich Olympic Area, in Munich, on 09.08.2024

4th International Civil Engineering & Architecture Conference
17-19 May 2025, Trabzon, Türkiye

An evaluation of the use of energy performance simulations in Türkiye

Gizem Ertaş*[1], Dinçer Aydın[2]

[1] Trakya University, Institute of Science, Department of Architecture, 22100 Edirne, Türkiye
[2] Trakya University, Faculty of Architecture, Department of Architecture, 22100 Edirne, Türkiye

Abstract. The construction sector, which accounts for more than 40% of global energy consumption, shapes its significant share of energy consumption not only through production and implementation processes, but also through design decisions that have a direct impact on energy performance, from the choice of materials to the shape of the building. In this context, the use of energy simulation tools plays a crucial role in effectively managing energy efficiency during the design process and is becoming an indispensable tool for achieving sustainable design goals. Energy simulation programs (ESPs) not only enable designers to compare alternative solutions and make informed decisions, but also aim to optimize performance, reduce costs and ensure safety. The high energy consumption of buildings has necessitated the management of energy performance and led to the development of various software solutions in this area. Simulation programs make it possible to identify problems in the construction process at an early stage, facilitate the search for solutions and minimize errors. However, while energy simulations are frequently used in large-scale projects in Türkiye, in smaller projects energy and environmental factors are often only considered in order to fulfill legal requirements. Therefore, this study examines the reasons for the use of ESPs in Türkiye, identifies the types of programs used for different project sizes, and aims to increase planners' awareness of energy simulation tools. To analyze the use and preferences of ESPs in Türkiye, theses from the construction sector were selected as a sample. It was determined that EnergyPlus, DesignBuilder, Ecodesigner Star, Grasshopper, IES-VE, ANSYS Fluent and WUFI are globally recognized energy simulation programs. These programs were analyzed for their content and their capabilities were compared. Consequently, this study seeks to reveal the reasons behind the preference for ESPs in Türkiye.

Keywords: Architecture, energy, energy simulation, energy simulation programs (ESPs), graduate theses.

1. Introduction

The industrialization process has changed humanity's interaction with nature and has led to global environmental crises due to increased energy demand, emissions from production and rising consumption of natural resources in the 20th century. Unfortunately, with the expansion of industrialization and urbanization, the consumption of natural resources and raw materials has also increased, while studies on the efficient use of energy have remained insufficient and limited. This situation has not only exacerbated environmental problems, but has also significantly increased the demand for energy. Considering consumption figures, a large proportion of energy consumption is attributable to the construction sector. The construction industry directly influences energy consumption not only through its production processes, but also through its choice of materials and design decisions. The sector's high energy consumption has highlighted the need for sustainable design practices and energy efficiency-focused solutions. In this context, the construction industry plays a critical role in reducing environmental impacts and optimizing energy consumption (UNEP, 2019).

In the construction sector, various simulations can be carried out during the design phase to determine and optimize the energy performance of a building in areas such as heating, cooling and lighting. These simulations are crucial for improving energy efficiency in the early stages of the design process (Aziz N., et al., 2020). The energy performance of buildings is directly related to factors such as the choice of materials and systems, building form, and thermal insulation. Globally, the building sector accounts for around 40% of total energy consumption (IEA, 2020; Huang et al., 2018), with the operational energy consumption of buildings accounting for the largest share of this percentage. In response, many countries have set targets and developed regulations to improve the

* Corresponding author, E-mail: gizemerta13@gmail.com

https://doi.org/10.31462/icearc2025_a_aen_288

energy efficiency of buildings in order to reduce energy consumption and even construct near-zero energy buildings.

The life cycle of a building extends from the design phase through construction and operation to its eventual demolition. However, the environmental impact of a building is not limited to the construction phase. Over time, design errors can lead to significant environmental impacts during the operational period (Bueno et al., 2018; Hollberg & Ruth, 2016). Decisions made in the design phase play a crucial role in various environmental impacts, such as energy consumption, water management and waste disposal. At this point, design decisions made in the early stages are critical to the energy performance of a building. Considering that the average lifespan of a building is around 50 years (Kara & Kayılı, 2021; Hollberg & Ruth, 2016; Harputlugil, 2011), it is foreseeable that the environmental impact of poorly designed buildings will only increase over time. Therefore, the design phase is the most critical process for minimizing the environmental impact of a building. Since modifications or structural changes made later are often costly and inefficient, early detection of design errors provides significant environmental and economic benefits.

Building energy analysis and simulation programs calculate the energy consumption of a building by taking into account factors such as geographical location, the duration of sunlight exposure, the electrical appliances used in spaces, the number of occupants and their physical activities, and the materials used in construction (Kozan İ.H., 2021). In the design process, decisions such as the compatibility of a building with environmental conditions, the selection of materials and their application affect a larger scale, from the human scale to the national and global level. Regardless of scale, proper planning of performance requirements in design strategies is critical. These requirements can be effectively met through the integrated design of building subsystems (Hensen & Lamberts, 2011). The subsystems that influence building performance are shown in Fig. 1.

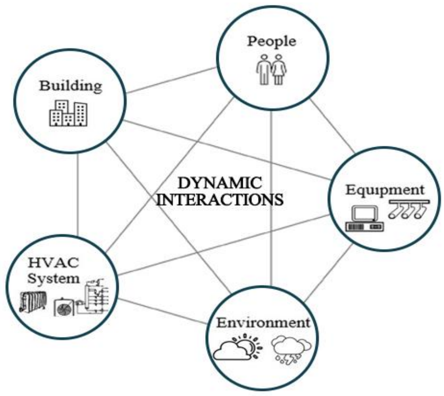

Fig. 1. Dynamic interactions of subsystems in buildings (adapted by authors from Hensen & Lamberts, 2011).

The complexity of building design requires the collaboration of experts from different disciplines to develop design solutions that meet all performance criteria (Yang & Bouchlaghem, 2010). However, dealing with conflicting interdisciplinary perspectives is a difficult, lengthy and complex process. Evaluating the energy performance of buildings and deciding on the materials and systems to be used requires complicated methods and interlinked calculations. In this regard, simulation programs that enable interdisciplinary collaboration, optimize energy consumption, maintain thermal comfort and reduce both short and long-term operating costs are essential. These programs, developed to model the energy consumption of buildings, help optimize energy performance during the design process and contribute to achieving the goals for zero-energy buildings (Hensen & Lamberts, 2011).

Energy simulation programs (ESP) were first developed in the 1960s to optimize energy consumption and, in particular, to reduce energy costs in large industrial and commercial buildings (Spitler, 2006). The lack of precision and practicality of manual calculations increased the demand for computerized analysis programs. Accordingly, building ESPs, which provide the ability to test expected performance criteria under different parameters, significantly reduce the workload of designers, facilitate effective decision-making in the design process and shorten this process (Kozan İ.H., 2021; Hensen & Lamberts, 2011; Yu Ş. et al., 2015). By using building ESPs throughout the design process, from the initial phase to completion, it is possible to calculate the heating and cooling energy demand, primary energy consumption of electricity and gas and energy efficiency criteria, as well as to determine the ideal range for thermal comfort for different time periods (Harputlugil & Hensen, 2006).

Today's building performance simulation tools, while diverse, generally operate based on real-time data and analytical calculations, are integrated with intelligent information systems, support fully integrated modeling, and provide interoperability with other software (Tunalı, 2012). The core theory behind these tools is based on the calculation of performance parameters such as heating, ventilation and air conditioning (HVAC) loads and the energy required. Numerous ESP software and tools have been developed by various companies and institutions. However, the selection of these programs varies according to their capabilities, advantages, disadvantages and limitations (Tunalı, 2012).

The aim of this study is to analyze the use and selection trends of these programs specifically in Türkiye and to identify the most commonly used ESPs. In addition, this study aims to evaluate the current status of energy performance simulation programs in the building design process, raise awareness among designers about the use of these programs and promote their integration into architects' workflows. In order to determine the input and output parameters of ESPs in the simulation process and to evaluate their frequency of use in Türkiye, a sample of graduate and postgraduate theses in the fields of architecture and civil engineering in the construction sector available at the YÖK Thesis Center until December 2024 were examined. Consequently, the study aims to identify the most suitable ESPs for Türkiye's conditions and needs in the field of energy efficiency and to provide a guide for future research on ESP selection.

2. Materials and Methods

This study focuses on determining the prevalence of energy performance simulations in Türkiye. The main objective is to identify the most commonly used energy simulation programs in Türkiye, examine their capabilities in data collection and analyze their advantages, disadvantages and limitations in comparison with each other. Within this framework, a search was conducted in the YÖK Thesis Center using the keyword "energy simulation" across all disciplines, admission status and thesis types. As a result of this search, a total of 158 theses were identified, including 128 master's theses and 30 dissertations.

Energy simulation programs are effectively used at various scales, from urban scale to buildings and building components. Accordingly, the data collected also analyzes how and at what levels these programs were used. The review identified which programs were used at each level. In order to ensure meaningful comparisons, the study was limited to simulation programs that were used in the construction sector and functioned at at least two different scales. Based on this criterion, the following energy simulation programs were analyzed: EnergyPlus, DesignBuilder, Ecodesigner Star, Grasshopper, IES-VE, ANSYS Fluent, MATLAB and WUFI. The research methodology and the methods used are summarized in Fig. 2.

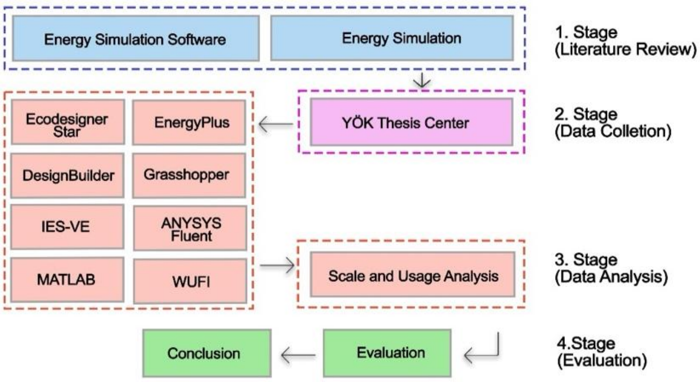

Fig. 2. Methodology Flow Diagram

3. The Use of ESPs in Türkiye

Energy simulation programs (ESPs), used to predict and analyze building performance in advance, have become significant tools that are much more effective and economical for eliminating potential problems before the use phase of buildings and increasing energy efficiency. They are constantly evolving to achieve accurate and appropriate modeling and performance calculations. In order to develop, evaluate, implement and standardize models and programs, global initiatives such as rating systems like LEED and BREEAM, incentive programs like the U.S. EPAct (Energy Policy Act) and regulations like the EPBD (Energy Performance of Buildings Directive) have been created (Hensen & Lamberts, 2011). In Türkiye, the construction sector has also issued the Regulation on the Energy Performance of Buildings (BEP), especially to optimize the energy efficiency of buildings and reduce the impact on the environment, and recommended the use of simulation tools, especially for large and complex buildings. The BEP regulation aims to define the calculation rules that allow an assessment of the total energy consumption in a building and to manage the energy consumption for heating, cooling, lighting and hot water production in buildings for primary energy (Harputlugil, 2014). However, most of these regulatory calculations are based on general assumptions and do not take into account the variable climatic conditions/regimes (Bayram, 2011).

The use of building performance simulations is generally limited to measuring the impact of façade designs on energy efficiency, estimating the risk of overheating in summer and heat losses in winter, and calculating the maximum cooling or heating load, taking into account equipment sizing (Augenbroe, 2002; Harputlugil, 2011; Hensen & Lamberts, 2011). ESPs are also used to optimize the use of natural daylight in buildings and/or to efficiently solve artificial lighting loads (Kalaycıoğlu & Yılmaz, 2019; Tozzi & Jo, 2017). All these simulations are used in a wide range, from urban scale to building scale and building component scale, to optimize energy performance (Hensen & Lamberts, 2011). In this context, it is crucial to accurately determine the scale on which energy consumption is calculated, paying attention to the targeted efficiency range. Accordingly, the first step is to decide on which scale the energy performance should be investigated and then select and use appropriate simulation programs that allow analysis on that scale.

The use of energy simulation programs at the building component scale focuses on analyzing the effects of the material properties and performance of the building elements on energy consumption (Harputlugil & Hensen, 2006). This scale focuses in particular on assessing the thermal transmittance of building materials, their thermal insulation capacity and their impact on energy efficiency, as well as measuring the impact of window and glass designs on thermal performance. It was found that DesignBuilder, EnergyPlus and MATLAB are the most widely used energy simulation programs that allow the processing of more specific material properties at the building component level. In addition, it was found that studies in the fields of architecture and civil engineering are more widespread at this scale than in other disciplines. Fig. 3 shows the energy simulation programs used at the building component scale and their disciplinary preferences, based on the analysis of the theses available in the YÖK Thesis Center.

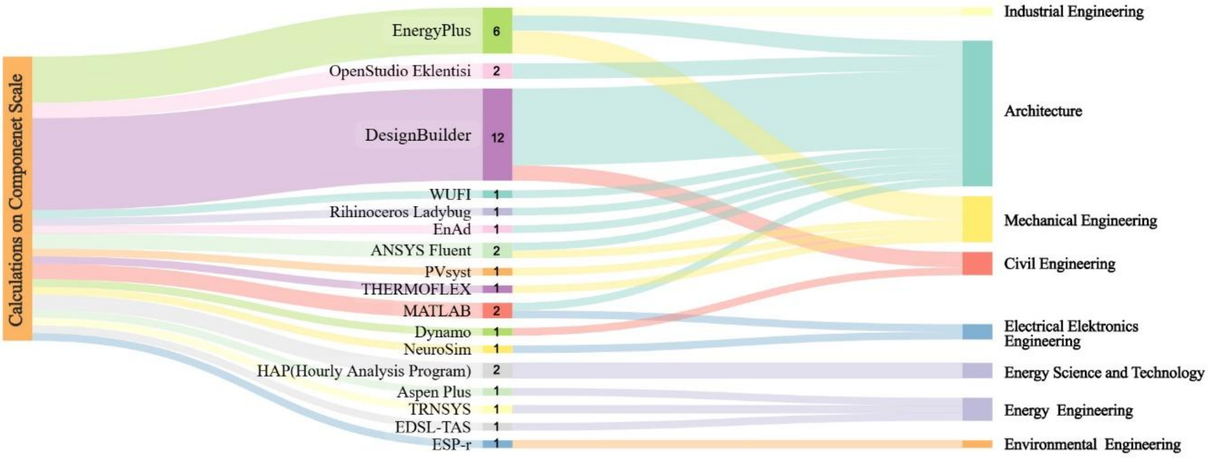

Fig. 3. Analysis of ESPs Used in Calculations at the Building Component Scale and the Studied Disciplines

As a result of the literature review conducted at the YÖK Thesis Center, it was found that among the 158 theses examined, analyzes were conducted at the building level in 124 theses, at the building component scale in 46 theses and at the urban scale in 27 theses. This finding shows that ESPs are not only used for specific calculations at a particular scale, but are also used in energy consumption analyzes at different scales. In support of this observation, 26 studies examined both building components and building scale together, while 13 studies considered both building and urban scales. The analysis results indicate that energy simulation programs in Türkiye are predominantly used at the building and building component level. Within this framework, the applications performed serve critical functions such as calculating heating and cooling loads, determining lighting and electricity consumption, evaluating indoor comfort and analyzing the impact of design decisions on energy efficiency (Hensen & Lamberts, 2011; Yu B. et al., 2015). Especially in the field of buildings, architecture is the area where energy simulation programs are most commonly used. The preferred energy simulation programs for calculations at the building level are DesignBuilder, EnergyPlus and eQuest.

In the field of architecture, these programs are generally used for applications such as the design of building envelopes, the analysis of the impact of building shapes on energy consumption and the evaluation of indoor thermal comfort (Kozan S., 2021). Energy simulations are also commonly used in the disciplines of mechanical and energy engineering. In these fields, energy simulation programs are preferred for the design of mechanical systems, the sizing of HVAC (heating, ventilation and air conditioning) systems and the optimization of energy systems (Aziz N.D. et al., 2020). However, in other disciplines, especially in fields such as electrical and electronic engineering and urban planning, the use of energy simulation programs seems to be quite limited (Fig. 4).

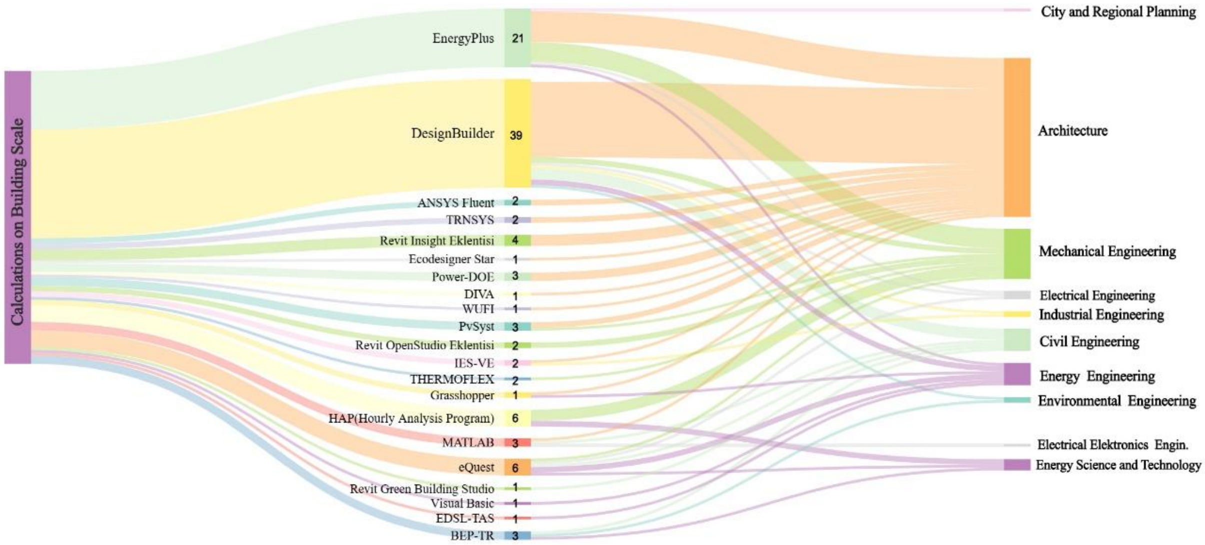

Fig. 4. Analysis of ESPs Used in Calculations at the Building Scale and the Studied Disciplines

It has been shown that the use of energy simulation programs at the urban scale is more limited compared to the building and building component scale. Urban-scale applications generally focus on specific topics such as solar radiation potential assessment, urban energy demand modeling, and energy system integration (Haung et al., 2018). At this scale, DesignBuilder, MATLAB and EnergyPlus are the most commonly used energy assessment software. Fig. 5 summarizes the energy simulation programs used at the city scale and the disciplines in which these programs are preferred. The overviews show that these calculations are primarily used to measure the interactions between buildings and to estimate their energy requirements. However, the limited number of studies in this area underlines the need for further development and widespread application of energy simulations at the urban scale.

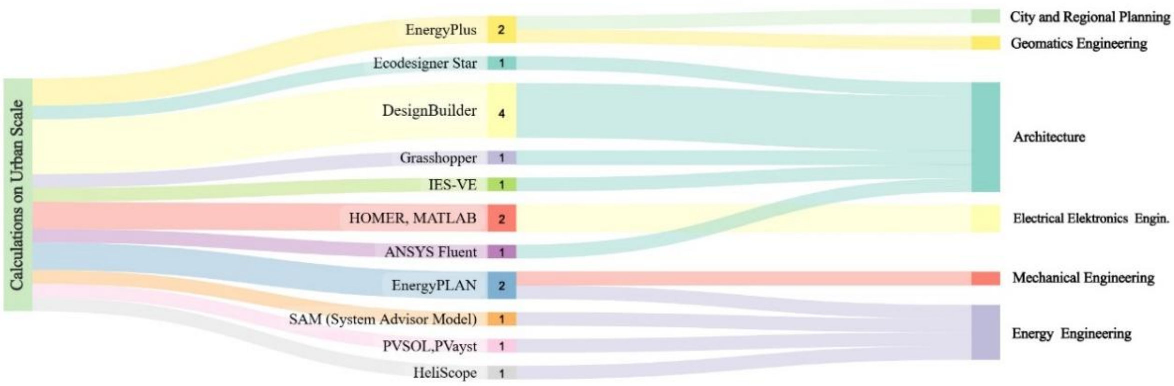

Fig. 5. Analysis of ESPs Used in Calculations at the Urban Scale and Studied Disciplines

Research has identified the most commonly used programs in all theses in Türkiye. The energy simulation programs used in the construction sector and suitable for different scales include Ecodesigner Star, EnergyPlus, DesignBuilder, Grasshopper, IES-VE, ANSYS Fluent, MATLAB and WUFI. In this context, these ESPs were examined individually in terms of the solutions they offer, the reasons for their preference and the specific problems they address.

3.1. EcoDesigner STAR

"EcoDesigner STAR was developed to enable highly efficient building design by converting Archicad Building Information Models (BIM) into multi-zone Building Energy Models (BEM). It enables the creation of thermal bridge analysis at any stage of the project within a short time and is used for energy efficiency analysis"

(EcoDesigner, 2024). The program offers advantages such as a user-friendly interface and integration with CAD programs, which makes it easier to use in practice. However, as more technical knowledge is required when working with complex models, it can be a disadvantage for new users (Yang & Bouchlaghem, 2010). In the studies examined, this software was preferred for performing simulations related to smart building design and energy consumption, as it allows the impact of green building applications and CO_2 emissions to be assessed.

3.2. EnergyPlus

EnergyPlus is an open-source building simulation software used to dynamically simulate heating, cooling, ventilation, lighting and other energy consumption systems in buildings while optimizing indoor comfort and calculating energy efficiency (Crawley et al., 2001). Due to its detailed modeling capabilities, it provides accurate simulation analysis for even the most complex systems. Additional features of this software include advanced window analysis, general building envelope calculations (external and internal surface convection algorithms), advanced infiltration and ventilation modeling, multi-zone airflow calculations, environmental emissions analysis, energy cost estimations and life cycle cost assessments (Saffari et al., 2017). However, since the input data is in text format, it is more difficult to use compared to programs with a graphical user interface (Tunalı, 2012; Tokuç, 2009). The reviewed theses indicate that this software is preferred especially due to its ability to create detailed models to simulate the interactions between the building and the external environment, to accurately model the potential of new integrated materials to optimize energy losses and to comprehensively calculate parameters such as energy consumption, indoor temperature, humidity and solar radiation gains.

3.3. DesignBuilder

DesignBuilder is a simulation engine that integrates EnergyPlus modeling and workflow control into a more user-friendly interface. It enables fast simulation of large models. DesignBuilder is a visual simulation program developed for the analysis of building energy consumption, carbon emissions, lighting and comfort controls (Aktacir et al., 2011). It is widely used to evaluate the impact of different design options on building energy consumption, perform life cycle analysis, assess façade options in terms of overheating and visual appearance, calculate the thermal performance of naturally ventilated buildings, predict daylighting performance through Radiance simulations, and determine the size of heating and cooling equipment (DesignBuilder, 2024). However, due to its limited ability for detailed modeling, it is not suitable for complex models. In studies conducted in Türkiye, it was preferred due to its ability to integrate multiple parameters into the model and develop a holistic approach to building design.

3.4. Grasshopper

Grasshopper is primarily a parametric design tool and is often integrated with Rhinoceros software. Integration with parametric modeling allows designers to quickly optimize the performance of buildings. This software mainly helps in testing and optimizing building components during the design process (Tunalı, 2012). However, it may be insufficient for performing highly detailed energy simulations. The studies reviewed show that Grasshopper has been used in simulations to analyze bioclimatic parameters for regional energy efficiency and to optimize the energy and daylighting performance of the building envelope..

3.5. Integrated Environmental Solutions Virtual Environment (IES-VE)

IES-VE enables detailed modeling of various parameters, including heating, cooling, electricity consumption and indoor comfort, enabling optimized building performance. It also provides comprehensive reports on the energy consumption and environmental impact of buildings (Hensen & Lamberts, 2011). IES-VE has a broad user base and is often used for energy simulations in the building sector. However, the user interface and functions can be very complex for new users. The software is primarily used to evaluate the effects of building shape on airflow and thermal conditions and to assess the performance of natural ventilation strategies.

3.6. ANSYS Fluent

ANSYS Fluent is a simulation program mainly used for computational fluid dynamics (CFD) and thermal analysis. It is typically used to analyze indoor airflow, thermal comfort and the performance of building components. In contrast to general building energy performance simulations, ANSYS Fluent is better suited for detailed component and system level analysis (Yang & Bouchlaghem, 2010). From the studies reviewed, it was mainly used to evaluate how the depth of courtyard design affects air movement, temperature distribution and indoor comfort.

3.7. MATLAB

MATLAB is often used for technical calculations and the development of algorithms. It enables customized calculations in simulations of the energy efficiency of buildings. However, the limited visual modeling capabilities and the required programming skills pose a challenge for new users (Harputlugil & Hensen, 2006). The studies examined show that MATLAB is primarily used for calculating solar radiation data and analyzing the performance of photovoltaic cells when assessing renewable energy consumption.

3.8. WUFI

WUFI is capable of accurately modeling moisture and heat transport in building components and provides detailed analysis in these areas (Künzel, 1995). However, its ability to evaluate the overall energy performance of buildings is limited and it often needs to be used in conjunction with other simulation programs for a comprehensive analysis. It has been widely used in studies to analyze the material properties of ecological thermal insulation materials, to evaluate dynamic thermal and moisture performance, and to assess airtightness.

4. Findings: Comparison of ESPs

As a result of the analyzes carried out of the areas of application and functions of energy simulation programs at different scales, a comparative table was drawn up to illustrate how these programs are used at urban, building and building component scales. In this context, the benefits of each program and their intensity of use were evaluated in detail. Table 1 summarizes these analyzes and shows the interdisciplinary usage trends of energy simulation programs.

Table 1. Advantages and Usage Intensity of the Analyzed Programs

Scale	**Usage**	**Ecodesigner Star**	**EnergyPlus**	**DesignBuilder**	**Grasshopper**	**IES-VE**	**ANYSYS Fluent**	**MATLAB**	**WUFI**	**TOTAL**
Urban Scale	Energy Demand Analysis	1	1	3	1	1	1	2	0	**10**
	Interaction Betwen Building	0	2	3	1	1	1	0	0	**8**
	Greenhouse Gas Emissions & Carbon Footprint Calculations	1	0	3	0	0	0	0	0	**4**

	Coatings and Structural Elements	1	5	9	1	1	2	1	2	**22**

The evaluations show that energy simulation programs are used extensively at different scales and for different purposes. The analysis shows that energy simulation programs are more limited at the urban scale compared to the building and component scale and are mainly used to assess energy demand. In particular, programs such as EnergyPlus and DesignBuilder are preferred for analyzing the interactions between buildings and energy demand processes. This indicates that these software tools are suitable for modeling energy performance on an urban scale. In addition, DesignBuilder stands out in the calculation of greenhouse gas emissions and carbon footprint, while other programs are not as commonly used for this purpose.

At the building scale, analysis of theses shows that the primary functions for which energy simulation programs are most commonly used are heating and cooling systems, lighting and electricity consumption, indoor comfort and structural efficiency analysis. In this context, EnergyPlus and DesignBuilder dominate across all application areas. In particular, DesignBuilder has a high usage rate for structural efficiency assessments. MATLAB contributes to specialized calculations, especially for indoor comfort and lighting analyzes. ANSYS Fluent is used less frequently than other programs, but plays an important role in the analysis of structural efficiency and indoor comfort.

At the component scale, the most important areas of application for energy simulation programs include thermal insulation layers, structural elements and the design of window openings. EnergyPlus is a powerful tool for simulating the heat transfer, material performance and energy impact of building components, making it particularly valuable for windows and thermal insulation layers. However, DesignBuilder remains the leading software for performance evaluation of building components and insulation methods. Due to its advanced capabilities in thermal and fluid flow analysis, ANSYS Fluent is used for detailed assessments of building components. MATLAB, on the other hand, enables the creation of detailed mathematical models and optimizations related to insulation materials, window design and thermal coatings and is characterized by its special functions. WUFI is primarily used to evaluate the performance of insulation materials, focusing on moisture and heat transfer, but has a more limited range of applications.

5. Evaluation and Conclusion

When analyzing how to improve the energy efficiency of buildings, energy simulation programs (ESPs) are proving to be effective tools for a holistic approach in which different alternatives are evaluated in the early stages of the planning process. ESPs are particularly important for optimizing the energy performance of large and complex multi-zone buildings as they provide realistic estimates (Harputlugil, 2014). In Türkiye, the Regulation on the Energy Performance of Buildings has created a framework that promotes performance analysis. This regulation emphasizes the need for the use of simulation programs capable of making detailed assessments at the urban, building and component scales. The research results show that in Türkiye, the use of energy simulation programs is more pronounced at the building and component scales, while the application at the urban scale remains quite limited. In addition, ESPs are used extensively in fields such as architecture, mechanical and energy engineering, while their use in other disciplines remains relatively low. This points to the need for a wider and more effective implementation of energy simulation tools at different scales and disciplines. Expanding their use will contribute significantly to achieving energy efficiency goals and promoting the development of sustainable buildings.

Table 1 in this study clearly summarizes the usage trends of ESPs in different disciplines and scales. At the building scale in particular, DesignBuilder and EnergyPlus are the preferred tools. However, strategies should be developed to increase the use of ESPs at urban and component scales. For example, raising awareness of programs such as WUFI and ANSYS Fluent, which are very effective in specific analyzes, could help to expand their user base.

In summary, the wider application of energy simulations across different disciplines is crucial to optimize the energy performance of buildings and contribute to global sustainability goals. The promotion of interdisciplinary collaboration and the development of more user-friendly software will support the more effective use of energy simulation tools.

[1] *Konya Technical University, Department of Architecture, 42250 Konya, Türkiye*

Abstract. The depletion of energy resources has become a global issue, necessitating measures to reduce energy consumption. Since the construction process is one of the primary causes of energy consumption, methods to enhance energy efficiency from the design phase to the end of a building's lifecycle must be developed. This study adopts an energy-efficient approach to building design.

Simulation tools developed for energy performance assessment have not been widely adopted in the sector. The reasons include the continued use of traditional design methods and the perception that energy calculations add an extra burden to the design process. This study aims to develop a tool that provides designers with fast and effective alternatives. Accordingly, a parametric/algorithmic design and energy optimization approach was adopted, with a focus on residential buildings while considering zoning constraints.

The study employs swarm intelligence algorithms, specifically the Artificial Bee Colony to optimize energy performance calculations, which were implemented in MATLAB. A case study was conducted on an existing residential building, and the energy consumption of the existing structure was compared with the alternatives generated using the developed design tools. The results demonstrated that the new tool improved energy performance. This implies a 7.4% reduction in energy consumption, achieved through the optimization of architectural design parameters.

The proposed normative tool enhances energy efficiency in building design while promoting environmental sustainability. It can be adapted to different climatic conditions and building typologies and can be integrated with artificial intelligence to improve usability. Additionally, the system has the potential to be used by urban planners to guide zoning regulations and promote energy-efficient urban development.

Keywords: Energy efficient; Algorithm; Optimization; Early design phase.

1. Introduction

Architectural design has evolved into a complex, information-rich process influenced by environmental, legal, and technical data. Traditional intuition-based methods are no longer sufficient for addressing the increasing demands of sustainability and energy efficiency. With buildings accounting for approximately 37% of total energy consumption in Turkey (Canbay Türkyılmaz & Polatoğlu, 2012), the construction sector faces growing pressure to adopt more energy-conscious strategies starting from the early design phase.

This study focuses on the critical role of early-stage design decisions in shaping energy performance. It emphasizes that zoning regulations and building codes should not be treated as restrictions, but as parameters that can drive innovative and energy-efficient form generation. The research aims to develop an algorithm-driven computational tool that generates, evaluates, and optimizes multiple design alternatives within the boundaries of legal constraints. The tool uses criteria such as heating and cooling.

The proposed approach integrates energy simulation, generative design, and optimization into a unified framework. Instead of relying on separate plug-ins and manual data transfer between modeling and analysis platforms, the tool operates autonomously using swarm intelligence algorithms such as Artificial Bee Colony (ABC) (Karaboğa & Akay, 2007).

The originality of this tool lies in its in-house algorithmic foundation that performs design generation, performance analysis, and optimization in a single loop. It responds to limitations of existing CAD-based tools by offering a continuous workflow tailored for early-stage architectural design. By digitizing zoning constraints and embedding them into the generative logic, the tool ensures that proposed designs comply with regulatory frameworks while also achieving energy performance objective .

Overall, the study contributes to energy-efficient architecture by providing a holistic design methodology that integrates computational thinking with regulatory awareness. It offers architects and urban planners a scalable,

adaptable solution to reduce environmental impact, increase design efficiency, and meet sustainability goals aligned with both national and international energy policies (OECD/IEA, 2017).

2. Material and Methods

This section presents the methodology used in developing an energy-efficient design optimization tool that integrates various parameters from environmental, regulatory, and building-related data sources. The aim is to improve architectural decision-making in the early design phase by incorporating energy performance considerations into algorithm-driven design generation. The data were categorized into three major groups: building data, legal regulatory data, environmental data. These inputs were digitized into matrices for integration into the algorithmic system. Regulatory data—including height limits, setback distances, and floor area ratios—were obtained from local zoning documents and similarly converted into numerical inputs to comply with computational requirements (Yasan,2011; Koengkan, 2023). Environmental data were collected from WhiteBox Technologies' climate files and from site-specific observations of topography, vegetation, and the spatial configuration of surrounding buildings. Building-related parameters were split into two categories: usage-dependent (occupancy levels, HVAC specifications, lighting and appliance loads) and design-dependent (form, orientation, WWR, envelope characteristics) (Morbitzer ,2001).Usage-dependent variables are typically undefined in early design and thus were assigned default values from literature (Gerçek&Durmuş Arsan, 2016). Design-dependent inputs, on the other hand, were dynamically generated through optimization algorithms, influencing building orientation, layout, and massin (He et al.,2020).

The methodology distinguishes between stable, dynamic, and area-dependent parameters. For instance, climate and topography are stable and fixed per location, while window-to-wall ratios and orientation are dynamic, adjusted per generated design iteration. This distinction allows the tool to maintain site-specific integrity while enabling design flexibility.

EPC simulation calculation data was used in the energy performance calculation of the existing building and for the design alternatives designed based on the algorithms.Energy performance assessment was based on EN ISO 13790 (2008), implemented through the Energy Performance Calculator (EPC) developed at Georgia Institute of Technology (Lee et al., 2013). EPC is a normative, monthly-based simulation tool widely accepted for evaluating annual energy consumption per unit area (EUI). It supports energy evaluations across heating, cooling, ventilation, hot water, and lighting systems by incorporating multiple international standards including EN ISO 13789, EN 15241–42, EN 15316, and EN 1519.

The EPC tool calculates total energy demand by balancing energy losses—via transmission and ventilation—and gains—via solar radiation and internal sources. EPC ensures that calculations reflect real-world conditions, aligning simulation accuracy with that of more complex dynamic tools (Lee et al., 201; Simmons,2011; Simmons et al.,2015; Zhang & Augenbroe,2018). Its outputs include monthly energy consumption, CO_2 emissions, and primary energy usage, providing a comprehensive dataset for optimizing sustainable building forms.

Optimization algorithm used in this study were Artificial Bee Colony (ABC) . Due to the infinite nature of design solution space, manual optimization is computationally infeasible. Therefore, swarm intelligence algorithms were employed to systematically explore design possibilities. These algorithms were implemented in MATLAB, which allowed seamless integration of EPC data through tabulated sheets for climate input, system configuration, and performance metrics (Uran & Jezernik,2016).

A seven-dimensional vector (short and long building edges, orientation, and the opaque-to-transparent surface ratios for each facade. Building height was excluded due to being pre-defined by zoning laws) was used to represent potential design solutions, allowing the algorithms to search within the bounds defined by setback distances, planned areas zoning regulation standards, and transparency ratios. The objective function and constraints were programmed into MATLAB using EPC-derived input data and structured to maintain realism and legal compliance. ABC algorithm was each run for 3,500 iterations, producing 70,000 design alternatives and enabling robust analysis of optimization efficiency.

Table 1. Representation of a Potential Solution – Design Parameters (Search space size)

Dim. 1	Dim. 2	Dim. 3	Dim. 4	Dim. 5	Dim. 6	Dim. 7
The short building edges	The long building edges	building orientation (main directions 0 intermediate directions 1)	opaquesurface /transparent surface	opaquesurface /transparent surface	opaquesurface /transparent surface	opaquesurface /transparent surface

In the field study section, the methodology described here was applied on an existing building.

2.1 Case Study
This section applies theoretical frameworks to real-world conditions by analyzing and optimizing the energy performance of a residential buildings in Konya, Turkey, through algorithmic design methods that integrate regional climate data and comply with regulatory constraints.

A parcel with a total area of 1425.88 m², located in Yaylapınar Neighborhood, Meram District, Konya Province, was selected as the project site (see Fig. 1). This building consists of 4 floors.The selection criteria included the presence of a low-rise building on the site and ease of access to zoning information.

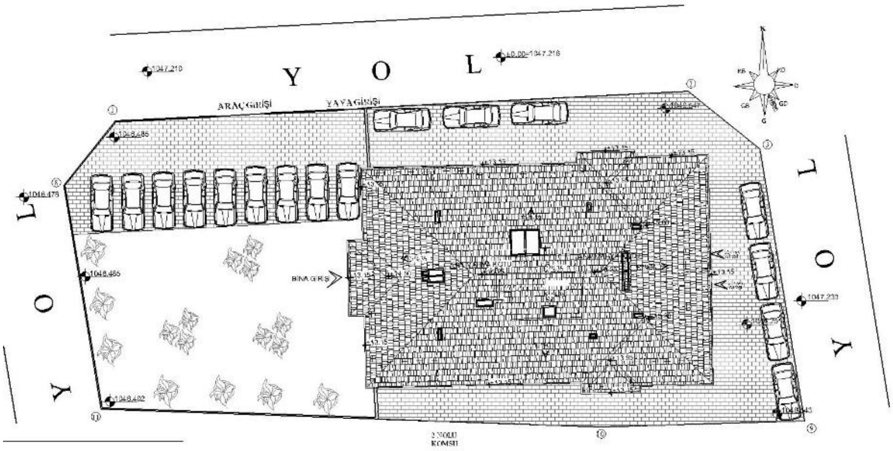

Fig. 1. Site plan of the existing building

Information regarding the existing land(zoning information) is as follows:

- Building Coverage Ratio (TAKS): 0.25 (can be increased by +0.05)
- Floor Area Ratio (FAR): 1.00
- Based on this, the calculated EPC data are as follows:
- Ground Floor Area: 1425.88 × 0.25 = 356.47 m² or 1425.88 × 0.30 = 427.76 m²
- Total Construction Area (FAR): 1425.88 × 1.00 = 1425.88 m²
- Volume: 1425.88 × 3.60 = 5133.16 m³ (Based on the maximum residential building height of 3.60 m according to Turkish Planning and Zoning Regulations)
- Setback Distance: Max. 18.90 m × 47.10 m

Information regarding the existing building data is as follows: EPC Data of the Existing Building:

- Ground Floor Area: 392.72 m²
- Total Floor Area (FAR): 1425.86 m²
- Volume: 5133.96 m³ (with h = 3.00 m)
- Transparent–Opaque Surface Areas: (see Fig. 2).
  - East: 130 m² (opaque), 85 m² (transparent)
  - North: 208 m² (opaque), 100 m² (transparent)
  - West: 140 m² (opaque), 75 m² (transparent)
  - South: 208 m² (opaque), 100 m² (transparent)
- Roof Area: 526 m²

Fig. 2. North,south,west east facades (form left to right)

The vectors of the existing building according to these criteria are given in Table 2.

Table 2. Early Design Parameters of the Existing Building

Dim. 1	Dim. 2	Dim. 3	Dim. 4	Dim. 5	Dim. 6	Dim. 7
17.00	24.36	0	140.05 / 75	208.15 / 100	130.05 / 85	208.15 / 100

Monthly energy consumption data of the existing building are given in Table 3.

Table 3. Monthly Energy Load of the Existing Building

Month	Monthly Energy Demand [kWh/m²]
January	25.13
February	26.85
March	21.7
April	16.53
May	19.65
June	23.48
July	27.19
August	26.74
September	21.92
October	17.24
November	23.96
December	29.05

Total: 279.43 kWh/m²

3. Result and Discussion

The findings of the field study are given in this section.

Information regarding the data of the Algorithmically Designed Building is as follows:. The building generated through algorithmic design must comply with the following criteria:

- Ground floor area must not exceed 427.76 m².
- Maximum short side length: 18.90 meters; long side length: 47.10 meters.
- Total site area must not exceed 1425.88 m².
- Roof area was calculated by adding 150 cm to both the short and long side lengths.

The vectors of the optimized building according to these criteria are given in Table 4.

Table 4. Optimized Design Parameters of the Algorithmically Generated Building

Dim. 1	Dim. 2	Dim. 3	Dim. 4	Dim. 5	Dim. 6	Dim. 7
18.83	18.91	0	45.19 / 180.76	45.38 / 181.53	45.19 / 180.76	45.38 / 181.53

Monthly energy consumption data of the optimized building are given in Table 5.

Table 5. Monthly Energy Load of the Optimized Building

Month	Monthly Energy Demand [kWh/m²]
January	23.07
February	25.55
March	20.93
April	15.28
May	18.03
June	21.27
July	24.53
August	24.15
September	19.93
October	16.15
November	23.07
December	26.84

Total: 258.79 kWh/m²

The comparison between the existing building and the algorithmically optimized one reveals that the differences in energy performance can be attributed to the following factors:

- Building Geometry

- Existing Building: Has a floor area of 392.72 m², a total FAR area of 1425.86 m², and a volume of 5133.96 m³. It is relatively taller and closer to a rectangular form.
- Optimized Building: Designed to remain within setback limits, it features a more compact and nearly square footprint. Reduced height and volume contribute to lower energy consumption.

- Surface Areas

- Existing Building: Has relatively larger total surface area and more transparent surfaces, which leads to increased heat losses and higher solar gain.
- Optimized Building: Surface areas are optimized for better thermal balance. Transparent areas are reduced, decreasing winter heat loss and summer overheating. However, a design limitation is the algorithm's tendency to converge toward the lowest transparency ratio regardless of orientation.

- Roof Area

- Existing Building: With a roof area of 526 m², it experiences greater heat loss since the roof is one of the primary surfaces for energy loss.
- Optimized Building: The optimized roof area, achieved by reducing side lengths, results in reduced thermal loss.

- Energy Consumption Results

- Existing Building: 279.43 kWh/m² annually
- Optimized Building: 258.79 kWh/m² annually

Table 6. The comparison between the existing building and the algorithmically optimized building

Building	Alternatives	Area	Short Side	Long Side	Taks	Kaks	Floor Number	Energy Consumption
Area	Border	1425,88	18,90	47,10	356,47	1425,88		
	Current		17,00	24,36	392,72	1425,86	4(h:12.65)	279,43
	Generated (ABC)		18,83	18,91	356,08	1424,30	4(h:12.00)	258,79
								20,64

According to the inference made from the data shown in Table 6; this implies a **7.4%** reduction in energy consumption, achieved through the optimization of architectural design parameters.

4. Conclusions

The global depletion of energy resources has made reducing energy consumption across all sectors an urgent priority. The construction industry, being one of the major consumers of energy, must adapt by implementing strategies that improve efficiency throughout a building's life cycle. This study responds to this need by adopting an energy-efficient approach during the design phase. The primary goal is to reduce energy consumption through a computational design method that integrates legal constraints and multiple design parameters.

Although various simulation and evaluation tools for energy performance exist, they are not widely adopted in the industry due to their complex data input requirements and the perception of energy efficiency as an additional burden. To address these challenges, this study developed a parametric design tool that facilitates rapid evaluation of multiple design alternatives, streamlining the workflow and helping designers incorporate zoning regulations, such as FAR and TAKS, into early-stage decisions.

After an extensive literature review, the Artificial Bee Colony (ABC) algorithm was selected for its effectiveness in solving architectural optimization problems. With the algorithm implemented in MATLAB and supported by EPC simulation data, a simplified energy optimization tool was developed. This tool was applied to residential building cases at different scales. Energy consumption for existing buildings was first calculated, and then compared with algorithmically optimized versions generated using ABC algorithm. Results revealed that optimized models exhibited better energy performance, achieving a noticeable reduction in energy consumption.

The tool also successfully incorporated zoning regulations and design constraints to produce practical, legally compliant and sustainable alternatives. It enabled fast and efficient generation of alternative layouts, demonstrating the potential to transform conventional design workflows. The tool's versatility allows for adaptation to different plot sizes, design typologies, and user-specific conditions, making it a scalable solution for sustainable architecture.

- This study presents a parametric design and optimization tool that integrates energy performance analysis with zoning regulations and environmental goals.

- The algorithmic design approach significantly reduced energy consumption through informed early-phase decisions.
- Swarm intelligence algorithm proved effective in generating diverse and sustainable alternatives under legal and design constraints.
- The tool provides a novel method for improving both energy performance and design efficiency in architecture.
- Future enhancements include AI-based personalization, adaptation to different climates and building types, and user-friendly interfaces for broader usability.
- The tool also offers potential use in urban planning by optimizing zoning parameters to prioritize sustainability at the city scale.

Abstract. Defined as rain that moves horizontally in the atmosphere due to the effect of wind, wind-driven rain (WDR) has a greater potential to penetrate building facades compared to vertically falling rain. The increasingly heavy rainfall and strong winds due to climate change suggest that the rain driven by the wind will accumulate more moisture on building facades. This study aims to examine the effects of rain coming from different wind directions on building facades through photographs and to validate these effects using a moisture measurement device and a thermal camera. In this context, the study aims to determine the impact of wind-driven rain on building facades through photographs taken in the designated area, to detect the moisture accumulation on facade building materials using a moisture measurement device, and to make comparisons between the facades. As part of the study, the Kanuni Campus of Karadeniz Technical University in Trabzon, located in a temperate humid climate region, was chosen as the study area. Measurements were taken at the same points on a pilot building where visible deterioration of the building facades occurred due to atmospheric effects, using a humidity device, and meteorological data were recorded. Measurements were taken on the northwest facade, where winds can create intense rain and humidity effects on building facades when combined with humid and rainy climate conditions, the southeast facade, where winds can carry warm and humid air to the building facades and increase moisture damage on the materials, and the southwest facade, which is exposed to storms blowing from the west in every season. Based on the obtained measurement results, facade damages caused by moisture were compared according to wind directions, and the relationship between wind speed, direction, and precipitation intensity with the amount of moisture on the facade was analyzed. As a result, it was determined that the distribution of moisture varies in facades facing different wind directions. The highest humidity levels, contrary to expectations, were not recorded on the blank northwest facade facing the prevailing wind direction; instead, they were observed on the southwest facade, which is continuously exposed to western winds, where window frames are densely located, and the most damage was also observed.

Keywords: Wind driven rain (WDR); Climate change; Façade damages; Humidity measuring device; Masonry façade

1. Introduction

The 2023 report of the Intergovernmental Panel on Climate Change (IPCC) has revealed that climate change is leading to a wide variety of weather and climate extremes worldwide, and these effects are becoming increasingly evident (Intergovernmental Panel on Climate Change, 2023). Climate change is showing its effects in many areas, including the construction sector. In the construction sector, although studies on the thermal performance of building facades generally attract attention, rain and wind are also climatic elements that need to be considered and studied. As research continues on the changes in precipitation amounts, wind speeds, and primary wind directions as a result of climate change, one of the most significant impacts of these changes on buildings is the increasing rain and wind-related building damage.

Rain penetration means the entry of rainwater through window joints, walls, wall and window/door connections, wall joints, roof insulation, protrusions such as chimneys on the roof, and working joints. Water penetrating into the structure, even if not visible, causes various damages to the building (Özdeniz, 1978):

- Degradations in building materials and components,
- Decrease in thermal insulation capacity,
- Plaster blistering, decoration deterioration, staining,

https://doi.org/10.31462/icearc2025_a_aen_325

● Mold and moss on walls and ceilings,
● Separation of other cladding materials,
● Continuous freezing-thawing damage in systems made with lightweight concrete,
● The increased corrosion rate of the reinforcement and other steel supporting systems within the reinforced concrete.

Wind, while causing mechanical wear on building surfaces with the particles it moves, also creates pollution by accumulating elements like dust, smoke, and sand in the recessed and unprotected areas of facade surfaces. Additionally, the wind imparts a horizontal velocity component to raindrops that are expected to fall vertically, causing this water to strike the building surfaces. Rainwater striking the surface of the structure seeps in through cracks and openings due to its kinetic energy, causing both the wall to become wet and the existing damage to progress. This seepage triggers various physical and chemical degradation processes within the wall, causing building damage (Tüz, 1996).

Affected by the surrounding topology (natural and structural formations in the environment), building geometry (the height, shape, and surface structure of the building), facade details (facade materials, windows, balconies, etc.), and all relevant meteorological parameters, WDR can lead to various undesirable outcomes on the wall surfaces of buildings, such as mold formation, efflorescence, material degradation, freeze-thaw damage, water penetration, and surface pollution (Blocken & Carmeliet, 2004). As wind speed increases, raindrops move more horizontally, resulting in reduced protection from eaves and balconies that would otherwise shield against rain falling more vertically (Kubilay et al, 2016).

In the future, it is anticipated that the load of wind-driven rain (WDR) reaching the facades of buildings in a horizontal direction will increase due to the impact of more intense rainfall and wind events.WDR, which constitutes a significant environmental load for buildings, plays a decisive role, particularly on the hygrothermal performance and long-term durability of facades (Blocken & Carmeliet, 2004; Ge et al., 2017). The intensity and distribution of this load are significantly influenced by meteorological parameters such as wind speed, direction, and precipitation intensity, as well as geometric factors such as building configuration, geometry, facade details, and roof shape (Gholamalipour et al., 2024). Therefore, anticipating the impacts of climate change and designing building facades to withstand this increased load has become a critical necessity for sustainable building performance.

Studies on wind-driven rain (WDR) can generally be classified into two main groups: the first group focuses on research aimed at quantitatively determining the WDR load that buildings are exposed to (Blocken and Carmeliet 2004; Nik et al. 2015; Ge et al. 2017; Wang et al. 2020; Zhou et al. 2023); the second group examines the physical and performance-based responses of building facades to this rain load (Tang et al., 2004; Abuku et al. 2009) (Gholamalipour et al. 2022). This study, on the other hand, is a comprehensive and original research that combines both approaches by quantitatively determining the WDR load on facades facing different wind directions using moisture measurement devices and evaluating the responses of the facades to this load through thermal imaging and field observations.

Trabzon, which is the subject of this study, is located in the Eastern Black Sea region, is a coastal city, and exhibits a temperate humid climate with abundant rainfall almost every month of the year. In almost all the buildings located in the Eastern Black Sea Region, problems related to rain passage are encountered. In the facades of the buildings facing west and northwest, water and wind-related building damages have been observed (Özdeniz, 1978). The speed and direction of the wind, as well as the intensity of the rain, can cause different types of damage depending on the type of materials used on the building's facade, its design, and maintenance methods. As secondary issues resulting from building damage caused by moisture penetrating from the building facade, the deterioration of hygrothermal comfort, increased energy consumption, and higher maintenance and repair costs can be listed.

Considering the role of the building envelope in controlling climatic elements, it is vital during the design process to anticipate the varying environmental loads on different façades and to formulate tailored architectural responses. To design buildings that are resilient to changing climate conditions due to climate change and to prepare existing buildings for future climate conditions, it is essential to first understand the rain loads carried by the wind on building facades. For this purpose, in the study, the building damages caused by rain-driven water and moisture on the northwest, southeast, and southwest facades of the selected pilot building in the Trabzon KTÜ Kanuni Campus were examined and evaluated. Based on the evaluation results, design proposals for the improvement of the facades have been developed.

2. Materials and methods

Research on rainwater flow is conducted through field observations, field measurements, laboratory experiments, and both analytical and numerical modeling approaches. Field observations provide valuable qualitative data on the phenomenon. Findings from such observations indicate that rainwater flow typically initiates at the upper parts of façades where WDR (Wind-Driven Rain) intensity is highest, and that, in tall and wide buildings, the lower sections of façades are exposed to significantly less WDR due to the wind-blocking effect (Blocken et al., 2013).

It has been noted that most studies related to WDR have been conducted on isolated buildings. For a standalone building without specific façade details such as overhangs or balconies, the windward façade directly facing the prevailing wind direction receives the greatest amount of WDR. In the presence of a roof overhang, the maximum WDR occurs near the base of the windward wall, and this maximum value is considerably lower compared to that on a building without an overhang (Gholamalipour et al., 2022).

During precipitation events, prevailing wind directions cause significant exposure variations on different facade orientations of the same building (Kim et al., 2022). Wind speed and wind direction have a greater impact on the WDR on facades than rainfall intensity (Zhou et al., 2023).In line with this information, the study data have been supported by field measurements, not limited to just field observations. In this context, in the northwest, west, and southwest facades facing the directions where storms are most frequently observed, points close to the ground and at the corners were identified, and humidity measurements were taken in these areas on specific days. At the same time, meteorological data have been recorded simultaneously.

As the study area, the Kanuni Campus of Karadeniz Technical University, located in the province of Trabzon, where problems related to water ingress in building facades are observed due to its coastal location and heavy rainfall throughout the year, has been selected. The Biology Department building, located on this campus, has been considered the pilot structure (Fig. 1). Meteorological parameters (wind speed and direction) were obtained from the Trabzon Meteorology Station. As part of the study, during the preliminary fieldwork conducted on March 21, 2025, the facades and specific points for measurement were identified, field conditions were evaluated, and appropriate data collection strategies were developed. Additionally, trial measurements were conducted to verify the accuracy of the equipment. After this preparation process, humidity and temperature measurements were conducted at selected points on March 22 and April 26, 2025, to quantitatively determine the effects of wind-driven rain on the building facades. During this period, although the measurements were planned because the field conditions were suitable, according to the data from the Turkish State Meteorological Service, the months with the highest number of rainy days (an average of 13 rainy days per month) and relative humidity values in Trabzon are also March and April (Turkish State Meteorological Service, n.d.). Therefore, the study period provides an appropriate meteorological context for observing the WDR effect.

The Test building is a four-story building located in the KTÜ Kanuni Campus (Fig. 2). The Biology department, which started its education in the Mathematics Building in 1984, has been continuing its education and teaching in its building since 2000 (Karadeniz Technical University, n.d.). It has a slightly sloped roof without an eave. To the northeast, approximately 17 meters away from the building, there is a four-story building parallel to it. The building is 65 m long, with the northwest facade being 13 m wide, the southeast facade 20 m wide, and it is 13 m high. The building facades face the northwest, southwest, southeast, and northeast directions. Its short facades face northwest and southeast. It is quite open to the northwest (NW), west (W), and southwest (SW), which are the directions from which storms most often come, making it an ideal building for wind-driven rain studies.

Fig. 1. Study site (Karadeniz Technical University, n.d.)

Fig. 2. Test Building

2.1 Trabzon climate:
The region with a temperate humid climate; the coastal area facing the humid winds of the Black Sea and the high parts of the mountains receive abundant rainfall, while the valleys formed by the rivers cutting through the mountains and the southern slopes of the mountains receive little rainfall. In the rainfall regime observed in the coastal area, maximum rainfall occurs in autumn, while the amount of rainfall is at a minimum at the end of spring. In mid-August, heavy downpours moving from the northwest (NW) to the southeast (SE) are observed in the coastal region (Karadeniz, 1995).

In Engin's (2011) study evaluating 31 years (1960-1990) of observation data from the Trabzon Meteorology Regional Directorate, it was noted that in Trabzon, severe winds from the western sector were predominant in every season, followed by the northern sector. It has been determined that storms predominantly blow from the northwest (NW) (Karayel) direction, followed by the west (W) (Günbatısı) and southwest (SW) (Lodos) directions. When examined seasonally, it has been emphasized that storms from the western sector dominate in every season (Fig. 3).

According to Erinç (2014), the foehn wind movements occurring along the Eastern Black Sea coasts during the cold period blow as South (S) and Southeast (SE) winds.

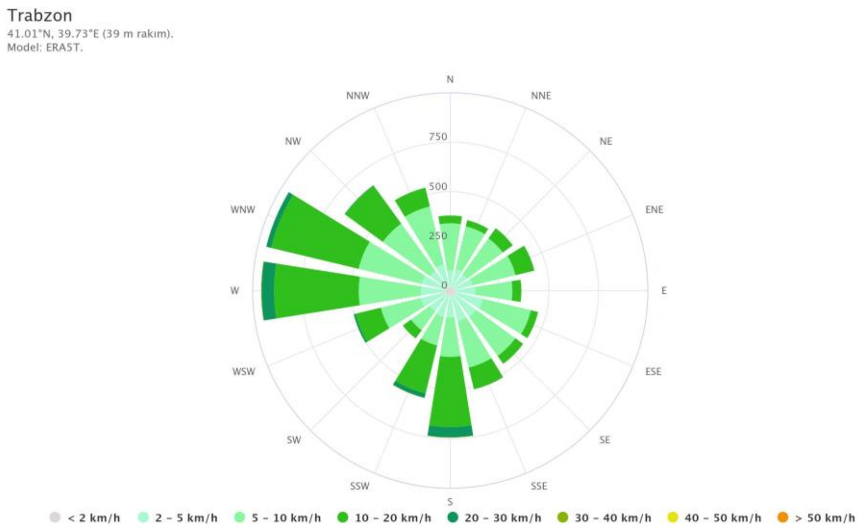

Fig. 3. Trabzon wind rose (Meteoblue, n.d.)

2.2 Moisture meter:
In order to support the field observations with field measurements, a portable Testo 606-2 moisture meter (measuring range from 0.7 to 8.6 %, measuring accuracy ± 1 %) was used to measure the facade moisture (Fig. 4).

Testo 606-2 (Testo, Lenzkirch, Germany) resistance moisture meter measures moisture-dependent electrical resistance using a pair of electrode nails driven into the structure.The device includes a sensor to determine the ambient temperature and relative humidity (Běťák et al. 2023).The feature of electrical resistance technology to reflect surface moisture distribution and provide a comprehensive regional assessment (Wang et al. 2024) has played a role in the selection of this moisture meter.

The field test was conducted on March 22, 2025, under overcast weather conditions with an average temperature of 8.6 °C. Then, about a month later, on April 26, 2025, another measurement was taken outdoors under an average temperature of 14.4 °C. The night before the measurements, the weather conditions were rainy. Measurement areas were determined on the northwest, southwest, and southeast facades of the test building. Since the southwest facade is the long facade, two separate measurement areas were determined in the north and south. A total of 4 measurement areas were obtained (Fig. 5). According to the studies in the literature (Abuku et al. 2009; Blocken et al., 2013; Gholamalipour et al. 2022), care was taken to place the measurement locations close to the wall edges and the ground, which receive the most WDR load after the facades. In each area, 5 moisture content readings were randomly taken, and the average moisture content of each area was calculated. Based on these calculations, the moisture content distribution was tabulated (Table 1).

2.3 Thermal imaging:
In addition to field observations and moisture value measurements, imaging was conducted on facades where moisture value readings were taken with a thermal camera to determine the hygrothermal performance of the structure. The thermal images taken with the Bosch GTC 400 C thermal imaging camera (Fig. 4), which provides rapid data sharing and easy documentation of thermal images, were measured while maintaining a fixed distance of 50 cm from the measurement point. The resolution is 160 × 120 pixels. Additionally, it has a thermal sensitivity of <50 mK, making even small temperature differences visible.Measurements range from -10 °C to +400 °C, with a measurement accuracy of ±3 °C.

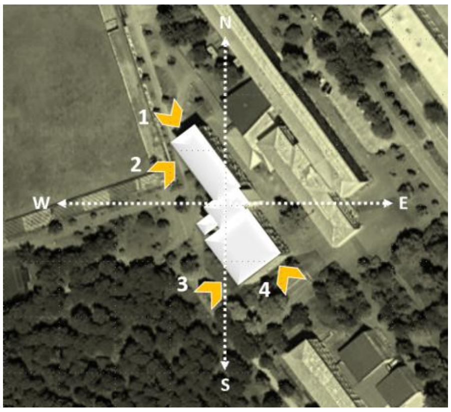

Fig. 5. Measurement points

3. Results and discussion
Fieldwork was conducted in two stages: field observations and field measurements, and the observations and measurements were examined by comparing them.

3.1 Field observations:
The northwest facade is a blank facade without openings such as windows and doors; although some paint spatter is observed, there is not much visible damage (Fig. 6). Paint and plaster applications are observed on the roof parapet edges and facade corners. Since a brick facade cladding of one and a half meters in height has been applied to the area close to the ground, there is not much damage caused by splashes and ground water, although some bricks have been found to have fallen in certain places.

The southwest facade is the facade where building damage is most commonly observed (Fig. 7).The edges of the facades, the edges and bottoms of the joinery are the areas where dirt and paint-plaster peeling are frequently observed.In buildings without eaves, the areas close to the ground on the wind-exposed facade are particularly where building damages are concentrated.

On the southeastern facade where the foehn winds blow, building damages are visible at the edges of the roof parapet, window sills, and the lower part of the enclosed balcony (Fig. 8).

Fig. 6. Northwest façade

Fig. 7. Southwest façade

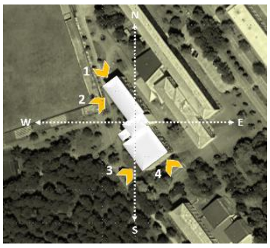
Fig. 8. Southeast facade

3.2. Field measurements:

In the study area, the average facade measurements taken with the Testo 606-2 material type hygrometer on March 22, 2025, and April 26, 2025, are presented in a table (Table 1). On Saturday, March 22, 2025, at noon, the weather, which had been rainy before, was very cloudy, with an air temperature of 8.6 °C, wind direction from the East, and an average wind speed of 4 km/h. On Saturday, April 26, 2025, at noon, the weather, which had been rainy in previous days, was clear, with a temperature of 14.4 °C, wind direction from the Northeast, and an average wind speed of 8 km/h. Looking at the humidity ranking, in the measurement on March 22, 2025, the highest humidity values were in the order of 3> 2> 1> 4 measurement points. In the measurement dated April 26, 2025, the highest moisture values are in the order of 2>3>4>1 measurement points.

In the study area, the images obtained using a thermal imaging device on March 22, 2025, and April 26, 2025, are presented in tabular form (Table 2). It has been observed that temperature differences occur on different facades. In the measurement dated March 22, the lowest temperature at the measurement point 1 located on the northwest facade was measured as 11.5 °C, while the area close to the brick-covered ground was measured as 12.9 °C.In the images taken from two different measurement points on the southwest facade, the measurement point number 2, where the humidity value in the wall under the window was lower, showed a higher temperature compared to the measurement point number 3. In the measurements taken on April 26, while the humidity levels on the facades generally decreased, the temperatures on the wall surfaces increased due to the rise in air temperature.At measurement point 1, the highest temperature was measured at 16.8 °C, while the area near the brick-covered ground was measured at 14.8 °C. In the images taken from two different measurement points on the southwest facade, the highest temperature measured at the second measurement point, where the humidity value is higher on the walls under the window, was lower than the highest temperature measured at the third measurement point. At measurement point 4, the lowest temperature was measured at 17.3 °C and the highest temperature at 20.2 °C.

Table 1. Measurement results



Measurement point	Facade direction	Average humidity value (%)	
		22.03.2025	26.04.2025
1	NW	1.4	0.8
2	SW	2.4	1.2
3	SW	2.6	1.1
4	SE	0.9	1.1

Table 2. Thermal images

	Measurement point	Facade direction	Lowest temperature (°C)	Highest temperature (°C)	Thermal image	Real image
22 March 2025	1	NW	11.5	12.9		
26 April 2025	1	NW	14.8	16.8		

Table 2 continued

22 March 2025	**2**	**SW**	**10.4**	**16.9**		
26 April 2025	2	SW	22.5	41.9		
22 March 2025	3	SW	10.1	14.2		
26 April 2025	3	SW	24.7	39.1		
22 March 2025	4	SE	10.7	12.4		
26 April 2025	4	SE	17.3	20.2		

3.3. Discussion

When the field observations and humidity measurement results are evaluated together, it has been observed that both data sets are generally consistent with each other; however, there are differences in some facades. As predicted, it was observed that the distribution of humidity also varied on facades facing different wind directions as a result of the measurements taken.

Firstly, when examining the difference between the experimental measurement conducted on March 21, 2025, and the measurement on March 22, 2025, it was observed that due to the measurement taken after prolonged rainfall on March 22, there was a significant increase in humidity levels on all facades. The significant increase in humidity levels on March 22, 2025, compared to March 21, indicates that the rainy weather conditions from the previous night directly affected the moisture accumulation on the facade surfaces. This situation has been significant in relating the obtained humidity values to environmental conditions. In the measurement dated April

26, it was observed that the humidity values measured on the facades had significantly decreased. It is believed that this situation was caused by the air temperature rising to approximately twice that of the previous measurement days. Nevertheless, the southwest front is still the one with the highest humidity value.

According to Tang (2004), building walls facing the prevailing wind directions generally receive more driven rain, but understanding the distribution of rain due to local airflows and the wind's influence is challenging due to limited data sets and complex interactions. As visually analyzed in the field observation, it was determined that the facade with the highest moisture content is not the blank NW northwest facade, which receives the most wind, but rather the SW southwest facade, which is continuously exposed to west winds due to the opening in front of it and has many window frames and thus joints. In this case, it is believed that local airflows and local winds, as well as other parameters (environmental factors, building geometry, surface characteristics, etc.), are also influential.

Especially on the southwest facade, the intense deterioration observed during field inspections (paint peeling, plaster spalling, pollution, and material delamination) overlaps with the high humidity levels determined in field measurements. This situation confirms that the inadequacy of the structural joint details and direct exposure to wind increase moisture accumulation. Despite the presence of sills on the windows of the southwest facade, the extensive damage is believed to be caused by the impact of rain droplets driven by the rapidly arriving wind and errors in the joinery-sill-building connection details. The inadequacy of solutions to ensure waterproofing at the junctions of the sill and wall, as well as the absence of drip edges, may have contributed to this situation. However, it is estimated that the water coming from the ground through splash and capillary action has caused damage to the wall above the ground. It is thought that the change in the percentage ranking of moisture values in two measurements at two points (measurement points 2 and 3) on the SW facade, where the most facade damage is observed, may be related to the instantaneous variation in wind direction.

Observations for the northwest facade have revealed that there is limited surface deterioration, particularly with localized peeling in the brick cladding areas. In the measurement results, lower moisture values than expected were obtained on this facade compared to the other facades. This situation suggests that the lower moisture levels can be attributed to the façade being a blank wall, lacking joints or connection points (such as window frame-wall intersections) through which rainwater could penetrate the inner layers.

The southeastern front stands out as the least affected front in terms of both field observations and measurement data. The limited visual distortions observed are consistent with the low humidity levels in the measurement results. In the first measurement at the 4th measurement point on the SE facade, the lowest humidity value was observed, which is thought to be due to the presence of a closed balcony on the facade and the wall and trees in front of the measurement area reducing the impact of rain driven by the wind. In the second measurement, it is thought that the reason the average humidity value on the SE facade was not the lowest, despite the increasing temperature, is due to the trees in front of the facade and the covered protrusion on the facade casting shadows on the measurement point. It is thought that the projections, trees, and neighboring structures on this facade are physical barriers that restrict the rain carried by the wind from directly reaching the facade.

As a result of comparing thermal camera images with humidity measurement data, a direct and reciprocal interaction between the amount of moisture on the building facade and the surface temperature has been identified. It has been observed that damp surfaces generally exhibit lower temperature values. It is understood that this situation leads to lower temperatures in the relevant areas compared to their surroundings as a result of the evaporation process occurring on the surface and the heat being removed from the environment. However, as predicted, it has been determined that in areas where building damages are visible and at the window-wall junctions, the temperature values are either lower or higher, resulting in heat losses. In the blank facades (northwest and southeast directions) where building damages are less observed, it has been determined that the differences between the lowest and highest temperature values are more limited. This finding reveals the relationship between building damage and the moisture balance and thermal comfort conditions of the wall surface, demonstrating that the moisture effect directly influences surface temperature fluctuations. It is anticipated that moisture accumulation can adversely affect the indoor temperature and humidity balance of the structure, which in turn may lead to a deterioration of indoor comfort conditions and an increase in energy consumption for heating.

The comparison made reveals that not only the visual distortions observable on the facade surface, but also the moisture accumulating beneath the surface, play a significant role in the formation of building damages. When limited to visual observations, it may not be possible to detect internal deterioration caused by moisture sources that structural elements are exposed to, indicating that field inspections must be supported by technical measurements. Quantitative analysis methods such as moisture measurements and thermal imaging reveal subsurface moisture movements and the potential damage they cause, allowing for a holistic assessment of structural health. Therefore, to accurately analyze the performance of the structure and effectively determine intervention strategies, it is critical to not only rely on observations but also to complement them with scientific measurements.

4. Conclusions

In this study, the effects of wind-driven rain (WDR) on building facades have been examined through both visual field observations and quantitative field measurements.Based on the findings obtained, the following conclusions have been reached:

- On the Northwest facade, which faces the Northwest where storms are most commonly observed, no expected high humidity levels or significant damage were observed due to the absence of openings and joints. However, some paint-plaster peeling and brick falls were observed on the brick facade cladding and the roof parapet edges.
- At the southwest facade, it has been observed that rain droplets, driven by rapidly coming winds, are causing severe facade damage due to structural joint errors and lack of waterproofing.
- Due to the effects of the foehn winds, structural damage has been observed on the edges of roof parapets, window sills, and under enclosed projections on the southeastern facade; however, the low humidity at the measurement point, the enclosed projection, and surrounding obstacles have reduced the wind's impact.
- As a result of the measurements taken, it was observed that the distribution of moisture varied on facades facing different wind directions. The facade where the most moisture was observed was not the blank northwest facade where the prevailing wind comes from, but the southwest facade, which is constantly exposed to western winds and has many window frames, and where the most damage was also observed.
- An increase in humidity levels has been observed after prolonged rainfall. With the increase in temperatures, a decrease in humidity levels has been observed.
- The ranking of humidity values at the measurement points varies due to instantaneous changes in wind direction and the influence of environmental factors.

Considering the changing climate conditions and increasing humidity levels, design solutions that can bear the moisture load should be developed and implemented in the facades of newly constructed buildings to ensure cost and comfort efficiency. Improvements should be made in existing buildings. In existing or newly constructed buildings, the following recommendations are made to consider wind-driven rain loads and prevent their adverse effects:

- Different design solutions can be applied according to the directions.
- Problems can be prevented with appropriate detailing on facades (steel angle brackets, joint sealant, polyethylene foam filling, etc.) (Swinton & Kesik, 2005).
- Even a small facade detail (e.g., a 10 cm window sill) can reduce the WDR load by up to 37% (Kubilay et al., 2016).

In conclusion, measures such as selecting the right materials, waterproofing, and calculating wind loads are necessary to enhance the durability of building envelopes against wind-driven rain. Reducing the impacts of such environmental factors, extending the lifespan of buildings, and increasing energy efficiency are very important in terms of lowering economic and environmental costs.

Capillary active thermal insulation materials used in architecture

Tuğba Yıldız*[1], Leyla Tanaçan[1]

[1] Department of Architecture, Istanbul Technical University, Turkey

Abstract. Approximately 40% of the energy produced worldwide is used in the construction sector. 60% to 80% of the heating and cooling loads in buildings are due to heat transfer through the building envelope. Among these building elements, external walls play a major role and can account for approximately 25-30% of the total heat loss. Studies on enhancing the energy efficiency of historic buildings are crucial because 30% of the current building stock is classified as historic. It is unable to insulate buildings with cultural historical value from the outside due to the preservation of their original architectural expression. Today, it has been suggested to use capillary active insulation materials as substitutes for traditional insulation materials. Those materials with their specific hygrothermal characteristics, have also been determined to enhance building energy efficiency. Capillary active thermal insulation materials allow the moisture that may accumulate at the interface between wall structure and thermal insulation resulting from the rain water pushed from the outer surface of the facade and/or condensation of the vapour transmitted from the inside to the outside to dry inwards. Hence in this study, recent research done on capillary active thermal insulation materials; their practical applications in architecture and comparative material properties according to the expected performance requirements are scrutinized and probable potential materials that can be used for this aim are suggested by literature review. With the recommended capillary active insulation materials given in this study; in cases where it is necessary to preserve the character of the building facade, the energy cost can be reduced by reducing the heat loss of the building and a healthy indoor environment free of mold and moisture will be created.

Keywords: Interior insulation; Hygrothermal performance; Capillary active insulation; Capillary absorption coefficient; Thermal conductivity

1. Introduction

As the targets for reducing energy consumption increase in the world, it has become important to take energy improvement measures in existing buildings. For this purpose, it is planned to introduce minimum energy performance standards, to gradually remove buildings with poor performance from use, to continuously improve the building stock and to achieve the target of a decarbonized building stock by 2050 (Energy Performance of Buildings Directive, nd). Buildings account for 40% of energy consumption (Directive - 2010/31 - EN). More than 60% of residential buildings were built before 1960 (Hansen et al., 2018).

One of the natural precautions taken in the building envelope to reduce energy consumption is thermal insulation. Thermal insulation is important not only for energy loss but also for the thermal comfort and indoor air quality of the space (Balocco et al., 2008). Building insulation can be in the form of external insulation and internal insulation. Although external insulation is the common option that protects the existing structure from the external environment and eliminates thermal bridges, the protection and restoration of culturally valuable structures can be possible with internal insulation. The use of internal insulation is risky due to damages such as frost damage, mold formation, condensation at the interface, and salt efflorescence (Klõšeiko et al., 2017) (Zhao et al., 2017). In order to reduce the risk of damage and support the preservation of cultural heritage, vapour-open capillary active internal insulation systems that allow vapour exchange between the internal and external environments are encouraged (Grunewald et al., 2006; Remmers 2014; Vereecken & Roels, 2015).

The systems currently marketed as capillary active cannot be comprehensively evaluated through a generalized analysis based on a single standard system. This highlights the need for more detailed and specific approaches that consider the multifaceted performance characteristics of such materials. Accordingly, this study aims to contribute to defining the necessary thresholds for enhancing the hygrothermal performance of capillary active insulation materials, while maintaining low thermal conductivity, and to support the development of multifunctional insulation materials suitable for use in the building sector.

2. Capillary active insulation materials and parameters affecting their performance

Capillary active insulation materials are vapour permeable systems that prevent condensation at the interface thanks to the capillary forces of the insulation material, but also allow drying. These systems aim to dry out the original wall by allowing the condensation occurring at the interface between the wall layers to dry inwards. On the other hand, vapour impermeable systems can pose potential risks such as frost damage, increased moisture content in the wall and various structural damages, while traditional vapour open systems can lead to intermittent condensation (Vereecken & Roels, 2014). For this reason, the use of capillary active interior insulation systems has been encouraged. The working principle of capillary active interior insulation systems is as follows:

1.During the heating season, moisture moves from the inside of the wall to the outside due to the temperature and vapour gradient.

2.Condensation occurs when the temperature between the adhesive mortar and the insulation material drops below the dew point.

3.The capillary active insulation material absorbs the condensed water and carries it inwards following the capillary pressure gradient. Thanks to this mechanism, condensed water does not accumulate in the wall structure and the wall is allowed to dry.

The main reason for choosing capillary active systems, whose working mechanism is generally explained from the perspective of condensation at the interface, is that these systems have drying-allowing and vapour-permeable characteristics (Vereecken & Roels, 2016a) (Fig. 1).

Studies have shown that the use of vapour-open materials can increase hygrothermal performance (Finken et al., 2016; Klõšeiko et al., 2015; Marincioni & Altamirano, 2014; Morelli & Moller, 2019; Odgaard et al., 2018). Certain systems exhibit such low capillary absorption coefficients (and thus minimal liquid permeability) that they can scarcely be considered capillary active. This may lead to increased moisture accumulation on the warmer side of the masonry wall and in the adhesive mortar. However, it also reduces the risk of excessive inward moisture flow, such as during heavy wind-driven rain exposure. There are also studies where high humidity values occurred at the interface (Odgaard et al., 2018) (De Mets et al., 2017). When using capillary active insulation materials on the interior side of a wall, humidity-related concerns within the wall must be addressed. One key consideration is the compatibility between the insulation and the adhesive properties. Studies have been conducted to examine the effects of insulation and adhesive mortar on moisture distribution in the wall (Kočí et al., 2013) (Vereecken & Roels, 2016b).

The application method of the insulation material is also an aspect that requires attention. Interstitial condensation can be managed effectively, provided there is proper contact between the masonry wall and the insulation. For this, the insulation material should have lower vapour permeability, lower thermal conductivity and capillary conductivity values than the adhesive. If this is not the case, the adhesive prevents the water formed by condensation from being transmitted back. In cases such as existing building renovation and restoration, it can cause mold formation. (Fig. 2a).

Scheffler and Grunewald (2003) proposed a two-layered capillary active interior insulation system to prevent moisture-related issues in buildings, particularly when an air gap exists between the insulation and the masonry wall. This system uses a retarder layer (with higher thermal conductivity, lower capillary conductivity and higher vapour diffusion resistance than the insulation layer) close to the wall structure and an insulation layer (with lower thermal conductivity, higher liquid conductivity and lower vapour diffusion resistance than the retarder) on the room side. The increase in thermal conductivity of the retarder layer reduces the amount of vapour diffuses, resulting in less condensation in the old wall structure.

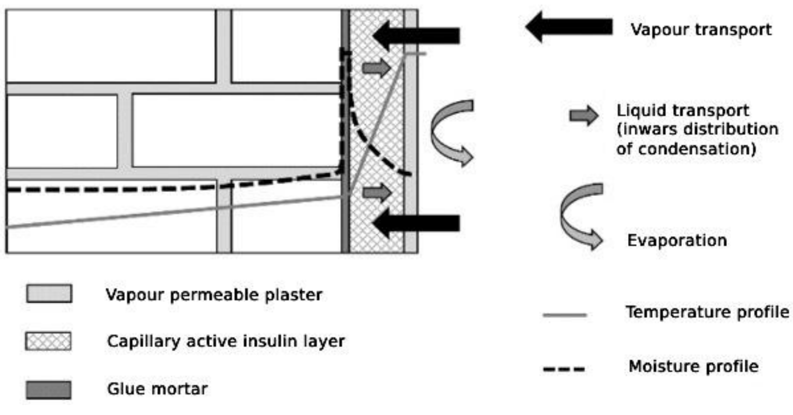

Fig. 1. Working mechanism of a standard capillary active insulation system (Vereecken & Roels, 2016a)

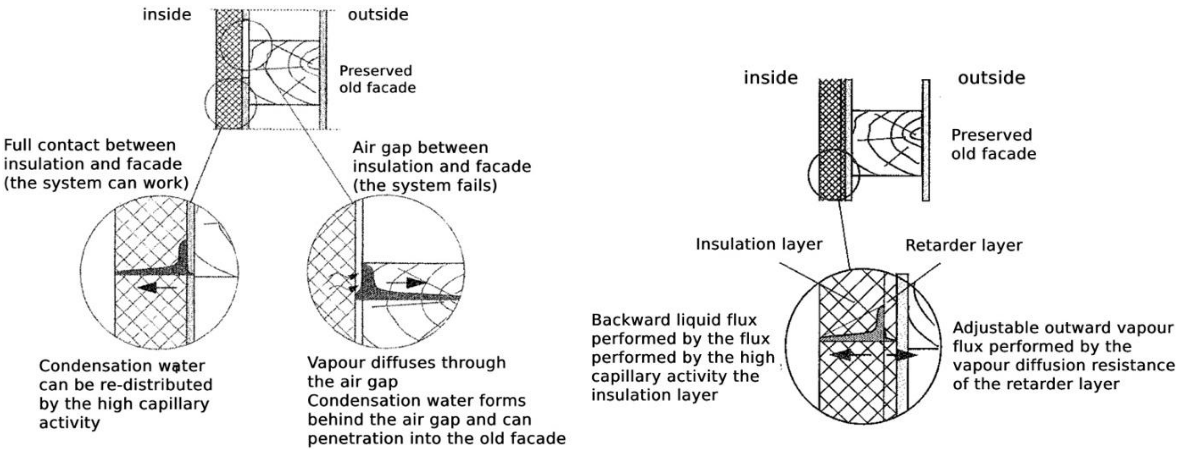

Fig. 2. Air gap problem between capillary active materials (a) and the wall and proposed system (b) (G.Scheffler & Grunewald,2020)

Table 1. Performance comparison of capillary active and traditional vapour-tight internal insulation systems

Capillary Active Systems	Vapour Tight Systems
Lower thermal resistance	Higher thermal resistance
Water vapour diffusion factor is low	Water vapour diffusion factor is high
High water absorption coefficient	Low water absorption coefficient
Allows moisture to move easily from the wall to the room	Prevents moisture from moving from the wall to the room.
Recommended for wooden beam ends in historic buildings	Not recommended for wooden beam ends in historic buildings
Higher indoor relative humidity during the heating season	Lower indoor relative humidity during the heating season
Rain load from wind affects the relative humidity of the interior surface	Rain load from wind does not affect the relative humidity of the interior surface.
Wind-driven rain load affects thermal resistance more	Wind-driven rain load affects thermal resistance less
It performs better on thick walls or walls that are protected against wind-driven rain loads	Performs less effective, "worse" on thick walls or walls protected from wind-driven rain loads

This design encourages condensation to form between the two layers, rather than in the wall structure, so that the insulation layer can manage moisture and protect the structure from potential damage, particularly mould growth. As a result, this system offers a vapour permeable and thermally efficient internal insulation solution. It also allows air gaps to be createdadhes between the insulation and the existing façade, without its performance being affected by the bonding methods used (Fig. 2b).

A comparison of the performance of capillary active and traditional vapour-tight internal insulation systems is given in Table 1.

Capillary active insulation systems perform better than vapour-proof systems if they are applied to a sufficiently thick wall or a wall protected from rain. If the wall is thin or exposed to rain, the moisture diffusing inside may cause undesirable situations. Some of the moisture will be stored while some will disperse into the room. This will cause a decrease in the performance of the insulation material when the indoor relative humidity is high (Vereecken & Roels, 2015).

3. Performance requirements of capillary active insulation material

Upon reviewing the literature, it was observed that no qualitative criteria have been established to characterize the hygroscopic and thermal properties of capillary active insulation materials. A methodology was proposed for classifying the hygroscopic properties of insulation materials to facilitate the selection of appropriate insulation for the envelopes of historical buildings (Posani et al., 2021a). High vapour permeability, low thermal conductivity and the ability to transfer moisture in liquid form at low humidity levels are the three physical properties that an active insulation material must have. One of the basic elements that determine the working principle of the systems is the property defined as capillary activity in the literature (GA Scheffler, nd).

3.1 Moisture content

In the analysis of moisture accumulated in wall assemblies, a systematic distinction is made between moisture accumulated in the wall structure outside the insulation system and the surface finish layer and moisture accumulated within the insulation system. When the effect of wind-borne precipitation is excluded from the evaluation, the amount of moisture in the load-bearing brick layer is generally negligible. However, in capillary active systems, a certain amount of moisture accumulates in calcium silicate and adhesive mortar. In contrast, in systems using XPS, either no moisture accumulation is observed or it is much less (Finken et al., 2016). Since moisture accumulation can cause a decrease in thermal resistance, it should be taken into account in thermal performance analyses.

3.2 Water absorption coefficient

When the material is in direct contact with water, the water uptake resulting from capillary suction can be measured by the water absorption coefficient. It has been stated that capillary active insulation materials applied to building envelopes with porous and capillary active character absorb the liquid water formed as a result of condensation and buffer it to the interior space, thus ensuring the envelope dries (Vereecken & Roels, 2015). The importance of using insulation materials with similar hygroscopic properties to the existing wall in preserving the general drying capacity of historical materials and regulating the water absorption of the wall exposed to rain loads has been emphasized (Finken et al., 2016). When the water absorption coefficient values found in the literature for various insulation materials widely used in the refurbishment of historical buildings were compared, it was seen that inorganic materials (Mineral Wool, Calcium Silicate and Cellulose) had relatively high absorption coefficients (Posani et al., 2021b).

3.3 Thermal conductivity coefficient

According to the DIN 4108 standard, materials with a thermal conductivity coefficient (λ) below 0.1 W/(m K) are classified as thermal insulation materials in the construction sector. Materials with a λ value below 0.03 W/(m K) are considered to have high insulation performance, while those in the range of 0.03–0.05 W/(m K) are moderately effective; values above 0.07 W/(m K) indicate low insulation capacity (Jelle, 2011; Koru, 2016; Pfundstein, Gellert, et al., 2008). The ranges of the thermal conductivity coefficient for different material groups contain various uncertainties: for inorganic materials, this value generally varies between 0.03–0.07 W/(m K), while for organic materials it is 0.02–0.055 W/(m K), and for advanced materials, values mostly below 0.01 W/(m K). In general, the nominal thermal conductivity coefficient of porous materials varies between 0.02 and 0.08 W/(m K); for alternative insulation products based on natural fibers, this range is at the level of 0.04–0.09 W/(m K) (Hung Anh & Pásztory, 2021).

3.4 Vapour diffusion resistance factor

The higher the water vapour diffusion resistance factor of the insulation materials, the lower their moisture absorption capacity. A thermal insulation material with sufficient thickness and sufficiently high water vapour diffusion resistance should be selected to prevent condensation. When more than one layer of building material is used, the water vapour diffusion resistance of the building component should be calculated by considering the thickness and water vapour diffusion resistance factor of each material separately. If the water vapour diffusion resistance factor of the capillary active insulation material is lower than that of the adhesive mortar, the risk of condensation between the adhesive mortar and the insulation should be taken into consideration (Bademlioğlu et al., 2018; Insulation Materials-Properties, n.d.).

3.5 Bulk density

Density is highly correlated with thermal conductivity, vapour diffusion factor and water absorption. There are studies that thermal conductivity and vapour diffusion factor generally show a linear correlation (Conti et al., 2016; Costes et al., 2017). It has been determined that the water vapour resistance factor is lower in materials with lower density due to increased porosity (Marques et al., nd). Lebed and Augaitis (2017) modeled the relationship between the water vapour resistance factor and density (in the range of 60–180 kg/m³) by means of a polynomial function based on the data obtained by the wet cup method (Zhou et al., 2022). However, some studies have concluded that the water vapour resistance factor is not significantly affected by density, it is relatively insensitive to this parameter (Cascone et al., 2019; Marques et al., nd; Reif et al., 2016).

3.6 Spesific heat

Capillary active materials have a porous structure that affects water vapour and moisture transfer. Having a high specific heat ensures that surface temperatures remain more stable. This reduces the risk of condensation and prevents mold formation and material deterioration, thus increasing the durability and performance of the material. Having a high specific heat in capillary active insulation materials increases the material's capacity to store and slowly release heat(Gündüz et al., 2001).

4. Capillary active insulation materials

Nowadays, various capillary active materials are available for internal insulation improvement. Initially, most of the studies on capillary active internal insulation systems focused on calcium silicate-based systems that provide a large amount of capillary liquid transport with pore sizes ranging from 0.1–1 µm (Häupl et al. 2003; Grunewald et al. 2006; Vereecken and Roels 2014b; Vereecken et al. 2015; Scheffler and Grunewald 2003). Later, different types of capillary active internal insulation systems have been introduced. Examples are aerated concrete (e.g. Multipor®), mineral foam, wood fiber board (WFB), cellulose, capillary-active, diffusion-open wood fiber insulation, composite internal insulation system with PUR foam and mineral coating, PUR/VIP-Reinforced calcium silicate composite, etc. These materials have a wide range of properties and working mechanisms, as described below.

Recently, some researchers have also developed biodegradable capillary active insulation materials, such as sheep wool (Gu et al., 2020; Zach et al., 2012), hemp (Scrucca et al., 2020), flax (Benmahidddine et al., 2020), jute (Senbagan et al., 2020) and corn stalk (Ahmad et al., 2020; Ahmad et al., 2019; Ahmad&Chen 2020; Ahmad et al., 2018). These biomaterials are sustainable and offer hygroscopic and capillary active properties. However, there is insufficient research on their usability as capillary active insulation materials.

- CaSi

Calcium silicate foam (CS) consists of calcium and silicon oxide plus 3–6% cellulose aggregate as raw materials. By mixing these materials with water, calcium silicate hydrate (CSH) is produced. The cellulose content plays a role in increasing the flexibility and edge stability properties of the material. During the production process, the mixture is poured into pre-prepared molds and then subjected to an autoclaving process, where high pressure and steam are applied together. Following this process, the product is cut into sheets and the surface is treated with metallic soaps or siliconates to provide water-repellent properties. The resulting structure is in the form of a finely porous, open-celled and rigid foam (Pfundstein, Söffker, et al., 2008) (Fig. 3a).

- AAC

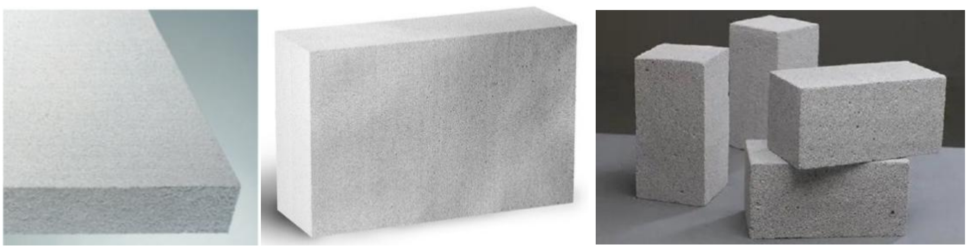
Autoclaved aerated concrete (AAC) consists of quartz sand, mineral lime and cement. The components are mixed by adding water and the expansion agent aluminum paste reacts with the alkali elements in the cement during the pre-curing process to form gaseous hydrogen. In the later stages of the production process, the hydrogen gas formed is released into the atmosphere and removed from the cavities in the block. Then, the material is subjected to an autoclaving process under high temperature and pressure for a certain period of time. After steam curing is completed, the material is dried with hot air to its final state and becomes ready for use (Mathey & Rossiter, 2009) (Fig. 3b).

- Mineral Foam

Mineral foam (MF) is produced from a mixture of lime, finely ground quartz sand, cement and a pore-forming component. The production process is similar to the production of autoclaved aerated concrete. However, the main difference is that natural protein-based foams are added to the mixture in order to provide a biologically sourced pore structure during the pore-forming stage. The organic components in these protein-based foams are decomposed and removed from the environment during steam curing during the autoclaving process (Zhou et al., 2022; Institute of Building Biology) (Fig. 3c).

- Wood Fiber Board

It consists of long-fibre softwood and sometimes hardwood wood fibres. Depending on the production method, wax-based emulsions containing latex or aluminum sulfate as binding material can be preferred. Boric acid is added to the production process to increase the resistance of the material to pests and fire. In addition, some wood types are treated with bitumen or natural resin-based emulsions to provide additional water-repellent properties. The production process begins with the wood raw material being first chopped into small pieces in a chipper; these pieces are then pulped in an autoclave and then pretreated between grinding rollers before being pulverized. The resulting pulp is pressed in molds and finally dried to obtain the final product (Pfundstein, Söffker, et al., 2008) (Fig. 4a).



a) b) c)

Fig. 3. a) Calcium silicate (CaSi), b) Aerated concrate (AAC), c) Mineral foam (MF)

a) b)

Fig. 4. a) Wood fiber board, b) Cellulose

- Capillary-active, diffusion-open wood fibre insulation system

It consists of system components of wood fiber, mineral functional layer, clay or lime plasters. The core material is wood fiber obtained from coniferous wood waste such as sawdust and woodchip. These fibers are processed by a thermomechanical method using lignin, the natural binding agent of wood. The mineral functional layer is a capillary active surface treatment that balances vapour resistance with breathability. It is available on the market under the trade name Pavatex Pavantro (Soprema United Kingdom) (Fig. 5a).

- Composite internal insulation system with PUR foam and mineral coating

This material, produced under the trade name IQ-Therm is a composite insulation material consisting of rigid polyurethane foam panels laminated with a mineral nonwoven layer, offering a synergistic solution for thermal insulation and moisture management in interior applications. This combination results in a capillary-active, diffusion-open insulation material that effectively balances thermal performance with moisture control. In such a system, if condensation occurs in winter due to temperatures dropping below the dew point, or if heavy rain penetrates the façade, with iQ-Therm the moisture is not retained behind a film, but is instead directed out of the wall section via the mortar and released back into the room air without causing damage (IQ-Therm 2.0) (Fig. 5b).

- PUR/VIP-Reinforced Calcium Silicate Composite

This material, produced under the trade name Calsitherm Xtra, is a composite insulation system composed of calcium silicate together with Polyurethane (PUR), pyrogenic silicas or VIP (Fig. 5c). It is formed in a reaction between lime (calcium oxide) and sand (silicon dioxide), under high pressure steam in an autoclave process. This process results in a microporous structure that is both breathable and moisture regulating. The fact that approximately 93% of the volume is air gives the material thermal insulation and moisture buffering ability. The high alkalinity of the material makes it naturally resistant to mold and eliminates the need for chemical biocides (CALSITHERM).

Table 2 shows the water absorption coefficient, thermal conductivity, moisture content, sd value, vapour diffusion resistance factor, bulk density, and specific heat values of capillary solid insulation materials, which are important for their hygrothermal performance, and have been investigated using literature findings.

Table 2. Capillary active insulation material properties

Materials	Water absorption coefficient [kg/m²√s]	Thermal conductivity coefficient(λ) [W/mK]	Moisture content [kg/m^3]	sd for r=2.5 (m^{2}K/w) [m]	Vapour diffusion resistance factor (μ) [-]	Bulk density [kg/m^3]	Spesific heat [J/kgK]	Referance
CaSi Foam	0.95-1.07	0.045-0.065	20	1	3-20	115-300	1000- 1180	(Pfundstein et al., 2008)
AAC	0.006-0.008	0.042-0.045	25	0.55	6.7	98.5	1210	(Zhao et al., 2017)
Mineral foam	0.102	0.047	-	-	6.7	128.4	893	(Zhao et al., 2017)
Wood fiber board	0.07	0.042-0.09	30	0.47	5-10	40-270	1600-2100	(Pfundstein et al., 2008)
Cellulose	-	0.04-0.045	160	-	1.7-3	30-80	1700-2150	(Pfundstein et al., 2008)
Composite internal insulation system with PUR foam and mineral coating	0.013	0.031	-	2.25	39	-	-	(IQ-Therm 2.0)
PUR/VIP-Reinforced Calcium Silicate Composite	-	0.059	-	0.4	3	180-187	-	(CALSITHERM)
Capillary-active, diffusion-open wood fibre insulation	0.2	0.0443	-	0.95	5-12	180-700	1700-2100	(Soprema United Kingdom)
CS-1	2.92	0.11	-	4.42	16.07	662	1362	(Ahmad et al., 2021)
CS-2	1.82	0.06	-	1.78	11.85	598	1607	(Ahmad et al., 2021)

It has been observed that the water absorption coefficient of Autoclaved Aerated Concrate is relatively low compared to other alternatives. This situation may be insufficient in terms of liquid permeability when compared to CaSi Foam. Thermal conductivity levels are lower than the required 0.1 W/(mK) except for the CS-1 alternative. Since the vapour diffusion values are low, the Sd values are lower than those of traditional insulation materials. The vapour diffusion resistance factor of Composite internal insulation system with PUR foam and mineral coating is relatively higher. The vapour resistance factor of other insulation materials should also be improved to a level that will allow vapour to pass through but will not allow condensation at the interface. It has been observed that density levels sometimes match or exceed the desired 50-70 kg/m3 level in foam insulation materials (Mühendisleri et al.). The densest materials were CS-1 and CS-2, which were suggested as composite capillary active alternatives. Specific heat of natural fiber insulation materials generally provided the range of 800-1200 or higher.

The comparison of the property range of capillary active insulation materials with the traditional insulation materials (glass wool, stone wool, PUR, XPS, EPS) which are based on standard industry ranges are given in Table 3.

Table 3. Comparison of the property range of capillary active and traditional insulation materials.

Material	Thermal Conductivity (λ) [W/m·K]	Moisture Content [kg/m³]	Diffusion Resistance Factor (μ) [-]	Bulk Density [kg/m³]	Specific Heat [J/kg·K]
Capillary Active	0.031–0.11	20–160	1.7–39	98–662	893–2100
Glass Wool	0.032–0.040	<1	1–2	10–50	840
Stone Wool	0.033–0.040	<1	1–2	30–150	840
PUR	0.022–0.028	<0.5	30–100	30–50	1400
XPS	0.030–0.038	<0.5	100–200	25–45	1300
EPS	0.030–0.040	<1	20–70	15–30	1300

Capillary active materials are designed for moisture management, which makes them heavier and more moisture-absorbent compared to traditional insulation materials, with a moisture content of 20–160 kg/m³ versus <1 kg/m³ for glass wool, stone wool, XPS, and EPS, and <0.5 kg/m³ for PUR. Their water absorption coefficient ranges from 0.006–2.92 $kg/m^2 \cdot s^{0.5}$, significantly higher than traditional materials like PUR, XPS, and EPS (0.013 $kg/m^2 \cdot s^{0.5}$) and glass wool and stone wool (0.7 $kg/m^2 \cdot s^{0.5}$), reflecting their ability to actively manage water. They can match the thermal performance of glass wool, stone wool, XPS, and EPS at their best (0.031–0.040 W/m·K), but PUR outperforms them in insulation efficiency (0.022–0.028 W/m·K). Their vapour permeability is moderate, with a diffusion resistance factor (μ) of 1.7–39, compared to 1–2 for glass wool and stone wool, and 20–200 for PUR, XPS, and EPS, making them suitable for specific applications where moisture regulation is critical.

5. Conclusion

With the increasing importance of energy savings, there will be a greater need for capillary active insulation materials in the near future.

Capillary active materials, designed for moisture management, are heavier and more moisture-absorbent than traditional insulation materials like glass wool, stone wool, PUR, XPS, and EPS. They exhibit a higher water absorption coefficient, reflecting their ability to actively manage water, compared to the lower absorption of traditional materials. Their thermal performance can rival that of glass wool, stone wool, XPS, and EPS, though PUR offers better insulation efficiency. With moderate vapour permeability, capillary active materials are well-suited for applications where moisture regulation is essential, unlike traditional materials with varying degrees of vapour resistance.

The application method of capillary thermal insulation material is one of the aspects that requires attention. In traditional internal insulation systems, to prevent condensation within the cross-section, the vapour diffusion resistance factor (μ) of the material layers should decrease from the inner surface of the wall towards the outer surface. In capillary active systems, however, the insulation is fixed with an adhesive mortar that has higher thermal conductivity and lower vapour permeability than the insulation material, ensuring that the condensation layer remains on the insulation material side. This system can provide a vapour-permeable, thermally effective interior insulation solution.

The development of novel capillary active insulation materials presents significant challenges. It requires producing a single panel, derived from a uniform insulation material, that combines multiple properties, including capillary activity, thermal insulation, and adjustable vapour permeability. Additionally, the panel must be easily applicable, incorporating an air gap between itself and the existing structure, while maintaining effective insulation within practical thickness constraints. Innovative composite materials with hygrothermal performance compatible with the properties of capillary active insulation materials can be developed using bio-based or polymer waste fibers, lightweight waste aggregates, or foamed inorganic binders. Additionally, studies are needed to evaluate the long-term durability and environmental impact of these composites, as well as to optimize their composition and processing properties.

In future research, if studies comparing the hygrothermal performance calculated through simulations with the actual on-site performance of an insulated structure become more widespread, the assumptions about capillary active insulation materials will become clearer.

Improving the thermal comfort of traditional housing by adapting a high-performance material

Bencheikh Hamida[1*], Candidate Taleb Boulerbah[1]

[1]*Department of architecture, Faculty of Civil engineering and Architecture, Amar Teldji University Laghouat, Algeria*

Abstract. The use of built with earth (Adobe) materials in Algeria is a very old tradition. The present work purpose was to improve the mechanical and thermal resistance of Adobe bricks, as well as to demonstrate the advantages of their use in buildings in the Sahara. Three clay samples were chosen from three different traditional houses in Zgag El Hadjaj ksar in Laghouat, south of Algeria. Two types of clay bricks were made from these three samples: bricks M1 (80% soil plus 20% clay) and M2 (70% soil plus 30% clay) According to the literature review, the M1 and M2 bricks were tested to study the effect of the mixture's combination on the physical, mechanical, and thermal properties of the adobe bricks. The laboratory test shows that bricks M2 give the best properties; in order to improve the M2 bricks properties, the following percentage is needed: 0%, 0.1%. 1.5% and 2% of straw with a length between 2 and 5 cm were added to the mixture. The experimental results showed that the mixture containing 2% straw was the most effective and improved the thermal conductivity from 0.71 w/m². k. to 0.51 w/m².k. compared to one without straw. These ratios of 2% of straw in the mixture increase the compressive strength from 19 bars to 32 bars, which is within the scope of the literature. The study shows the clay brick made with M2 mixture and 2% of straw with a thermal conductivity of 0.51 w/m². k. can produce the same thermal performances during summer time with less thickness from 60 cm to 40 cm and give the same inside air temperature in the space.

Keywords: Earth architecture; Thermal comfort; Thermal inertia; Ksar of Laghouat; Clay material, Courtyard

1. Introduction:

Earth construction has been one of the techniques used extensively in construction in different historical ages. Man began to use earth construction at least 6000 years ago in Mesopotamia, and it has been used much more by different civilizations all around the world. Nowadays, it is estimated that between 30% and 50% of the world's population lives in earth structures, where earth construction techniques are still predominantly used for new housing, mainly to ensure comfort to the occupants and architectural compatibility with historically established environments**.** (Hui Xi and al. 2024) investigated the indoor thermal comfort in traditional dwelling and new residences during summer time, they found that traditional house indoor temperatures were acceptable, due to buildings envelope materials. (Ines Costa-Carrapico and al. 2022) evaluated the thermal comfort in vernacular dwellings in Portugal, the study found that the summer thermal comfort reached in naturally ventilated vernacular houses. (Mahmoud Murtata Farouq and al. 2024) examine the integration of phase change material into earth wall to improve its thermal performance, they found that the integration of PCM offers a promising solution to enhance thermal comfort. (Amal Chkeir and al. 2024) studied the thermal comfort in traditional and contemporary houses in Lebanon, their results show that traditional houses perform better in terms of thermal comfort, due to their use of natural and passive methods.

This study presents the results of an experimental work carried out on raw earth materials with 0 to 2% of weight of barley straw. Straw is a local agricultural waste was used to improve the material thermos-physical properties. Mechanical and thermal properties were thus measured to enrich the databases of earth biomass construction materials. The mean Aime of the study was to make a comparison between the old material (adobe), and the improved ones in order to evaluate the thermal efficiency of the two materials and to find the optimal wall thickness that can be achieved with the new brick, and this according to the material thermal resistance.

2. House description model:

In order to study the envelope effect on the building thermal behavior, a house in traditional architecture design was studied. The spatial organization of this house revolves around a central courtyard on the ground floor see fig. 1, where living spaces, 03 bedrooms, living room and kitchen are located. Upstairs, the 3 bedrooms also open on to the central

Corresponding author, E-mail: h.bencheikh@lagh-univ.dz

https://doi.org/10.31462/icearc2025_a_aen_393

golden light publishing

patio. Access to the upper floor is via 3.00 m-high staircases, which are located in the middle of the patio. The presence of vegetation around the courtyard softens the temperature of the air inside.

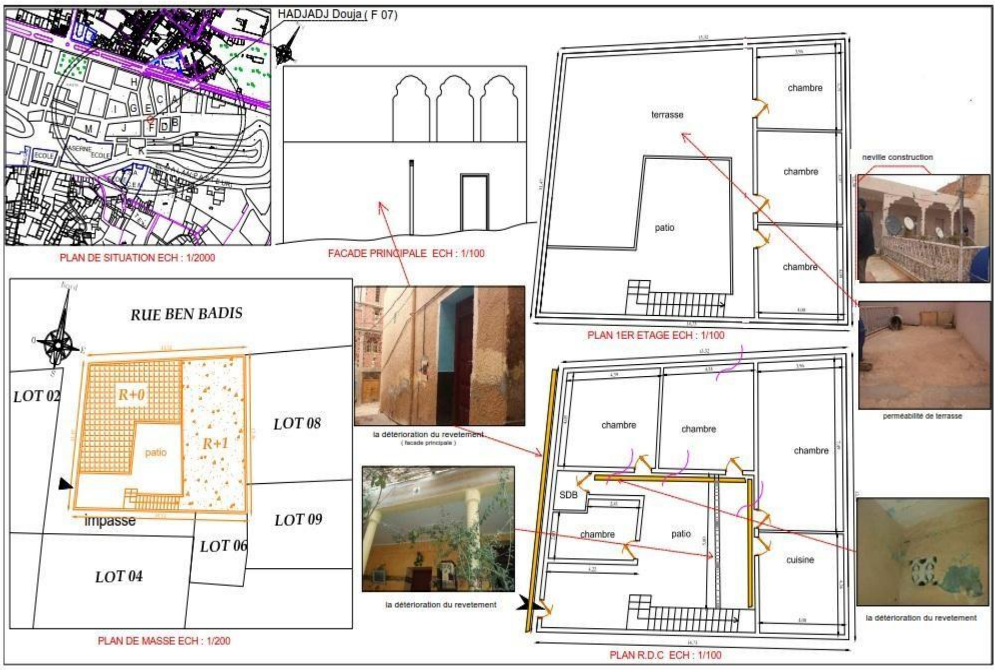

Fig. 1. The simulated house floor plans

The load-bearing adobe walls are 3.00 m high on each level. The characteristics of the envelope of this dwelling are:

- The exterior walls are double-walled with 60 cm-thick mud bricks.
- The interior walls are single-wall mud brick, 40 cm thick.
- Exterior and interior rendering are lime mortar.
- The roof is composed of a traditional slab made up of different layers of lime whitewash and lime mortar, a layer of clay soil, a layer of reed matting and palm trunk beams.
- Adobe is a local product made from malleable local earth, water and a little straw. The mixture is agglomerated in a parallelepiped Mold. Once dry, it is used to build the wall.

3. Measured parameter:

The brick of dimension (28x12x8cm) cut by shearing device in order to take the test pieces of (5.5.5 cm) which will be subjected to crushing. These tests are carried out on the pilot bricks of earth M1 and M2 aged 28 days and stabilized with the following fiber contents: 0%, 1%, 1.5% and 2% straw. These tests were carried out on bricks of dimensions 5. 5. 5 cm using the two mixtures of earth with: - Four fiber rates: 0%, 1%, 1.5%, 2%, for Adobe M1 and M2. The dimensions of the fibers vary between 2 and 5 cm and the water content used in the mixture was 19%. In addition to the fiber content, the day of crushing was taken into consideration, for M1 and M2Adobe, the compressive strength was determined after 30 days which is the curing period required for the brick to acquire sufficient strength and the influence of the fiber content on this period.

The variation of compressive strength as a function of the straw percentage is shown for the raw earth brick M1 and M2 in Fig. 2, It is noted that despite the nature of the material used (earth) and the random distribution of the fibers, the correlation coefficient of the lines obtained in the interpolation of the experimental points is acceptable (R = 0.85), and the curves given in the fig. 3 and 4, for the other earths show that there is an optimal percentage of fiber corresponding to the maximum compressive strengths of the bricks. When its optimal fiber contents are equal, 2% for earth M1 and M2.

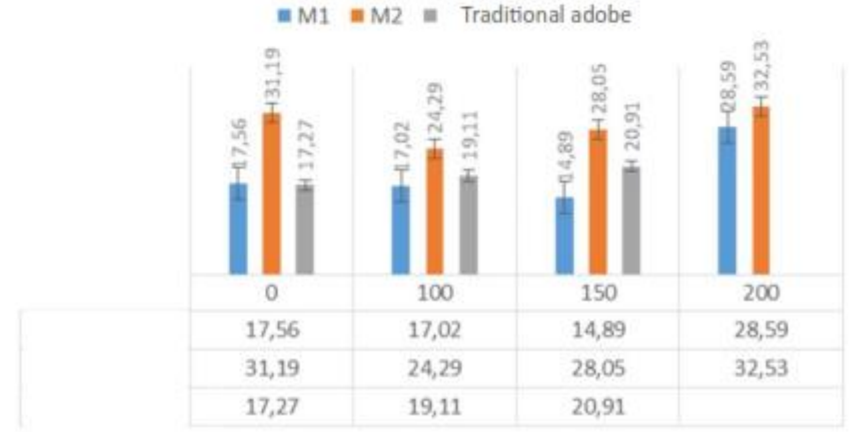

Fig. 2. New and traditional Adobe strength

4. The main methods of measuring thermo-physical properties:

The two types of earth bricks M1 and M2 were characterized at the laboratory scale. Their thermo-physical properties were determined and presented in the tables (1 and 2) and figures (3 and 4). The improvement of adobe; the making of new adobe;

M1= 80% soil+20% Sofabril clay + X % straw. M2= 70% soil +30 % Sofabril clay + X% straw.

Table 1. Sample M1 thermo-physical properties

Sample	M 1+0%	M1+1%	M1+1.5%	M1+2%
Dimensions L × l × h (mm)	280×120×80	280×120×80	280×120×80	280×120×80

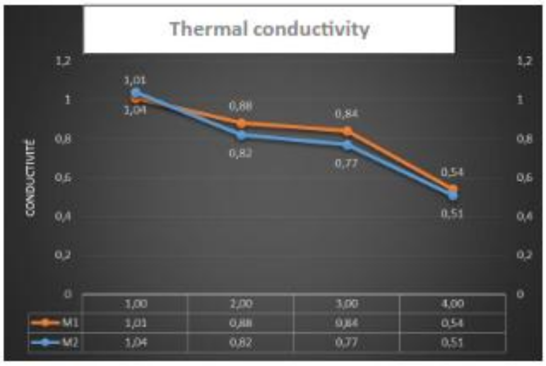

Fig. 3. Adobe M1 and M2 Thermal conductivity

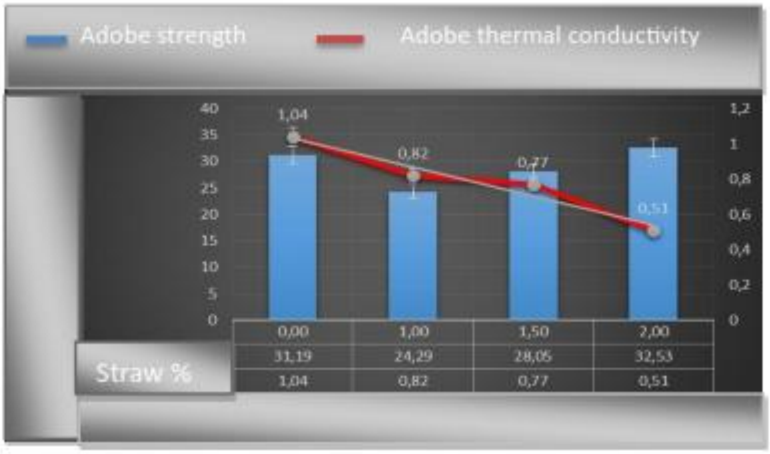

Fig. 4. Adobe M2 thermal conductivity and Compressive strength variation with straw percentage

5. The optimal composition:

From the above figures, the compressive strength and the thermo-physical properties of the different mixtures of raw earth and straw, the adobe M2 plus 2% straw give the high compressive strength of 32.50 bars and low thermal conductivity of 0.51 w/m².k., this adobe was selected to carry out the study.

The current work aims to study the effects of thermo-physical properties of this type of raw earth bricks by experimental research, and their dynamic thermal execution (thermal capacity, time lag and decrement factor) depending on the wall thickness. The objective is to determine the ideal thickness of a raw earth wall, established by these bricks, to achieve the optimum values of thermal inertia. These bricks were produced manually in the laboratory and the used process was by recycling the old adobe from demolished walls in the old city of Laghouat Zgag el hadjedj district. The main difference between the two types of bricks is the amount of added clay that was extracted from Mraigha quarries for the manufacture of baked clay bricks and the percentage of straw. They were characterized to determine their physical and geotechnical properties, and to identify their impact on the development and production of raw earth bricks.

6. Thermal resistance:

The thermal resistance of a material characterizes its capacity to slow down heat transfer by conduction. It is the ratio between the thickness of the material and the coefficient of thermal conductivity in (m^2.K)/W.

7. Assessment of the optimal wall thickness:

In the old city of Laghouat the outside wall thickness was 60 cm and sometimes exceeds made by adobe, the exterior walls in raw earth brick 60 cm and a thermal conductivity of 0.71 w/m.°k. the total thermal resistance is equal to 0.860 m² °k/w before improvement. The new improved adobe M2 plus 2% of straw with 0.51w/m°k thermal conductivity can give the same thermal resistance of 0.860 m² °k/w by only 42.6 cm of thickness. A theoretical study by simulation is conducted in order to appreciate the thermo-physical behavior of the adobe studied for the construction of an exterior wall in arid regions. Two different parameters have been varied in this study: the thickness of the wall, and the thermo-physical properties of the studied adobe made with M2 plus 20% straw.

The time lag ф, decrement factor *ƒ* and sol–air temperature are very important parameters to determine the heat storage capabilities of any material. The time takes a heat wave to propagate from the outer surface to the inner surface is named as ''time lag'' and the decreasing ratio of its amplitude during this process is named as ''decrement factor''. The schematics of time lag and decrement factor are shown in Fig. 5. In this study, the time lag and decrement factor are computed as follows. The time lag is defined as (H. Asan & Y. S. Sancaktar, 1998 and H. Asan, 2000)

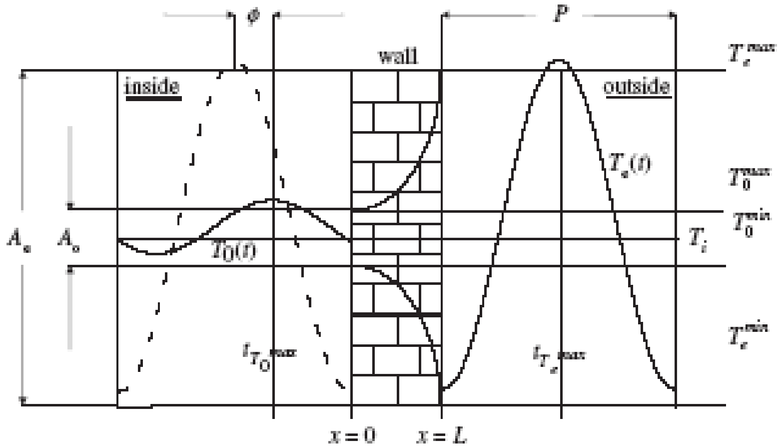

Fig. 5. The schematic representation of time lag ф and decrement factor ƒ

$$\phi \begin{cases} t_{T_0}max > t_{T_e}\max \rightarrow t_{T_0}max - t_{T_e}\max \\ t_{T_0}max < t_{T_e}\max \rightarrow t_{T_0}max - t_{T_e}\max + P \\ t_{T_0}max = t_{T_e}\max \rightarrow P \end{cases} \quad (1)$$

where **t** $(\boldsymbol{Tse_{max}})$, **t** $(\boldsymbol{Tsi_{max}})$ and (h) represent the time in hours when inside and outside surface temperatures are at their maximums, respectively, and P (24 h) is the period of the wave. The decrement factor is defined as,

$$f = \frac{A_0}{A_e} = \frac{T_0^{max} - T_0^{min}}{T_e^{max} - T_e^{max}} \quad (2)$$

Where A_o and A_e are the amplitudes of the wave in the inner and outer surfaces of the wall, respectively. The sol–air temperature, Tsa, includes the effects of the solar radiation combined with outside air temperature and changes periodically. This temperature is assumed to show sinusoidal variations during a 24-h period. Since time lag and decrement factor are dependent on only wall.

8. Results and Discussions:

During winter time fig. 6. below, the graph shows that the outside temperatures have a high amplitude of 14°C between the maximum value (21°C) recorded at 3:00 p.m. (in the afternoon) and the minimum value (6°C) recorded around 5:00 a.m. (in the morning). On the other hand, the ambient temperatures of the patio and those of the upstairs bedroom are almost constant, with amplitudes of around 2°C, unlike the temperatures recorded in the ground floor bedroom which approximately follow the path of the outside temperature curve, which give a time lag of 5 hours and a decrement factor of 0.067. The stability of the temperatures marked during the first ten hours in the patio (about 12 °C) is reflected by the damping of external contributions (whose temperatures fluctuate between 6 and 14 °C) ensured by the adobe brick (Motari, N., 2008), delaying the transfer of cold through the walls for six hours (from 6:00 AM to 12:00 PM) thanks to its thermal inertia and its thickness. This damping had a negative impact on the thermal behavior of three spaces evaluated during the afternoon, whose external temperatures were more pleasant, reaching the comfort range set by Givoni between 20 and 27 °C, around 2:00 PM

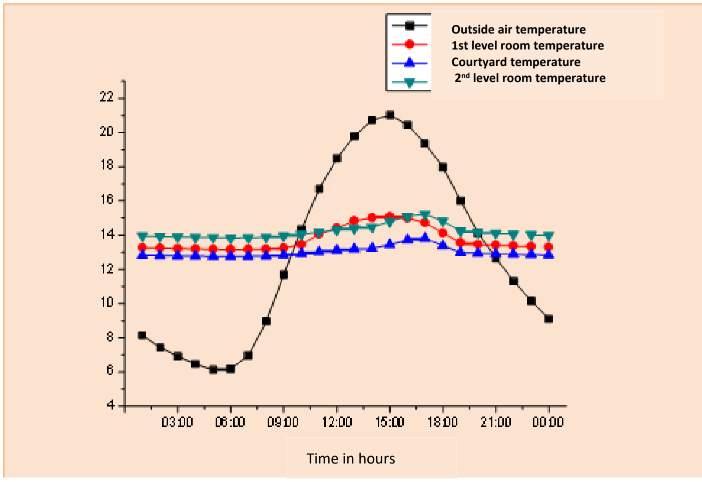

Fig. 6. Traditional adobe, Winter Inside spaces and outside air temperatures

During summer time, the results obtained from fig. 7, presented below show the temperature variation between the outside and the inside, the highest temperature difference of 10 °C was recorded in the upstairs bedroom around 3:00 PM, with a maximum outside and inside temperatures were respectively 45 °C and 35 °C. The minimum outside and inside temperatures were respectively 22°C and 32°C, which give a time lag of 5 hours and decrement factor of 0.087. These results are justified by the material's ability to store heat during the day and release it at night. (D. Medjelakh and S. Abdou 2008), However, this high thermal capacity of the material used causes an overheating, but the use of night natural ventilation can cool the mass of the building. in order to evacuate the hot air accumulated in the space during daytime to be cooled. This is clearly established according to the temperatures of the patio, which presents the most and least pleasant space (whose average temperature is 32 °C). Nevertheless, this temperature remains higher than the comfort range mentioned above.

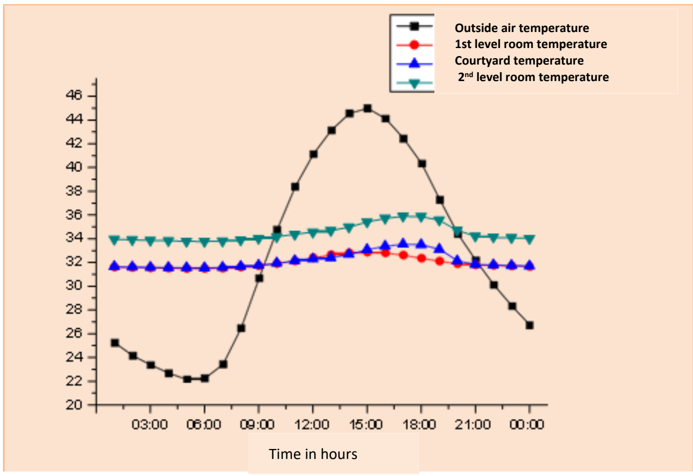

Fig. 7. Traditional adobe, Summer Inside spaces and outside air temperatures

8.1 The effect of improving the thermal conductivity of adobe

The improvement made on the thermal conductivity of the adobe allowed to optimize the thermal performance of the house, despite the reduced thickness of the wall (from 0.6 to 0.4 m). From fig. 8, an increase in ambient temperature was marked in all the spaces evaluated, with an average of 0.3 °C, in the typical winter day. From fig. 9, However, a stability of interior temperatures was marked after the improvement of the material in the summer period, whose thermal resistance was preserved, depending on the wall thickness and thermal conductivity (0.51 w.m/K).

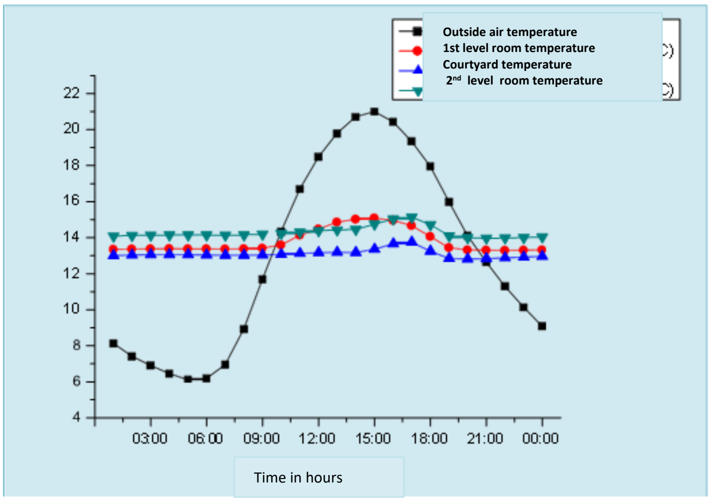

Fig. 8. Improved adobe, Winter Inside spaces and outside air temperatures

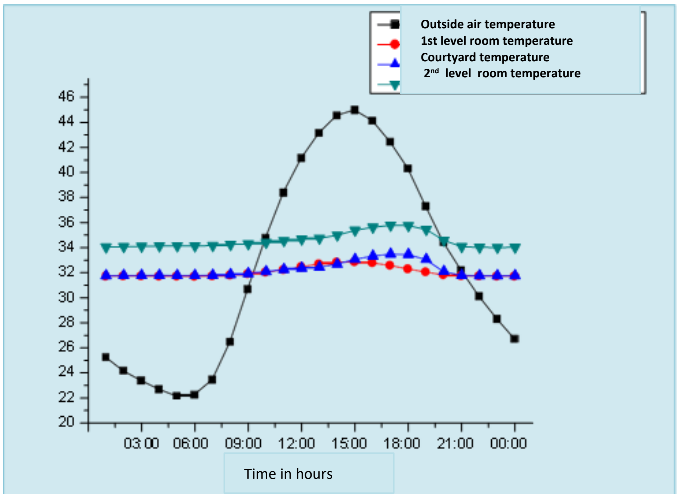

Fig. 9. Improved adobe, Summer Inside spaces and outside air temperatures

Comparing the results of this simulation (after the improvement) with the comfort range set by Givoni (20-27 ° C), it is shown that the thermal behavior of the house studied is outside the comfort range, whose average winter temperature is approximately 13 ° C and that of summer is equal to 33 ° C. Thermal inertia and night ventilation are the recommended solutions under the climatic conditions of June in the city of Laghouat. Night ventilation was neglected during the simulation, which justifies the summer results obtained, (S. Abdou and M. Boumaza, 2004)**.** On the other hand, all the parameters influencing thermal comfort were taken into consideration during the evaluation of the winter thermal behavior of the house, this shows that the results of the typical winter day reflect the real behavior of the spaces evaluated.

9. Conclusion:

Earth architecture is misunderstood and despised because it is linked to images of archaism and poverty. For nearly 9,000 years, man has tended to build cities entirely in raw earth and remains one of the most widely used building materials on the planet. This remarkable universal cultural heritage has been hidden since man has known the technique of transformations. We must therefore rediscover the evidence of what some have believed to be synonymous with poverty and precariousness. It is in this context that work on earth as a material has been undertaken by certain pioneers such as François Cointeraux and Hassan Fathy. The latter have given confidence to designers and others that it is indeed possible to build in earth. The revaluation of earth architecture must involve shedding light on a more in-depth knowledge of the material. In order to master it and highlight all its ecological virtues and thermal performances, with all the positive impacts that it can achieve on the energy, environmental and aesthetic level. In developing countries, the search for solutions to the problems posed by housing has become difficult due to an unfavorable economic context. In Algeria, the use of earth is a very old tradition. It was used not only in the countryside, but also in cities and Ksour. Currently, despite the trend towards using cement concrete, more than 50%

of the homes in the Algerian Sahara are still in "Toub". Almost all so-called traditional constructions are made with earth combined with other additional materials such as plant (straw and others) or mineral additions. In recent years, we have witnessed an interesting surge in research on so-called traditional materials. We are looking for affordable housing due to the scarcity and excessive cost of housing for developing countries, especially Algeria, where architects were convinced that the solution was in the past. However, the problem that raises some concerns is the improvement of its durability when subjected to deleterious climatic conditions. Indeed, much remains to be done to improve the poor image that earth construction currently offers and to develop an appropriate technique intended to lay the foundations for the promotion of this material and a future guarantee of well-adapted quality.

However, the determination of the dynamic thermal performance of these bricks showed the advantages of raw earth and its contribution to comfort. Indeed, the study showed that a thickness of 40 cm for M2 + P = 2% bricks, a stability of interior temperatures was marked after the improvement of the material in the summer period whose thermal resistance was preserved, depending on the wall thickness and thermal conductivity (0.51 w.m / K). This part of the work aimed to evaluate the thermal performance of the old building material (adobe) after improving its thermal conductivity, in order to reduce the wall thickness while preserving the same quality of the interior environment of the house under study. The results showed that the improvement made it possible to optimize the thermal comfort of the Ksourian dwelling during the winter period, and to preserve the same performance during the summer. However, these results were outside the comfort range, for this, an improvement was proposed in order to improve winter thermal comfort. The addition of a nylon cover at the patio level made it possible to increase the interior temperature, with a difference of 2 ° C between the two improvements. This cover is often used by the inhabitants of the old Ksar of Laghouat during the winter period, in order to remove it during the summer to let the air cool. The simulation carried out on a type of traditional house with a patio, these simulations made it possible to observe the role of this material in damping fluctuations in outdoor temperatures and in stabilizing the interior temperature. The latter which does not reach 32 ° C, during the summer months, thus limiting overheating of the house. This project has promoted the development of raw earth construction in the protected sector. It has now allowed the company to start some major construction projects.

Evaluation of lightweight steel construction systems as an alternative to conventional construction systems

Beyza Nur Cabacı*[1], Ali İhsan Ünay[1]

[1] Gazi University, Faculty of Architecture, Master's Program, Çankaya, 06570 Ankara, Turkey

Abstract. Light steel building systems are constructed using galvanized sheet steel profiles that are suitable for cold forming and feature lower carbon content compared to structural steel. Their prefabricated nature enables faster construction processes than conventional methods, making them an increasingly attractive option for modern building needs. Conventional systems often struggle to meet the growing demands for sustainability, rapid construction, and economic efficiency. In this context, light steel systems offer notable advantages such as flexibility in design, speed of assembly, and suitability for various building types. This study provides a comprehensive overview of the characteristics, design principles, and global applications of light steel structures. It also discusses the comparative advantages and limitations of light steel systems relative to conventional building methods. Through a review of existing literature, technical guidelines, and standards, the study highlights how light steel systems contribute to addressing contemporary challenges in construction. By examining different regional practices, the study aims to offer an insight into the current status and future outlook of light steel structures in the global construction market.

Keywords: Light Steel Construction; Conventional Construction; Sustainability; Structural performance; Architectural flexibility; Economic Efficiency

1. Introduction

The construction industry faces numerous challenges globally, including the increasing demand for sustainable practices, faster construction processes, and the necessity for structures that can withstand seismic events. These problems are especially pertinent in earthquake prone areas, where building safety and resilience are of utmost importance. Previously, construction practices have depended on the use of materials like concrete, brick, wood, and stone. In spite of centuries of such success for these materials, they have limitations including greater environmental impact, increased construction duration, and similar levels of seismic performance.

Light steel construction systems have been recognized as a promising substitute for conventional construction techniques. The systems provide numerous benefits including decreased construction time, better seismic resistance, and greater sustainability thanks to steel recyclability. Despite these benefits, the global adoption of light gauge steel building systems has been uneven, and comprehensive studies comparing their performance with conventional methods in various contexts have been limited.

This study aims to address this gap by conducting a global comparative analysis of the sustainability and seismic performance of light gauge steel building systems and conventional construction methods. The study will focus on key regions, including Europe, North America, and Asia, where these systems have been implemented to varying degrees. Through this analysis, the research seeks to provide insights into the advantages and challenges associated with lightweight steel construction, thereby contributing to the broader discourse on sustainable and resilient building practices. Through knowledge of the comparative benefits of lightweight steel systems, stakeholders in construction are able to make more informed choices, and this could reflect in higher adoption of the systems in regions where conventional methods still dominate. The research is not only timely but also critical in global efforts towards enhancing the sustainability and resilience of the built environment.

2. Material and Methods

This study presents a comparative evaluation of lightweight steel and conventional construction systems, focusing on sustainability, seismic performance, and economic efficiency. It is based on existing literature and building codes. The systems analyzed include reinforced concrete, timber framing, heavy steel structures and light steel systems made of cold formed, thin walled steel sections. They are reviewed in terms of structural behavior,

golden light publishing

construction processes, and environmental impact. The methodology relies on a literature review using academic databases. Additionally, construction practices from Europe, North America, and Asia were examined to understand practical applications

3. Conventional Construction Systems

3.1 Reinforced Concrete Systems

Concrete and reinforced concrete are widely used throughout the world, especially in the United States and Canada, as the primary structural building material. Concrete, also known as "man-made stone," is made by mixing cement, sand, aggregate and water, and can be molded into almost any shape when it has a plastic consistency. This flexibility enables flat slabs or panels to serve the dual purpose of a load-carrying structure and a finished floor or ceiling surface. Concrete developed in the 19th century, when Portland cement was discovered, has low tensile strength; steel reinforcement embedded in the concrete to improve strength in this direction gives ductility and moment stability to the structure by resisting tensile forces after cracking. Modern reinforced concrete design was shaped by the work of European engineers in the late 19th century and is now widely used in critical engineering projects such as buildings, bridges, and dams (Yakut, n.d.).

Reinforced concrete structures are made up of interconnected members that work together to bear the loads placed on them. For instance, the second floor in Fig. 1 uses concrete joist-slab construction. A series of parallel joists support the weight of the upper slab. The forces from these joists are transferred to the beams, which are then supported by columns. The ductility provided by steel reinforcement during earthquakes increases structural safety. Another advantage of reinforced concrete systems is that they provide 1-3 hours of fire resistance without the need for additional fire insulation. Additionally, the wide availability and ease of transporting materials like sand, gravel, crushed stone, water, cement, and reinforcing steel make reinforced concrete systems both economical and practical, especially in remote or logistically challenging areas. With the rapid growth of urban populations in both developing and developed countries, reinforced concrete has become the preferred material for residential construction. However, the lack of design and application expertise in many regions makes proper reinforcement placement and detailing even more critical (Wight, 2016).

3.2 Wooden Systems

Conventional timber building systems are categorized into masonry (log masonry) and frame systems (Çakır, 2000 as cited in Yıldırım, 2010). In modern practice, they are classified as log, frame (post and beam), and panel systems, with additional structures using layered wooden elements for spanning large openings (Götz et al., 1989, as cited in Yıldırım, 2010).

Log masonry systems, requiring large amounts of timber and exhibiting poor earthquake resistance compared to frame systems, have seen limited use. In contrast, timber frame systems, characterized by smaller load-bearing sections, ease of transportation, and flexible architectural solutions, became more widespread. Conventional timber frames often used regional infills like stone, brick, adobe, or wood. However, heavy stone infills increased seismic vulnerability, while timber infills enhanced strength and rigidity during earthquakes, especially when reinforced with slats to support plaster (Acar et al., 2004, as cited in Eren, 2015).

In traditional timber construction, wall studs were left exposed, and lateral stability was achieved through corner braces. In more advanced timber systems, cladding elements took over this role, boosting rigidity (Eren, 2015). The development of these advanced systems in the 19th century was driven by steam-powered routers and machine-made nails, which allowed for more efficient joints, faster construction, and standardized components (Eren, 2015)

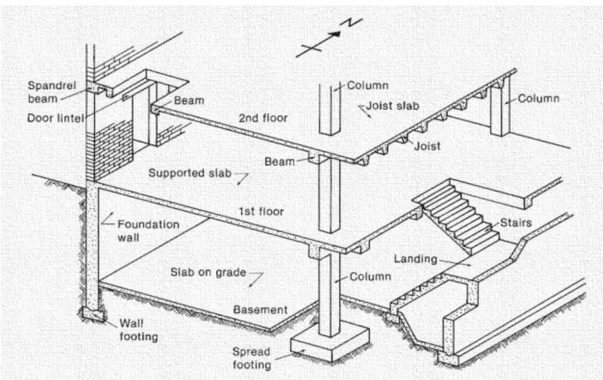

Fig. 1. Reinforced Concrete System (Wight, 2016)

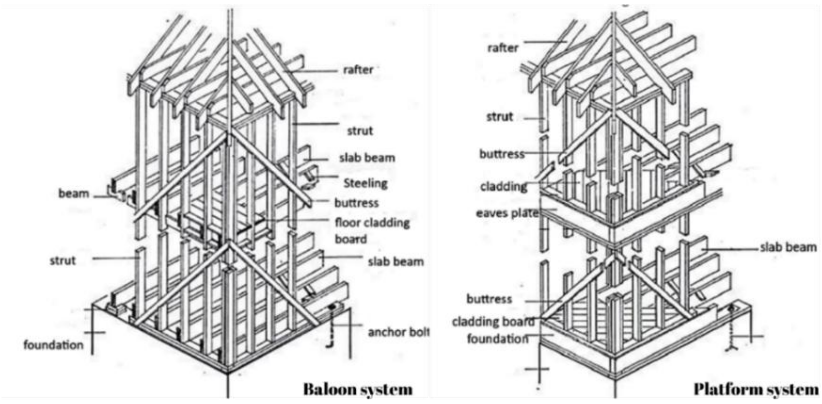

Fig. 2. Platform System and Baloon System (Eren, 2015)

In frame systems, wall and floor elements are assembled on site. These systems are classified as either single base or double base, depending on how they connect to the foundation (Çakır, 2000, as cited in Yıldırım, 2010). In platform frame systems, one story wall panels are prefabricated for each floor using a standard method. Timber studs are evenly spaced and covered, forming strong, continuous load-bearing walls. This approach boosts both strength and construction speed (Çakır, 2000; Avlar, 2002; Chiuini & Underwood, 2007; Götz et al., 1989, as cited in Yıldırım, 2010).

Balloon frame systems, an early form of the advanced timber system, feature slender, closely spaced uprights running continuously from foundation to roof. Although initially praised for their lightweight nature, balloon frames declined due to fire risks and construction challenges associated with lengthy uprights (Eren, 2015). Fig. 2 illustrates the schematics of the balloon and platform systems.

Both conventional and modern systems require metal fasteners for joint integrity. Conventional joints suffered from strength loss due to material removal at connections, whereas today, adhesives and threaded plates, albeit limited to factory conditions, improve joint performance. Nevertheless, simple mechanical fixings generally suffice in timber construction (Eren, 2015).

3.3 Structural Steel Systems

The use of metal materials as load bearing elements became widespread in the first half of the 19th century; in the previous period, metals primarily served as connection components. The Severn Bridge, completed in England in the late 18th century, is recognized as the first structure made entirely of metal. While steel was initially preferred for commercial buildings, it soon found widespread use in housing as well. This shift was largely due to its ability to span long distances, offer slender and durable sections, remain lightweight, and allow for efficient heat conduction. Additionally, since steel components were produced in factories and assembled on-site, construction times were significantly reduced. Thanks to dry assembly, construction was unaffected by weather conditions, and the need for site space was minimized. After the completion of the structure, steel frames could also be adapted to new functions, thus extending the service life of the building (Eren, 2015). The connection technology of steel structures also evolved over time. Riveting was widely used in the 1920s and was displaced by bolting in the 1930s. In the 1950s, welding in workshops became established, followed by on-site welding in the 1970s. In the 1990s, controlled on-site welding and other systems of connection began to appear. Most common types of connections today are bolted connections, which are friction-dependent, bolt shear and bearing, and welded connections, which consist of full or partial penetration grooves and fillet welds (Design and Construction of Structural Steel Work, 2021). Steel construction eliminates the need for formwork and scaffolding, allowing for smaller foundations. It can be reused even on weak ground, offers greater flexibility in architectural design, and enhances the visual appeal of buildings. Its lightweight nature makes it suitable for high-rise structures, while its earthquake resistance ensures safety in seismic regions. In addition, steel speeds up the construction process, facilitates on-site inspections, and allows for later transportation and modifications. Being 100% recyclable, it also supports sustainability, and it can be used to strengthen structures when necessary (Türk Yapısal Çelik Derneği, 2020).

4. Lightweight Steel Construction

Two types of structural systems are used in steel structures: one is the widely preferred system consisting of hot-rolled heavy steel structural members, and the other is the light steel structural system consisting of cold-formed thin-walled steel profiles, which is increasingly being used. The definition of "light" is related to the thinner cross-sections of the elements and components used in the construction. Light steel structures are completely different from steel frame structures in terms of the profiles used and structural system features (Ozcan, 2005).

Stainless steel cold formed sections are commonly used for structural components where the focus is on material efficiency rather than high strength. This construction method is cost effective, offering a high production potential with minimal investment in manufacturing technology. Cold formed sections are created from flat sheets, typically using two main techniques: press braking and roll forming. Press braking works best for simple shapes and smaller quantities, making it ideal for prototyping. Roll forming, on the other hand, is perfect for producing larger quantities and more intricate shapes. As illustrated in Fig. 3, the roll forming machine is used in the production process, and Fig. 4 presents the most common section profiles.

The light steel system is a construction method where structural elements, such as wall panels, roof panels, and floor beams, are pre-fabricated in factories and then assembled on site. The elements of the light steel system work both independently and in combination with supporting components to form a complete structural system. Due to its durability and fast installation process, the light steel system is a preferred choice for projects requiring efficiency, strength, and quick turnaround times (Ozcan, 2005).

Steel consists of 0.16–0.20% carbon and the remainder is iron; as the carbon content increases, hardness also increases. It also contains nitrogen, phosphorus, silicon, copper, and manganese; with the addition of nickel, chromium, molybdenum, and vanadium, high-quality alloys are obtained. Compared to structural steel, light steel has lower carbon content and strength because it is produced from softer alloys suitable for cold forming; its profiles and sheet thicknesses are thinner. Therefore, in the light steel system, all walls are load-bearing (Özcan, 2005). The light steel system is similar to the timber construction system consisting of load-bearing walls; horizontal floor and roof beams, along with vertical interior and exterior walls, carry all the loads of the building. Galvanized thin-walled profiles are reinforced to withstand both horizontal and vertical loads. Connection elements, cross bracing, and sheathing panels provide additional rigidity to the structure (Yıldırım, 2010). Standard-section light steel panels are designed to match the dimensions of 5 cm thick structural timber (Eren, 2015). Because of their limited spanning capacity, light steel elements are generally more suitable for residential and low-rise buildings. Their easy manufacturing, transportation, rapid assembly, and low dead loads make them particularly advantageous for smaller projects. On the other hand, conventional heavy steel systems, which are perfect for large spans and high rise structures, are not cost effective for smaller buildings and demand more complex organization and skilled labor (Ekinci, 2006).

4.1 History of Light Steel Systems

Cold formed steel structural members have been used for over a century, with their application expanding significantly in the last few decades. These members are highly versatile, allowing for optimization in size and design. This flexibility brings both theoretical and practical design challenges, but also offers innovative solutions. The growing use of cold formed steel is driven by improved understanding of its behavior, the availability of design standards and suitable materials, and the increasing demands of the construction industry (Baehre et al., 1982).

Initially used in interior partition systems and as roof supporting beams (purlins) due to their light weight, cold-formed steel profiles gradually became widespread in simple building and roof systems in industrial structures and recreational facilities. The first technical studies on cold-formed steel began in the 1930s in the United States, and the first standards prepared by AISI were developed by 1946. In the post-World War II periodesearch on light steel structures expanded, particularly in Japan, Germany, and Scandinavian countries, with the first use of this technology occurring in Germany by the late 1950s. In the 1980s, the light steel frame system reached its current form. During the same period in the United States, with the increasing demand for wood and rising costs, light steel houses began to replace conventional timber frame structures thanks to advantages such as portability and 100% recyclability of light steel. Today, approximately 20% of single and multi-story buildings in the United States are constructed with light steel frame systems. While these developments also continued outside the United States, especially in Australia and Canada, the sector did not develop at the same rate in Europe due to the existing building stock being largely completed and the relatively lower housing demand. Today, the light steel industry has reached its most advanced level in the United States (Mimarlar Odası İzmir Şube, 2006).

With the development of production techniques that made the use of cold formed steel profiles possible in the construction sector, this material also started to find a place in building construction. With the introduction of light steel into the sector, the use of cold formed panels became widespread in building components such as roof coverings and floor reinforcements. In addition, both cold formed and pressed profiles were developed for curtain wall cladding, beam systems, and formwork elements. The first applications of these materials were seen in simple, fire resistant film studio buildings constructed in the United States and the United Kingdom. During this period, the Lowell House designed by Richard Neutra attracted attention by being completed in a very short time based on the principles of the light steel system; this prefabricated light steel building, introduced at an exhibition in Chicago in 1933, stood out for its similarity to the timber platform frame system. Following these developments, the light steel system became a common construction method in the United States in the pre-World War II period (Eren, 2015).

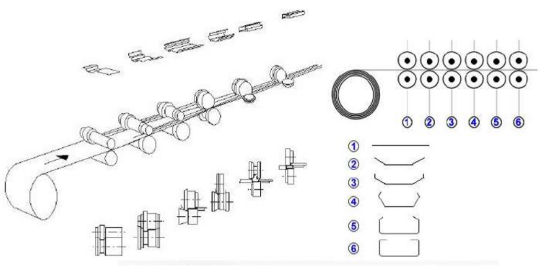

Fig. 3. Roll Form Machine (Mendes, 2019)

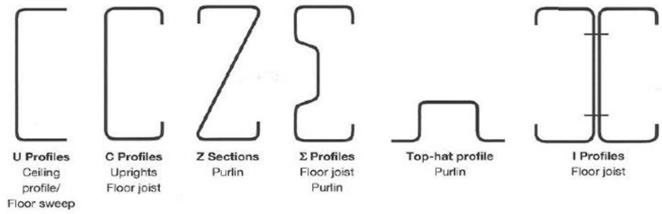

Fig. 4. Most Common Section Profiles (Mendes, 2019)

4.2 System Design

In light steel building systems, the plan geometry is of great importance in terms of the behavior of the load bearing system. The most suitable plan types are square or rectangular plans where the load bearing walls are placed at right angles. This arrangement simplifies the connections and increases the stability of the structure.

Sloped or curved plans can also be applied according to architectural requirements; however, in such arrangements, connection points and load-bearing behavior must be carefully addressed.

According to the AISI (1995) standard, the spacing of steel studs in load bearing walls should not exceed 60 cm, and floor joists should be aligned on the same axis as the wall studs. Especially in cases where joists are placed at an angle to the wall plane, the spacing should be tightened. In corner joints that are not at right angles, structural continuity should be ensured by using special profiles (Yıldırım, 2010). In walls with curved plans, the header profiles are bent according to the curved form. Flexible, standard compliant elements such as "Contour track" or "Flex-C track" have been developed to reduce buckling that may occur during this process. However, if the cladding material does not adapt to the curvature, loss of rigidity and visual distortions may occur. Therefore, for curved walls, a minimum radius of 12 meters and a maximum stud spacing of 3 meters are recommended. OSB, gypsum board, and laminated wood can be used for cladding (Yıldırım, 2010).

In light steel structures, facade design is a critical component not only in terms of aesthetics but also in terms of load bearing capacity. Since facade walls serve as load bearing elements in these systems, the placement, size, geometry, and cladding details of openings directly affect the structural performance. While the load bearing system determines the facade design, elements such as the possibility of leaving openings, their dimensions and forms, and the texture of the cladding material are considered as fundamental design criteria. Openings in walls can be arranged according to architectural requirements; in such cases, the stud spacing can be narrowed depending on the system module. However, since walls in light steel systems serve as load bearing elements, such interven-

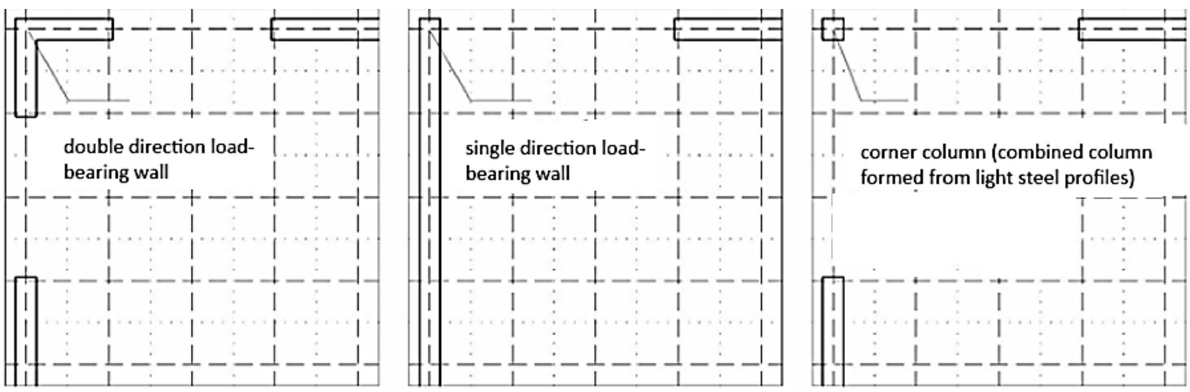

Fig. 5. Examples Of Load-Bearing Walls On Facade (Yıldırım, 2010).

tions must be planned in a way that does not affect the load bearing capacity. Since the profiles are usually placed behind the cladding, the structural system remains hidden from the outside, giving the facade a mostly solid appearance. Similar to masonry buildings, large wall openings can weaken the structure, so light steel systems also tend to feature wide surfaces with smaller openings. However, instead of using load-bearing facade walls, it is also possible to use rigid light steel frames that carry loads through moment transfer. In these systems, the frame itself provides rigidity without relying on diagonal bracing or cladding panels. In cases that require greater stiffness, the studs can be designed as box (composite) sections. When diagonal bracing is used, wall openings are not possible in those areas, so the placement of bracing elements must be planned with both structural stability and facade design in mind Yıldırım, 2010).

Corner points are among the most critical areas in terms of structural rigidity. Therefore, the principles of light steel systems do not recommend creating openings at corner points. Just like in masonry systems, these regions, where load bearing walls support each other, provide resistance especially against horizontal loads. If an opening must be created at a corner, the load-bearing capacity should be ensured by a moment resisting steel frame, and the studs at the connection points should be designed as composite sections and columns. As shown in Fig. 5, various design methods for corner windows in light steel structures are presented.

The shape and orientation of openings on the facade also affect the structural behavior. In particular, openings that extend horizontally with limited height reduce the resistance of load bearing walls against horizontal loads. This is because such openings interrupt the transfer of diagonal loads and weaken the walls' ability to carry shear forces. As a result, buckling and shear effects may occur in the studs near the openings (Yıldırım, 2010).

4.3 Materials Used in Lightweight Steel Structural Systems

The materials used in light steel structural systems both enhance structural strength and meet performance criteria such as thermal and acoustic insulation. In these systems, structural sheathing materials can be used as alternatives to horizontal and diagonal bracing; however, this choice must be considered during the early stages of design. Materials such as Oriented Strand Board (OSB) and plywood stand out for structural sheathing purposes. It is recommended that OSB Class 3 panels have a minimum thickness of 11 mm, and plywood panels at least 12 mm; during installation, self-drilling screws should be used at intervals of no more than 20 cm along the edges and 30 cm in the middle areas. According to findings from the NAHB Research Center, materials like OSB, plywood, or gypsum board provide more effective support for the buckling resistance of steel studs compared to bracing methods. Reducing the screw spacing creates more contact points on the steel profiles, thereby increasing this resistance; moreover, sheathing panels with a 2:1 aspect ratio contribute higher strength compared to those with a 4:1 ratio. However, as the screw spacing decreases, the impact of this ratio difference on structural strength diminishes.

According to North American standards, the thicknesses of OSB panels used in light steel structures vary depending on their area of application. For structural sheathing in load bearing walls, a minimum thickness of 9 mm is recommended; for floor substrates, 18 mm; for bottom sheathing of roof trusses, again a minimum of 9 mm; and for flat roofs or attic spaces, panels with a thickness of 18 mm are advised (Akay, 2013). OSB and gypsum boards, which are widely used in light steel systems, have a broad range of applications from exterior facades to roof surfaces and floor coverings. OSB is a moisture-resistant, high strength panel that has become a widely used alternative to plywood around the world (Yıldırım, 2010). It is not only suitable for exterior facades but also works well on interior walls where heavy furniture or decorative elements need to be mounted (Mendes, 2019). OSB panels are made by pressing wood strands, each about 10 cm long, into layers with each layer oriented perpendicular to the one below. In light steel structural systems, they are especially valued for sheathing and providing rigidity. Their light weight, ease of transport and cutting, and ability to be screwed into easily make them highly practical during construction.

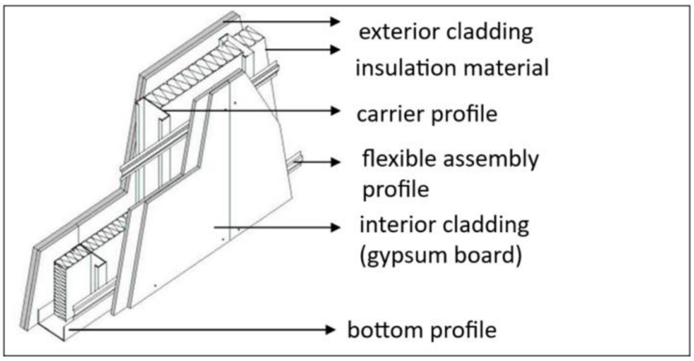

Fig. 6. Light Steel Wall Section (Ekinci, 2006)

Designed to withstand harsh weather conditions, these panels simplify exterior facade applications and are capable of carrying heavy loads such as furniture and decorative objects. In addition to providing structural strength, they also offer thermal insulation, making them a versatile material. Thanks to their high performance in horizontal applications, they help distribute stresses evenly within structures, thereby increasing stability. Shear tests have shown that OSB panels significantly enhance the ductility and stability of wall systems.

According to the EN 300 standard, OSB panels are divided into four classes based on their usage conditions and mechanical properties: OSB/1 panels are used for general purpose interior decoration and furniture in dry environments, while OSB/2 panels are suitable for structural use in dry environments. OSB/3 panels are recommended for structural use in humid environments, and OSB/4 panels are preferred for applications requiring high structural performance in humid conditions. Today, OSB/3 class panels are widely used in light steel systems due to their superior performance against weather conditions during the construction process (Mendes, 2019).

Another wood based material, cross laminated timber (CLT), was developed in Germany by Friedrich Otto Hetzer in the 20th century. This material is produced by gluing together layers of wooden lamellae arranged in crosswise directions, preserving the natural properties of the wood while eliminating internal defects. Due to its layered structure, stress is distributed more evenly across the surface instead of concentrating at specific points, giving the material a more homogeneous load-bearing capacity.

Another material is composite panels, which are produced by combining wood particles with Portland cement and shaping them through pressing. These panels combine the flexibility of wood with the durability of cement, and are used in both interior and exterior cladding applications, offering high resistance to impacts, fire, sound, moisture, and fungal attacks. However, they also have disadvantages such as high cost, heavy weight, and the need for wider metal profiles during installation. Moreover, due to their rigid structure, they can be prone to cracking (Mendes, 2019).

Non-structural cladding materials are also widely used in light steel systems. This group includes non-standard OSB panels, as well as gypsum boards, which are particularly preferred for interior cladding and decorative finishing layers. Gypsum boards are produced by placing a gypsum-based mixture between two layers of paper, and depending on the additives used, they can be applied in different environmental conditions. Commonly used for interior walls and ceiling applications, these panels can be mounted directly onto the steel frame or on top of OSB panels; their joints are sealed with tape to prepare the surface for paint or ceramic finishes. Isolpro panels, produced from a mixture of lightweight concrete and polystyrene, provide thermal and acoustic insulation and can be adapted for a variety of surface applications on interior and exterior walls, floors, and façades.

In Turkey, gypsum boards are commonly applied on the interior surfaces of external walls, on both faces of internal partition walls, and on ceilings. Insulation materials such as glass wool or rock wool are placed behind these boards to provide both thermal and acoustic insulation. Manufactured in compliance with the TS EN 520 standard by companies such as Knauf, Lafarge-Dalsan, and ABS, these products include the ALB type, white in color, used for interior spaces, and the moisture-resistant ALY type, green in color, used in wet areas and exterior applications. For curved surfaces, 6 mm thick boards are shaped with water before installation. Both OSB panels and gypsum boards can be used for structural sheathing purposes; however, OSB panels offer a higher degree of stability (Akay, 2013). The typical configuration of a light steel wall section is illustrated in Fig. 6.

Another fundamental material used in light steel structures is mineral stone wool. Since steel does not naturally provide thermal insulation, this deficiency is compensated by filling materials. In the panels, profiles are placed at 60 cm intervals with a maximum thickness of 1.5 mm, limiting the formation of thermal bridges to only the areas where steel is directly present. The surface area ratio of these thermal bridges is a maximum of 0.375%, while all remaining areas are insulated with stone wool. In addition to this insulation, polystyrene-based cladding is commonly applied on facades to ensure waterproofing and eliminate thermal bridges. Due to the low thermal mass in light steel systems, HVAC systems become effective in a short time, allowing the indoor climate to be rapidly adjusted without waiting for walls to heat up or cool down. This results in lower energy consumption compared to conventional buildings.

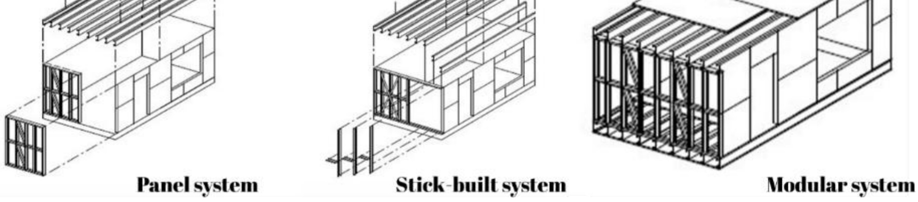

Fig. 7. Panel System, Stick Built System, Modular System (Mendes, 2019)

Fig. 8. Modular Construction (Lawson et al., 2008)

Moreover, stone wool significantly contributes to sound insulation. The use of high-density materials together with low density layers enhances acoustic performance; thanks to the multilayered panel structure, while OSB and gypsum board applications provide structural support, stone wool plays a key role in resonance reduction and sound damping. This combination provides sound insulation up to three times better than conventional construction methods (Mendes, 2019).

4.4 Lightweight Steel System Construction Techniques

The light steel system has attracted the attention of many organizations worldwide and has become an increasingly widespread construction method thanks to its ease of production, clean site conditions enabling fast assembly, waste-free structure, and cost advantages that can compete with reinforced concrete. In light steel residential construction, three primary assembly methods are employed: the bar (stick-built) system, the panel system, and the modular system, as illustrated in Fig. 7.

Among these systems, the panel construction method stands out as the most widely adopted technique. Profiles are manufactured in factory settings according to project-specific dimensions and transported to the construction site as wall, roof, and floor panels. These panels are then assembled on a pre-prepared foundation. The lightweight nature of the panels significantly eases the transportation and installation processes (Eğitmen, 2013). Compared to the bar (stick) system, the panel system offers a fourfold faster assembly process (Özcan, 2005). Furthermore, it enables uninterrupted work regardless of weather conditions, thereby ensuring the timely completion of projects, and eliminates deformation risks such as shrinkage, swelling, and warping commonly encountered in conventional materials like wood. The integration of door and window openings during the panel production stage further reduces on-site assembly time. Factory-based production enhances quality control and dimensional accuracy while minimizing the need for site labor and promoting greater automation opportunities. In addition, compared to on-site production, it offers a fivefold safer working environment, providing significant advantages in terms of occupational health and safety. Panels manufactured in controlled factory environments deliver high geometric precision and reliability (Grubb et al., n.d.).

Another method employed in the production of light steel structures is the stick-built system. In this construction technique, profiles prepared to the full story height are transported to the construction site, and the assembly operations are carried out directly on-site. Compared to modular and panel systems, this method generally results in a longer construction period. Moreover, if the galvanization on the profiles is damaged during transport or processing, the affected areas must be recoated with anti-corrosion paint (Eğitmen, 2013). In this method, panels are assembled piece by piece on-site, and then surface cladding and other components like insulation are added. The profiles come with pre-punched holes, which makes installation easier. The stick-built system also offers flexibility, as changes can be made during construction. Unlike modular systems, it does not require manufacturers to invest in a dedicated factory, which significantly reduces initial costs (Yandzio et al., 2015). Another construction method is the modular building system. According to Terim (2006), this system was promoted globally by the United Kingdom and several major companies. To enhance fire resistance, special thermal insulation solutions have been developed specifically for modular elements. Moreover, by using additional connection components, it is possible to construct buildings up to six stories high within this system (Mimarlar Odası İzmir Şubesi, 2006). The modular units are transported by crane and stacked on top of each other, with the entire system stabilized through steel cables or tensioning elements. This method stands out due to its rapid assembly within 2–3 days and the transportable and reusable design of its modules (Eğitmen, 2013). In this construction method, units are completed in the factory and then transported to the site for horizontal and vertical assembly (Yandzio et al., 2015). Especially in large-scale productions, it is considered the most cost-effective system because fixed costs such as prototyping and assembly, which are independent of scale, can be spread across many units. Additionally, conducting production off-site provides a significant advantage in terms of occupational health and safety, as it is five times safer compared to on-site construction. The world's largest structure built with the modular system, consisting of approximately 1,400 modules, is located in Manchester, and its visual representation is provided in Fig. 8 (Lawson et al., 2008).

The elements used in the assembly of light steel structural systems are important in terms of strength, economy, and production speed. Assembly elements and methods can be classified as fasteners such as screws and bolts, spot welds and rivets, and anchorage elements. Screws and bolts are removable fastening tools, whereas spot welding, riveting, and welding processes are non-removable fastening methods. Anchorage operations are generally performed by fixing light steel structural profiles to reinforced concrete foundations.

Welded joints are not typically used in light steel systems since they ruin galvanized coatings and quality cannot be guaranteed under site conditions. Heavy equipment requirements and extended application time also make welding less convenient. In addition, replacement and dismantling are not practical with welded joints. Spot welding is also not ideal since it ruins the galvanized surface and reusability is not practical. Alternatively, bolted connections are also commonly used. They offer efficient assembly of light steel elements with reinforced concrete or other steel elements. In light steel systems, bolted connections are commonly used to join light steel elements to reinforced concrete or other steel components (Yıldırım, 2010). When connecting steel profiles to OSB panels, the screw heads should have a minimum diameter of 7mm and must be countersunk into the OSB to prevent any protrusions that could affect the surface finish. Since OSB panels serve a structural function, screws should be placed at least 9mm from the panel edges. Additionally, the spacing between screws should be carefully calculated to ensure the stability of shear walls under horizontal loads (Mendes, 2019).

5. Lightweight Steel System Practices in Selected Regions

In Europe, cold-formed profiles have primarily been used as purlins or beams since the 1950s, and were later incorporated into various structural applications such as columns, wall studs, primary load-bearing elements, and roof trusses. The fact that cold-formed steel became more economical compared to timber and hot-rolled steel accelerated this trend (Baehre, 1982). During the 1970s, the use of high-yield-strength steels and deep sections became widespread to enhance load-bearing capacity, while longitudinal and transverse profile shaping techniques were developed. In the same period, the "stress skin" design, where the surface bears horizontal loads, also provided economic advantages. In Western Europe, especially in the United Kingdom and Scandinavian countries, Cold-Formed Steel (CFS) is frequently employed in multi-storey residential buildings. In these structures, CFS panels reinforced with OSB are applied in combination with dry materials or lightweight concrete. Within the EU, manufacturers are heavily investing in R&D activities focused on CFS solutions for multi-storey structures. It is noted that the Spanish company Teccon Evolution has obtained a European Technical Approval for this system. A study conducted in the United Kingdom found that the Metsec SFS system was 39% more cost-effective than conventional block walls, offering additional advantages such as reduced labor costs, environmental benefits, and quicker project completion (Nagy & Dubina, 2011).

In the North American residential market, light steel structures account for 20% of the share. They are commonly used in the construction of single or two storey villa type homes, especially in earthquake-prone areas like California, where cold-formed C-section steel profiles are typically employed. Rising timber prices and the growth of the supporting industry have made steel-framed housing an economically viable alternative (Wang et al., 2014).

Cold-formed steel elements are produced using C and Z section profiles and are typically applied in the form of either attached or detached structures. Due to inadequate sound insulation, their use in multi-storey buildings remains limited. Two main methods are employed to resist lateral loads and seismic effects: the first involves light steel shear walls formed with gypsum boards and galvanized steel sheets, and the second utilizes diagonal steel bracing elements. Vertical loads are carried by the light steel structure, while horizontal loads are resisted by conventional steel bracing. Additionally, placing glass wool within the wall studs and floor joists effectively interrupts thermal bridges, thereby providing thermal insulation (Wang et al., 2014).

CFS systems are also used in multi-storey buildings through structural shear wall panels, load-bearing wall panels, and floor/roof panels. In Canada, Bayley Metal Products constructed the six-story Kingsway Arms

Retirement Home, 9,890 m², with this system. Steelform developed a unique solution named the "Mega Joist" to provide additional structural support for the wall beams and intermediate floors. Moreover, in 2007, the American Iron and Steel Institute (AISI) published the first seismic design standard specifically for CFS structures (Nagy & Dubina, 2011).

Japan has shown significant interest in light steel structures due to its high seismic risk. Structures known as "Sheet Steel Housing" are constructed using box-shaped steel panels and floor systems. Steel sheets with a thickness of 1.0 mm are utilized, and both surfaces are covered with gypsum boards to provide durability, stability, thermal, and acoustic insulation. The use of timber has been limited due to its combustibility and the long reconstruction time required after disasters, while the preference for steel has also increased as part of efforts to preserve forests. In 2000, 70% of residential buildings in Japan were made of steel, 19% of wood, and 11% of reinforced concrete. The production of cold-formed steel has risen since the 1950s, and by 1980, 70% of these products were being used in the construction sector (Nagy & Dubina, 2011). Following the 1995 Hanshin earthquake, approximately 50,000 temporary housing units were constructed, of which around 3,000 featured steel frames. In the same year, the Japanese Ministry of Construction published performance standards for steel-framed houses. In 1996, steel manufacturers initiated studies focusing on structural performance and insulation. By 2005, approximately 20,000 steel-framed houses had been constructed (Nagy & Dubina, 2011). The KC (Kozai Club) light steel construction system, introduced in 2000, was officially recognized with the publication of new regulations in 2001 and gained widespread acceptance in the market (Kawakami, 2008). In this system, fire, thermal, and sound insulation are provided by applying thermal insulation and ventilation layers on the exterior surfaces and gypsum board on the interior surfaces. In KC-type structures, wood based cladding materials are generally preferred; in three-story buildings, the ground floor is constructed with reinforced concrete, while the upper floors are built using a steel framing system. This type of structure provides 60 minutes of fire resistance. To achieve higher fire and seismic performance, Nippon Steel developed the "Nittetsu Super Frame" (NSF) system. Seismic safety is addressed in two stages: during moderate earthquakes, the focus is on maintaining structural rigidity, while during more severe seismic events, the ability to dissipate energy becomes crucial. When wood cladding is not sufficient, new ceramic-based panels with high rigidity and energy dissipation capacity have been introduced. In the NSF system, floors are built using the platform framing method, and interstory deformation is prevented by high-rigidity connectors. The system received official structural performance approvals in 2005 and 2007. Moreover, in line with ISO 834 standards, fire insulation for cladding elements is achieved through the "membrane method," which protects against fire temperatures up to 945°C.

While light steel construction systems have reached usage rates of up to 20% in the housing sector in Western countries, this rate remains below 1% in Türkiye. This situation reveals that industry stakeholders in Türkiye have not shown sufficient interest in light steel systems (Türk Yapısal Çelik Derneği, 2020). In Turkey, light steel systems are generally applied as panel systems, and these systems are referred to as prefabricated structures. Around 80–90% of prefabricated construction companies utilize this system (İMO Eskişehir Şubesi, 2020, as cited in Fenli & Ünal, 2023). In addition, the on-site cladding system, in which panels are assembled directly at the construction site, is also widely preferred (Seçkin, 2022, as cited in Fenli & Ünal, 2023). In terms of design, the TS 11372 standard was followed until 2014. After this date, within the scope of harmonization with the European Union, the TS EN 1993-1-3 Eurocode 3 standard was adopted. Furthermore, the Turkish Building Earthquake Code, which came into force in 2019, includes a dedicated section for light steel structures and sets out the rules for sizing structural system elements. The regulation specifies that horizontal load-bearing systems must be designed either as "sheathing panel systems" or as "braced panel systems" (Fenli & Ünal, 2023). Fig. 9 illustrates the construction requirements for light steel structural systems as specified in the Turkish Building Earthquake Code. In practice, the production of steel structures consists of three main stages: the production of steel panels, the assembly of the load-bearing system, and cladding with OSB panels. All production and assembly processes are carried out in accordance with the project specifications, and the structure is anchored to the reinforced concrete foundation using steel anchors (Taşkıran, 2005, as cited in Fenli & Ünal, 2023).

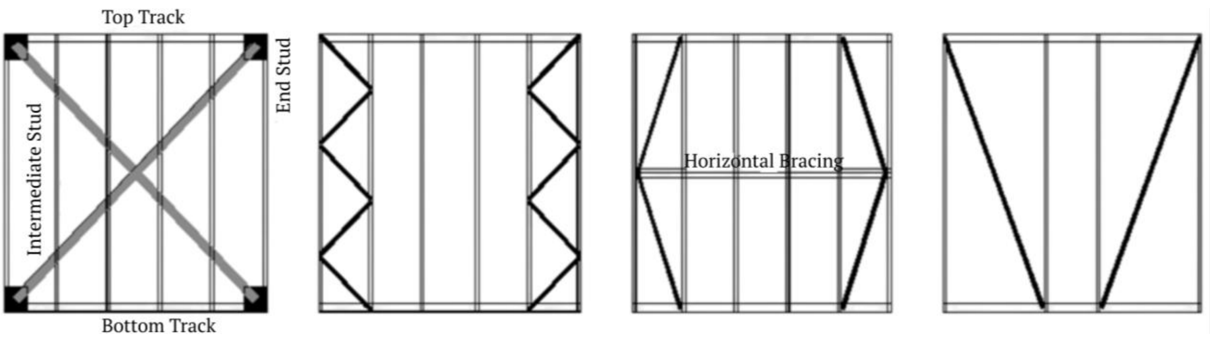

Fig. 9. Turkish Building Earthquake Code Light Steel Framing System (Çevre ve Şehircilik Bakanlığı, 2018)

6. Universal Design Codes

The development of standards for stainless steel structural design began with the American Iron and Steel Institute (AISI), which published the first specific standard in 1968 based on research conducted at Cornell University. This standard underwent revisions in 1974 and was later superseded by an American Society of Civil Engineers (ASCE) standard in 1991. In Europe, the Guide to the Design of Stainless Steel Structures, published by Euro Inox in 1994, was incorporated into Eurocode 3 in 1996. Japan and South Africa introduced their own standards in 1995 and 1997, respectively, while Australia and New Zealand followed with a standard in 2001. These initiatives established the global framework for stainless steel structural design (Gardner, 2005).

In Turkey, the regulation titled TS 11372, "Steel Structures - Lightweight - Formed with Cold-Formed Profiles - Rules of Calculation" came into force on April 28, 1994. This standard outlines calculation rules based on elastic theory for sizing thin-walled elements produced by cold-forming structural steel plates, intended for use as load-bearing elements not subjected to significant impact loads. After 1999, the use of light gauge steel for permanent structures in Turkey became increasingly common. However, TS 11372 is not specifically tailored for light gauge steel; it applies more broadly to cold-formed steel elements within structures. The mention of "steels thicker than 4 mm" further emphasizes that the regulation was not designed with mild steel applications in mind (Öncü, 2010).

The AISI initiated early efforts for the use of cold-formed steel elements in construction as early as the 1930s. Recently, the CSA S136 standard developed by the Canadian Standards Association (CSA), widely used in Canada, was merged with AISI standards and is now implemented as the AISI - North American Standard (NAS). This unified standard is also referenced in countries lacking their own codes for light gauge steel structures (Öncü, 2010).

Eurocode 3, developed for the design of steel structures across Europe, dedicates its third part specifically to structures composed of cold-formed steel. Beyond Europe, Eurocode 3 is commonly used as a reference in African nations and parts of the Middle East. Furthermore, in Australia and New Zealand, where light steel construction is prevalent, a standard issued by the National Association of Steel-Framed Housing (NASH) is applied, and a joint-use agreement with Japan supports its implementation. Scandinavian countries are also actively conducting research and developing standards in the field of light gauge steel construction (Öncü, 2010).

6. Results and Discussion

CFS (Cold-Formed Steel) framed houses offer significant advantages in terms of environmental comfort and health. These houses maintain temperature balance with heating and cooling properties that enhance energy efficiency. Additionally, the steel used in CFS framing systems does not require additional protective chemicals and does not emit gases or volatile organic compounds, thereby improving indoor air quality. Steel is also resistant to mold and decay, which is an important factor for health. These structures offer healthier living conditions, energy efficiency, and sustainability.

The earthquake and fire resistance of CFS provides a major advantage, especially for regions with seismic and fire risks. Steel has the capacity to absorb energy and, with its flexibility, helps the structure sustain less damage during earthquakes. Light structures are less affected by earthquakes compared to conventional heavy structures, which increases the suitability of CFS for earthquake-prone regions. In steel frame systems, Framecad CFS profiles are securely connected with screws to form a robust structure. The long-term durability of these structures is based on the material quality and structural integrity.

The modular prefabrication method provides a significant advantage in accelerating construction processes and reducing labor costs. CFS enables the transportation of prefabricated components to the site, minimizing the need for labor and shortening construction time, thus making the construction process more efficient. Additionally, prefabrication improves construction quality and reduces site congestion and waste.
While the global adoption of CFS is significant in some regions, it remains limited in others. One of the main reasons for this is the lack of comparative analyses and comprehensive research on the performance of CFS framed building systems. However, the advantages offered by these systems hold substantial potential, especially in earthquake-prone areas. Steel structures provide a strong alternative to conventional methods, with their flexibility in architectural designs, recyclability, and sustainability.

7. Conclusion

This study has comprehensively examined the advantages of light steel frame systems compared to conventional construction methods in terms of sustainability, seismic performance, and economic efficiency. The prefabricated nature of these systems allows for faster construction processes and offers significant advantages, particularly in regions with high seismic risks. Moreover, the adoption of these systems is of great importance in meeting the rapid urban development requirements driven by increasing urbanization demands.

The global use of light steel systems is widespread in some regions while limited in others. One of the strongest aspects of these systems is their earthquake resistance, which is crucial in seismically active areas. Additionally, their flexibility in architectural design, recyclability, and low carbon emissions contribute to sustainability, making them an attractive alternative to conventional construction methods.

However, a major barrier to the widespread adoption of light steel frame systems is the lack of sufficient comparative analyses and the need for more comprehensive research on the global dissemination and performance of these systems. This study highlights the importance of addressing this knowledge gap and emphasizes the need for further research to promote the broader adoption of these systems. Looking ahead, it is expected that light steel frame systems will gain wider acceptance. Real-world applications and comprehensive studies will further demonstrate the benefits of these systems, and they will become a critical component in the urbanization process by offering sustainable, efficient, and resilient construction solutions.

Urban identity and architectural representation: A studio practice

Aslan Nayeb*1

1 Yeditepe University, Department of Interior Architecture, 34758 İstanbul, Türkiye

Abstract. Urban identity is the sum of elements that define the character and uniqueness of a city. In this context, exploring the architectural representation of urban identity elements in a historically and culturally rich city like Istanbul holds significant importance. This study was conducted within the framework of the Architectural Representation studio, part of the Master's Program in Architecture at Yeditepe University, involving six students. The study consisted of three stages: the selection of identity elements, research and analysis, and scenario development. In the first stage, students were asked to select one of Istanbul's urban identity elements. This phase helped students understand the city's historical and cultural dynamics. In the second stage, the reasons why the selected element constitutes an identity component for Istanbul were researched and documented in written form. During this process, students had the opportunity to engage in critical thinking by questioning the architectural reflections of urban identity. In the third stage, students created a scenario based on their selected urban identity element and produced a media form to provide a visual representation of this scenario. This exercise aimed to enhance students' creativity and technical skills. As a result of the study, a total of six architectural representations of different urban identity elements in Istanbul were produced. The project offered students an opportunity to deeply understand the concept of urban identity while contributing to their comprehension of Istanbul's architectural and cultural layers. Furthermore, it introduces an innovative perspective to the literature by emphasizing the importance of architectural representation of urban identity elements. The findings serve as a valuable reference point for architectural education and urban design practices.

Keywords: Urban identity; Architectural representation; Creativity; Architecture education

1. Introduction

Urban identity encompasses the distinctive physical, cultural, historical, and symbolic attributes that collectively define the character of a city. It is not a static entity but a dynamic and evolving construct shaped by both tangible forms such as buildings, streetscapes, and monuments and intangible elements including memory, tradition, and social practices (Rapoport, 2005; Sepe, 2013). As cities continue to be reshaped by globalization, migration, and technological change, preserving and interpreting local identity has become an increasingly urgent concern in architectural discourse and practice (Alawadi, 2017; Erkip, 2000). Architecture plays a central role in articulating and reinforcing urban identity. Built environments do not merely serve functional needs; they act as symbols and carriers of meaning, reflecting societal values and historical narratives (Smaniotto Costa, 2008; Vale, 2008). Architectural representation is a key medium through which these meanings are explored, critiqued, and communicated. Representation thus becomes both a design tool and a cultural lens, offering ways to visualize and reimagine how identity is embedded in space (Corner, 1999; Kolarevic, 2013).

Architectural representation plays a critical role in both design thinking and education, functioning not merely as a means of visual communication but as a cognitive and exploratory tool. It enables students to externalize abstract concepts, test spatial ideas, and critically engage with cultural, historical, and social contexts (Evans, 1997; Corner, 1999). In educational settings, representational techniques ranging from traditional drawing and model-making to digital media and narrative-based outputs encourage iterative thinking and reflective learning. These methods foster students' ability to synthesize complex information, develop spatial literacy, and communicate design intentions with clarity and depth (Salama & Wilkinson, 2007; Ostwald & Williams, 2008). Moreover, when representation is positioned as an interpretive act rather than a purely descriptive one, it enhances students' critical thinking skills by prompting them to question how space, identity, and meaning are constructed and conveyed (Kolarevic, 2013). Thus, architectural representation not only supports technical skill development but also cultivates a deeper conceptual and contextual understanding—essential for shaping future architects as thoughtful and culturally aware practitioners.

Within architectural education, studio-based learning provides an ideal environment for students to engage with such complex and layered topics. Studios encourage active, project-based exploration, integrating analytical thinking with creative production. Recent pedagogical studies emphasize the value of thematic studios that focus on real-world issues such as urban identity and cultural continuity as a means to develop students' contextual awareness and design sensibilities (Salama & Wilkinson, 2007; Ostwald & Williams, 2008). When these studios are situated in historically rich and culturally layered cities like Istanbul, they offer unique opportunities to engage directly with the urban environment. Istanbul, straddling Europe and Asia, is a palimpsest of civilizations and architectural epochs. From Byzantine and Ottoman heritage to modernist and contemporary interventions, the city's urban fabric embodies a diversity of identity markers. However, rapid urban transformation in recent decades has placed many of these elements at risk, making it essential to cultivate a deeper understanding of what constitutes Istanbul's identity and how it can be meaningfully represented (Bozdoğan, 2012; Kuban, 2010).

The aim of this study is to investigate how architectural representation can be used as a pedagogical method to explore and communicate urban identity, through a studio-based practice conducted with graduate architecture students in Istanbul. This paper presents a graduate-level studio project conducted within the Architectural Representation course at Yeditepe University, where six students were tasked with exploring the architectural representation of Istanbul's urban identity. The studio followed a three-phase process: identification of an urban identity element, critical research and documentation, and the creation of a narrative scenario expressed through a form of a media production. This process aimed not only to enhance students' representational and technical skills but also to foster a critical and reflective approach to the city's evolving identity. By framing urban identity as both a subject of investigation and a representational challenge, the study demonstrates how studio-based education can contribute to broader discussions in architectural theory and urban design. It highlights the potential of narrative-driven, research-informed design practices to foster critical engagement with the city and cultivate culturally responsive architectural thinking.

2. Materials and methods

This study adopts a qualitative, practice-based methodology embedded within a graduate-level architectural studio titled Architectural Representation, conducted at Yeditepe University. The participants consisted of six Master's students enrolled in the studio course during the academic term. The study was structured around a three-stage design process that aimed to deepen students' understanding of urban identity while enhancing their representational and critical thinking skills (Fig. 1).

Stage 1 – Selection of Urban Identity Element: In the first phase, each student selected a specific urban identity element associated with the city of Istanbul. These elements included culturally significant spaces, historical landmarks, architectural typologies, or symbolic public areas. The selection process encouraged students to reflect on the socio-cultural, historical, and spatial significance of their chosen elements and to articulate their relevance to the city's identity.

Stage 2 – Research and Analysis: Following the selection, students conducted individual research to explore the historical background, cultural meaning, and architectural implications of their chosen identity elements. This involved both textual analysis and visual documentation, including sketches, photographs, and conceptual diagrams. Students were also encouraged to consider how these elements have evolved over time and how they are currently perceived within the urban context. This stage was documented in short essays supported by visual material.

Stage 3 – Scenario Development and Representation: In the final phase, students developed a conceptual scenario based on their selected identity element. Each student created a storytelling frame or a short video as a medium of architectural representation, incorporating narrative structure, spatial interpretation, and symbolic visual language. This allowed for a creative synthesis of research, representation, and storytelling, enabling students to communicate their understanding of urban identity through an expressive and personalized format.

Throughout the process, desk critiques, group discussions, and peer reviews were used as part of the pedagogical strategy to encourage critical reflection and collaborative learning. The final outputs six representations in various mediums served both as representational products and as documentation of the students' interpretive journey. Data for this study were gathered through observation of the studio process, student reflections, and the analysis of the final visual submissions.

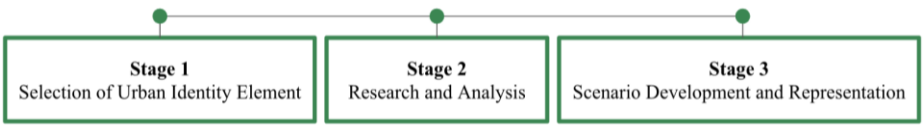

Fig. 1. Practice process stages

3. Results and discussion

The outcomes of the studio revealed that architectural representation served as an effective tool for exploring and communicating the multifaceted nature of urban identity. Each of the six student projects demonstrated a distinct interpretive approach, reflecting the individual's perception of Istanbul's layered urban fabric. (Table 1)

Table 1. Urban Identity Element and their features chosen by students

	Urban Identity Element	Location	Representation Title
Student 1	Mehmet Ayvalıtaş Square	Moda/Kadıköy	Gather Around
	Features: Almost unnoticeably, in the middle of the bustling streets of Moda, is a common park that eludes the harried attention of pedestrians. This little green area quietly defies expectations in the middle of the busy metropolitan landscape by hiding behind a façade of daily routine. Even though its architectural elements appear ordinary, they have a subtle appeal that only becomes apparent to those who take the time to observe its modest surroundings.		
Student 2	Maiden's Tower	Salacak/Üsküdar	Maiden's Myths
	Features: The myths to be explained are represented by the colors chosen around the Maiden's Tower. The Bosphorus line of the Maiden's Tower, a section of the Üsküdar coast-line and the Istanbul skyline are also reflected in the visuals of the work. Historical evidence shows that the tower was first mentioned in 410 BC. Although it has undergone various restorations since then, it continues to maintain the same value and iconicity.		
Student 3	Galata Tower	Bereketzade/Beyoğlu	Historical Journey of a Street Extending To Galata Tower
	Features: Galata Tower, which brings this street its significance, is located on the southern shore of the Historical Peninsula, separating the Karakoy and Beyoglu districts of the Bosphorus. Galata Tower, regarded as one of the oldest towers in the world, is one of the most significant structures that shapes the silhouette of Istanbul. Furthermore, due to its location at the end of Istiklal Avenue, recognized as one of the city's busiest, liveliest, and most important thoroughfares, and nestled among the historical narrow streets of the Galata and Beyoglu neighborhoods, the tower has consistently been a major attraction point from a tourist perspective. In this way, Galata Tower creates an atmosphere that provides both tourists and locals with the opportunity to experience Istanbul's rich cultural heritage up close.		
Student 4	July 15 Martyrs Bridge	Kuzguncuk/Üsküdar	From the Bosphorus Bridge to the 15 July Martyrs Bridge
	Features: The Bosphorus Bridge, now known as the 15 July Martyrs Bridge, is an important architectural structure that connects the historical and cultural fabric of Istanbul. This magnificent bridge, which was completed and put into service in 1973, is not only a transportation point by connecting the Asian and European continents, but also stands out with its architectural aesthetics and engineering success. The Bosphorus Bridge has a great symbolic value in the history of Istanbul. This bridge connected the European and Asian continents, changing the physical structure of the city and strengthening social ties. Contributing to the iconic silhouette of Istanbul, the bridge is more than just a means of transportation, it symbolizes the unified identity of the city. This structure, which encourages cultural interaction between people, has increased tourism and made the city a world-renowned center of attraction.		
Student 5	Kadiköy Ferry Pier	Caferağa/Kadıköy	Ferry Traffic
	Features: Kadıköy district has an important location in terms of country and city transportation. Some main transportation lines connecting various centers in Anatolia to Istanbul and various districts within the city pass through Kadıköy District. The biggest feature of this place is that it is crowded. A significant part of this crowd uses city line ferries. Therefore, the Ferry Pier and its surroundings in Kadıköy were considered as the area.Since representation is a method based on design knowledge in the mind, concepts related to the field have been determined. In other words, by determining the field, the concepts that this field creates in the mind are selected.		
Student 6	Altıyol Square	Söğütlüçeşme/Kadıköy	Altıyol Day/Night
	Features: Altıyol Square is recognized as one of the most iconic "public spaces" in the region, connecting the Metrobus, ferry terminals, and Bahariye Street. For many years, this square has served as a meeting point for people. Additionally, the bull statue located in the square contributes to the iconic status of the area. Considering all these features, it is essential to question the emotional impact that such a "public" space has on individuals. Despite being a meeting point and connecting important roads, the square falls far short of being an enjoyable area where one can spend time.		

As each student has chosen their own urban identity element they have also chosen the main features and specified their aims of creating their representations. Student 1 focused on the overlooked presence of an urban park, emphasizing its invisibility within the daily rhythm of city life. The aim was to draw attention to how this green space, despite its physical existence, often goes unnoticed and unrecognized. In the final representation in a form of a still storytelling frame, the student employed a combination of visual techniques to reinforce this concept: an overhead view highlighted the spatial context, while liquefaction effects distorted surrounding buildings to convey a sense of confinement and neglect. The use of red-painted human silhouettes in motion underscored the contrast between the park's passive anonymity and the city's active, unaware population, thus effectively portraying the tension between presence and perception in urban environments. (Table 2)

Student 2 explored the layered myths surrounding the Maiden's Tower, aiming to intertwine historical narratives with contemporary visual storytelling. The intent was to represent four prominent legends through a color-coded symbolic approach, integrating myth with spatial context. In the final visual work, the student utilized illustration techniques to depict the tower against a vivid pink sunset sky, embedding it within the modern Bosphorus setting, the Üsküdar coastline, and the current silhouette of Istanbul. Each color was carefully selected from naturally occurring tones in the scene to correspond with specific mythic elements, blending the factual and the legendary. This approach not only highlighted the cultural memory embedded in the tower but also demonstrated how representation can bridge historical continuity with present-day urban imagery. (Table 3)

Student 3 centered their study on Büyük Hendek Street and its evolving relationship with the Galata Tower, aiming to visually narrate the street's transformation from its historical roots to its current state. Through a sequential series of images, the work first emphasized the architectural shifts by illustrating stark structural changes over time. In later visuals, the focus transitioned from built form to everyday usage, capturing the ways in which people have interacted with and experienced the street across different periods. By combining architectural and social dimensions, the project effectively conveyed the layered temporal identity of the street, illustrating how urban space is continuously redefined through both physical change and lived experience. (Table 4)

Table 2. Student 1 representation aim and result

Aim	In this practice, emphasis is placed on the park's inconspicuous presence, deliberately overlooked within the natural course of life. It is highlighted that the park goes unnoticed, remains unexplored, and even upon entry, the spatial elements evade recognition.	Result	In this study, multiple techniques have been employed. The overhead view of the space is utilized as the main image, and the buildings enclosing and trapping the park are exaggerated using the liquefaction technique. People, absorbed in the flow of the city, pass around the park without noticing or perceiving it. The painting of human silhouettes in red is intended to emphasize the main character and the movement in the flow of the street.	

Table 3. Student 2 representation aim and result

Aim	In this study, which focuses on the Maiden's Tower, it is aimed to combine the myths of the tower from the past to the present with visuals. The myths to be explained are represented by the colors chosen around the Maiden's Tower. The Bosphorus line of the Maiden's Tower, a section of the Üsküdar coast-line and the Istanbul skyline are also reflected in the visuals of the work.	
Result	In conclusion, the 4 legends of the Maiden's Tower are the main figures, with the heartwarming pink sky around the Maiden's Tower at sunset, today's Bosphorus traffic, the use of the Üsküdar coastline and the current silhouette of Istanbul reflected in the background of the work. All the colors used in the stories were chosen from the shades of colors found in the work, including the sky. The reason for this is that this study aims to reflect existing, known myths and all the colors seen in the study are chosen from the reflections of this visual. This expression was combined in an image with the illustration representation method.	

Student 4 focused on the Bosphorus Bridge—now known as the 15 July Martyrs Bridge—highlighting its transformation from an infrastructural landmark to a symbolic monument of national significance. The aim was to explore and represent the events that have imbued the structure with historical weight, particularly the pivotal moment of July 15, through graphic and auditory means. The final video used visual layering, sound, and symbolic imagery to convey the bridge's dual identity: as an engineering marvel shaping Istanbul's skyline, and as a charged cultural site embodying collective memory and national resilience. This approach allowed the student to move beyond a technical portrayal and instead capture the emotive and socio-political layers of architectural meaning. (Table 5)

Table 4. Student 3 representation aim and result

Aim	In this study, it is aimed to offer the audience a visual experience of the historical development of Büyük Hendek Street leading to Galata Tower, through its transformation from the past to the present by providing an architectural representation of the street.	
Result	This study initially emphasized the significant structural differences by revealing the major structural differences in the first three images. Subsequently, in the following visuals, while the street retained its silhouette with minor variations, the focus shifted to highlighting the diverse ways it has been utilized and experienced in daily life. Together with all of these elements, an effort has been made to express how Buyuk Hendek Avenue and its relationship with Galata Tower have undergone changes throughout history.	

Student 5 explored the dynamic spatial experience generated by the arrival of a ferry at the Kadıköy Ferry Pier, with a focus on the concepts of circulation and crowdedness. The aim was to represent the fluid movement patterns and social density associated with this daily urban ritual. Through animated sequences supported by sound effects, the student illustrated each phase of the passenger flow—from the approach of the ferry to the dispersal of the crowd—emphasizing temporal progression and spatial rhythm. This audiovisual approach successfully conveyed the vibrancy and organized chaos typical of Istanbul’s ferry culture, transforming an ordinary transit moment into a rich subject of architectural representation. (Table 6)

Finally, student 6 aimed to investigate the spatial perception of a selected urban area by emphasizing its visual, auditory, and kinetic dimensions. The representation was constructed through a stylized 3D animation that deliberately avoided mimicking real-life camera footage. Instead, the student chose a static, orthographic perspective to abstract and clarify the spatial characteristics of the site. This methodological choice allowed for a more analytical representation, encouraging viewers to focus on spatial relationships, movement patterns, and environmental cues without the distraction of photorealism. The result was a controlled and conceptual exploration of urban perception, reinforcing how representation techniques can shape and guide architectural understanding. (Table 7)

Table 5. Student 4 representation aim and result

Aim	The Bosphorus Bridge is represented architecturally in this study. The events that took place on the bridge will be discussed by graphing them. The representation methods used to express this work will be examined.	
Result	As a result, the 15 July Martyrs Bridge, with its new name, is one of the rare structures that combines aesthetic and technical perfection with its architectural representation. The Bosphorus Bridge is known for the aesthetic value, engineering achievements and symbolic importance it adds to the Istanbul skyline. Moreover, it is not only a transportation structure but also a cultural heritage and source of pride. With this video representation method, these issues are processed graphically and this representation is supported with sounds. In this representation, the story of the Bosphorus Bridge becoming the 15th of July Martyrs Bridge was intended to be told through video and graphics.	

In their final representations, students integrated research findings with symbolic visual strategies, using spatial abstraction, sequencing and narrative devices to express meaning. These representations went beyond literal documentation; they functioned as interpretive mappings of Istanbul's identity, encapsulating the tension between memory and transformation, tradition and modernity. The creative freedom provided in the scenario-building process encouraged students to engage in speculative thinking, resulting in outputs that were both intellectually grounded and emotionally resonant.

Moreover, the studio process fostered active engagement with Istanbul’s urban fabric. Students reported increased awareness of the cultural and historical contexts shaping the city, as well as a deeper appreciation for the role of architecture in reflecting and shaping urban narratives. Peer discussions and critiques contributed to the emergence of shared themes, including temporality, hybridity, and the fragmentation of identity in contemporary urban life.

Table 6. Student 5 representation aim and result

Aim	With the formation of concepts, this study aims to produce a representation of the circulation created by the movement of the ferry arriving at the Kadıköy Ferry Pier.	
Result	In this study it was tried to be represented through the concepts examined. In other words, in this study, animation produces representations of circulation and crowds. Each stage in the flow is shown in order and the work is enhanced with sound effects. That's why, this study aims to produce a representation of the circulation created by the movement of the ferry arriving at the Kadıköy Ferry Pier. The main concepts to be emphasized are circulation and crowded space.	

Table 7. Student 6 representation aim and result

Aim	The purpose of choosing this project area is to examine the spatial perception of the area and draw attention to its various aspects.	
Result	The chosen methodology for examining visual, auditory, and motion-related issues in the project area involves the creaƟon of a 3D animation video. The animation is stylized to avoid resembling a camera video, and a static, orthographic angle is preferred.	

4. Discussion

The findings of this studio practice highlight the pedagogical value of integrating urban identity as a core theme within architectural representation courses. By positioning representation not merely as a technique but as a method of inquiry, the studio encouraged students to think critically about how spatial forms and cultural meanings intersect. The act of selecting and researching an identity element required students to engage with the socio-political and historical dimensions of the place, fostering an understanding of architecture as a cultural and communicative practice.

Across the six student projects, a diverse range of urban identity elements from overlooked green spaces to iconic landmarks like the Maiden's Tower and Bosphorus Bridge were interpreted and represented through various techniques including video, animation, illustration, storytelling frames and graphic composition. Each project uniquely addressed the spatial, historical, and experiential dimensions of Istanbul's urban fabric, emphasizing narrative, symbolism, and perceptual experience. The students demonstrated an ability to translate research into creative outputs, using architectural representation not only as a visual tool but as a medium for critical reflection and meaning-making.

5.Conclusions

This studio practice highlights the pedagogical potential of architectural representation in fostering critical engagement with urban identity. Through the act of representing spatial and cultural elements of Istanbul, students were able to question, interpret, and reframe their understanding of place. As argued by Ockman (2012), architectural education should move beyond skill acquisition to support interpretive and reflective practices that connect students with broader social and cultural narratives. This project aligns with such an approach, offering students a platform to engage with history, memory, and meaning through creative processes.

Moreover, integrating representational media such as video and animation supports the development of visual literacy and narrative competence-skills increasingly emphasized in contemporary architectural education (Kolarevic & Klinger, 2008; Salama, 2015). By situating urban identity at the center of the design inquiry, this project not only enriched students' perception of Istanbul's layered urban fabric but also contributed to a growing body of educational practices that prioritize critical, place-based learning. The results affirm that architectural representation, when applied as a reflective and expressive tool, holds significant value in both design education and urban discourse.

Abstract. The construction industry has a never-ending growth potential, but it also causes significant consumption of global natural resources and generates large amounts of waste. This leads to environmental problems around the world. The global architecture, engineering and construction industry is increasing its efforts to explore and implement sustainable construction methods to solve these problems. This study examines the reuse trends in building material research in architecture through bibliometric analysis. The development trends of the publications in the field of reuse of building materials obtained from Scopus databases in recent years, the relationships between stakeholders such as authors, institutions and countries in this field, and the prominent keywords in the field of study were revealed by bibliometric analysis. The findings show that between 1989-2019, technically oriented concepts such as 'Building Information Modelling (BIM)', 'energy demand' and 'embodied energy' stand out, but in the period 2020-2024, sustainability-based research such as 'sustainability', 'circular economy', 'waste reduction' and 'green building' increased. According to the results of bibliometric analysis, China, USA, UK and Germany are among the countries with the highest number of publications. Circular economy, life cycle assessment (LCA) and CO_2 emission reduction are among the most frequently researched topics for the reuse of building materials. Sustainable material utilisation and waste management are becoming increasingly important in the sector. This study emphasises that future research should focus on low-carbon construction strategies and recycling efficiency. It is also suggested that policy makers and industry professionals should develop new regulations that support circular economy orientated practices.

Keywords: Architectural materials, bibliometric analysis, building materials, recycling, reuse

1.Introduction

The construction industry exhibits substantial potential for perpetual growth and scalability; however, it simultaneously imposes significant strain on global natural resources and is a major contributor to solid waste generation worldwide (Hu & Chong, 2019). This paradoxical situation exacerbates a range of environmental challenges that necessitate urgent and coordinated global responses. In an effort to address these pressing issues, the architecture, engineering, and construction (AEC) sectors are increasingly prioritizing the exploration and adoption of sustainable construction practices aimed at enhancing resource efficiency and mitigating environmental degradation (Jayawardana et al., 2023). Among the emerging frameworks to address these challenges, the Circular Economy (CE) paradigm has garnered growing attention. CE emphasizes the closed-loop utilization of resources, extending material lifespans, and minimizing waste generation through strategies such as reuse, recycling, and product life extension. Nevertheless, despite its widespread promotion, CE remains a concept without a universally agreed-upon definition, leading to variations in its interpretation and application. As highlighted by Moraga et al., CE distinguishes itself from traditional linear economic models by designing goods and products for durability and by facilitating the recovery and reutilization of raw materials (Moraga et al., 2019; O'Grady et al., 2021). The environmental footprint of the construction sector underscores the critical necessity for systemic transformation. It is estimated that building construction activities alone account for approximately 40% of global natural resource consumption and contribute between 35% and 40% of the world's total solid waste output throughout their life cycle (Kamali et al., 2019; Maués et al.,2020). These figures highlight the imperative to integrate circular economy principles into construction processes, thereby promoting a more sustainable, low-carbon, and resource-resilient built environment. When buildings reach the end of their operational lifespan, it is estimated that only 20–30% of construction materials are effectively recycled or reused, highlighting a critical inefficiency in current resource recovery practices (Adams et al., 2017). Furthermore, the construction industry

* Corresponding author, E-mail: z.ertosun@alparslan.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_427

faces mounting pressure to not only mitigate the environmental impact of the growing volume of construction and demolition waste but also to enhance the overall efficiency of resource consumption throughout the building lifecycle (Smol et al., 2015).

The academic literature encompasses a diverse range of studies focused on the recycling and reuse of construction materials, widely accessible through various academic databases. These studies generally employ keyword-based search strategies targeting recyclable construction materials. For instance, Nie et al. (2023) explored the transition of the United Arab Emirates (UAE) towards a circular economy, emphasizing the management of construction and demolition waste during the pre-construction phase. Employing a case study methodology, their work advocates for the integration of circular economy practices to foster sustainable construction processes through more effective waste management strategies. Similarly, Suárez-Riera et al. (2024) reviewed methodologies aimed at minimizing the environmental footprint of cement-based materials. Their findings suggest that enhancing the environmental performance of cementitious materials can play a pivotal role in achieving broader sustainability objectives while simultaneously reducing the construction sector's ecological impact. Shaban and Ali (2024) examined the application of Building Information Modeling (BIM) in residential construction projects, highlighting its potential to improve environmental performance. They advocate for the more widespread adoption of BIM-based methodologies as a means to enhance sustainability across the construction industry. Azari et al. (2024) provided an overview of current advancements and future directions related to construction materials and façade systems in the context of energy-efficient building design. Their study underscores the role of innovative material technologies and façade systems in significantly improving the energy performance of buildings. In another study, Lokko et al. (2024) conducted a comparative life cycle assessment of the carbon impacts associated with conventional versus biogenic building materials used in major residential building typologies in Ghana and Senegal. The research contrasts traditional materials such as concrete and steel with biogenic alternatives like bamboo and rammed earth blocks, evaluating carbon emissions across all phases from production to operational energy consumption and end-of-life disposal. Their findings advocate for the promotion of biogenic materials to reduce the carbon footprint of the construction sector and emphasize the need for policy interventions that encourage the use of locally sourced, sustainable materials. Zhu et al. (2024) assessed the environmental impacts of a pavilion designed according to circular economy principles. Their study illustrates how circular architectural practices — particularly those emphasizing disassembly, modularity, and material reusability — can significantly lower carbon emissions associated with material production and disposal. The pavilion, built entirely with recycled and reusable components, demonstrates the practical benefits and scalability of circular design strategies in sustainable architecture. Xiang et al. (2024) investigated strategies to minimize the carbon emissions associated with the production, transportation, and assembly stages of prefabricated buildings. Their analysis identifies material selection, modular design optimization, and improved manufacturing processes as key levers for reducing embodied carbon, emphasizing the importance of innovative approaches to achieve low-carbon prefabricated construction. Finally, Zotova et al. (2024) explored the thermal performance of wall panels manufactured from lignocellulosic by-products, enhanced with bio-based microencapsulated phase change materials (PCMs). Their study highlights the potential of such composite materials to improve energy efficiency in buildings while contributing to the development of sustainable, bio-based construction solutions. Aziminezhad and Taherkhani (2023) conducted a comprehensive bibliometric analysis to examine the application of Building Information Modelling (BIM) in the deconstruction process. Their study systematically reviews the existing literature, identifying how BIM is utilized in building demolition activities, the potential advantages it offers, and emerging research trends within this domain. The authors provide insights into the evolution of scholarly interest by analyzing publication growth, keyword distribution, and thematic developments related to BIM and deconstruction practices.Similarly, Geng et al. (2017) performed a bibliometric analysis focused on scientific research concerning Life Cycle Assessment (LCA) within the construction sector. Their work investigates the breadth of LCA applications in building design and construction, offering a detailed evaluation of research development trajectories, prevailing themes, and future research directions. It was observed that LCA-related studies predominantly address areas such as energy efficiency, carbon footprint mitigation, material optimization, environmental impact assessment, and sustainable design practices. The study further emphasizes the critical need for the integration of LCA methodologies into decision support systems to facilitate their broader adoption in practical building sector applications. In another notable contribution, Wu et al. (2019) conducted a bibliometric analysis of research activities concerning construction and demolition waste (C&DW) management. Their study delineates the evolution of scientific inquiry into C&DW, highlighting key trends related to waste reuse, recycling practices, management strategies, environmental impacts, and economic evaluations. The findings suggest that research in this field is increasingly aligned with broader sustainability initiatives, emphasizing the connections between C&DW management, energy efficiency, and green building practices. Moreover, Owojori et al. (2021) performed a bibliometric review of the scholarly literature on the adaptive reuse of buildings. Their analysis identifies a growing research emphasis on energy consumption, material efficiency, and innovative design strategies within the adaptive reuse context. The study underscores the expanding relevance of adaptive reuse practices in advancing sustainable construction objectives and highlights critical areas for future investigation.

This study employs a comprehensive bibliometric analysis to investigate emerging trends and the current state of research on the reuse of building materials within the field of architecture. The primary objective is to examine how reused materials are represented and utilized in scholarly literature, as well as to identify the purposes for which they are adapted. Publications concerning material reuse were systematically analyzed using the Bibliometrix and Biblioshiny software packages, operating within the R programming environment, based on datasets retrieved from the Web of Science (WoS) Core Collection.

The analytical process was guided by the following research questions:

1. What are the recent developmental trajectories in publications related to the reuse of building materials?
2. How are the relationships among stakeholders—such as authors, institutions, and countries—structured and evolving within this research domain?
3. What are the prominent keywords emerging in this field, and how are these keywords thematically clustered?
4. What are the principal elements, overarching trends, and dominant themes characterizing research on building material reuse at a global scale?

These research questions are designed to provide an in-depth understanding of reuse-oriented investigations in architectural material research and to critically evaluate both the current landscape and potential future directions of the field. By employing bibliometric techniques, the study systematically examines content trends, thematic developments, and scholarly collaborations, thereby offering novel insights into the reuse of waste materials in line with the principles of reuse, reduction, and renewability. Furthermore, this study aims to generate valuable implications for architects, engineers, policymakers, and material suppliers seeking to advance sustainable building practices. It also seeks to identify existing research gaps, key thematic concentrations, and high-impact areas for future scholarly inquiry, contributing to the broader agenda of promoting circular economy strategies within the construction and architectural sectors.

2.Methodology

Bibliometric analysis has become an increasingly popular research method in recent years. This approach examines academic publications by categorizing them typically into articles, authors, and journals (Merigó and Yang, 2017). Bibliometric tools are utilized to analyze academic data and facilitate the construction of a scientific framework based on that data (Gaviria-Marin et al., 2019). In this study, scientific mapping and visualization processes were conducted using software tools such as VOSviewer and Biblioshiny. While VOSviewer visualizes relationships among academic publications through diagrams, Biblioshiny generates data on parameters such as citations, countries, and keywords. Biblioshiny is a product of the Bibliometrix R package and is supported by the Bibliometrix project. In this research, connections among the most highly cited articles were examined through bibliometric analysis. Academic studies published in the Web of Science database were examined to conduct a bibliometric analysis on adaptive reuse**.** The Web of Science Core Collection was selected due to its interdisciplinary scope and comprehensive scientific publication content. In this study, keywords such as "reduce"**,** "reuse"**,** "recycle"**,** "renewable", and "3R" were utilized. In addition, the terms "architectural design" and "architectural building" were also considered to define the focus of the research. The review encompassed academic studies published between 1989 and 2024, focusing on document types such as articles, book chapters, conference papers, and reviews. Only publications written in English were included in the analysis. Based on these criteria, a dataset comprising 359 publications and 1,106 authors was obtained. The steps followed in the research process are illustrated in the PRISMA flow diagram presented in Fig. 1. No additional exclusion criteria were applied, and all retrieved documents were included in the bibliometric analysis.

As a result of the analysis conducted in Scopus, a graph illustrating the number of publications by year is presented in Fig. 2. According to the graph, there was no notable increase in the number of publications between 1989 and 2004. A significant rise is observed between 2005 and 2010. Following 2010, the number of publications began to increase rapidly, and from 2018 onwards, a sharp and fluctuating upward trend has been identified. In this context, the highest number of publications occurred in 2024 (N=38), 2023 (N=34), and 2020 (N=33).

Fig. 3 displays a graph showing the number of documents by subject area in Scopus. According to the graph, the most prominent fields are identified as Engineering (N=244)**,** Environmental Science (N=89)**,** Energy (N=74)**,** Computer Science (N=47)**,** and Materials Science (N=34)**.**

In terms of document types, the distribution is as follows: Article (N=177), Conference Paper (N=152), Review (N=19), Book Chapter (N=6), Conference Review (N=4), and Retracted (N=1).

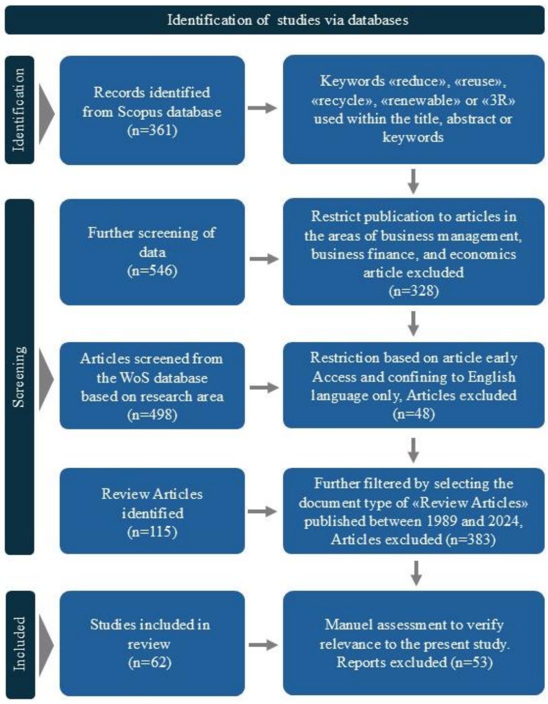

Fig. 1. Prisma flowchart

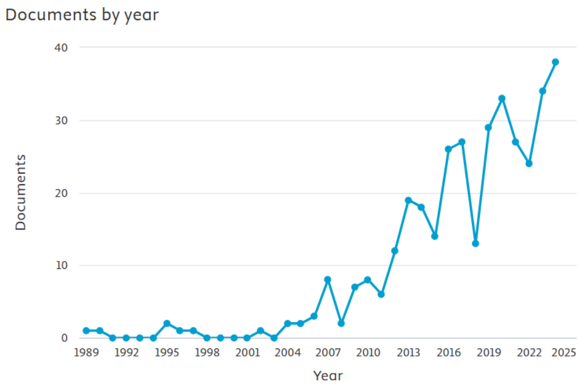

Fig. 2. Documents by year in scopus

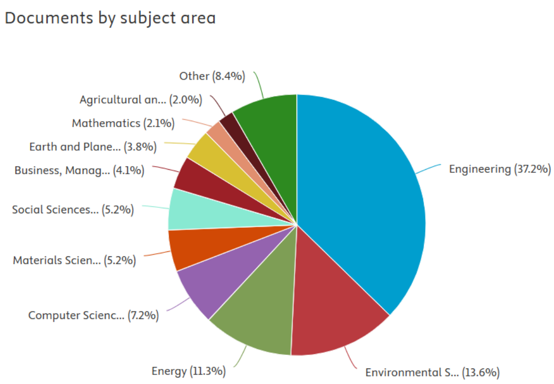

Fig. 3. Documents by subject area in scopus

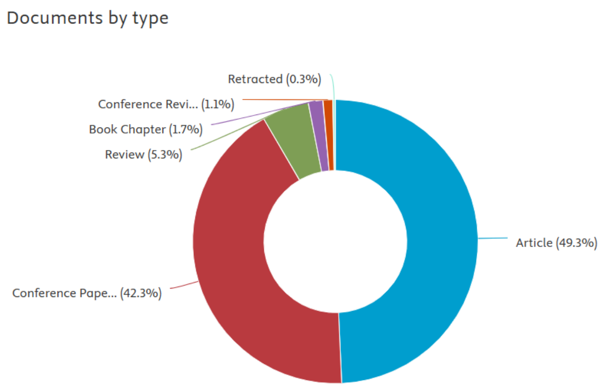

Fig. 4. Documents by type in scopus

A total of 359 documents retrieved from the Scopus database were analyzed using Bibliometrix Biblioshiny within the scope of this study.

3.Results

For the bibliometric analysis conducted using the Bibliometrix R package, documents were retrieved from the Scopus database in CSV format. Only documents written in English were included in the analysis, and any retracted documents were excluded from the study. As a result of these criteria, the main findings of the study are presented below. According to the data, a total of 359 documents published across 192 sources were identified between 1989 and 2024. The analysis revealed 1,106 unique authors, with an annual growth rate of 10.95% and an average citation per year of 21.26. In total, 250 documents were included in the detailed analysis, indicating that the topic has received considerable attention in the academic literature and constitutes an area of significant scholarly interest (Fig. 5). The examined time span from 1989 to 2024 suggests that the field has been the subject of research for approximately 35 years. This highlights both the historical depth of knowledge and the contemporary relevance of the topic within the scientific community.

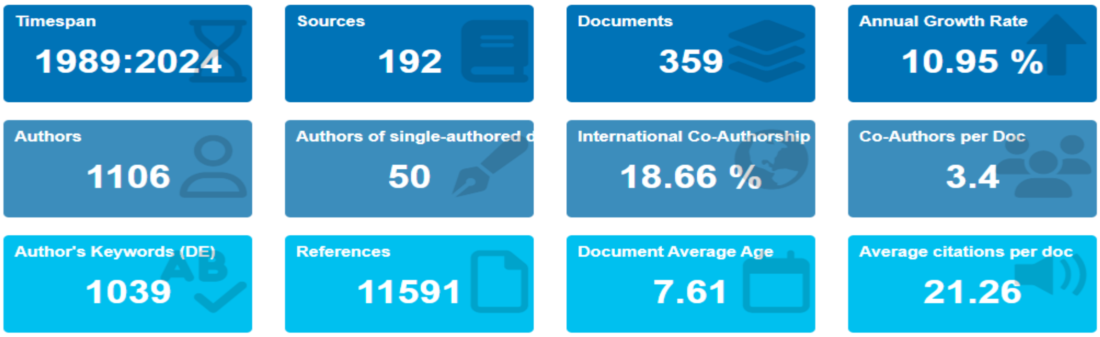

Fig. 5. Main information

Fig. 6 presents a three-field plot, illustrating the relationships among keywords (left), authors (center), and institutions (right). Within this framework, Park Hubei University of Technology, Yonsei University, and Bristol Business School emerge as the most prominent institutions. This visualization effectively demonstrates the connections between specific keywords, authors, and institutions. An analysis of the line density associated with keywords indicates that certain topics are linked to a greater number of authors and institutions. According to the figure, the keywords “building information modeling,” “circular economy,” “sustainability,” and “construction” stand out as the most frequently associated terms. This suggests that these topics are highly popular and actively researched within the scholarly community. The density of the connecting lines reflects the level of collaboration between authors and institutions. Areas with broader collaboration and more extensive knowledge exchange are represented by denser lines. In contrast, topics such as “sustainable building,” “energy consumption,” and “embodied carbon” are associated with fewer connections. This may indicate that these areas are either emerging fields or currently involve lower levels of collaboration.

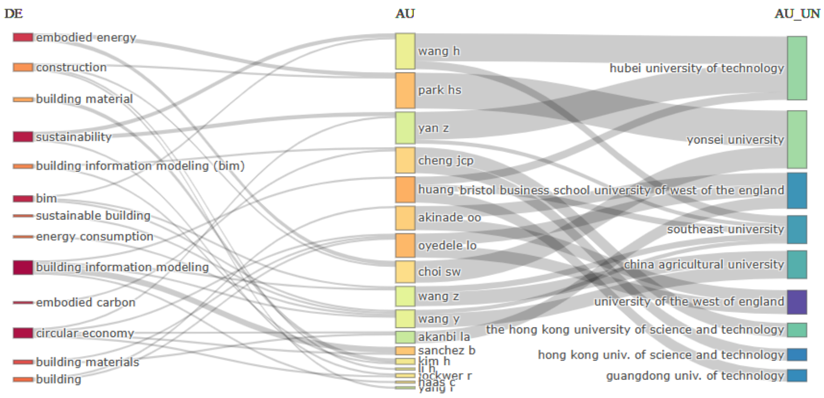

Fig. 6. Three field plot

3.1.Most Relevant Sources

In this bibliometric analysis, the section titled "Most Relevant Sources" examines the leading journals publishing on trends and the current state of reuse in building material research within the field of architecture. The data reveal the sources through which the literature has evolved and highlight the influence of specific journals in shaping the discourse in this area. As illustrated in Fig. 7, the Journal of Cleaner Production stands out as the most prolific source in the literature, with 17 published articles. According to Table 1, the second most active source is the journal Lecture Notes in Civil Engineering. This journal contributes to the discussion from a civil engineering perspective, providing insights into emerging trends related to reuse in architectural building material research. This shows that the study has a strong relationship with engineering practice is the most important. First ranked Journal of Cleaner Production magazine's new magazine on sustainability, energy efficiency and environmental remediation. Focus on issues is an important factor in studies on reuse. Ranked third, Applied Mechanics and Materials magazine is an important source of information for materials science and mechanics source. As a conference, the IOP Conference Series is a particularly innovative and provides an important platform for sharing experimental research. This onesource, research on the reuse of building materials in architecture is a dynamic and constantly evolving field. Energy and Buildings Magazine, which focuses on energy efficiency and building engineering fields, provides valuable information in the context of energy management and sustainable building design with 9 articles. Similarly, the Journal of Building Engineering Magazine, which focuses on building engineering, ensures that sectoral practices are handled on a scientific basis. When Fig. 7 is taken into consideration, Journal of Cleaner Production and Energy and Buildings focus on environment and energy efficiency, while Lecture notes in Civil Engineering and Applied Mechanics and Materials, engineering and technical approaches. In particular, it is noteworthy that publications in magazines such as Journal of Cleaner Production and Lecture Notes are expanded in the context of sustainability and engineering. The conference series allows you to share new ideas and pave the way for innovative solutions.

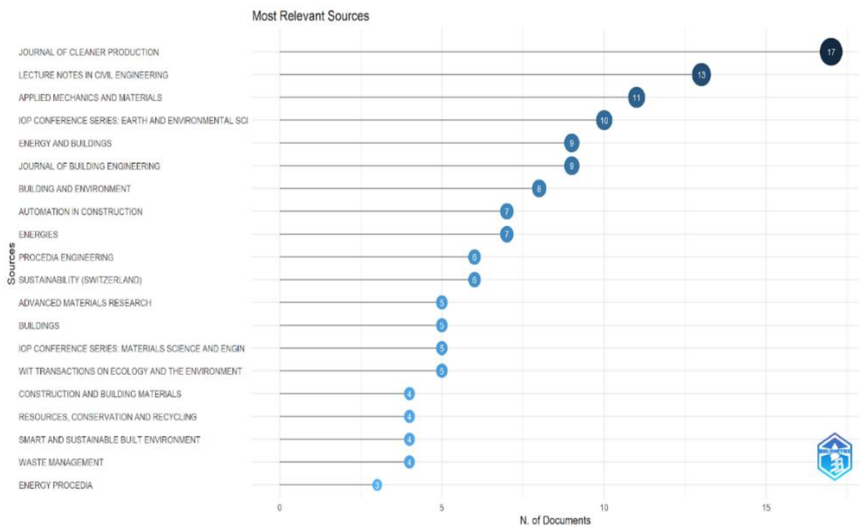

Fig. 7. Most relevant sources

Table 1. Most broadcasting magazines

Magazine name	Article number
Journal Of Cleaner Productıon	17
Lecture Notes In Cıvıl Engıneerıng	13
Applıed Mechanıcs and Materıals	11
Iop Conference Serıes: Earth and Envıronmental Scıence	10
Energy and Buıldıngs	9
Journal of Buıldıng Engıneerıng	9
Journal of Cleaner Productıon	17

3.2.Core Sources by Bradford's Law

The Bradford law is a bibliometric technique used to determine the basic sources of scientific literature on a particular subject. This law examines the distribution of scientific articles between journals on the subject and proposes that a small number of journals should publish intensive publication on a particular issue and the remaining publications should be distributed wider. According to the Bradford Law, three regions are defined. The region, which is described as nuclear region, is comprehensive in a small number of magazines in which most of the articles on the subject are published. When we look at Fig. 8, Journal of Cleaner Production, Lecture Notes in Civil Engineering, Applied Mechanics and Material, IOP Conference Series, Energy and Buildings and Journal of Building Engineering magazines are the core part of the Bradford Law. The so -called second region includes magazines in which fewer articles are published. The magazines between the Building and Enviroment magazine and the IOP Conference Series Materials Science and Engineering constitute the second region (Fig. 8). The third region includes magazines that contain very few articles and are generally indirectly related to the subject. According to Fig. 8, the right side of the IOP Conference Series Materials Science and Engineering magazine is located in this region.

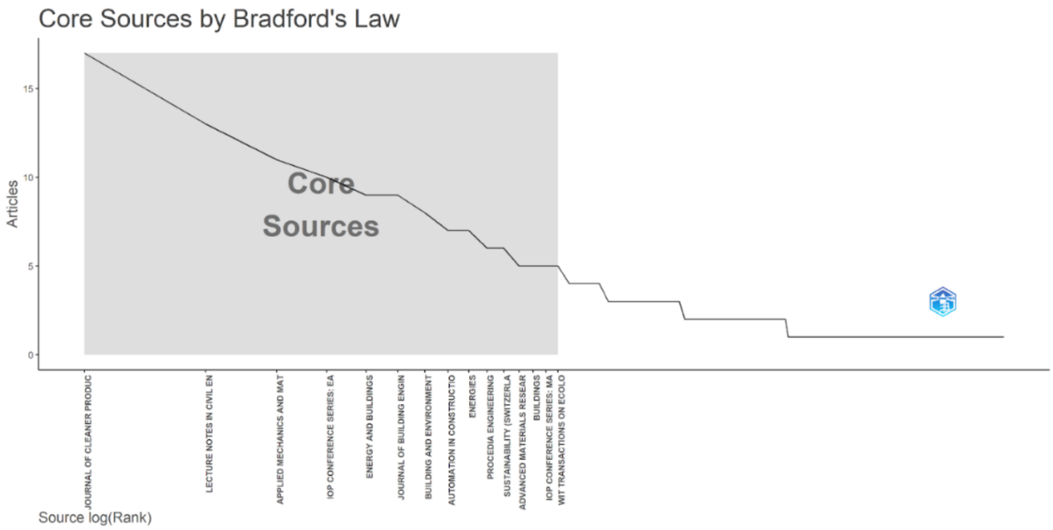

Fig. 8. Core sources by Bradford's law

3.3.Sources' Local Impact

The local impact of a source analyzes the effect of a journal on a particular research area or subject. This measurement usually measures how frequent references to articles published in a journal by other researches in this field. In bibliometric analysis, when evaluating the local influence of a journal, the validity and contribution of an article in a subject or discipline can be better understood. The Journal of Cleaner Production magazine has the highest referenced articles compared to other magazines in this field. This shows that the local influence of the magazine is high. This magazine is considered an important source of information of renewable energy researchers. Building and Enviroment, Energy and Buildings, Journal of Building Engineering, Automation in Construction, Energies, Procedia Engineering magazines, which are less cited in architecture, include disciplinary studies related to the reuse of building materials (Fig. 9).

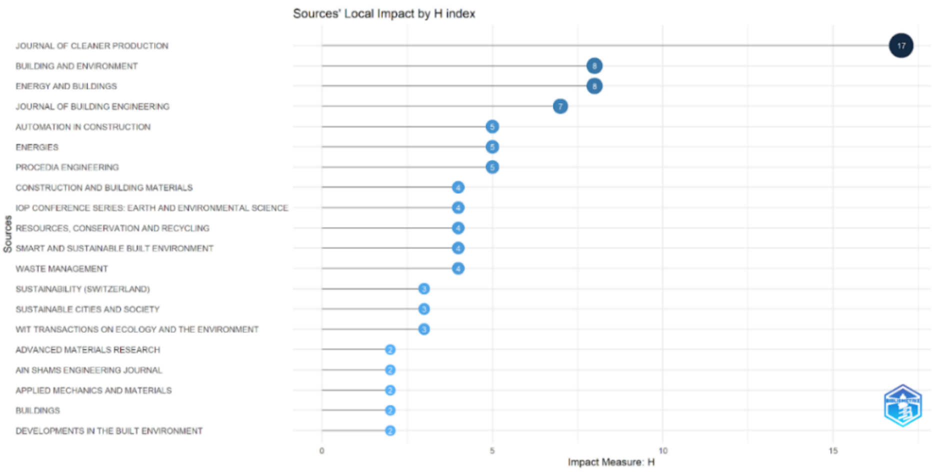

Fig. 9. Sources' Local Impact

3.4.Most Relevant Authors

Most Relevant Authors analysis provides a strategic guide for those who do literature screening and wanting to direct their work by identifying the most effective researchers in an area. The work of these authors is the cornerstones of the information in the field of research. In Fig. 10, all authors show equal productivity with four articles. Considering Table 2, the Park HS has the highest effect score with 0.89, which may indicate that its articles receive more references or more effective than other authors. Huang Y is second with 0.87 and has a similar high effect. Olayle Lo has a lower effect score to 0.65 than others.

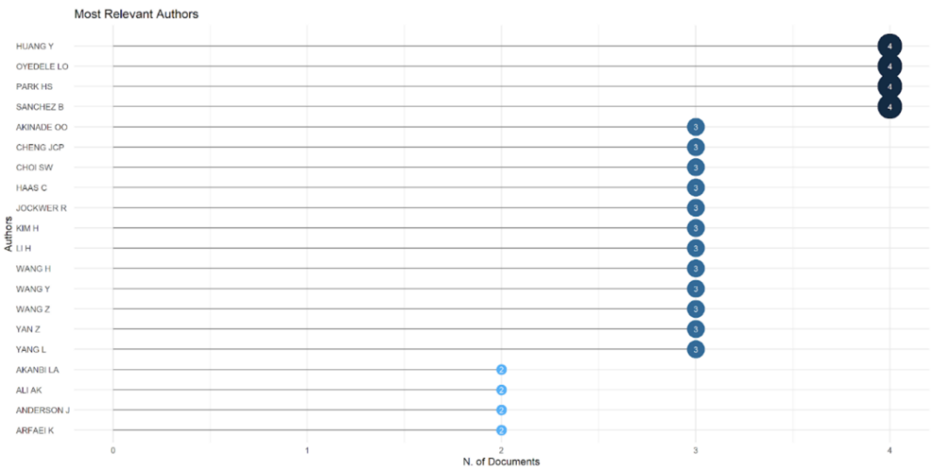

Fig. 10. Most Relevant Authors

Table 2. Number of Articles and Impact Factor

Author	Number of Articles	Impact factor
Huang Y	4	0.87
Oyedele LO	4	0.65
Park HS	4	0.89
Sanchez B	4	

3.5.Authors' Production over Time

Authors 'Production Over Time Analysis is used to examine the productivity of authors' productivity at a certain period of time and the tendencies of their work over the years. This analysis helps to understand the historical development of scientific production, the tendencies of research and the contributions of authors' careers at different points. Oso Lo, Akinade O 2019; Haas C, in 2020, Li H, 2021 (2 publications), Wang Z (2 publications) and Yan Z (3 publications) 2023'te the most broadcasting (Fig. 11).

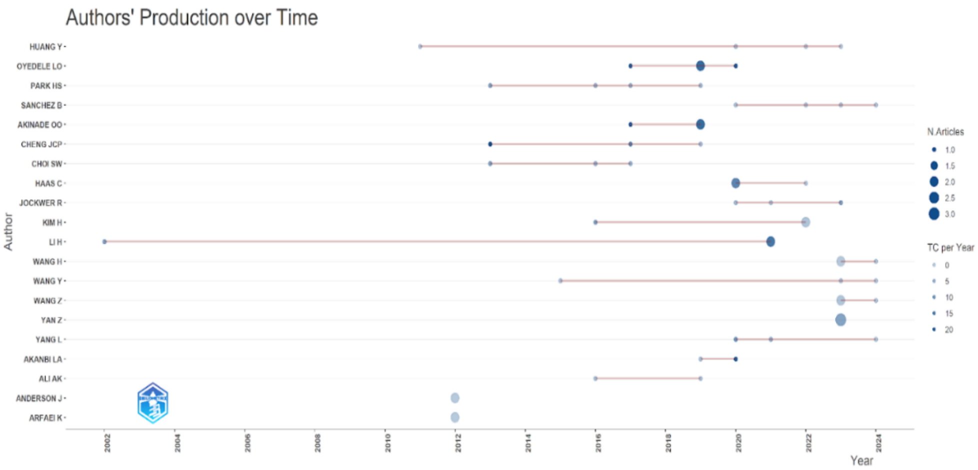

Fig. 11. Authors' Production over Time

3.6.Author Productivity through Lotka's Law

The Lotka Law is a bibliometric model that measures the productivity of writers in a research field and examines the distribution of this productivity. This law proposes a distribution in which a small number of writers broadcast extensively and published only one or two articles by many authors. In the graph, the X axis represents the level of productivity of authors. The Y axis shows the ratio of authors with each productivity level (%) to the total audience. The rapid fall of the flat line shows that high -productivity writers are in the minority, but that few writers play a central role in total information production. These authors can be seen as core information manufacturers in the field. The cut line refers to a theoretical threshold or an important distribution limit in accordance with Lotka's Law. The cut line refers to low productivity authors that make up the majority of authors in the field. This group has made a limited contribution to the literature, but plays a role in the expansion of the area and its spread to different issues. The rapid decrease of the line shows that highly productivity writers are low in number but have a significant effect.

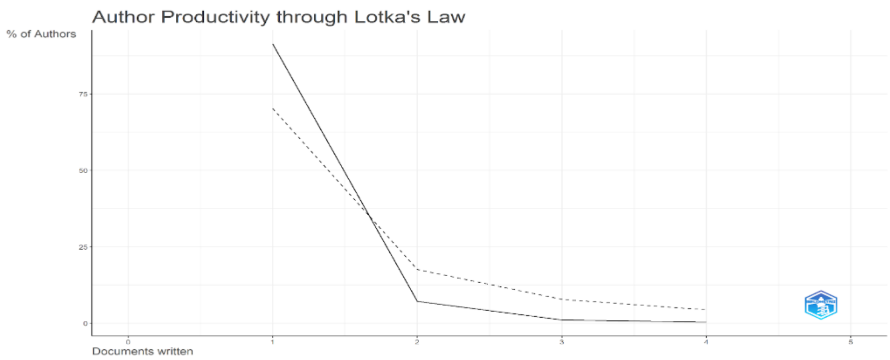

Fig. 12. Author Productivity through Lotka's Law

3.7.Thematic Map

This study employed thematic mapping to identify the major conceptual structures and research trends in the reuse of building materials within architectural research. Using data retrieved from Scopus and visualized through the Bibliometrix platform, thematic maps were generated based on Keyword Plus and Author Keywords. The thematic map based on Keyword Plus revealed four distinct thematic clusters (Fig. 13). *Niche themes* such as *Material Reuse* and *Sustainable Construction* are positioned in the niche quadrant, representing specialized areas with high internal coherence but limited connectivity to the broader research field. These themes are important for targeted advancements but currently exert minimal influence on the wider scholarly network. In contrast, *Motor themes* including *Life Cycle Assessment (LCA)*, *Building Information Modeling (BIM)*, and *Circular Economy* emerged as central, highly developed, and influential topics. Their strategic positioning reflects their critical role in driving innovation and shaping the future direction of sustainable building practices. Meanwhile, *Emerging or Declining themes* were represented by *Building Information Modeling (BIM)*, identified as an increasingly important but still peripheral topic. Although the volume of BIM-related research is growing, its broader integration into sustainability-focused studies remains limited, suggesting significant opportunities for future interdisciplinary research. Finally, *Basic themes* such as *Energy Efficiency*, *Energy Consumption*, *Renewable Energy*, *Embodied*

Carbon, and *Circular Economy* were found to constitute the foundational framework of the research area. Despite their wide-ranging connections across the field, these basic themes require further detailed investigation to strengthen both theoretical understanding and practical applications in sustainable construction and material reuse research.

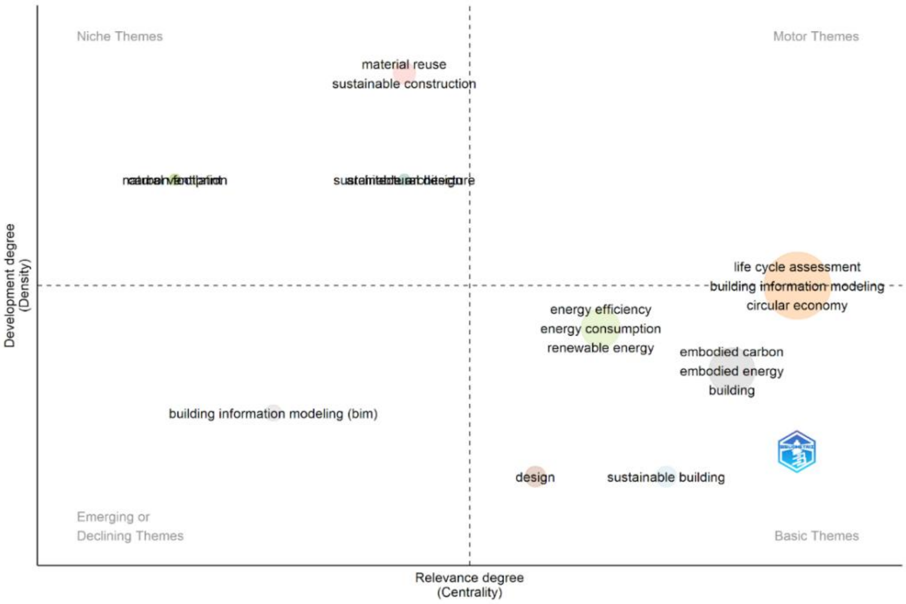

Fig. 13. Thematic Map

The thematic analysis based on Author Keywords (Fig. 14) similarly revealed evolving research structures and emerging focal areas. The *green cluster* represents emerging themes such as *Life Cycle*, *Environmental Impact*, and *Construction Industry*, reflecting an increasing research interest in integrating life cycle assessment methodologies with sustainable construction practices. In contrast, the *red cluster* comprises established themes like *Waste Management* and *Building Materials*, highlighting their central and highly interconnected position within the literature and underscoring their fundamental role in achieving sustainability objectives within the construction sector. The *blue cluster* encompasses niche, technology-driven research areas, including *Energy Conservation*, *Energy Efficiency*, *Energy Utilization*, and *Intelligent Buildings*. These topics are primarily associated with advancements in smart building technologies and energy management systems, representing specialized fields that offer significant opportunities for technological innovation, albeit with relatively limited connections to broader sustainability frameworks.

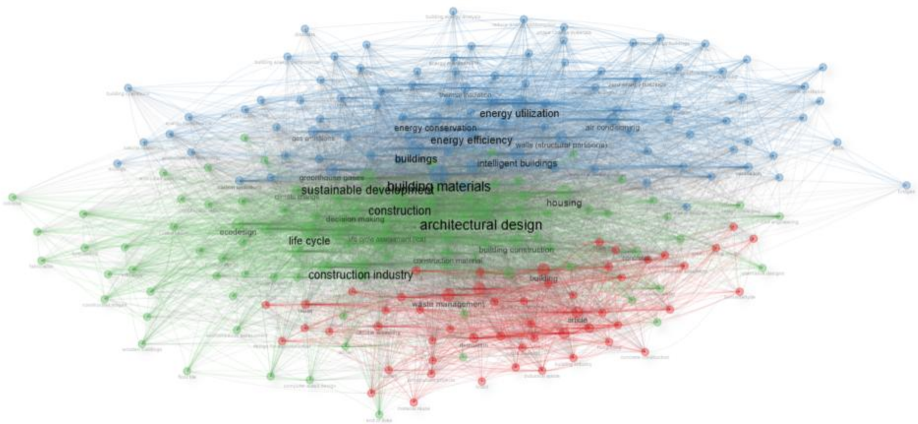

Fig. 14. Thematic Map by Keyword Plus

The comparative analysis of keyword trends from the periods 1989–2019 and 2020–2024 demonstrates a notable thematic shift within the field. Earlier research predominantly concentrated on technical and energy-related topics such as Building Information Modeling (BIM), Embodied Energy, and Energy Demand. However, more recent studies have transitioned towards broader sustainability-oriented concepts, including Circular Economy, Waste Reduction, and Green Building. Likewise, the notion of reuse has evolved from basic resource recovery strategies to more analytically driven frameworks centered on Life Cycle Assessment (LCA) and CO_2 emissions reduction. This thematic evolution underscores the increasing importance of evaluating building material reuse within the contexts of environmental impact, resource optimization, and circular economy principles, reflecting a deeper commitment to achieving comprehensive sustainability in the architecture and construction sectors.

4. Conclusion

This study has presented a comprehensive bibliometric analysis focusing on the reuse of building materials within architectural research, drawing on data from the Scopus database. The findings illuminate the dynamic evolution of scholarly interest in material reuse and highlight key thematic developments in the context of sustainable construction and circular economy frameworks.The analysis reveals a distinct shift in research orientation over the past decades. While studies conducted between 1989 and 2019 predominantly emphasized technical and computational approaches such as Building Information Modeling (BIM), energy demand, and embodied energy, the period from 2020 to 2024 has witnessed a substantial rise in research focused on sustainability, circular economy, waste reduction, and green building design. This indicates a broader transformation in architectural research towards low-carbon, resource-efficient design paradigms. In terms of geographic distribution, China, the United States, the United Kingdom, and several European technical universities have emerged as leading contributors to the academic discourse on sustainable building materials. These regions play a pivotal role in advancing innovation and setting the research agenda in the field. The most prominent studies reflect growing attention to life cycle assessment (LCA), carbon emission mitigation, and construction waste management. In parallel, there is an increased emphasis on adaptive reuse practices and circular design principles aimed at extending the lifespan of materials and reducing environmental impact. Notably, the integration of BIM technologies to support sustainability assessment has gained momentum, further reinforcing the synergy between digital innovation and environmental performance.

Based on the insights gained, this study underscores the following key implications:

- The use of sustainable and recyclable materials should be prioritized in architectural practice to align with global sustainability goals.
- Circular economy principles must be further integrated into the design, construction, and policy-making processes.
- Future research should focus on the development of quantitative frameworks to assess material reuse efficiency, the optimization of waste management systems, and the adoption of low-carbon construction strategies.
- Policymakers and industry stakeholders should work collaboratively to establish regulations and incentives that support the adoption of circular construction practices.

In conclusion, advancing research and practice in building material reuse is essential for the transition to a more sustainable and resilient built environment. This study contributes to the body of knowledge by mapping current research trajectories, identifying gaps, and providing directions for future scholarly inquiry in architecture and construction.

A cost-effective optimization of post-fire strengthening of concrete columns with FRP fabrics using heuristic algorithm

Nefise Akdağ*[1], Uğur Demir[1]

[1]İzmir Institute of Technology, Department of Architecture, 35430, İzmir, Türkiye

Abstract. Reinforced concrete (RC) structural elements exposed to fire suffer various losses in terms of their mechanical properties depending on the maximum temperature and the duration of the fire. In most cases, RC structures that have been exposed to fire require repair and/or retrofitting work on an element or system basis, depending on the extent of the fire damage. The method of circumferential wrapping fiber reinforced polymer (FRP) fabrics is an innovative method for this purpose. Given that the columns are generally main load-bearing members in RC structures, their post-fire performance is of vital importance to ensure structural safety after fire events. This study aims to develop a systematic approach to optimize post-fire retrofitting techniques for critical load-bearing elements. For this purpose, a heuristic algorithm is used. In the algorithm design, the number of FRP layers and the mechanical properties of FRP were chosen as variables. Genetic algorithms were used to identify the optimal combination of FRP composite type and layer quantity to restore and enhance structural integrity. The optimization framework focuses on minimizing costs while maximizing the load-bearing capacity and deformability of fire-damaged columns. The study highlights the role of advanced computational techniques in improving post-disaster recovery strategies for RC buildings. By combining material selection and cost efficiency, this research contributes to the broader field of sustainable structural retrofitting. The results demonstrate the potential of heuristic algorithms in guiding decision-making processes for the repair of fire-affected infrastructure.

Keywords: Concrete Column; Fiber-Reinforced Polymer; Genetic Algorithm; Heat-Damaged; Optimization

1. Introduction

Numerous studies were conducted to investigate the behavior of RC structures at elevated temperatures. The composition of reinforced concrete (RC) includes not only solid components but also a capillary porous structure that contains gaseous and partially vaporized forms of liquid (Bajc et al., 2022). It is known that the behavior of concrete at elevated temperatures changes according to the type of aggregate used in the mixture of concrete (Bilow & Kamara, 2008), while the evaporation of the water in it also has an impact on behavior (Khoury, 2000). This change can be explained by the deterioration of material properties at elevated temperatures, the restraint condition caused by thermal expansion, and the redistribution of structural loads during high temperatures (Qiu et al., 2021). Therefore, heat-damaged RC structures fail to fulfill the requirements in terms of structural safety (Ma et al., 2019).

According to the research conducted in the last decades, there are several recommended strengthening methods for RC structures after fire. Among the main strengthening methods for RC structural members, concrete, steel, or FRP jacketing methods stand out as most commonly known techniques. Due to its easy implementation, high efficiency, and low cost, FRP strengthening methods are becoming increasingly popular within this context (Baji et al., 2018). FRP can be defined as a composite product namely reinforced with carbon, glass, basalt, and aramid fibers, and it is mostly used with epoxy, which is mostly based on vinyl (Alberto, 2013). It is primarily aimed to increase the ductility of RC structural elements with FRP strengthening methods (Awoyera et al., 2024). It has been shown that a significant increase in strength and ductility can be achieved by using FRP strengthening methods in concrete columns after fire (Bisby et al.,2011; Lenwari et al., 2016; Demir et al., 2019; Ouyang et al., 2021; Song et al., 2021; Elhamnike et al., 2022). Moreover, it is acknowledged that the strengthening of RC structures is preferably done only once within the service life of the building. For this reason, the strengthening process to be carried out should be carried out in the most optimal scenario possible. Optimization, as a description, is the tool that finds the best solution within all possible solutions (Dede, 2019). There is limited research where FRP strengthening of RC structures was evaluated in terms of cost (Zou et al., 2007; Choi et al., 2014; Chisari & Bedon, 2016; Chisari & Bedon, 2017; Choi, 2017). The utilization of FRP at the design stage and strengthening

*Corresponding author, E-mail: nefiseakdag@iyte.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_454

of heat-damaged RC structures should be evaluated to optimize the cost while meeting the criteria of relevant standards.

According to the best literature survey of the authors, there is no study in the literature that comparatively recommends the most suitable strengthening methods to reduce the cost of FRP material by considering optimization methods based on the performance of heat-damaged structures. In this study, a methodology to find the optimum cost of strengthening and the number of required FRP layers for heat-damaged RC columns strengthened with FRP wrapping is proposed. This procedure is based on a cost-dependent reliability method. Despite the fact that carbon FRP (CFRP) sheets are more commonly demanded in practical strengthening applications in Türkiye, findings reveal that using GFRP can provide sufficient and optimal structural performance under post-heated conditions while reducing overall strengthening expenses.

2. Materials and Methods

Elevated temperatures are known to significantly reduce the compressive strength of concrete Fig. 1. However, an increase in strain values is observed compared to the initial case, unheated state (Bisby et al., 2011). As previously discussed, the loss in compressive strength can be partially recovered through confinement with FRPs. To estimate the axial stress–strain response of heat-damaged concrete itself, the model proposed by (Chang et al., 2006) is used within the scope of this study. In this model, $f_{c\Theta}$ is the unconfined compressive strength of heated concrete after cooling, f_c is the unconfined compressive strength of unheated concrete, $\varepsilon_{c\Theta}$ is the unconfined axial strain of heated concrete after cooling, ε_c is the unconfined axial strain of unheated concrete, and T_m is the maximum temperature. These variables are employed in Equations (1–3), as recommended by (Chang et al., 2006). It is also noteworthy in this study that the heating scenario includes two target temperatures, 300°C and 500°C, which are used in the application of Equations (1–3).

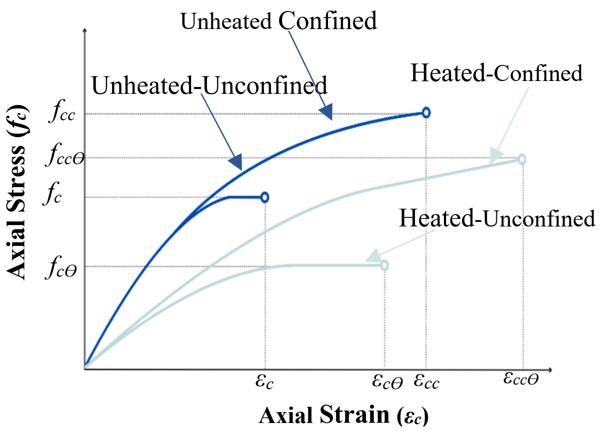

Fig. 1. Stress-strain behavior for the unconfined and FRP-confined concrete at ambient and elevated temperatures (adapted from Bisby et al. 2011)

$$f_{c\Theta} = (1.01 - 0{,}00055)T_m \quad 20°C \leq \; T_m \leq 200°C \tag{1}$$

$$f_{c\Theta} = (1.15 - 0{,}00125)T_m \quad 200°C \leq \; T_m \leq 800°C \tag{2}$$

$$\varepsilon_{c\Theta} = ((7.7 - 0.1f_c)(\frac{e^{0{,}01\times T_m - 5{,}8}}{e^{0{,}01\times T_m - 5{,}8}+1} \text{ - } 0.0219) + 1)\; \varepsilon_c\;) \tag{3}$$

2.1. FRP Confinement Model for Heat-Damaged Concrete

In the literature, many experimental studies have been carried out to predict the stress-strain behavior of FRP-confined heat-damaged concrete. ACI 440.2R-17 models have been modified in this regard to predict the ultimate condition of FRP-confined unheated concrete. With this aim, a model based on ACI 440.2R-17 was developed by (Bisby et al., 2011), as summarized in Eqs. (4-9). In these equations, $f_{cc\Theta}$,the compressive strength of FRP-confined heat-damaged concrete is first calculated. The effective confinement pressure (f_{lu}) is calculated using Eq. 5, where E_f is the modulus of elasticity of the FRP wrap in the hoop direction, $\varepsilon_{f\varepsilon}$ is the effective strain in the FRP wrap at the ultimate state, and the thickness of the FRP is shown by t_f. The effective strain in the FRP at failure, $\varepsilon_{f\varepsilon}$, is calculated using Eq. 6, where k_ε is the strain efficiency factor and ε_{fu} is the design rupture strain of the FRP wrap. In addition, in Equations (7-9), $\varepsilon_{cc\Theta}$ is the ultimate strain of heated concrete after FRP confinement, while

ε_{cc} is the ultimate strain in FRP-confined unheated concrete.

$$f_{cc\Theta} = f_{c\Theta} + 3.3 f_{lu} \quad (4)$$

$$f_{lu} = \frac{2 n t_f E_f \varepsilon_f}{D} \quad (5)$$

$$\varepsilon_{f\varepsilon} = \varepsilon_{fu} k_\varepsilon \quad (6)$$

$$\varepsilon_{cc\Theta} = \varepsilon_{c\Theta} + (\varepsilon_{cc} - \varepsilon_c) \quad (7)$$

$$\varepsilon_{cc} = \frac{1.71(5 f_{cc} - 4 f_c)}{E_c} \quad (8)$$

$$E_c = \frac{2 f_c}{\varepsilon_c} \quad (9)$$

2.2 FRP Types

Glass, basalt, carbon, and aramid fibers are the most used materials to produce FRP composites, and they all have different physical and mechanical behavior (Nanni et al., 2014). The most used fiber in the materials of FRP is glass fiber reinforced polymer (GFRP) because of its relatively lower price (Khodadadi et al., 2024). Besides, CFRP has a wide range in terms of application fields, although its price is relatively high many times. In addition, substantial qualifications of carbon FRPs, including their sensitivity to creep rupture, resistance to alkaline and acidic solutions, and capacity to absorb higher sustained stresses, make them a satisfying material in many applications such as prestressing (ACI 440.2R-17). On the other hand, basalt fiber polymer (BFRP) is made from melted basalt rocks. Due to the mechanical qualifications of BFRP and satisfactory price, the use of BFRP is increasing (Khodadadi et al., 2024). In literature, researchers are developing various methods to eliminate the negative aspects of aramid FRP, such as physical methods, chemical grafting, coating methods, and nanostructures (Zhang et al., 2021). Fibers are the load-bearing components of FRP, and the type to be applied has a critical impact on the mechanical behavior of heat-damaged concrete. Considering this, information about the four types of commonly used FRPs is comparatively presented in Table 1. The data was compiled from different exporters in Türkiye.

Table 1. FRP Properties

FRP Type	E_f (GPa)	f_f (MPa)	t_f (mm)	ε_{fu} (%)	Cost per m^3
CFRP-1	228	1600	0.11	0.02	9$
CFRP-2	228	2000	0.11	0.02	10$
CFRP-3	228	3000	0.11	0.02	11$
CFRP-4	228	4000	0.11	0.02	12$
GFRP-1	76	3450	0.35	0.02	1$
GFRP-2	97	4830	0.35	0.02	1.5$
BFRP-1	85	2900	0.12	0.02	2.5$
BFRP-2	86	3000	0.12	0.02	3$
BFRP-3	87	3100	0.12	0.02	4$
AFRP	118	2060	0.19	0.02	5$

2.3. Optimization Problem

Axial compressive strength and the ultimate strain of the concrete depend on several effects, including but not limited to i) the thickness, ii) tensile strength and iii) elastic modulus of the confining FRP, iv) unconfined concrete strength, and v) cross-sectional shape of the column. As shown in Fig. 2, within the scope of this study, a hypothetical column is confined with various configurations of FRP wrap after being exposed to fire. The cost of strengthening configuration was calculated through Equations (10-12), where V_f is defined as the volume of FRP, C_f is the circumference (mm) of FRP, and μ is the cost of epoxy. In addition, V_o defines the volume of overlap length (mm) of FRP, n_f indicates the number of layers of FRP, δ is the cost per volume. The cost equations used in this study (Eqs. (10-12) are adopted based on the expressions given by Zou et al. (2007), with some modifications in terms of full wrapping conditions of the columns, which are not considered by Zou et al. (2007).

The proposed scenario is applied over 100 cm (D)×200 cm (L_f) cylindrical column with 100mm overlap length of FRP, which is shown in Fig.2. Initial compressive strength *(f_c)* of the column was assumed to be 28 MPa and the initial axial strain *(ε_c)* of the column was adjusted to 0,002 at the beginning of the heating process. Increase at confined-heat-damaged compressive strength and axial strain with respect to the initial cases (before fire) was calculated by gain functions given at Eq. (13). To put it more simple, compressive strength gain per axial strain gain defined as gain ratio. In practical FRP applications after a fire event, it is usually aimed to increase the deformability of the column members rather than its strength. This phenomenon may vary depending on the location of the intervened building i.e. in relation with the residual seismic risk after fire (Demir et al., 2020a, b). Therefore, in objective function (f_{opt}), the goal is to make the most of confined compressive strength while maximizing axial strain, and the meantime keeping cost to a minimum. Gain ratio per cost is the aim of the algorithm, which is desired to be maximized. Compressive strength and axial strain vary relative to each other depending on the selection of FRP. The reason for the boundary of compressive strength is that, at least it is expected to be equal or more than at the value of initial compressive strength. Moreover, maximum axial strain value recommended by ACI 440.2R-17 is 0.01, but experimental studies show that the value allowed can go up to 0.02 (Bisby et al., 2011).So that, if the ultimate axial strain falls within the 0.01-0.02 range, rather than forcing it to higher strain gain values, it is preferable to increase gain ratio while remaining in the ultimate axial strain range. Considering these limitations, possible minimum conditions are constrained by strength ratio, and possible maximum conditions are constrained by strain ratio. This phenomenon is applied to the optimization process using Eq. (15).

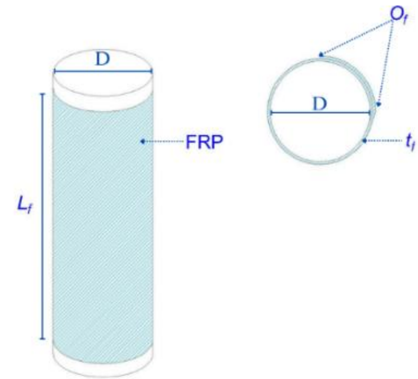

Fig. 2. FRP wrapping of columns.

$$\text{Minimum Cost } = \left(V_f \times n_f + V_o\right)\delta + \mu \times n_f \tag{10}$$

$$V_f = L_f \times C_f \times t_f \tag{11}$$

$$V_o = L_f \times O_f \times t_f \tag{12}$$

$$\text{Compressive Strength Gain: } \frac{f_{cc\Theta} - f_c}{f_c} \tag{13a}$$

$$\text{Axial Strain Gain: } \frac{\varepsilon_{cc\Theta} - \varepsilon_c}{\varepsilon_c} \tag{13b}$$

$$\text{Objective Function} \qquad f_{opt} = \frac{\left(\frac{f_{cc\Theta} - f_c}{f_c}\right)}{(V_f n_f + V_o)\delta \times \left(\frac{\varepsilon_{cc\Theta} - \varepsilon_c}{\varepsilon_c}\right)} \tag{14}$$

$$\text{Constraint Condition 1} \quad \varepsilon_{cc\Theta} \leq 0{,}02 \tag{15a}$$

$$\text{Constraint Condition 1} \quad f_c \leq f_{cc\Theta} \tag{15b}$$

2.4. Optimization Algorithm

The optimization algorithm used in this research is based on genetic algorithms (GA), which can be used in Grasshopper® interface, a Rhinoceros® (Mcneel, 2010) plug-in. The model uses Grasshopper's Galapagos tool for GA optimization. The main idea in this algorithm is to ensure that a population of many genes evolves and tries to find optimum scenario. The choice of the parameters used in GA depends on the problem. Basically, while some of the parameters control the investigation capabilities of the algorithm, such as population size, some of the parameters conduct the evolution of algorithms. The initial population is generated randomly in this approach, to prevent manipulating the evaluation of algorithms. It was inferred that the following initial conditions were adequate for solving the problem of this study:

- Population size: 10 individuals.
- Number of Generations: 20.

The procedure for finding the optimum number of FRP layers is presented via the flowchart shown in Fig. 3. Steps of this procedure can be summarized as follows:

1. Inputting the required information such as mechanical properties (E_f, f_f, t_f, ε_{fc}) and cost per volume of FRP, cost per volume of epoxy, maximum temperature reached (T_m), geometry of columns (D and L_f) and optionally the corresponding constraints of strain and strength which in default fixed as in Eq. (17),
2. Proceed with calculations of cost, gain functions as well as objective function than record the result,
3. Based on the given list of FRP, try all possible configurations,
4. Compare all the results and decide the optimal scenario based on the objective function.

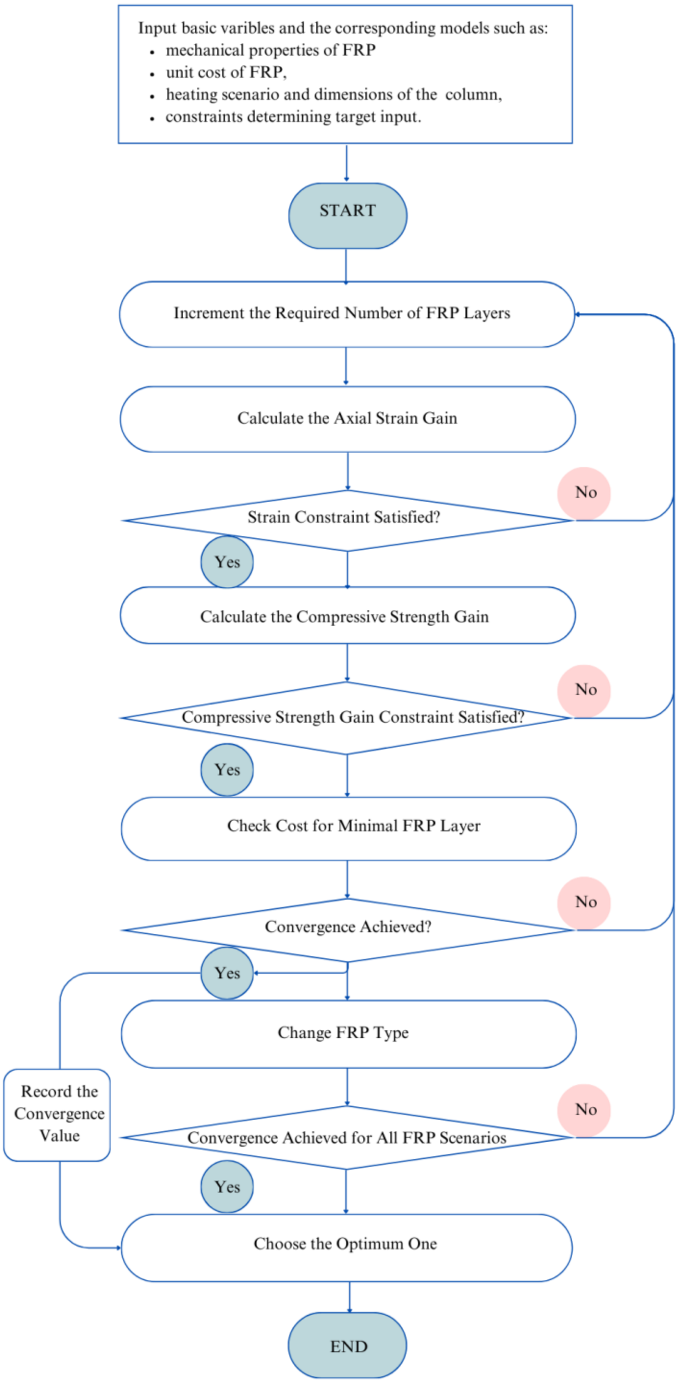

Fig. 3. Algorithm approach for finding the best FRP scenario.

3. Results

In the parameters configured according to the features specified in the previous section, genetic algorithm was used to achieve optimum scenario of FRP implementation on a concrete column. At the beginning of the process, the algorithm initialized with random values, to provide fair approach. The values circled in red in the graphs represent the optimal results. The relationship between the cost per volume of FRP and the gain ratio for different types of FRP is shown in Fig.4. In general, CFRP and GFRP wraps show higher gain ratios compared to AFRP and BFRP wraps. It has been seen that GFRP wraps performed the optimal results at both temperatures. The reason behind this scenario can be explained by Fig.5 as the slope of GFRP curve is greater compared to others. Also, this is expected due to most confined compressive strength gain per axial strain gain was beginning target of whole process. Thus, the algorithm converged to GFRP wrap. A notable improvement in stress-strain relationship was observed by confining GFRP-2 with one layer, at 300 °C. The value of compressive strength is observed to increase %135.7, and the value of axial strain has experienced a fivefold increase, as shown in Fig.5a. The corresponding cost has been determined to be \$10.63. On the other hand, two layers of GFRP-1 were confined at 500°C, which led to the achievement of the optimal result. The value of compressive strength is seen as to increase %142,8, and the value of axial strain has experienced a ninefold increase in this case, as seen in Fig.5b. The calculated cost for this scenario is \$18.36.

In Fig.6, the optimization process across iterations under different temperatures is presented. While the y axis represents gain ratio per cost values, the x axis shows the progression across iterations in algorithms. In each iteration, notable changes in FRP selection can be detected based on populations. In general, the reason why some genes of population are clustered between 0 and 0,001 is due to the high number of layers of FRP leading to increased costs. On the other hand, GFRP was found to be dominant at both temperatures. However, the performance of one-layer of GFRP-2 is followed by one-layer GFRP-1 and CFRP wraps and comprise a possible second choice for efficient strengthening at 300°C. Also, two layers of GFRP-1 observed as a unique wrap with no equivalent among other wraps at 500°C. The interesting point here is that some FRP confined-heat damaged concrete with one layer confinement have been observed to be unable to achieve the initial compressive strength. Thus, some genes failed to revert to their initial condition and remained under the 0 line, such as one-layer BFRP-1, BFRP-2, BFRP-3, and GFRP-1 at 500°C.

Based on these results, the effectiveness and efficiency of the proposed strengthening methods at different temperatures are emphasized. It has been observed that the process can be completed in a limited number of iterations, since the problem in this study can be considered as non-complex and includes only a few options to use as a parameter in GA. It is considered that this situation defines the reason behind scarcity in iterations.

4. Conclusions

This study presents a performance-based optimization in GA for the cost-effective selection of FRP types, and their layers used in strengthening concrete columns after fire exposure. According to the optimization approach, it was aimed to achieve maximum gain in strength of the heat-damaged column after wrapping, while also considering the feasible state, in the range of 0.01-0.02, for ultimate axial strain, at the state of minimum cost. The constraints of objective function were determined on the base of the minimum limit of $f_{cc\Theta}$ and maximum limit of $\varepsilon_{cc\Theta}$. Two different temperature scenarios were used in optimization process, 300° and 500°C.

The results highlighted that optimization approach was able to find the most effective cost with the highest gain ratio. In addition, it was determined that GA evolves towards the completion of the optimization process and finds the most optimal result at different temperatures. While optimum scenario for 300°C was found as wrapping the column specimen with one-layer of GFRP-2, two-layer of GFRP-1 exhibited the most cost-effective solution for the column specimen at 500°C.

It has to be noted that this technique defines only a prototype, considering the scarcity of parameters and possible solutions. It is suggested that the prototype should be improved to solve a more complex scenario, such including a notable number of FRP types and a case study application on a sample compartment, which includes multiple columns.

The millennium tent: A critical review on Astana Khan Shatyr

Damlanur İlipınar*[1]

[1] Karabuk University, Department of Architecture, 78050 Karabük, Türkiye

Abstract. Tents, the most primitive form of shelter, can be seen as traditional tensile architecture. Although the tent structure has existed for thousands of years, tents still offer a valuable starting point for designing modern tensile buildings. However, to enhance large-span modern tensile architecture, it is crucial to understand the inherent structural characteristics of the membrane rather than simply mimicking the form of tents. Thus, the rediscovery of traditional tensile buildings through advanced technology presents an opportunity to liberate architecture from the constraints of heavy formal designs. In this context, this paper examines the impact of tensile structures on form development and focuses on one notable modern tent-like building, Khan Shatyr (Tent of the Khan). This research introduces the Khan Shatyr project by Foster and Partners and explores its significance within modern tensile structures. The relationships between form and concept, material properties, and structural behavior of the Khan Shatyr are evaluated. In conclusion, the Khan Shatyr project is critically analyzed in terms of its architectural form, its interplay with its structural design, and its role as a megastructure. The study highlights how the project transcends traditional tensile design principles by leveraging advanced materials and innovative engineering. This examination underscores the redefined modern architecture by balancing form, functionality, and structural efficiency. Ultimately, the study highlights the challenges of translating traditional tensile principles into modern megastructures, raising questions about the balance between architectural expression and structural behavior in contemporary design.

Keywords: Millennium tent; Tensile structures; Megastructures; Astana Khan Shatyr

1. Introduction

Tents were some of the first and most successful fabric tensile constructions. Tent structures were built to provide a big enclosed space, seclusion, environmental adjustment, and protection under a fabric covering. Modern and complicated fabric structures originated from primordial tent structures by breaking away from the symbolic shape of vernacular tents. Furthermore, with technological advances in structural engineering, architects made structures more appealing by focusing on the new functional aesthetic (Kamal, 2020). Fabric membrane constructions have existed for millennia as simple, tent-like shelters. The guy ropes and tent poles in tents provide pretension to the fabric, allowing the structure to endure wind, rain, and snow loads.

This paper investigates the influence of tensile structures on form evaluation, with a focus on one noteworthy modern tent-like structure, Khan Shatyr (Tent of the Khan). The structural features of tensile structures are investigated. In the context of this paper, prior knowledge about cable structural systems is provided. The Khan Shatyr Entertainment Center in Astana is examined as a case study of cable-net tensile structures. The Khan Shatyr's form-concept relationships, material qualities, and structural behavior are all analyzed. Finally, the Khan Shatyr project is critically examined in terms of architectural form, structural design, and megastructure function.

2. Tensile Structures

Tensile membrane systems, which include cable net structures, shells, folded plates, and grid-domes, can only withstand tension loads (Berger, 1999), not compression or bending. These structures may span huge distances with little weight on their supports (Kamal, 2020), and advances in fabric technology are influencing building design methodologies. Tensile structures stretch membranes to form a three-dimensional surface, which is often supported by compression or bending elements such as masts, compression rings, and beams. Tensile structures have the advantage of being lightweight; the prestressed forms of the membranes provide design flexibility, allowing for large spans with less weight. Furthermore, the lightweight nature of these tensile components allows for easier transportation and assembly of the structures. The Olympia Roof in Munich, 1972, designed by Frei Otto and Bennish & Partners (Henrysson, 2012) can be considered a tension structural milestone. Its cable net structure on a vast scale gives up new possibilities in computer structural analysis and shape finding approaches.

https://doi.org/10.31462/icearc2025_a_aen_479

One of the most significant stages in designing tensile structures is the form finding process. According to Henrysson's (2012) research, tensile fabric structures only bear tension stresses, hence the majority of tensile fabric systems are anticlastic. Fig. 1 depicts some of these anticlastic shapes, including a conic, a hyper, and a barrel vault/arch support. Under heavy loads, prestressed anticlastic textiles are in tension in at least one direction.

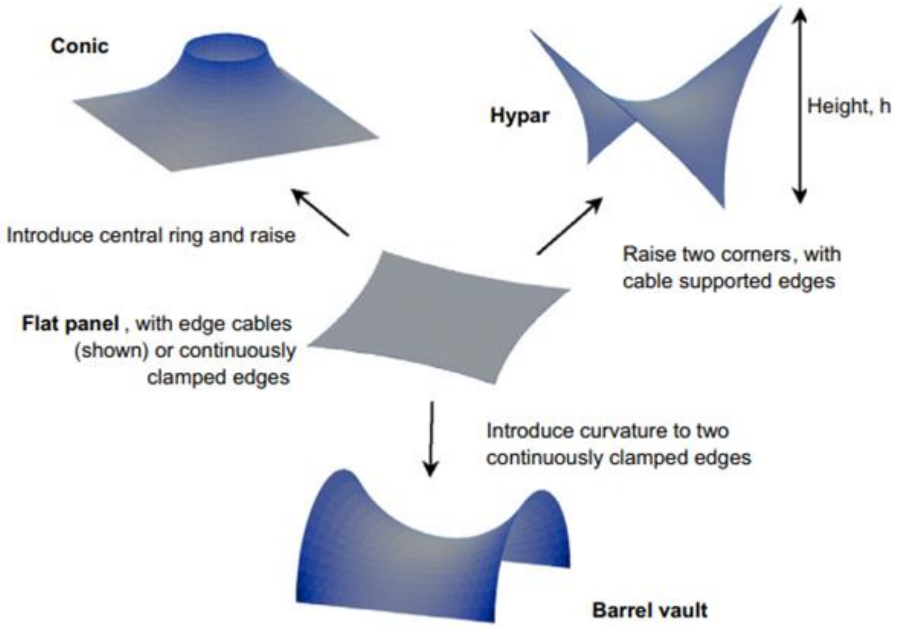

Fig. 1. Anticlastic structures with (a) conic (b) hypar (c) arch supports (Bridgens and Birchall, M, 2012)

A variety of tensile fabric systems can be used while developing the notion of tension fabric design. To create more intriguing and complicated designs, designed systems for anticlastic surface fabrics are integrated. According to Son (2007), the following systems exist: arch-supported structures, primary support structures, ridge-and-valley structures, and mast structures. These systems are explained in the following table (Table 1).

Table 1. Tensile Fabric System Types (Escrig and Sánchez-Sánchez, 2015)

Membrane Types	System Examples
Arch-Supported Structures The membrane in arch-supported systems is in entire tension, whereas the arch should be in complete compression. The contact between the membrane and the arch, which results in the fabric's saddle curve, provides appropriate buckling resistance for shorter span arches.	Structures with Primary Supports Saddle surfaces can also be formed in the membrane using primary point supports that, unlike the arch-supported system, do not lie on the same plane. The cable stays must be kept in tension regardless of the loading.	
Table 1. continued

Ridge-and-Valley Structures	Ridge-and-valley constructions are designed to create a minor saddle by putting cables in an adjacent pattern with opposing curvature. The membrane is formed and supported by alternating ridge and valley cables.	
Mast Structures	Fabric is suspended from cables strung off masts or other compression elements in tensioned fabric structures with masts as its supporting framework. This type of technology is perfect for long-span roofs.	

3. Materials and Method

This study demonstrates how the transcends typical tensile design concepts by utilizing new materials and inventive engineering. In this regard, the Khan Shatyr, a mega tensile structure, is critically examined in terms of architectural form, interaction with structural design.

3.1. Case Study- The Khan Shatyr

The Khan Shatyr ("Tent of the Khan") Entertainment Centre is one of the world's largest tensile constructions, and it offers a comfortable climate throughout the year. Foster and Partners designed the structure in 2006 as a huge transparent tent inspired by traditional nomadic construction forms (Foster + Partners, 2010). The massive edifice of Khan Shatyr incorporates a created icon of Kazakh nomadic history into Astana's architectural surroundings. The design concept is based on the traditional Kazakh yurt, emphasizing the importance of ethnicity in Kazakhstan's nation-building. Thus, the building in the shape of a traditional yurt awakens the Kazakh population's national memory; historical ideals of community are portrayed in a modern structure (Mkrtchyan 2013). In addition to producing symbolic strength with this massive structure, the design concept includes creating a strong iconic form on the skyline and designing a huge, free-spanning enclosure with minimal support (Dancey, 2010). The Khan Shatyr has a 200 m by 195 m circular base placed at the north end of the city's axis and is the highest point on the Astana skyline with its 150 m tall mast-stayed. The structure has 100,000 m² of internal space and includes an urban-scale park with a 450 m running track, shops, and leisure facilities like restaurants, cinema, wave swimming pools, and exhibition and event areas (Dancey, 2010).

The structural engineer for Khan Shatyr is Buro Happold. The structure is conceived as a tubular steel tripod mast that rises from the 195x200-meter elliptical base and supports the cable net in a conical shape. The tubular-steel tripod framework supports a suspended net of steel radial and circumferential wires, which is wrapped with a three-layer ETFE envelope constructed as 3.5 x 30-meter cushions - a lightweight, cost-effective, and thermally efficient solution. Fig. 2 shows the key structural pieces, tripod, cable net, and ETFE cushion.

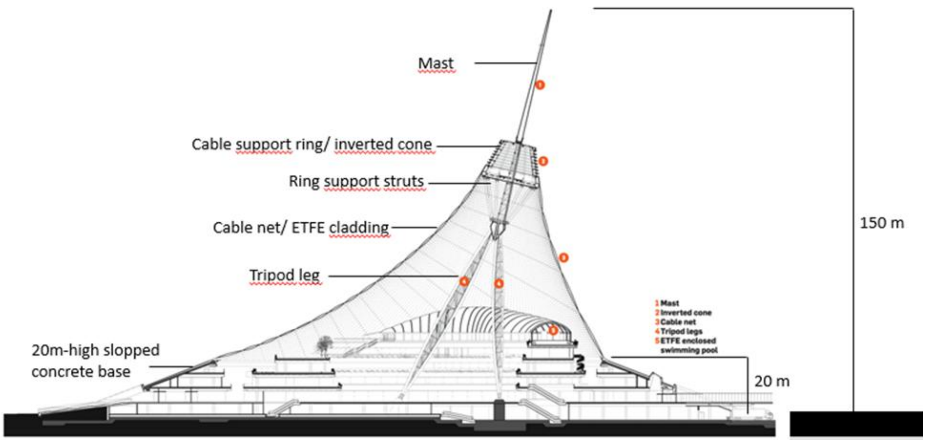

Fig. 2. Section through The Khan Shatyr shows structural elements of the building (URL-1)

The single-masted cable net is the obvious choice for providing such a massive, free-spanning enclosure with the least amount of support: a single compression mast elevates the cable net, creating a big volume beneath. The tensioned roof is constructed as a cable net, with cables being particularly effective load-carrying structural elements due to their efficient weight transfer via pure tension (Geyer et al., 2017).

The entire membrane structure is supported by a gigantic compression mast composed of three truss columns to withstand the massive compression force generated by the supported membrane structure. The steel tripod supports the entire cable net system. The basic premise behind its operation is to provide a single point of support to the core of the cable network. The roof skin is tensioned by a single compression mast, which lifts the net and creates a vast volume beneath. The entire mast (Fig. 3), including the tip, stands 150 metres tall and weighs around 2.500 tons of steel. The tripod is made up of one vertical rear leg that is 60 meters tall and two spread front legs that are 70 meters long. Legs are built of triangular tubular steel trusses grouped into three-chord trusses with 1000 mm diameter round hollow sections made of 40-millimeter-thick tin. The three-legged mast creates a sturdy ring in the air that the cables may be attached to on-site. A single mast was deemed too challenging to handle on-site at this vast scale. The mast's legs meet at a 7-meter-high hub made of 150-millimeter-thick steel plate; the hub center line corresponds to the axis of the cable net's axial force under prestress. A hub holds 12 pin ended struts of 800 mm diameter that reach the cable net's top ring. A 20-meter-diameter top ring is fixed. This is formed from a circular portion of 1.6m diameter and 40mm thick; its job is to gather the cables together (Numanova et al., 2020).

Building a massive cable net structure is thought to be the most efficient and cost-effective solution to cover such a big area because it only requires one central column, which is then surrounded by a giant roof. The cable net is shaped like a classic cone that has been pulled to one side. This creates the Entertainment Centre's characteristic sloping architectural form. The cable net consists of 192 radial cables and 16 circumferential cables (Birch 2009). To enhance handling, cable diameters were kept below 76mm, and cables are typically put in pairs to provide strength, which also simplifies clamping between radial and circumferential cables. Radial wires connect the top ring to the concrete plinth around the circumference. These support both the roof weight and the weight of any snow, which is significant in Kazakhstan's winters. The circumferential cables are used to stabilize the radial ones by pulling against them, as well as to confine the roof against wind stresses. Fig. 4 depicts 192 pairs of 38mm diameter radial wires that range in length from 125m at the tent's front to 70m at the back.

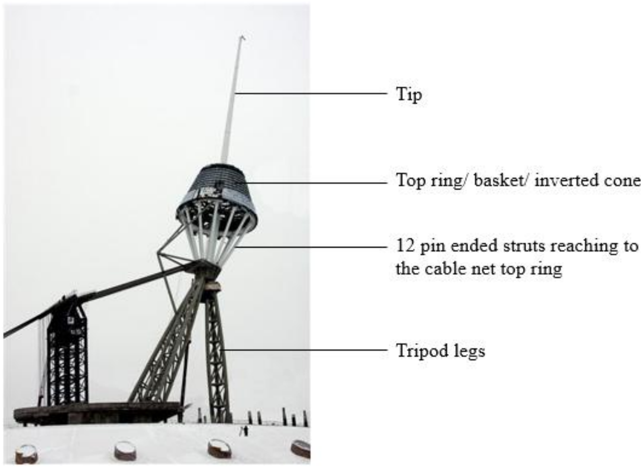

Fig. 3. Whole mast structure of the Khan Shatyr (Geyer et al., 2017)

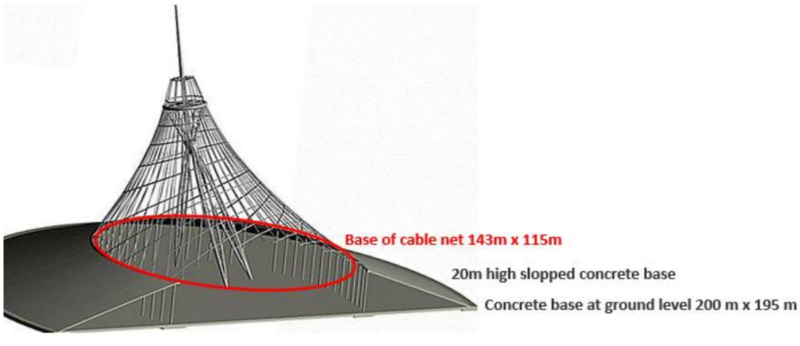

Fig. 4. The roof’s cable net, attached to the basket and concrete base (URL-2)

4. Conclusions

The Khan Shatyr, like most preferred tensile buildings since the 1960s, is supported by a mast, which acts as a compression element. The constructions often have a tensile membrane consisting of ETFE cushions, with bigger schemes necessitating cable netting for additional support. Their lightweight and cost-effective construction makes them perfect for covering vast areas like as exposition venues and sports stadiums. The Khan Shatyr's form-finding research began with standard hanging models to determine the overall behavior and contour of the cable net. The inclined cone shape was selected, and computer models were created to determine the overall shape and cable arrangements. The central support pole is meant to function as a solid tripod, allowing the net to move under various stresses. The ETFE cladding on the cable net maximizes the transparency that this type of construction enables, eliminating the need for a smaller glazing grid and making it flexible enough to withstand the rather large predicted movement of this tensile structure (Mangelsdorf, 2010). As a result, structurally optimum alternatives were identified. However, from an architectural standpoint, it is difficult to answer the questions of whether the Khan Shatyr is a modern building, whether the final form of the Khan Shatyr, which resembles a primitive tent, is the optimal form, and whether learning from or referring to history is the same as imitating it. To summarize, the Khan Shatyr's structural design accomplishment resulted in a rudimentary tent form on a massive scale. In the 2000s, a millennium structure, a landmark building in Astana, was constructed by directly scaling a traditional tent rather than exploring new designs.

In the context of urban memory studies: The relationship between boulevard and architecture (Ankara Apartments)

Aylin Aras[1*], Çağla Canca[2]

[1] Bursa Technical University, Department of Architecture, 16330 Bursa, Türkiye
[2] Architecture, Independent Researcher Ankara, Türkiye

Abstract. Memory interacts with space and time, establishing a sustainable relationship between the past and the future. This relationship, which is equally relevant for cities, emerges from the strong interplay between urban memory, space, time, and urban identity. The spatial and sociological transformations experienced by a city influence its urban memory, and consequently, the urban dwellers who are the primary actors of urban life.
The aim of this study is to analyze the relationship between collective memory and the city through the apartment buildings located on Atatürk Boulevard and its surrounding capillaries in Ankara, and to highlight the significance of civil architecture in shaping memory. As a first step, the study examines the relationship between Atatürk Boulevard and memory. The formation, development, and transformation of Atatürk Boulevard are analyzed within the context of the historical periods it has witnessed, focusing on its connection to the city through the buildings and functions present along the boulevard. In the second stage, the study explores the changes in daily life on the boulevard and investigates the role of civil architectural memory, represented by apartment buildings, as the spatial context of this life. By examining the architectural features of these buildings, the study discusses the impact of civil architecture on collective memory.

Keywords: Urban Identity; Urban Memory; Civil Architecture; Ankara Apartments; Atatürk Boulevard.

1. Introduction

Identity can be defined as "the totality of signs, qualities, and characteristics of a social entity" (Turkish Language Association, 30 July 2024). From this perspective, urban identity can be defined as a concept that distinguishes cities, which are –complex social entities–from others and defines their unique qualities.

The components of urban identity, interpreted through human perception, serve as an important link for cities to sustain their existence from the past to the present. Urban identity is shaped by the social traces and impressions left by the spatial and social elements that constitute the city on its users. Topçu, drawing on the definitions of Lynch, Tekeli, and Çöl, describes urban identity as a comprehensive set of meanings that is constantly shaped, changed, and transformed by the lifestyles of the society in which it exists, formed by the interpretation of physical, cultural, social, economic, historical, and formal factors in different parameters, and extending from the past to the future (Topçu, 2011). Urban identity is an organic structure shaped by all the physical, social, and cultural dynamics that belong to and influence a city (Köseoğlu, 1995).

The city itself can become the subject of collective memory, and the change and transformation of each building block that shaping the city, – along with the social, spatial and societal events–- directly influence collective memory and, consequently, humans. In this context, the study examines the relationship between Ankara — the capital of the Republic of Turkey and one of the leading cities in the development of the country's urban identity, which has undergone rapid transformation since the beginning of the 20th century— and Atatürk Boulevard, an important part of the city's memory, within the framework of collective memory.

Urban memory encompasses all values associated with a city and its inhabitants. All elements of life within a city have the potential to serve as building blocks of urban memory. When examining Ankara, Atatürk Boulevard holds great significance for the city's urban memory. The morphological and sociological changes that the city has undergone can be easily read through the boulevard, making Atatürk Boulevard a place of memory for the city. As a result of the spatial developments the city has undergone, the boulevard has undergone physical and sociological changes, and these changes have shaped the design criteria of the structures on the boulevard, transforming the living conditions, functions, habits of the community, and the flow of daily life, and thus affecting

*Corresponding author, E-mail: aylin.aras@btu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_492

collective memory. These collective memory readings are primarily realized through public spaces and structures that maintain a strong presence and a more distinct continuity along the boulevard. It is observed that the impact of civil architecture, – a significant part of the city's daily life shaped by social components– has been pushed into the background. At this stage, the aim of the study is to examine the multifaceted impact of the transformation of Atatürk Boulevard, which was influenced by planning efforts to create a modern capital city for Ankara, on collective memory, and to ensure that the importance of civil architecture, whose impact is considered to have been overlooked, is understood in light of the lasting impact of public structures on memory.

Collective memory is shaped by the interaction between space and time on an urban scale. Atatürk Boulevard is a place of memory that reflects morphological and sociological transformations specific to Ankara. The aim of this study is to explain the impact of civil architectural memory on urban memory through apartment examples on Atatürk Boulevard and its capillaries from a holistic perspective. At this stage, the development of the boulevard was examined with the help of relevant literature, and comparative architectural analysis methods were integrated based on selected examples.

2. Conceptual Framework

2.1. City, Identity, Memory- Urban Memory and Collective Identity

Cities acquire their identity through the effects and interactions of their surroundings over the course of historical development. The identity of a city is shaped by the relationships and interactions between the natural, social and built environments, which distinguish it from other cities. Urban identity is jointly produced by the cultural structure — rooted in natural environmental conditions and the social environment— and the built environment. Identity based on the built environment is shaped by the spatial structure which forms a cohesive whole through its form, location, type of use, and meanings. This situation is particularly evident in Turkey, where the diversity of cultures and the environmental data of the various natural, social, and built environments in cities contribute to a multi-dimensional and distinctive identity (Suher et al., 2004).

The concept of spatial memory acquires meaning by combining concrete data related to space with individual, social, historical, and cultural values existing in the individual's mind. This comprehensive entity is nourished not only by representations, signs, and symbols, but also by parameters such as social, political, architectural, and cultural events, traditions, habits, and neighbourly relations of its time (Avcıoğlu & Akın, 2017). The city, which is the subject of collective memory, and the parameters of the city, as well as the social and spatial changes that affect the city, influence collective memory and, consequently, its inhabitants. The fact that capitals are at the center of developments that shape the history of countries makes them symbolic cities in terms of cultural, political, economic and social issues experienced in the historical process. In the continuation of this study, the city-memory relationship will be examined within the framework of collective memory, focusing on the missions assigned to Ankara, the capital of the Republic of Turkey, as a capital city.

2.2 The Role of Boulevards in Urban Fabric

Lefebvre (1991) describes urban spaces as not merely physical areas, they are socially produced spaces for everyday life. Cities, as spaces inhabited by people, are dynamic formations where social, cultural, and economic balances are established.

Boulevards within cities serve as multi-layered axes that form the physical and spatial backbone of the city, connecting different functions and different times within the city and establishing a link between these spaces. These axes, where social interaction, transportation, circulation, and cultural representation occur simultaneously, play a crucial role in shaping the urban fabric. In urban design, boulevards, when considered together with the public spaces, residential areas, parks, squares, and socio-cultural spaces, serve as the main arteries that directly influence and shape daily life within the city. These areas also function as public realms that contribute to the collective memory of cities and where residents' memories of place are formed (Hayden, 1995; Rossi, 1982). From this perspective, the memories that city dwellers create within this backbone and the connected spaces form an emotional and historical bond with the city, fostering a sense of belonging to the city and internalizing the city's identity. The bonds that individuals first establish within themselves evolve into the production of a social memory as a result of their interactions with one another.

In conclusion, boulevards are not merely physical arteries; they are urban elements that play a role in shaping both the social and physical fabric of a city as urban backbones where different socio-cultural interactions take place, social memory is produced, and spatial continuity is ensured. From this perspective, Ankara Atatürk Boulevard serves as a notable example illustrating the effects of boulevards. According to Bozdoğan (2001), Atatürk Boulevard connects the old and new parts of the city along the main north-south axis of prestige. In this situation, it is possible to read both the effects of building a new city in terms of urban design and the traces of producing a new society ideologically through a capital city via Atatürk Boulevard.

.

2.3 Architecture as a Reflection of Urban Memory

Architecture, as the producer of space, is a potent reflection of social memory. To understand this relationship, we must first examine the relationship between space and memory, and then examine the impact of this relationship on an urban scale. While space can be defined in various ways, the prevailing view is that it isn't simply a physical concept, but rather a conceptual entity that derives its meaning from its connection with society. According to Al, space is a conceptual plane that is linked to belonging and identity and contains social connections (Al, 2011). Lefebvre (1991) describes space as a social product and explains the mutual relationship between space and society. Consequently, space, which affects humans, and humans, who produce space, are described as two phenomena that can't be evaluated independently of each other. According to Aytaç, space is an entity that parallels the mental world of its users, provides a common ground for social experiences, and, through its social meanings, reconstructs the people within it and provides them with a sense of belonging (Aytaç, 2013). In this sense, urban spaces are existential islands for urban dwellers. With their openness to daily routines, they are a kind of identity space. Space, with its different meanings, is a reference point for perceiving the city, people, and society. When the interaction between space and individuals is expanded to a larger scale, it evolves into an interaction between urban inhabitants and urban spaces. Within this relationship, people come together with their individual identities and form a collective identity. Architecture plays a pivotal role in shaping this identity and producing collective memory through urban spaces.

Urban spaces, as both reflectors and generators of collective memory, assume a symbolic and critical role in preserving the continuity of memory. They provide temporal continuity in the relationship between the past and the future for the city (Aytaç, 2007; Çalak, 2012). When examining cities, the ultimate subject of the space-urban space-city relationship, we observe living formations where socio-cultural, political, and economic dynamics are spatialized and memory is layered. According to Rossi (1982), the city itself is the collective memory of those who live there. Every piece of the city contains the city itself and its memory. Written and oral disciplines are insufficient for the transmission of this collective memory. In this context, architecture takes on a critical role as a means of transmission. The subject of this study is Atatürk Boulevard, which was designed to serve as a link between the existing city and the capital city that was intended to be built in in accordance with the ideology of the Republic. This design isn't merely a physical link, but rather an example of a memory space that reflects many various processes, such as the modernization process, the effects of ideological dynamics on the city, and the social effects of the construction of a new city. At this stage, civil architectural buildings located on Atatürk Boulevard and its capillaries, which are most experienced by city dwellers and therefore critical for urban memory, will be examined within this conceptual framework.

3. Collective Memory Reading on Ankara

Capitals are symbolic settlements that reflect the morphological and sociological experiences of countries. Ankara has become the symbolic city of the transformation that the country underwent with the proclamation of the Republic. Ankara, which has been at the forefront of the country's modernization process, has witnessed this process of change and transformation in various fields such as industry, social life, culture, education, architecture, and art. With Ankara becoming the capital, urban planning activities in the city were also regulated. With the development of industry, the city experienced intense migration between 1923 and 1950, leading to the establishment of housing policies specific to Ankara for the first time in Turkey and the allocation of resources for housing. During this period, individual housing production was replaced by collective housing projects and cooperatives (İrdem & Lenger, 2021).

1924 marked the beginning of planning efforts for Ankara began. The plan developed by Lörcher for the castle and old Ankara was deemed unrealistic and was therefore never implemented. In 1925, the Lörcher Plan, which covered Kızılay and its surroundings, laid down fundamental decisions regarding this area (Özkan, 2018). Although the Lörcher Plan was not fully implemented, it is regarded as having played a decisive role in in the city's development, both in terms of creating a strong boulevard axis connecting the nation's symbolic structures and in terms of design ideas aimed at integrating the old and new parts of the city (Uluiş, 2009).

Due to the city's rapid growth beyond what was anticipated in the Lörcher Plan, an international competition was organized, and Hermann Jansen's proposal was accepted (Özkan, 2018). It is considered that the Jansen Plan, with the opportunities it offers city dwellers to encounter the natural and built environment, reinforces their sense of urbanity and belonging. The most prominent feature of this process is the development of housing projects of varying scales and types (Güneri Söğüt & Baş Bütüner, 2023). The Yücel-Uybadın Plan, whose effects are most evident on Atatürk Boulevard, has led to an increase in urbanization due to the design of buildings and parcels around Kızılay (Günay, 2005). With the changes that cities undergo, city centers gradually lose their functions but strive to maintain their relevance. These areas continue to evolve, maintaining their central role in urban life. For this reason, city centers can maintain their use value when they have spaces that preserve their specific activities (Lefebvre, 2015). In this context, Ankara Atatürk Boulevard has established a strong urban backbone in the city's memory by creating a significant axis for the city and incorporating various functional dynamics that have changed and transformed over time.

3.1 Spatial Structure of Atatürk Boulevard

If Atatürk Boulevard is considered an axis of memory, there are points where it feeds off and comes into contact with different periods and different representations. These points can form a mental map in the memory of the city's inhabitants. In the case of Ankara, it is important to examine what the boulevard signifies for its inhabitants and to trace the memory remnants that have survived and those that have not reached the present day. Cengizkan (2024) summarizes the boulevard's multi-layered and multi-functional structure through nodes. The points referred to as nodes represent the parts of the city that define its identity and leave historical traces.

According to Cengizkan (2024), the first node is the part between Ulus and Opera Square. Ulus, where the boulevard begins, was considered the economic and political center of Ankara at that time. The section starting from the Ulus neighborhood, shaped by Lörcher's plan in 1924, and extending to Opera Square can be considered the starting point of the boulevard's collective memory. This section, where foreign embassies were located, gradually came to be known as “Bankers' Street.” In this node, public institutions and banks, which were the spatial counterparts of development initiatives that were prioritized for a country undergoing a political revolution and emerging from war, were established**.**

The second node is the area between Opera Square and Sıhhiye Square. In this node, the spatial counterparts of cultural development movements, which are the next step in the effort to create a modernist capital, can be seen. The cultural gaps created in society by a collapsing state were addressed, and steps were taken to support future generations in these areas. A cultural axis consisting of institutions of critical importance to society was designed and completed with a park dedicated to youth.

The third node, known as the central area of Atatürk Boulevard, is the section between Sıhhiye Square and Kızılay. Cengizkan (2024) describes this area as the most prestigious section of the boulevard. In contrast to the low-rise buildings of the new city, high-rise buildings overlook the tree-lined boulevard. Modernist lifestyle functions such as shops, cafes, bars, and cinemas are located here in their most prestigious manifestations. With this node, more specialized living standards have become part of the new capital's characteristics. Prestige has become a key feature of the modern capital and is beginning to shape the daily lives of its residents. This node serves as the focal point of both daily life and memory.

The fourth node begins at Kızılay-Güvenpark and continues to Akay Hill. This node is home to ministries and government agencies, hence its designation as Bakanlıklar-Akay (Ministries-Akay). Cengizkan (2024) emphasizes that the eastern sidewalk defines the character of this section. With the acceleration of apartment construction, embassies have been replaced by large stores, well-known pastry shops, and global brand representatives. Government institutions such as ministries have been included in this section to reinforce the prestige image designed for the third section. This node represents the prestige of the new state through a modern axis.

The fifth node covers the area between Akay and Kuğulupark. This area is largely home to embassies and symbolic structures of Ankara. Cengizkan (2024) describes this node as the most diplomatic area of Atatürk Boulevard. On the western side are foreign embassies and TRT, while on the eastern side are symbolic structures and important institutions of the new state. This is the node where diplomacy reigns and the memory of global connections is represented. The cultural interactions resulting from the embassies have also influenced the design of civil architectural structures. The sixth node is the Protocol Road that starts from Kavaklıdere and extends to the Presidential Palace.

Cengizkan (2024) dedicates the final node to Atatürk. A symbolic conclusion is reached, Culminating Mustafa Kemal Atatürk, the architect of all this transformation and after whom the boulevard is named. With this node, the boulevard conveys all the memories and representations it has brought with it to the true owner of this transformation.

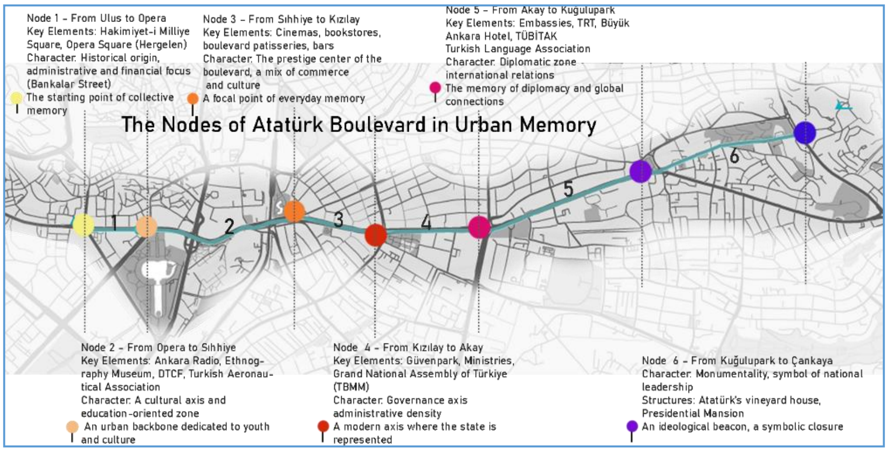

Fig. 1. The Nodes of the Boulevard. (Prepared by Çağla Canca.)

3.2 Atatürk Boulevard and Urban Memory

From the construction of the capital to the present day, Atatürk Boulevard connects Ankara's symbolic structures and the institutions that keep them alive, as well as the city's diverse urban spaces of varying scales and qualities where daily life continues. Over time, the boulevard, which extends from north to south and unites the city's districts, has acquired the function of a corridor that brings together the unique rhythms of different periods. From this perspective, Atatürk Boulevard can be considered a medium that preserves traces of Ankara's spatial change and transformation process, as well as a structural interface that records the social memory of the Republic of Turkey from its founding to the present day. With the 2000s, the increasing tendency to demolish and rebuild in urban space production, changing in form and scale, has affected the perception of memory. Understanding how this perception has been affected, how the traces recorded in space have been transferred to the present, and what their potential for the future is important for the sustainability of memory. With this quality, Atatürk Boulevard and its surroundings function as a laboratory (Birik, 2024). As explained in the previous section of this study, the boulevard tells the story of Ankara's transformation into the modern capital of a modern nation through numerous spatial traces and reflections, similar to a timeline. The boulevard and the collective memory it created have been largely destroyed, as has the rest of the city. This destruction can be attributed to many factors, including urbanization problems and misguided urban planning strategies, ideological and political reasons, population growth, and changing lifestyles (Fig. 2).

It is well known that many of the symbolic structures of the period, such as the qualified and even registered İller Bank, Danıştay Building, and Etibank General Directorate building, which were designed through competitions, have been demolished on the boulevard. The continuous demolition of structures on this axis and the alteration of the boulevard's silhouette are causing the loss of memory. Additionally, the deformation of the traffic route connecting the Opera and Çankaya districts through different road and route alternatives has been observed to disrupt the continuity of the boulevard's user experience and influence the city dwellers' perception of the boulevard (Cengizkan, 2012) (Fig. 3). In conclusion, it is believed that all the destruction and demolition that has taken place have led to the significant loss of the collective memory formed by Atatürk Boulevard which has witnessed every phase of the efforts to establish the new capital of the new republic and has been shaped by these phases, serving as a memory space in its own right for the city.

When examining the boulevard in the 2000s, it is evident that there are no traces of the high-quality buildings, squares designed with social life in mind, developments made for the sake of an ideology, or structures and spaces produced with design concerns that were present during that period. As a result, the Boulevard, which once served as a representation of memory, has evolved into a void within the city's collective memory, with information about it now accessible only through written and visual documents specific to the Boulevard. While the relationship between the public structures and spaces on the Boulevard and memory can be questioned through these documents, there is insufficient information and a lack of a network of connections regarding civil architectural elements. Following this section of the study, the relationship between civil architectural structures and life on the Boulevard will be examined, and civil architectural memory will be questioned.

4. Atatürk Boulevard and Civil Architectural Memory

Ankara's urban image has always referred to the state (Bayraktar, 2014). The city's status as a capital, the way ideologies express themselves through architecture, and the dominance of public structures have caused memory to be read solely through public structures. However, residential structures create a memory space that reflects the political, cultural, and socioeconomic data of the period by establishing closer contact with everyday life. Memory readings through civil architecture offer more layered data.

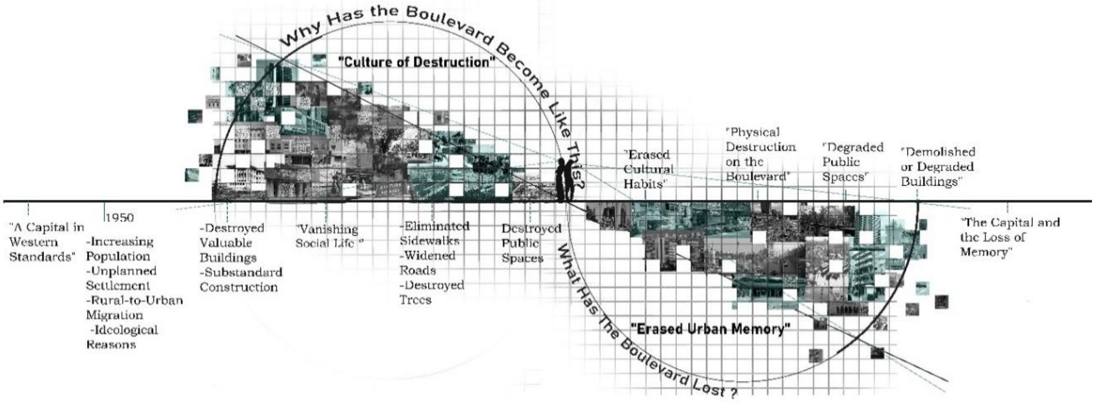

Fig. 2. Destruction of the boulevard. (Prepared by Çağla Canca.)

Fig. 3. The effect of demolition on the boulevard. (Prepared by Çağla Canca.)

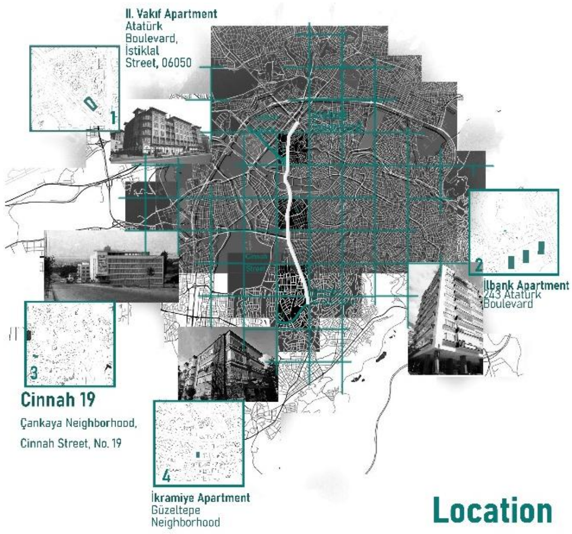

Fig. 4. Locations of the examined structures. (Prepared by Çağla Canca.)

In a new and modern urban development process, housing design criteria established according to planned and idealized social conditions have become a phenomenon that bears the traces of the era. The initiatives undertaken by the new republican regime during this period transformed the daily lives of the city's residents and profoundly reshaped housing production. From the location of housing within the city to its interior spaces, from the social character of neighborhoods to their physical, technical, and spatial characteristics, housing production in Ankara in the 1920s was determined by the contextual characteristics of the newly established Republic (Avcı Hosanlı, 2018). For this reason, comprehensive readings about the dynamics of the period can be made through these structures. At this stage, it is of great importance to create a civil memory in contrast to public memory through residential buildings. In this study, architectural-scale examinations of apartment buildings were conducted within the scope of civil architectural memory. Considering the importance of everyday life for urban memory, the impact of residential buildings, which are the spatial settings of everyday life, on the collective memory of the city cannot be denied.

Within the scope of this study, these traces were examined through the apartment buildings located on Atatürk Boulevard and the side streets feeding into it. In this context, İlbank Blocks, Cinnah 19, II. Vakıf Apartment, and İş Bank İkramiye Apartment, which met the housing needs of their time with different arrangements and are important in terms of memory spaces, were examined (Fig. 4.)

4.1 İlbank Blocks (İlbank Housing Cooperative)

The İlbank Blocks, Ankara's first housing cooperative, designed by architect Fatih Uran in 1957, are located between Iran Avenue and Atatürk Boulevard It is thought that the ideology of Unité d'Habitation, which also influenced other buildings of the period, lies at the basis of the design idea. The building's resemblance to *Unité d'Habitation*, which is thought to have been influenced by its structural features, reflects the aspiration to organize collective life. With this characteristic, it can be interpreted as a pioneering example among co-operative buildings of the period (Fig. 5).

At this point, it should be underlined that these co-operative buildings, similar to the Unité d'Habitation, almost all of them stand on pilotis, have a flat roof and feature common spaces where the residents can socialize both on the ground level and on the roof-terrace floor (Şumnu, 2018).

Şumnu (2018) states that this situation in the buildings of this period is at least as important as the interiors of the flats, emphasizes that the emerging approach focuses on communal integrity rather than isolation, and highlights the attempt to glorify the sense of 'we' beyond 'I' in residential buildings, and that these buildings, most of which are facing the danger of demolition today, are important examples of civil architecture that should be preserved not only for the architectural style decisions they embody, but also for the culture of communal life they represent.

İlbank blocks consist of 3 buildings, two of which have 8 floors and one of which has 9 floors. The blocks feature two basement floors and a two-story-high pilotis at ground level, above which they rise to eight or nine floors. The façades are based on a pattern formed by the protrusion and retraction of symmetrical balconies. The horizontal effect of the facade is strengthened with balcony parapets. In addition to the common/social spaces offered between the blocks in the settlement, common/social spaces are also designed within each apartment block. In the original projects, the ground floors of the blocks were left open to a height of two stories, and access to the upper floors was provided by passing through this space. Today, the ground floor spaces of the blocks (except for Block B) have been enclosed and reserved for commercial uses. Similar to the ground floor, the roof terraces is also considered as a common areas that can be used by the residents. In the projects, large open spaces on the roof terraces are supported by several service facilities (e.g., WC, kitchen, etc.) (Şumnu, 2018). By raising the blocks with pilotis, it is possible to maintain a continuous open space pattern that extends between the two boulevards on the ground and connects the boulevards, fed by closed public spaces that partially fill the ground floors of the blocks (Varol & Elibol, 2021). This has enabled the buildings to maintain interaction with Atatürk Boulevard.

The floor plans of the blocks consist of three flats located around two circulation cores. Two blocks are placed side by side to form a single block with two entrances. The four symmetrical flats located at the corners are entered from a large vestibule, which opens to a lounge-dining room and kitchen. The bedrooms, toilet and bathroom are reached through a corridor passing through the living room-dining room area. Detail solutions, such as niches created for storage on the balconies reveal the quality of the design. A similar design is seen in the symmetrical flats with two facades in the center. These flats are also entered through a vestibule opening to the lounge-dining room and kitchen, and this time a corridor leading from the vestibule leads to the toilet, bathroom and bedrooms. The wet areas of all apartments are ventilated by means of light wells, two of which are located in the circulation core and one in the center (VEKAM, 2014) (Fig. 5).

Modernization efforts have transformed daily life and, consequently, residential spaces. In İlbank Blocks, this transformation is seen in details that are not found in traditional Turkish houses such as garbage chutes descending from the kitchen to the basement, service windows between the kitchen and dining area, and storage niches on the balconies. The İlbank Blocks are considered an important and unique settlement with both the design approach and the vital facilities offered the users. Çapanoğlu (2007) states that in addition to its modernist elements, it was the most comfortable and tallest building in Ankara at that time with its site plan layout and neighbourhood relations. Many of the elaborate details used during the period and creating a prestige in the choice of housing have not survived to the present day.

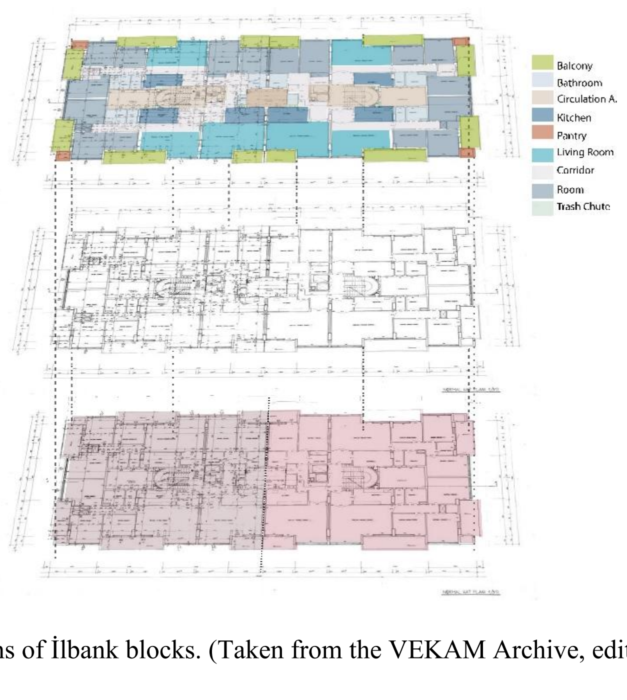

Fig. 5. Floor plans of İlbank blocks. (Taken from the VEKAM Archive, edited by Çağla Canca.)

4.2 Cinnah 19

Cinnah 19, designed by Nejat Ersin in 1955, is a building constructed with the housing incentive of the Real Estate Credit Bank of Turkey, founded by the employees of the Meydanlar Directorate Workers' Building Cooperative Partnership. It stands as one of the important examples of cooperative-based housing production from the period.

Ali Cengizkan summarises the architectural features of the building as follows: "The building is a highly contemporary product of the period in which it was planned and built. The reference to the 'Unit d'Habitation' block in Marseille, which is an important example of the 'modern' living and residential environments brought to architecture by the French architect Le Corbusier, the similarities, fidelity and the dimensions of their adaptation to the situation as original principled design elements are important: Emptying the ground and leaving the topography in its natural state; the democratization of the housing units by means of the duplex plan design, allowing them to benefit equally from all the blessings, while doing justice to the qualitative differences of the place; due to the importance attached to the collective way of life, to living together in a community as a culture, the proposal of a common garden on the ground, common coal cellars and storerooms, sheltered seating and a common stony area for sports; the provision of a framework where each unit, like a beehive, first establishes its own particular world and then opens to the upper world; elevated streets where passive encounter opportunities are created and swimming pool proposals on the terrace floor. All these have been reinforced by the use of the given right of construction as a design input in a way that does not disturb the location features of the environment such as landscape and slope and further emphasizes them, and by reflecting them on other architectural decisions such as interior furnishing, for example, a residential environment where contemporary values are emphasized has been obtained. (Cengizkan, 2002).The building was constructed as a reinforced concrete frame and brick infill system, with two basement floors below the road level, three normal floors consisting of duplex housing units above the road level and a terrace floor with a swimming pool (VEKAM,2014).

In the original project, the building was detached from the ground, the topography was invited within the building and a common living area was created here, but with the caretaker's apartment built later, this area was partially enclosed and to some extent, rendered dysfunctional. On the terrace floor there was a pool, American Bar, fireplace, shower, changing rooms and toilet. This part was used for about ten years and was closed due to concerns over the spread of polio that emerged there during the period.

The public spaces provided on the terraces and ground floors of the building are balanced with the calmness, quietness and even individuality of the private spaces provided on the residential unit floors. Since the corridor common spaces on the floors face south, the façade is given a very uniform and ornamental appearance with sun shades, and this harmony is enhanced by covering the corridor floor finish with black and white mosaic. Here, the discourse of modern architecture establishes a relationship with industrialized construction materials and artisanal construction techniques, which is a symbol of the search for freedom in the discourse of the 1950s in the field of "overly disciplined" architecture and is a very common attitude (Cengizkan, 2002). The first flat on the first basement floor is entered through a small vestibule opening to the kitchen, which leads to the dining area with an American bar and then to the living area. A corridor leading to the vestibule leads to the wet rooms, the maid's room and the bedroom, and the dressing room, which also opens to the corridor, leads to the bedrooms. In the second apartment, the vestibule is separated from the dining room and the living room with a fireplace by a wooden partition. A long corridor from the vestibule leads to the kitchen, maid's room and guest room, and a second corridor leading to the corridor leads to the dressing room associated with the nanny-child room and the bathroom (Fig. 6).

Fig. 6. Floor plans of Cinnah 19. (Taken from the VEKAM Archive, edited by the Çağla Canca.)

The duplex housing units are similarly accessed through an entrance hall, which opens to the kitchen and the Similar to the duplex housing units, the entrance is through the vestibule, which opens to the kitchen and the maid's room. Beyond the dining area which is connected to the toilet, library and kitchen through a small space, lies a lounge with an open staircase providing access to the upper floor. The hall on the upper floor, accessed via the staircase, is connected to the living room through the gallery space, and the hall is followed by the bathroom and bedrooms. The library also leads to the bathroom and bedrooms on the upper floor. Cinnah 19 is a unique and distinctive building with its relationship with the topography, design decisions, use of common space within the building, detail solutions, dynamic façade layout (VEKAM,2014) ((Fig. 6).

As a plan type, the duplex apartment targets a young, dynamic family type: Perhaps it is very appropriate in terms of timing to introduce private spaces on the floor planes for families who had to gradually detach themselves from the land in the overcrowded cities during the 1950s. Despite all the influences and inspirations, there is an "internalized modern attitude" here (Cengizkan, 2002).

4.3 Vakıf Apartment (Evkaf Apartment)

2.Vakıf Apartment is a building located on the boulevard, the design of which was started in 1927 by Architect Kemaleddin Bey and completed in 1930. During the period, there was a housing problem in the city with the increasing population. At this stage, it is known that the General Directorate of Foundations constructed the building to provide income through rent and to offer accommodation for its officers.

The building consists of seven floors: a basement, a ground floor, four residential floors, and a roof floor. On the outer perimeter of the ground floor, there are shops and a coffee house. In the courtyard in the central courtyard of the ground floor, there is a theatre hall that is still used as a theatre today. Until the 1940s, due to political reasons and the fact that theatre had not yet established itself in the city, this area was used for various purposes. Since the 1940s, it has operated as a state theatre under the name 'Küçük Tiyatro.' There are four different entrances on the ground floor of the building. The elevators at each entrance were considered quite luxurious for their time. These elevators are still operational within the building. The four entrances are currently used as the audience entrance, actor entrance, protocol entrance, and staff entrance (Fig. 7).

On the first floor of the building, the theatre hall continues in the central section, while apartments, offices, and a billiard hall are located on the façade. Along with the other three residential floors, there are a total of 40 apartments on the perimeter and 12 shops on the ground floor. In 1957, some of the shops on the ground floor were gradually merged to create a theatre hall. This development elevated the building to an important position in the theatre world and ensured cultural continuity within the space. In support of this initiative, Turkey's first theatre specialized library was opened within the building in 2011.

When examining the façade features, the long façades have a central section with five axes and two axes on each side, while the narrow façades have a central balcony section with single-axis side sections that extended outward and raised, covered with wide eaves. This design aims to achieve the massing form characteristic of the first national architectural period. The rounded lines of the balconies and railings at the four corners of the building, the mostly square-shaped windows without arches, and the minimal decoration are features that distinguish the building from the national style and reflect the rational-modernist approach of the period. The area where ornamentation is concentrated is the theatre hall, topped by an oval dome. The use of arches is limited to the half-circular arches connecting the evenly spaced columns on the ground floor. The reinforced concrete structure is covered with plaster, giving it the appearance of neatly cut stone from the outside. (Yazman, 2013). The building has been used for purposes other than residential use. In addition to being used as a theatre and library, it has also served as the Faculty of Language, History and Geography, the MIT building, and later as the General Directorate of State Theatres. The building has been used for functions such as residential, storage, theatre hall, and government office, and has also had a diplomatic role in the past.

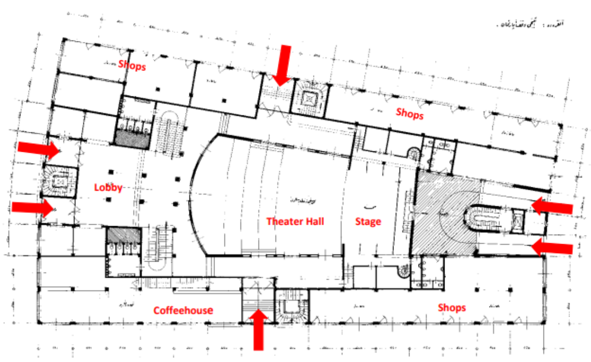

Fig. 7. Ground floor plan of the building (Originally from the Archive of the General Directorate of Foundations, adapted by Yalçın & Kula, as cited in Yalçın & Kula, 2024, p. 438).

In 1930, it was used as the Romanian Military Attaché's Office. The Evkaf Apartment stands out from other residential buildings due to its cultural activities, its combination of residential, office, and shop features, its inclusion of an elevator—a novelty of the time—and its role as a semi-permeable barrier between the city and its inhabitants. Additionally, it stands out as an example that reflects the spatial aspects of modernism through its innovative features.

4.4 İkramiye Apartments – İş Bank Apartments

İş Bank Apartments is a lottery housing complex designed by architect Lemi Varnalı in 1968, consisting of eight apartment buildings connected to each other by gardens. Each apartment building has five floors, comprising a basement, a ground floor, and three upper floors. Lottery apartment buildings, constructed on a limited scale in the 1950s under the influence of centralized state governance and global development models, evolved into a significant sector after the 1950s due to the impact of liberalism and the involvement of private banks. Banks not only provided financial support but also encouraged homeownership through advertising and lotteries. Through their housing projects shaped according to their own ideologies, they contributed to the diversification of civil architecture.

These apartment buildings, which are the latest example of İş Bank's lottery housing project in Ankara, are connected to each other by large communal gardens. In addition to the relationship established with greenery, the pools located at the entrance of the apartment building and on the floor of the basement overlooking the gallery space, as well as the gallery space that allows light to enter the building throughout the day, indicate the careful relationship established between the building and nature. This relationship with the surroundings continues in the apartments. Compared to the square meters of the enclosed spaces, each apartment has large semi-open balconies. These balconies, located in both the living rooms and bedrooms, not only connect the apartments to their surroundings but also to each other. This relationship between the apartments continues in the building's floor lobbies. These shared spaces, rich in architectural detail, are designed to facilitate communication between apartments on the same floor as well as those on different floors (Şumnu, 2014).

The pools at the entrance of the building serve as a threshold between the building and the exterior space. The entrance of the building is designed to be transparent, allowing the building to be easily viewed from the outside and showcasing the carefully designed interior space. Upon entering the building, one encounters a vertical circulation space that can also be described as an inner courtyard, which receives light throughout the day thanks to the skylight above it. This space, which is one of the building's distinctive features, has the potential to be used as a common area by the building's residents. Three apartments of different sizes are located around this area, with a fixed number of rooms. Access to the apartments is provided through an open space connected to the living room and kitchen, which leads to the entrance hall. The fireplaces located in the corners of the living rooms are the most striking feature of the apartments and create a different perception on the façade (VEKAM, 2014) (Fig. 8**).**

Looking at the facades of the building, it can be said that a minimal but impressive composition has been created with a well-designed balance of fullness and emptiness and material differences formed on horizontal and vertical axes. Large windows have been used on all facades, which has resulted in well-lit interior spaces and eliminated the massive effect of the building. Whether in terms of reflecting the characteristics of the period in which it was designed, providing insights into the housing policies of the years it was built, its unique design approach, or the architectural details it possesses, the İş Bank Houses es are an architectural heritage that deserves to be preserved and protected, despite their 'nakedness' and 'vulnerability' (Şumnu, 2012).

5. Conclusions

Cities construct their own collective memory. Collective memory, formed through the interaction between urban space and time, strengthens the sense of belonging between the city and its inhabitants. Shared memory is a crucial element for the social and physical sustainability of cities. Urban memory is shaped by the sociological and morphological changes experienced by the city, and this influence in turn affects the city's users and, consequently, the city itself. Atatürk Boulevard serves as a memory in its own right for the city.

With Ankara becoming the capital city, the aim of establishing a capital city in accordance with Western standards was pursued, and Atatürk Boulevard, which emerged during this period, has witnessed every transformation the city has undergone from that time to the present day and has undergone spatial changes alongside these periods. The changes that the boulevard has undergone have affected the structures, functions, spatial uses, and consequently the daily lives, habits, and social relationships of the users of the boulevard. In this context, all these changing conditions and interactions on the boulevard affect the collective memory of the city and its inhabitants.

This collective memory is read primarily through public structures and public spaces in Ankara. At this point, the impact of civil architecture, which constitutes a large part of the city's daily life, is directly in contact with daily life, and is shaped within the framework of social components, on collective memory is pushed into the background, preventing the memory from being fully understood.

As observed in architectural imaginations, political and ideological changes across cities and countries, as well as sociological and spatial transformations, directly affect the memory of civil architecture. A new ideology and a new capital city have given rise to a new way of life. Traditional housing couldn't longer accommodate the modernist new society. For this reason, similar to the goal to create a new city independent of the old city, the new capital has produced a new housing typology for itself. In this context, state-supported housing production was initiated first, but due to the inability to meet the capital's growing housing needs and the spread of liberalization policies, housing production began to take place with the support of private institutions.

Within the scope of the above study, these traces were analyzed through the apartment buildings located along Atatürk Boulevard and the side streets feeding into it. In this context, the İlbank Blocks, Cinnah 19, II. Vakıf Apartment and İş Bank- İkramiye Apartments, which addressed the housing needs of the period with various configurations and are significant in terms of memory spaces, were analyzed (Fig. 4).

In the analyzed examples, it is observed that the new modern lifestyle brought about new spatial configurations. For this reason, unlike traditional housing, common use areas such as terraces, pools, and cinema halls that support collective living were integrated into the structures. At the plan scale, elements such as American kitchens and service rooms, which are the characteristic of modernist living, are evident (Fig. 9).

Within the scope of this study, all these changes were analyzed in detail, and the civil architectural memory of the boulevard was examined in a multi-layered manner. It is envisaged that the memory readings of the boulevard will be completed with the missing part of the civil architectural memory. Thus, it has been concluded that when the collective memory of the city is supported in a multifaceted way, these interpretations can be based on a solid foundation.

Tectonics of actively bent gridshell, a holistic design and build approach for weaved timber morphology

Eslam Abdelkhalek*[1], Khaled Dewidar[1]

[1] British University in Egypt, Department of Architecture Engineering, Cairo, Egypt

Abstract. Gridshells are one of the most efficient structures that complies minimal use of material, aesthetic morphological composition and functionality of large spans. However, the complexity of its design and build process as well as the relay on multidisciplinary team in design makes it rarely used by engineers. Hence, this research aims to present a design and build approach for weaved timber gridshells, that can help in building a good understanding about the tectonical aspects of such structures; such as (design fundamentals, material behavior, construction technique and details). Due to the nature of such systems that relies mainly on extensive experimental work, the research methodology implies digital and physical experimental simulation for the construction of 1:1 scale model for the proposed approach. Firstly, a digital simulation model were created based on theoretical data to identify the fabrication of elements (members, connections and boundaries). Secondly, a 1:20 physical model created to understand the construction challenges and material behavior of the actively bent members. Finally, a 1:1 scale model was constructed for the proposed approach validation and highlighting the key challenges in large scale construction. As analysis of results the final constructed model showed an achievement of the intended design by 80 to 90% with 10 to 20% deflection due to the difference in scale and procedure of erection.

Keywords: Gridshell; Tectonics; Weaved surfaces; Digital Fabrication; Form Finding.

1. Introduction

Shell structures are a vital architectural element that merges structural efficiency with visual attractiveness, enabling architects to cover large spans using minimal materials. The advent of sophisticated computational design tools, principles inspired by nature, and cutting-edge fabrication methods has sparked renewed interest in wooden shell structures, especially those made from thin, pliable strips that can be bent and interwoven to form intricate shapes. The historical evolution of shell structures indicates a shift from design based on intuition and experience to approaches grounded in scientific and mathematical principles. Early shell designs predominantly utilized compression as their main structural mechanism, with forms inspired by hanging models and physical form-finding methods like the models used by Antoni Gaudi to examine his structural stability that was based on the catenary principles which allowed him to indicate the compression forces within his work (Huerta, 2006) (Fig.1).

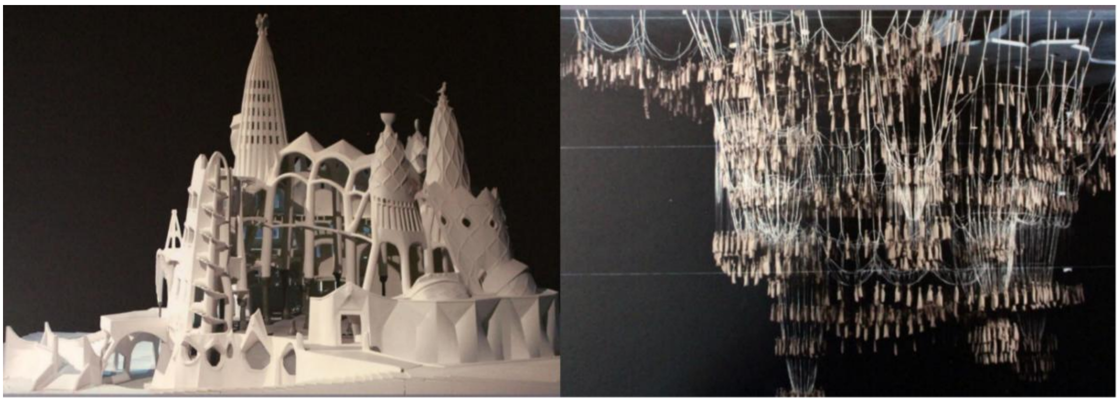

Fig. 1. Model for The Church of Colònia Güell (Huerta, 2006).

* Corresponding author, E-mail: eslam.abdelkhalek@bue.edu.eg

https://doi.org/10.31462/icearc2025_a_aen_499

Moreover, the idea and principles of shell structures gained momentum development in the mid-20th century on the hands of Heinz Isler, Félix Candela, and Frei Otto, each of whom introduced unique form-finding techniques that does not only indicate the compression forces but also had the ability to express tensile and bending forces. Hence, these innovators laid down essential principles that still shape modern shell design (Chilton, 2010). While historical shell structures primarily employed materials like reinforced concrete, timber has increasingly emerged as a sustainable option, which helped in the appearance of another shell typology called Gridshells. This typology represent a distinct advancement in shell structures, characterized by the replacement of a continuous surface with a framework of flexible linear segments (Fig 2). These innovative structural systems redefine the traditional notion of shell architecture by utilizing a lattice or grid of slender, adaptable members instead of a solid, uninterrupted surface. In contrast to conventional shells, which are typically made from materials such as concrete or masonry that create a unified surface, grid shells consist of a network of interconnected elements—often crafted from timber or steel—arranged in a regular or occasionally irregular mesh configuration, including shapes like squares, rectangles, or triangles (Pathade et al., 2022).

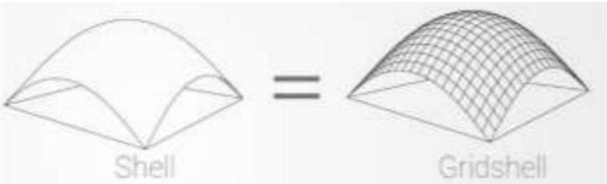

Fig. 2. Difference between Shell and Gridshell (Pathade et al., 2022).

Actively bent wood (elastically deformed) gridshells signify a transformative advancement in architectural engineering, combining structural efficiency with an organic aesthetic. These systems, characterized by their double curvature, utilize the natural flexibility of wood through the elastic deformation of initially flat strips, resulting in self-supporting frameworks that reduce material consumption while enhancing spatial functionality. However, their widespread implementation is hindered by the intricate relationships among material properties, geometric accuracy, and construction processes. Conventional methodologies often compartmentalize the design workflow into separate tasks, such as structural analysis, form-finding, and fabrication planning, leading to coordination difficulties that increase costs and technical uncertainties (Pone, et al., 2015). Hence, the research seeks to overcome these challenges by employing an integrated approach that combines computational design, material experimentation, and full-scale prototyping. Conceptualizing the gridshell as a cohesive tectonic system—where structural principles, material characteristics, and assembly methods evolve together—the study establishes reproducible processes for practitioners.

2. Actively Bent Grid Shell

According to (Huijben, 2011) In 1970 Frei Otto established a new identity for gridshell structure. That kind of shells have the same functional properties of normal shells, its difference is basically about removing an excessive amount of material to create a slender lattice grid pattern, the remaining are the load paths all over the surface. Hence, through the grid shell structure the forces are transferred by discrete or continuous members, not like to the normal shells where the forces are transferred through the whole body. Frei Otto gets his inspiration from the hanging models that was created by Antoni Gaudi, instead of transforming it to a solid sculptures he transform it to a grid shells by inverting the flexible strings hanging models (Fig. 3).

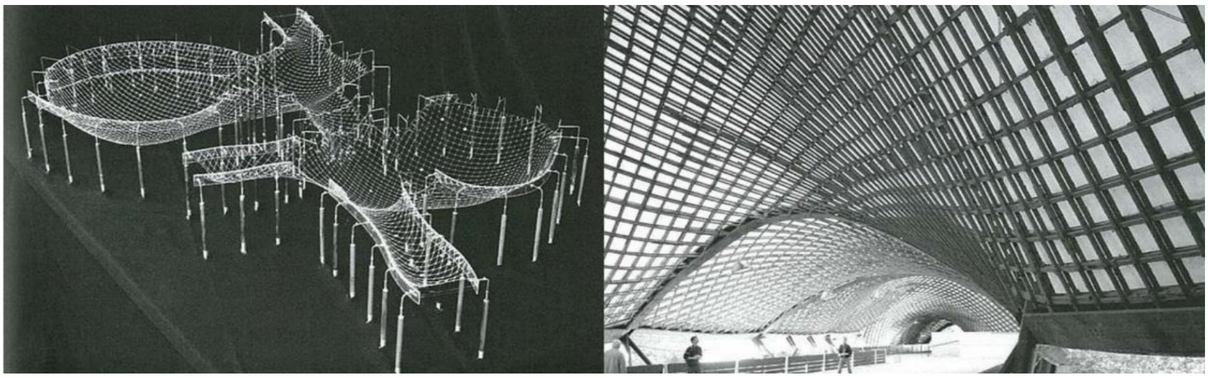

Fig. 3. the grid shell of Mannheim and the hanging model (Huijben, 2011).

From a constructive perspective; grid shells have also different way than normal ones, instead of creating a formwork and cast in-situ reinforced concrete, grid shell construction starts from a planer mesh, the discrete members are assembled on the floor level and then they lifted up or being deformed and pushed from the sides inwards to raise up the shell to get its final shape, after getting the desired shape the connections fixation takes place for the boundaries. Hence, it require the connections between the grid elements to be flexible; allowingScissoring and sliding motion in order to allow the initial deformation of the discrete members, then its fixation after the final shape could takes place if required (Pone, et al., 2015). Actively bent gridshells signify a transformative advancement in lightweight structural design, utilizing elastic deformation to convert flat grids of linear components into stable, doubly curved structures. In contrast to traditional shells that depend on rigid formwork or pre-shaped curvature, these systems generate their geometry through the deliberate bending of initially flat elements (see fig. 4) an approach that takes advantage of material elasticity while reducing fabrication complexity.

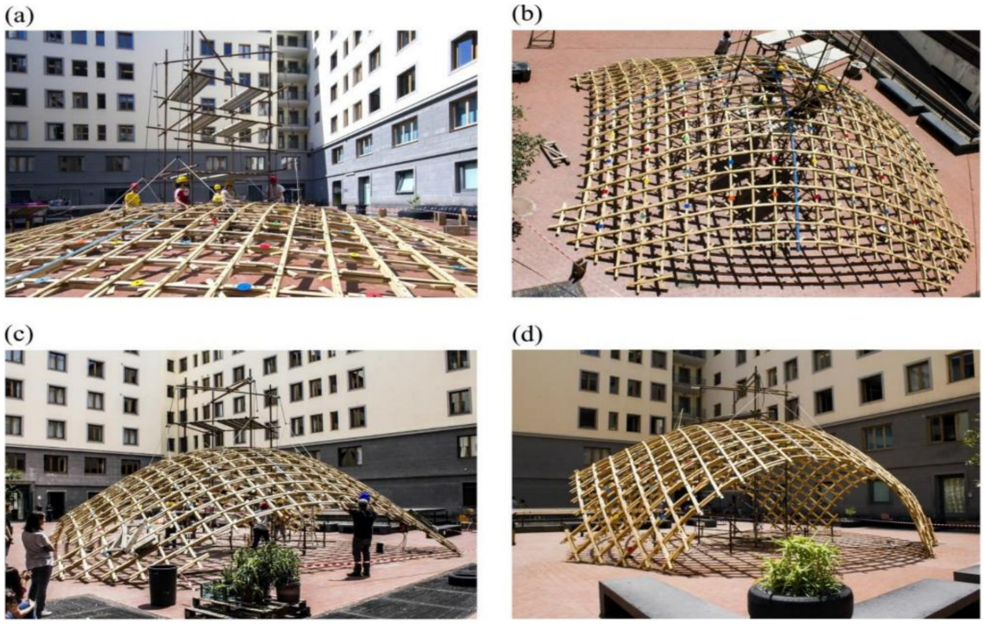

Fig. 3. Toledo grid shell 2.0. Construction process: (a - c) The central nodes are pulled up by means of cables; (d) Additional horizontal trust is added to the corner nodes to reach the final shape (Pone, et al., 2015).

The structural effectiveness of this method is rooted in its capacity to induce advantageous residual stresses during the forming process, as bending moments establish a self-equilibrating stress state that improves buckling resistance under operational loads (Hoyer, et al., 2024). Central to this phenomenon is the interaction between geometric stiffness (derived from curvature) and material stiffness (resulting from member cross-sections) (Pone, et al., 2015). As illustrated by the Weald and Downland Gridshell, the lattice's topology—commonly a quadrangular or triangular mesh dictates load redistribution strategies. Triangular meshes demonstrate enhanced torsional rigidity, thereby decreasing the need for bracing, while rectangular grids necessitate rigid joints to alleviate shear deformation. According to (Herda, et al., 2024) the Savill Garden Gridshell serves as a prime example of this concept, achieving a 60-meter span with 50 mm-thick laths through optimized mesh aspect ratios. In Conclusion, elastically deformed gridshells have key attributes that control their morphology, which are:

- Material Orthotropic: Wood is an anisotropic heterogeneous material. Hence, there is a bending stiffness difference when it bend along /versus the grain. Also, the slenderness ratio must balance the flexibility and buckling resistance (Beak, et al., 2018).
- Mesh Topology: Weather triangular, rectangular or geodesic hybrid, each one have a pros and cons. For examples; triangular are superior in torsion resistance and shape conformation. Rectangular are much easier in construction. Geodesic is in between (Goodarzi, et al., 2023).
- Boundary Condition: Mainly control the shape of the grid shall and play an important role in its stability (Beak, et al., 2018).
- Execution Sequence: Mainly based on controlled deformation from planner elements to curved element. Hence, it can minimize and maximize the residual stresses. For example sequential relaxation minimize overstressing on the bending members. But it is critical in maintaining the shape and could cause geometrical deviation (Beak, et al., 2018).

- Joints and Connections: The orthogonal joints between members must allow a scissor motion while erection. the connections could be made out of normal pins to hold the grid members together and also allow the scissor motion (Adriaenssens, et al., 2014). For thin plywood layers, it is typically more advantageous to utilize several continuous connections rather than a few larger ones, which impacts the advancement of innovative jointing methods.

3. Weaving Behaviour

Interwoven actively deformed grid shells constitute a distinct category of elastic grid shells, characterized by the interlacing of orthogonal timber laths into a textile-like framework, which is subsequently elastically shaped into doubly curved geometries. This construction technique capitalizes on the natural flexibility of wood while harnessing the structural advantages offered by woven configurations. The Tsinghua University grid shell sphere project exemplifies this approach, where the orthogonal interweaving of glass-fiber-reinforced polymer (GFRP) rods facilitated geometric self-stabilization through frictional interlock, resulting in a sphere with a diameter of 4 meters, supported solely by 3D-printed nylon hinge joints (Huang, et al., 2022). When applied to timber, this methodology presents distinct material challenges: the orthotropic nature of wood necessitates precise alignment of the grain direction with the primary bending axes to avert radial cracking during the forming process (Tang, 2012). Frictional interlock serves as an essential stabilizing mechanism in grid shells, especially those made of woven or elastically bent timber laths. This phenomenon occurs due to the interactions among structural components at their contact points, where friction opposes relative movement and redistributes loads (Huang, et al., 2021).

3.1. Behavior of wood Woven Morphologies

The orthogonal interlacing of timber laths creates a textile-like matrix that behaves as a continuous shell while maintaining discrete member identities. This duality offers distinct advantages:

- Geometric Self-Stabilization: The frictional interlock among intersecting laths effectively counters shear deformation, as evidenced by the GFRP sphere project at Tsinghua University. The prototype, measuring 4 meters in diameter, attained stability through: Orthogonal Weave density, interlacing Friction, and Number of layers. When it applied to wood a calibration must be made to counter the orthotropic nature of the wood. (Carrol, 2024).
- Torsional Stiffness: weaved systems show higher torsional resistance due to the Frictional intersection of two orthographic directions (Huang, et al., 2022).
- Shear Resistance: Dry Friction at cross members intersection increase the shear resistance.
- Buckling Resistance: the geometrical interlock converts the bending moment into membrane forces (Carrol, 2024) .
- Damage Resistance: in weaved systems when failure happens in one members 65% of the load at this point will be transferred to the adjacent members. On the other side, in single layer gridshell only 40% will be transferred (Huang, et al., 2022).
- Stress Concentrations: at the points of crossover the local bending moments increase by 2.5x (Caffarello, et al., 2022).
- Adjustments: due to geometrical lock, any post erection adjustments are hard to be done due to the friction between the members (Soriano, 2017).

4. Form-Finding

The methodologies for form-finding in shell structures have undergone considerable advancement, with modern techniques utilizing both physical modelling and sophisticated computational methods. These approaches seek to identify forms that are not only structurally efficient but also architecturally expressive.

According to (Fig.5) form-finding of shell structures composed of two main categories which are the digital form finding and physical form finding. Both methodologies are important and each one serve a unique feature in shell systems validation. The techniques of physical form-finding have a rich history in the design of shell design, tracing back to the hanging chain models of Antoni Gaudí and the frozen fabric forms developed by Heinz Isler.

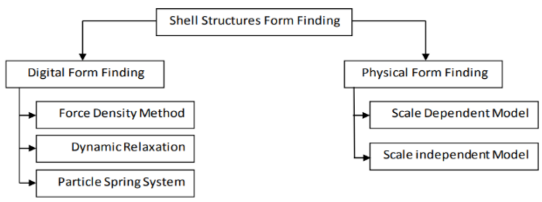

Fig. 4. Form Finding Types (Author, 2025).

These methodologies utilize physical forces to create shapes that are structurally optimal. It is important method, enabling designers to investigate structural behaviors via hands-on experimentation (Pone, et al., 2013). According to (Addis, 2014) "Designers of structures have used small-scale models when it is beneficial to do so, especially in order to raise the engineer's confidence in the design being proposed. This may have been for one of many reasons. For example:

- The existing calculation methods were too complex or time-consuming.
- The high cost of full scale prototype.
- It was believed that conventional analysis methods are not sufficient to model the structure.
- The structural geometry could not be defined by mathematical equation.
- The type of structure was unprecedented.
- There were no other means available. "

Moreover, Contemporary approaches to form-finding in shell structures are progressively dependent on computational tools that replicate physical forces and material properties. The advent of digital form-finding techniques has transformed the design process, allowing for the investigation of intricate geometries and structural enhancements that would be challenging to realize through traditional physical modeling methods (Pone, et al., 2013). Digital form finding have a lot of methods, one of them is the dynamic relaxation method which is the most suitable one for the active bending grid shells because of The ability of the method to integrate the material structure strain within the form finding process, make it able to be used in the form finding of grid shells that made of materials with high bending rigidity (material resistance towards bending) like wood, steel, and composite materials (Adriaenssens, et al., 1999) because the erection of grid shell happens by bending a planar grid as mentioned before. For example if the grid shell is made out of dense wood and a bending is applied (stress) at a certain value the wood will broke as strain behavior. The DR method process is to observe on a high frequency the behavior of each node (intersection of members) on the grid shell against artificial kinetic damping, until the nodes becomes at rest (Fig. 6). The artificial damping is then increased until it becomes equivalent to the material potential energy and stops. Which can conclude that the material got its apogee of kinetic force record to define its maximum state of bending stress, where afterwards the stress will result in a material failure strain (Barnes, 1999).

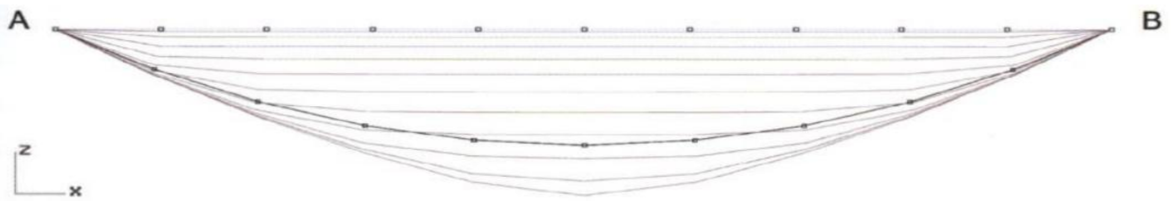

Fig. 6. example on kinetic damping behaviour from initial state to final geometry (Barnes, 1999).

4.1 Particle Spring System (PSS).

Dynamic Relaxation had been used for decades in order to aid with the physical form finding, but they are not easy for architects to use, as it based on difficult mathematical understandings (Kilian & Ochsendorf, 2005). On the other side Particle Spring Systems have a less complex version of dynamic relaxation method that can be used by architects in order to simulate the behavior of deformable bodies. In addition, it allows architects to simulate and update forces, physical properties and supports in real time (Tedeschi, 2014). The use of PSS method became popular after the development of CADenary software by John Ochsendorf and Axel Kilian, this software enables the user to manipulate the variables of the process virtually. According to (Kilian & Ochsendorf, 2005) , the method involves the use of particles in form of points resulting from a grid intersection lines and springs in form of lines of the grid connecting the points, then all the mass is concentrated in the particles, and the springs act as a straight linear elastic bars and each one is assigned a constant axial stiffness with an initial length and final length with a damping factor, which can be changed in real time simulation (Fig. 7), hence. From a scientific prospective Particle Spring Simulation could be described as follow:

"Particle-spring (PS) simulation finds steady-state equilibrium by defining a mesh topology for a network of lumped masses, called particles (nodes), and linear elastic springs (bars), and then by equalizing the sum of all forces in the system through motion. Out-of balance forces arise due to the stiffness and geometric lengths of the springs and gravity loads acting on the particles. The solution is often obtained by higher order explicit, or by implicit integration." (Bhooshan, Veenendaal, & Block, 2014) P.113.

PSS when used to simulate structural models, it is preferred to use implicit solvers, because it assumes springs (elastic bars) with high stiffness which minimize the deformation of the spring's length (Baraff, 2001). Also for validation and reliability, in the project of the Almond Pavilion that was simulated using particle spring system. The results attained a geometric fidelity of 92% between the simulated and constructed forms, while also decreasing the analysis duration by 40% in comparison to Finite Element Analysis. The system's user-friendly nature arises from the direct manipulation of visual parameters, such as spring stiffness and friction coefficients, instead of relying on abstract engineering metrics (Soriano, 2017).

According to (Tedeschi, 2014) in his book AAD_ Algorithms Aided Design, clarified the process in simpler way, by defining each element in the process as follow (Fig.7):

- Particles (Members Intersections): each node in the system is a lumped mass, that changes coordinates and velocity as the simulation runs.
- Springs (Grid members): a spring is an elastic linear connection between two nodes that behaves according to the Hooke's law: a spring has an initial resting length and a stiffness value (k).
- Forces (Axial): weights and external loads are simulated by vectors that are applied exclusively to the nodes.
- Anchor Points (supports): particles that do not change position during the simulation.

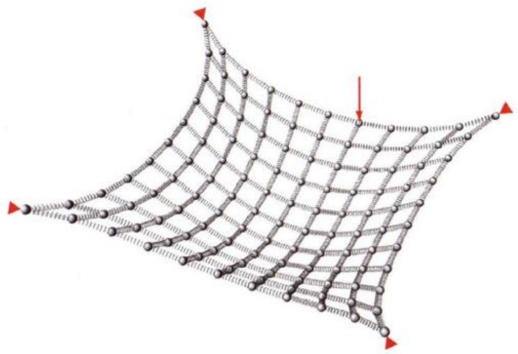

Fig. 5. Illustration for the PSS simulation elements (Tedeschi, 2014).

5. Weaved Gridshell Prototype (Sayesh Pavilion Method).

The aim of the research is to provide a simple method that can be used by architects in order to design and build weaved gridshells that made of wooden strips. Also, the approach must consider the key attributes of weaved gridshells that were previously mentioned in the theoretical study and their application in a prototype model.

The prototype model was designed to cover two pathways the one on the right is 4.6 meters span width X 7 meters length and 3.1 meters height. The one on the left is 1.7 meter space width X 3 meters length and 2.3 meters height. The used wood is yellow southern pine 15% moisture content with thickness of 6 mm for the width members and 4 mm for the length members.

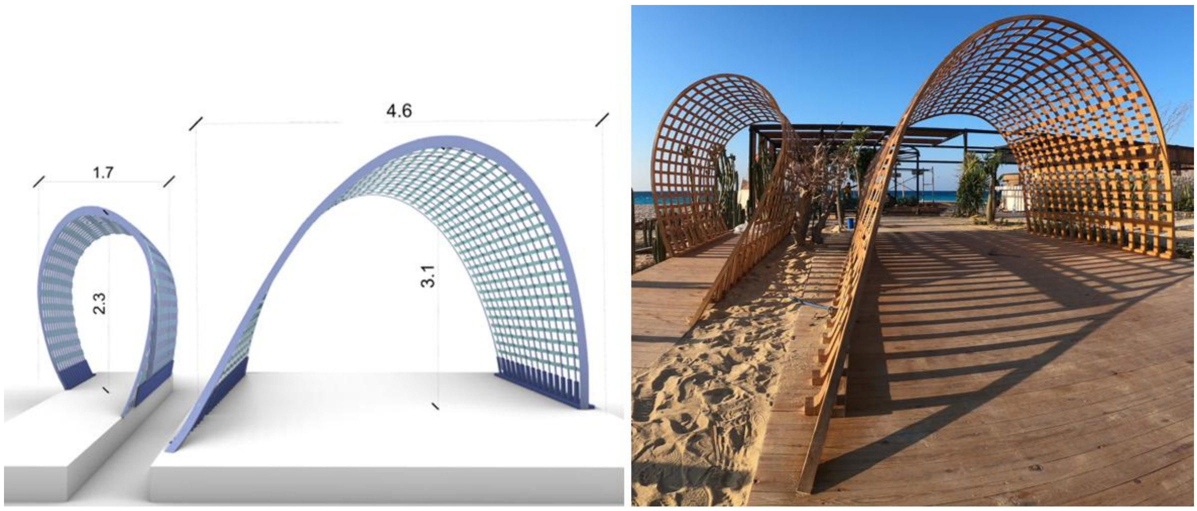

Fig. 6. on the left side the initial design for the prototype and on the right side the executed one (Author, 2025).

The prototype as presented in the above figure. In order to be executed a sequential process with feedback loops must take place (Fig.9)

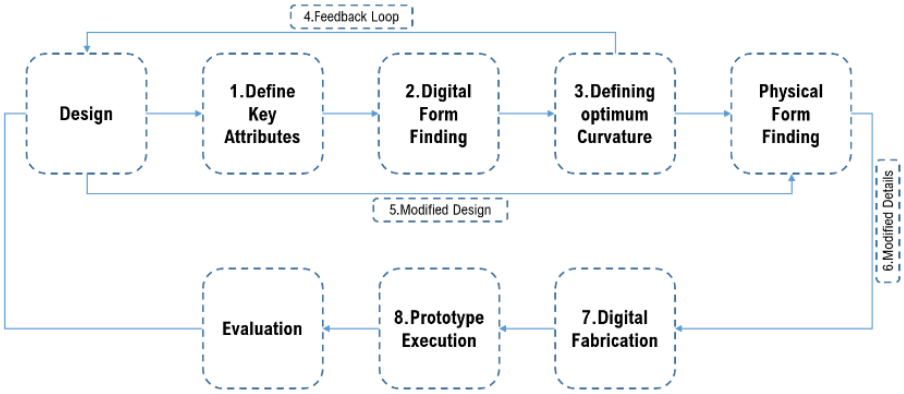

Fig. 7. the sequential process of developing weaved gridshell prototype (Sayesh Pavilion) (Author, 2025).

5.1. Defining Key Attributes.

According to the theoretical study, weaved grid shell key attributes start with the boundary condition which give the shell its shape and curvature profile, in the research prototype it was designed as straight lines with multiple fixed anchor points that was fabricated as part of the system curvature, which will constraint the starting point angle and ending point angle of each member in the x axis. Second attribute is the connections, for the boundary it was designed to be fixed using lose screws during erection and got tightened after achieving the desired curvature, for the interlace connection it was designed to be depended on the frictional interlock. The third attribute is the material orthotropic consideration, as all the bending must be done along the grain, which is considered while cutting the wood. The fourth attribute is the mesh topology, since the weaved grid shells have high torsional stiffness and frictional interlock, the topology chosen is quadrilateral for the ease of construction. Finally, the erection sequence in this prototype, the erection was sequential for the grid members, as that will early guide the process about failures, because the aim of the design is to be constructed without structural calculation. Hence, manual testing approaches was considered for failure indications (Fig.10).

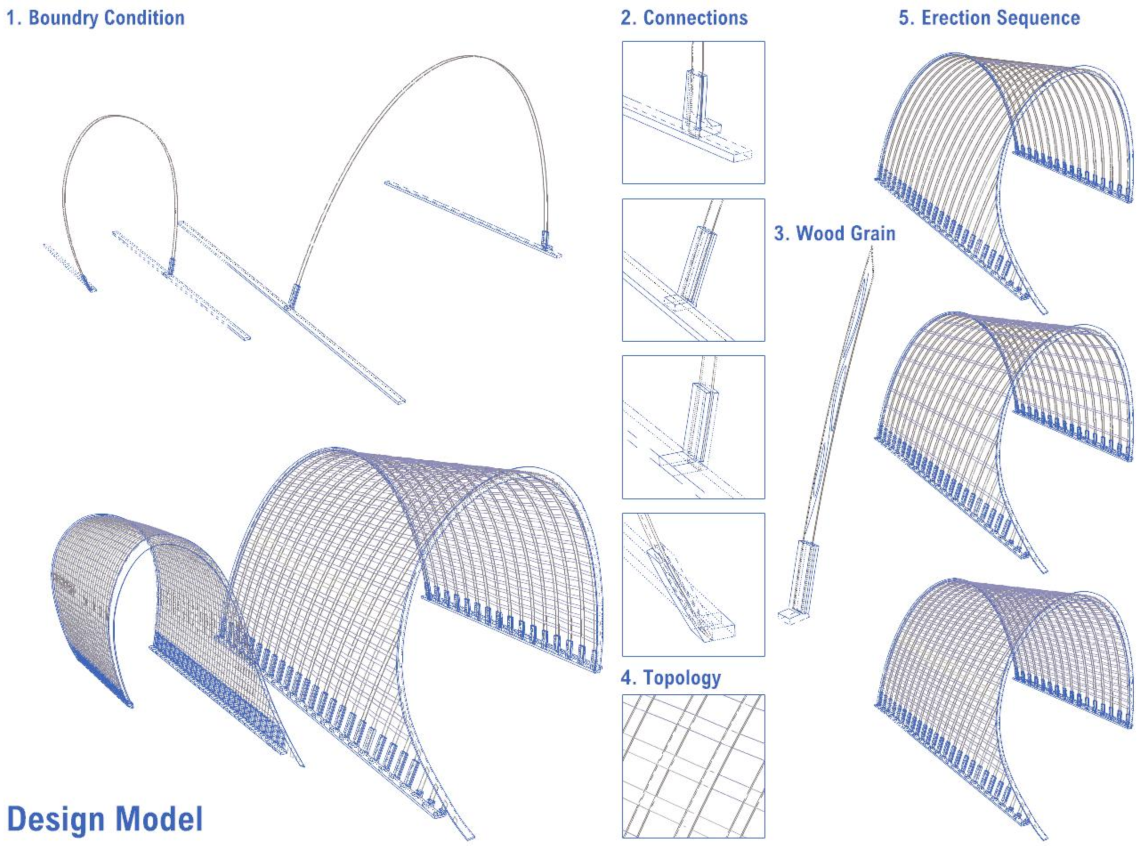

Fig. 8. the designed model with the key attributes details (Author, 2025).

5.2. Digital Form Finding.

At this stage the form finding was done using particle spring system method in Kangaroo plugin / grasshopper. The idea of the simulation is to figure out the right curvature for the wood bending behaviour. The simulation process started by defining the geometry to simulate. In the research case, the geometry chosen was the first and last member of the grid shell, since they have the maximum and minimum bending stress, and all the in between members are a range between the maximum and the minimum. After that the grid member is identified as a set of connected triangular mesh faces and the connecting line defined as axis of rotation for bending with a constraint for the angle to be Zero degree. Finally, starting and ending points of the grid member is identified as anchor points then sideward and upward force is applied. The previous composition of simulation inputs are sufficient to make a geometry act under bending behaviour (Fig.11).

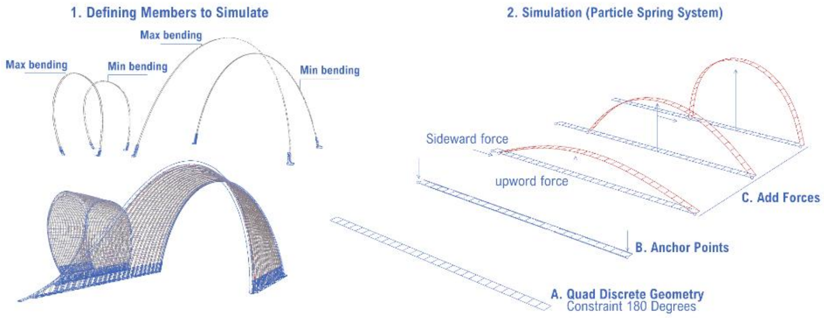

Fig. 9. digital form finding process illustration using kangroo plugin (Author, 2025).

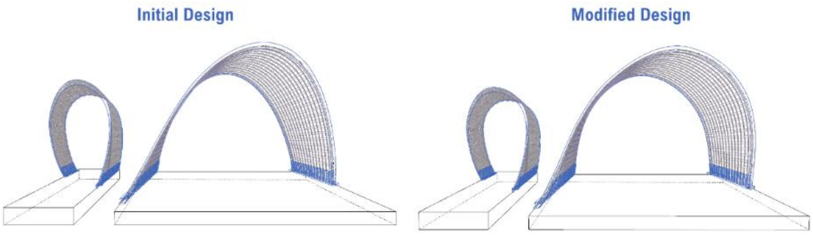
5.3. Defining Optimum Curvature.

The last step about the digital fabrication process. Showed there a difference between the designed curvature and the curvature resulted from the simulation. Hence, a feedback loop into the initial design at this stage is necessary in order to get the most accurate data to be fabricated for physical form finding (Fig.12).

Fig. 10. the difference between the initial design and the modified design (Author, 2025).



5.4. Physical Form Finding.

At this stage a full model with all the details is made on a scale 1:20. The model intention was to test the connections, boundary, bending behavior, and erection method. As concluded from the model, firstly the joints of the x axis members in order to get the exact length with a good bending behavior need to be overlapped by 50 cm in real prototype and this to avoid bending bumps. Secondly to get more bending stiffness for the entire system, 1/4 of the y axis members need to be wider. Finally some member of the y-axis got cracked while erection due to the slenderness ratio (Fig.13).

Fig. 11. the physical form finding model (Author, 2025).

5.5. Prototype Execution.
After the analysis of physical model and consideration of results. Digital fabrication drawings and files were issued for the prototype execution. The execution was done based on sequential process as planned (Fig.14).

Fig. 14. the process of sayesh pavilion execution (Author, 2025).

6. Analysis of results

The final prototype show an 80 to 90% of achievement related to the modified design after simulation. That based on the accuracy of dimensions and the bending curvature profile the prototype take (Fig.15).

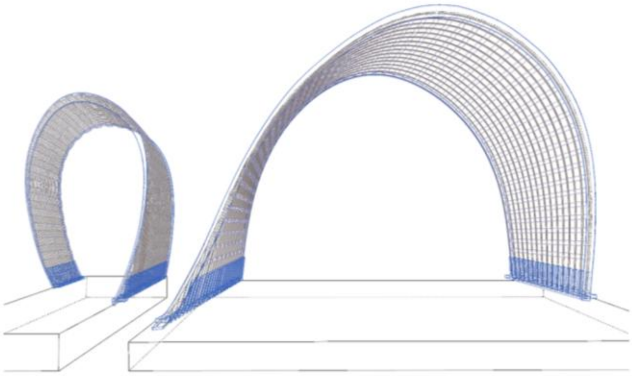


Fig. 15: comparison between the designed model and executed prototype (Author, 2025).

Although, a few problems appeared in the prototype that needs further development and research (Fig16). Firstly a safe ranged side buckling observed. Hence, the slenderness ratio of the x axis members need to be lower for more bending stiffness which will result in creating of a smoother curvature profile. Secondly, the weaving shows bumps in some of the areas which resulted due to the presence of minimal double curvature within the entire shell. Moreover, the joints for creating continues members need to be less stiff, its stiffness were because of the joints overlapping. Finally as a disadvantage of the sequential erection technique, the weaving activity of the last few y axis members were hard to install due to the increase of interlocking friction.

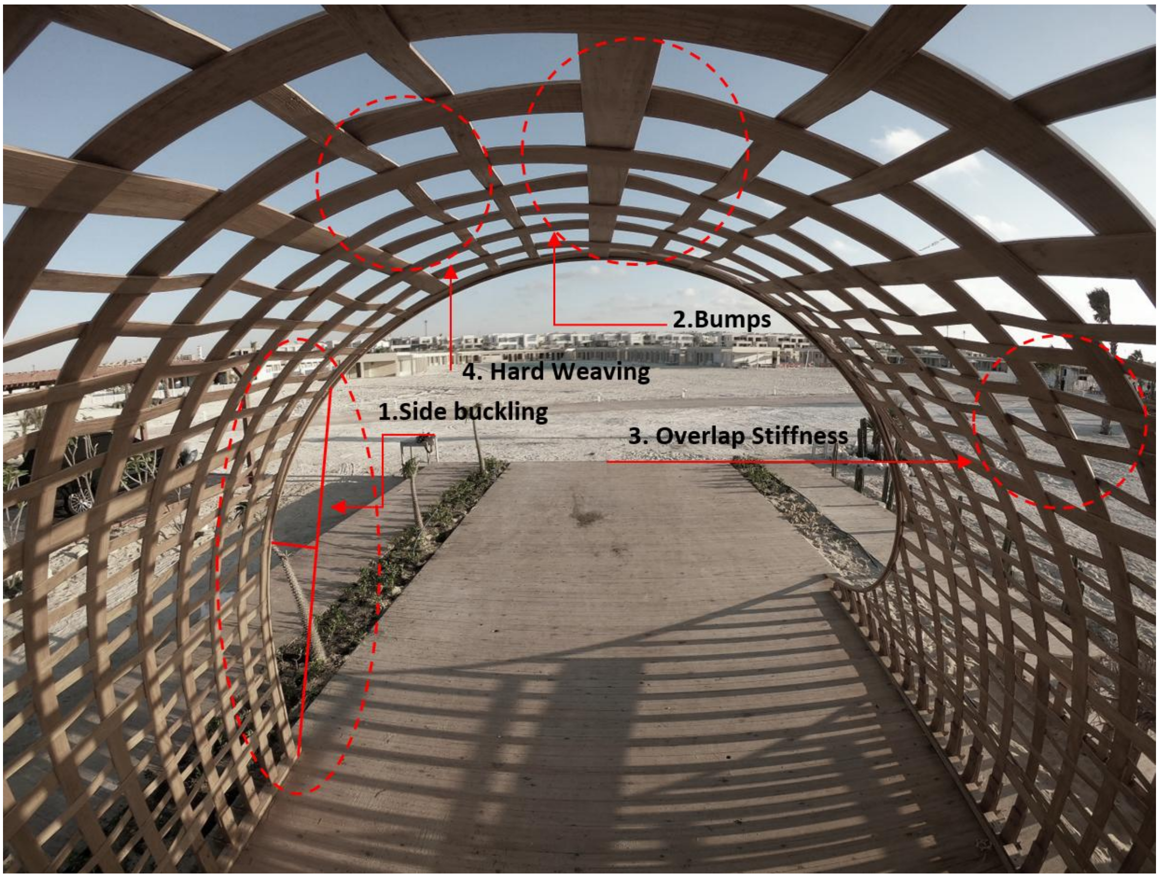

Fig. 16: photos highlighting the key problems in the prototype (Author, 2025).

7. Conclusion

The field of active bending gridshells, still need more research to fill the gaps related to the ease of simulation and fabrication by architects, as it is a multidisciplinary subject due to the combination of morphological aesthetics and structural performance. In addition, the material physics and behavior under different stresses need to be studied by architects, because it give an insights about the material ability and limitations. Moreover, the physical modeling and prototyping still modest to use as it helps in the phenomenal study and observation, like the hanging models, tensile membranes and soap film models. On the other side digital form finding is also very important as it fill the missing gaps related to the simulation and form finding scale.

The theoretical study showed that the idea of shells form finding have several ways and the software development and CAD programs avilable now make it much easier and faster.

The outcomes of each step in the making of the prototype, open the gate for research activity. As the relation between the physical form finding and digital form finding need to be linked to increase the performance of the process. Also the slenderness ratio in relation to the span and holistic shell morphology still an open subject and that because of the wood is a natural material that can behave differently depending on its molecular structure. In summery:

- the final executed prototype validet the Sayesh Pavilion Mehtod by almost 80 % .
- the key challenges for this method is the weaveing technique and slanderness ratio of the used wood.
- The combination of particle spring system method and physical modeling shows a good relaiability but it needs numerous experimentation to get the optimum values.
- The sayesh method represent a tectonic cohesive system for active bending weaved gridshell, as each detail and activity exist for the pavilion erection is a key stone in the end result
- This method is suitable mostly for single curved bending surfaces, more research need to be done for its application on doubke curved surface and freeforms.
- The interlock stiffness of weaved surface have its pros and cons. As it helps in interloction parts together with increase in the torsional resistance, but it also can results in bumped surfaces if it is not well considered.

Acknowledgment.

I would like to express my sincere gratitude to **"G'nK Group"** for their generous funding and visionary support as the client of this research project. Their commitment to exploring innovative architectural solutions made this work possible. I am also deeply thankful to my team at **"Prismatic Pillars Design Lab"** for their unwavering dedication, technical expertise, and collaborative spirit throughout the development and implementation phases. Their hard work and commitment were instrumental in translating theoretical exploration into built form. Additionally, I extend my heartfelt appreciation to **"The British University in Egypt"**, my academic home, for providing an intellectually stimulating environment that encouraged experimentation and gave me the opportunity to grow professionally and academically in the field of structural innovation and computational design.

Examining the earthquake behavior of Kırıkkale historical steel bridge with numerical analysis

Eda Gökçe Toprak*[1]

[1] *Kırıkkale Municipality, Deputy Mayor, 71100 Kırıkkale, Turkey*

Abstract. This study was conducted to investigate the seismic behavior of the historical steel bridge located in the province of Kırıkkale and the measures to be taken to improve such behavior. Historical structures are exposed to various effects from the time they are built to the present. To predict the potential permanent damage that natural disasters such as earthquakes may cause to structural systems, it is necessary to establish the numerical models and calculations of the structures. These studies involve an interdisciplinary process that includes architectural and restoration expertise as well as civil and earthquake engineering. Within the scope of this study, the time history analysis method, which allows the nonlinear evaluation of the dynamic structural response of structures under loading that varies with time, was examined among structural analysis programs and methods used in analyzing historical bridges. In this context, the Kırıkkale Iron Bridge, which was built in 1906 and is known as the first iron bridge in Turkish architectural history, was selected as a case study to shed light on the seismic behavior of historical bridges in our country.

Keywords: Historical structures; Earthquake; Numerical analysis; Time history analysis

1. Introduction

Investigating the seismic behavior of historical structures is of great importance in terms of restoration studies. The accuracy of these studies depends on the correct analysis of the load-bearing systems of historical structures. Structural analysis of historical buildings differs from the design of load-bearing systems of new constructions, as it aims to calculate the stresses and internal forces resulting from self-weight, wind, earthquake, ground settlements, and various other loads or physical external effects during use. The stresses and internal forces obtained from these calculations are compared with the load-bearing capacities or limit stress values determined for structural elements (Lourenço, 2002; Pena et al., 2010). This type of calculation and comparison is called the linear elastic approach. However, historical structures are complex in terms of both load-bearing systems and material properties. Therefore, understanding and utilizing nonlinear structural analysis methods is highly important not only from an engineering perspective but also in the fields of architecture and restoration.

In this regard, the steps required to determine the earthquake performance of historical structures using nonlinear time history analysis are addressed in this study. The method is explained in detail through the example of the Kırıkkale Historical Iron Bridge, which represents one of the earliest examples of this method.

Among transportation structures, bridges built to overcome natural obstacles are undoubtedly the most significant elements. Throughout history, numerous bridges with varying material properties and functional characteristics have been constructed. Among them, iron bridges, which have evolved alongside material development, are particularly significant due to their functionality, load-bearing capacities, and the spans they cover.

Following the widespread production of pig iron through blast furnace methods in 18th-century England, the use of iron as a construction material became possible. The first engineering structures built using iron were bridges. Many iron bridges built in the 19th and early 20th centuries are still in use today. These bridges, which have remained functional for over a century, have been subjected to loads that gradually change the structural and material properties of the bridge.

Examining the structural health of iron bridges still in use within the railway network or registered as cultural heritage is of great importance for prolonging their service life. In recent years, many historical bridges have undergone structural health monitoring, and the structural variables obtained from these observations have been incorporated into numerical models for more realistic earthquake analyses.

In Turkey, structural analysis studies have been conducted on many stone arch and iron bridges during restoration projects by the Historical Bridges Department of the General Directorate of Highways.

Examples of structural analysis and repair works on iron bridges are examined within the scope of this study. In the structural analysis of the historical Silahtarağa Bridge in Istanbul, it was found that the bridge could safely carry a pedestrian load of 400 kg/m² and, under exceptional circumstances, a vehicle load of up to two tons; however, it did not meet seismic resistance requirements in its current state. A stability analysis was performed for the historical Yatağan Dipsiz Stream Bridge, which was damaged in 2005 and partially suspended over a temporary support in the streambed after losing some of its load-bearing elements. In this analysis, the compatibility of the undamaged existing elements with the new ones planned for reconstruction was examined. Based on the analysis results, the restoration project proposed preserving the original sections and reconstructing the destroyed parts with materials compatible with the original. Structural analyses were also conducted for the 65-meter-long historical Çamçavuş Iron Bridge in Kars, which was planned to be relocated in one piece due to submersion by a dam reservoir. These analyses showed that during lifting with a 100-ton crane, the diagonals near the newly created support platform were stressed but remained within safe limits. It was also found that the bridge remained stable under its own weight. However, during transport, if the road gradient exceeded 15% or in cases where diagonally opposite supports were suspended during turning, diagonal connections were severely stressed. Finally, after being relocated, the analysis showed that when vehicles crossed the bridge, the stress/capacity ratios of the structural elements remained below critical limits (Sert and Partal, 2015).

National and international literature also includes many studies on updated bridge models based on structural health monitoring results, with significant findings and recommendations regarding their seismic performance.

Özçelik et al. estimated the modal parameters of a steel railway bridge operated by TCDD through experimental field studies and developed reference numerical models for the bridges (Özçelik et al., 2018). Siriwardane et al. determined the modal parameters of a six-span steel railway bridge during the passage of the heaviest train. A finite element model was evaluated based on displacement and stress data collected from the bridge, resulting in an updated finite element model. In this study, a damaged model was also created by removing potentially damaged structural elements from the updated model, and modal parameter estimations were made to identify changes caused by damage (Indika et al., 2015). Spyrakos et al. conducted an experimental and analytical study to assess the condition of a historical railway steel bridge. The seismic load-carrying capacity of the historical bridge was determined, and the analytical model of the bridge was updated based on static and dynamic field measurements (Spyrakos et al., 2004).

Within the scope of this study, the seismic behavior of the Kırıkkale Iron Bridge—which is one of the oldest iron bridges built in Anatolia and is still standing—will be examined in detail. In this context, restoration project reports of the bridge, which has undergone significant natural and human interventions over time, were reviewed. Load-carrying capacity calculations of the structural profiles concluded that there was no loss in carrying capacity (Highways, 2010). However, in the event of a potential earthquake in this region, analyzing the seismic behavior and potential damage zones of the bridge is of great importance.

2. Material

According to the information provided in the inventory card of the bridge issued by the 4th Regional Directorate of the General Directorate of Highways, the Kırıkkale Iron Bridge is also referred to as the Abdülhamit Bridge. Located over the Kızılırmak River in the Yahşihan District of Kırıkkale Province, the Iron Bridge was commissioned by Sultan Abdülhamit during the late Ottoman Empire. Construction began in 1905 and was completed in 1906 (Fig. 1). The Iron Bridge was registered as a historical monument by the Ankara Regional Council for the Conservation of Cultural Property on 20.11.1995 under decision number 4341. The most recent conservation and restoration projects were approved by the same council on 21.10.2010 under decision number 5482 (Fig. 2).

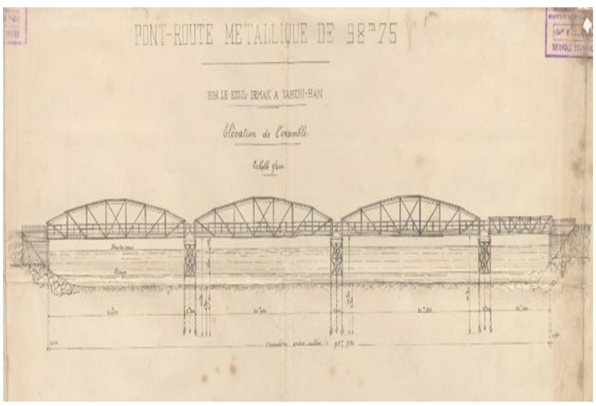

Fig. 1. Architectural drawing of the Iron Bridge and Current view of the Iron Bridge

The three central piers of the bridge are seated on a screw pile system. The total length from the bottom level of the main girders to the tips of the piles is 11.00 m, of which 6.00 m are piles driven into the ground. The piers, including the bearing pads, have a height of 5.00 m. In each pier, the distance between the outermost of the six screw piles is 2.30 m. On both the upstream and downstream sides of the central piers, metal pipes are arranged in a triangular formation, protruding 2.07 m from the main truss in plan view, reminiscent of classical stone cutwaters. The two end supports of the bridge were built using ashlar masonry. On both facades, three main truss spans with flattened arches are expressed across seven bays. Except for the central bay, the other bays are connected with single diagonal profiles, while the central bay is formed by intersecting diagonal members. The three left bays, from upstream to downstream, are constructed with diagonals sloping from left to right, while the three right bays slope in the opposite direction. The trusses with clear spans of 26.95 m are divided into seven equal segments, each 3.85 m in length. Another span, composed of four straight trusses, includes six bays. The two end bays on each side are formed with single diagonal profiles, while the two central bays use intersecting diagonals. This span is divided into six equal parts of 2.00 m each, totaling 12.00 m in length. Thus, excluding the abutments, the total length of the bridge is 98.75 m, and including the piers, it reaches 116 m. The height of the trusses starts at 2.00 m at the ends and increases to a peak of 4.58 m at the central bay. Diagonal bracing elements are placed above the trusses to connect them (Fig. 2).

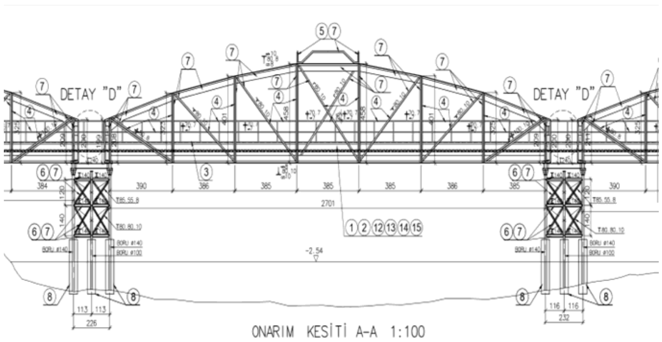

Fig. 2. Survey and restoration project (Highways, 2010)

The distance between bearing axes is 4.00 m, while the platform width is 3.61 m. Each bay contains four longitudinal girders supported by eight transverse girders. Diagonal braces connect the intersections of the longitudinal and transverse girders. The deck is covered with a material known as "zores iron" (omega plate), a fabricated profile with a reverse "S" shape that started being used in the second half of the 19th century, especially for railways. These elements range in length from 80 to 600 m. Pumice stone, a lightweight material, was spread over the zores iron to fill the gaps, followed by the placement of concrete and a wear layer. The original deck material is unknown, but it is currently finished with stamped concrete. Before the 2011–2013 restoration, the deck was asphalted. It is believed that the bridge might have originally been paved with cobblestones. The railings were made with iron elements measuring 50x50x5 mm.

Except for the ashlar masonry abutments filled with rubble and mortar, the monolithic railings on the abutments, the deck pavement, and the substructure of the deck, the entire bridge is made of iron. The truss system was formed by riveting standard structural profiles and using bolts and screws for some railing components and flat bars. Expansion joints, which allow the iron to accommodate thermal expansion and contraction, are placed between the trusses at the pier locations to allow independent movement of the structural system (Nas, 2024).

2.1. Numerical Analysis Methods and Nonlinear Time History Analysis

The purpose of numerical modeling is to determine the actual behavior of the entire structure, a specific part of it, or its load-bearing elements under various loads or environmental effects. The structural system of historical buildings and monuments is often highly complex. Therefore, many simplifications must be made when modeling such structures. In order to obtain a simple and straightforward model, the mechanical properties of the materials comprising the structural elements must also be accurately defined (D'Ayala and Speranza, 2003). The numerical model, also referred to as the Finite Element Model, is created by assembling finite elements to represent the overall behavior of the structure. In finite element analysis, the behavior of individual elements and the entire numerical model are both important (Mallardo et al., 2008). The following individual element types with defined geometric properties are generally used in finite element analyses:

- Beam or Frame Element: This type of linear element exhibits bending and shear deformation in both axes, as well as axial and torsional deformations. A typical beam element has six degrees of freedom. In numerical models used for structural analysis, node coordinates are defined relative to a global coordinate system. Finite elements also have their own local coordinate systems.
- General Shell Element: Shell or plate elements are used in the structural analysis of shells, slabs, walls, and any spatial forms. Shell or plate elements are typically formed by connecting three or four nodes to create triangular or quadrilateral shapes. Depending on the type of analysis, each node in the numerical model has four degrees of freedom. Local axes are used to define internal forces and stresses resulting from calculations. Local axes are usually determined by the sequence in which the nodes are listed.
- Three-Dimensional Solid Element: Also known as "brick" elements due to their shape, these elements typically consist of eight connected nodes. At each node, which has six degrees of freedom, the stress and deformation results are calculated along the global axes. They are used to model massive, three-dimensional structural components and load-bearing elements. Since the structure examined in this study is an iron bridge, the system was modeled using frame elements (Fig. 3).

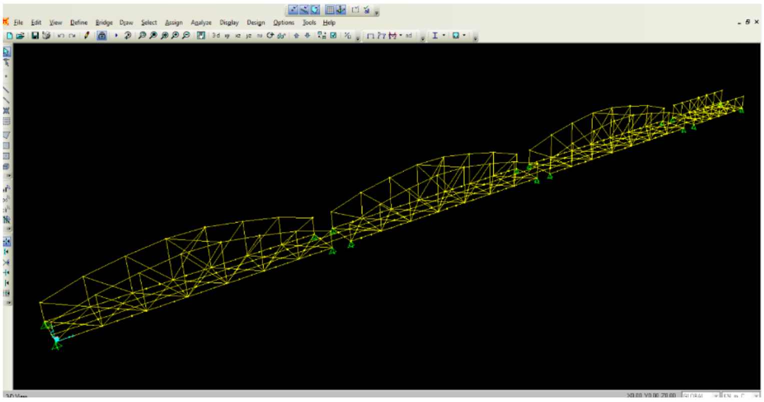

Fig. 3. Modeling the Iron Bridge using SAP2000

Linear analysis in the time domain is not a design method for creating a structure from scratch but rather a sophisticated analysis technique used to verify whether the load-bearing elements of an already designed structure have been effectively dimensioned. Compared to conventional design methods, this approach allows the designer to reach optimal solutions with a lower budget. When the mathematical model of the structural system is solved step by step—by defining the nonlinear behavior of structural elements based on their material and cross-sectional properties and updating the stiffness matrix at each step—the process is referred to as nonlinear time history analysis, or in other words, nonlinear dynamic analysis (Budak, 2015).

In nonlinear time history analysis, the effects of stiffness and strength degradation of materials—especially concrete and steel—before and after cracking or yielding are taken into account. These effects are considered both at the element level and at the overall structural system level (Başot, 2010).

3. Method

In this section, details of the nonlinear time history analysis conducted using the SAP2000 software are provided, including the creation of the analytical model of the Kırıkkale Steel Bridge in the software and detailed analysis settings.

3.1. Time History Analysis with SAP2000

The analysis method that considers the nonlinear behavior of the material and the time-dependent variation of loads acting on the structure is called nonlinear time history analysis. This method is the most effective for realistically estimating the response parameters of structures under earthquake effects. In this method, the equations of motion of 31 structural systems, including time-dependent seismic loads acting on the structure, are solved step-by-step. At each step, the displacements, rotations, and internal forces in each element are calculated. The effectiveness of this method in predicting structural responses depends on the accuracy of the structural model and the appropriate selection of earthquake ground motion records.

During the nonlinear time history analyses, both material and geometric nonlinear behaviors were considered. Plastic hinges were defined at the beginning, middle, and end points of each beam element using the fiber PMM plastic hinge module within SAP2000 (SAP2000, 2000). For geometric nonlinear behavior analysis, the large displacement rule was utilized. The Newmark direct iteration method was used for time history analysis. Analyses were conducted for three directions of earthquake records: two horizontal and one vertical.

3.1.1. Creation of the Numerical Model

The finite element model of the Steel Bridge was developed based on the modeling features and rules of the SAP2000 software. All geometric dimensions and measurements necessary for creating the analytical model of the structure were obtained using previously prepared architectural surveys. Modeling and calculation parameters are listed below:

- Considering the construction period of the bridge, it was assumed that the steel material used belonged to the ST 37 steel class, and the model was created using the properties of ST 37 steel.
- The bridge is suitable for modeling with frame (bar) elements.
- The base model used in calculations consists of 415 nodes and 782 frame elements.
- The material properties of the structural elements were selected based on prior studies on similar structures published in internationally refereed journals and international literature recommendations, as well as values suggested by the current Earthquake Code for steel structures.
- Determining the damage limit states in bridges plays a critical role in assessing the seismic performance of the bridge. Since each bridge element may possess different characteristics, the damage sustained by each component and the overall structure may vary. The damage states of bridge elements were defined using the four damage states described in HAZUS-MH (FEMA, 2003): slight, moderate, extensive, and collapse. Each damage class is determined based on the corresponding loss in serviceability and the time required for repair (see Table 1 and Table 2). In this way, when evaluating the damage in different components, the effects of these damages on the overall bridge are taken into account. As a result of analytical studies, fragility curves were obtained for each bridge element separately, allowing for a performance-based seismic evaluation of each element and determining which components should be prioritized in retrofit measures (Yılmaz and Çağlayan, 2018).

Table 1. Moment-curvature damage limit values for steel elements.

Component	Damage Limit Values			
	Slight	Moderate	Extensive	Collapse
Beam rotation ductility $\mu\varphi$	1	3	6	8

Table 2. Bearing displacement damage Limit States (Nielson, 2005)

Component	Damage Limit Values			
	Slight	Moderate	Extensive	Collapse
Short-type steel fixed bearing - Length (mm)	6	20	40	255
Short-type steel fixed bearing - Width (mm)	6	20	40	255
Short-type steel expansion bearing - Length (mm)	50	100	150	255
Short-type steel expansion bearing - Width (mm)	6	20	40	255

- The bridge deck was evaluated using data from the restoration project. Although assumptions were made regarding the modulus of elasticity and unit weight of the deck materials, to shorten analysis time, the deck load was transferred to the beams as a line load.
- To perform nonlinear time history analysis, plastic hinges were defined at the start, middle, and end points of each beam element using the PMM plastic hinge module in SAP2000.

In the first stage of the time history analysis, a nonlinear initial condition was defined in SAP2000 under the "Load Case Data" section as G + G2 + 0.3Q. Here, G refers to the permanent load, G2 refers to the line load from the slabs to the beams to reduce analysis time, and Q represents the live load (Fig. 4 and Fig. 5).

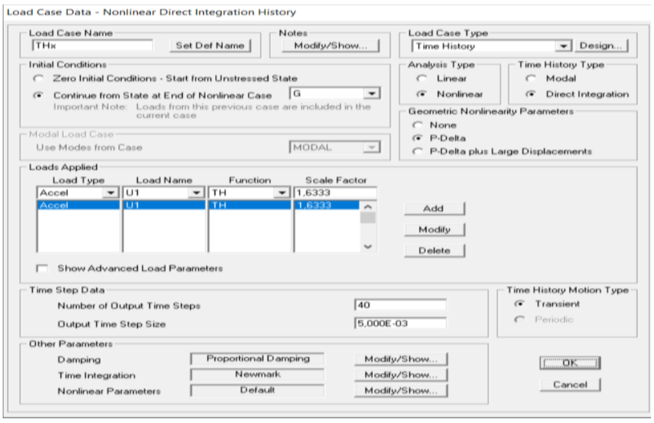

Fig. 4. Initial condition definition in SAP2000

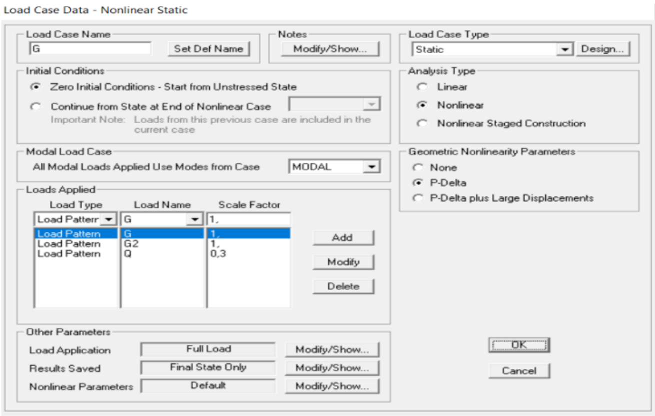

Fig. 5. Time History analysis settings

Nonlinear analyses using the direct integration method were conducted for both directions, labeled Thx and Thy. Second-order effects (P-Δ), arising from axial forces in the deformed structural system, were also considered.

3.1.2. Creation of Earthquake Records

To study the seismic behavior of structures using nonlinear dynamic time-history analysis, the selected acceleration records must meet certain criteria. Acceleration records for analysis are obtained in three ways:

1. Artificial (compatible with design spectra)
2. Simulated (considering seismic source and wave propagation characteristics)
3. Real earthquakes (Fahjan, 2008)

Real acceleration records are generally superior to the other two as they better reflect the nature, amplitude, duration, phase, and frequency content of the earthquake and accurately represent source, propagation medium, and site conditions.

Table 3. Criteria for selecting earthquake records (Sönmezer, 2016)

Parameter	Criterion
Fault Type	Strike-Slip
Magnitude	6,5-7,5
Distance (km)	0-40
Vs30min, max (m/s)	360-760

Based on the criteria in Table 3, selected earthquake records from the PEER database are listed in Table 4.

Table 4. Earthquake records selected according to criteria (Toprak, 2024)

No	Data	Earthquake	Year	Station	Magnitude	Fault	Rjb (km)	Rrup (km)	Vs30 (m/s)
1	1155	Kocaeli	1999	Bursa/T	7,51	SS	10,56	13,49	523,00
2	1148	Kocaeli	1999	İznik	7,51	SS	30,73	30,73	476,62

Rjb *= Joyner-Boore distance,* ***Rrup*** *= Closest distance to the rupture surface,* ***Vs30*** *= Shear wave velocity*

These real earthquake records listed in Table 4 were selected in accordance with the requirements specified in TBDY 2018 (TBDY, 2018), and were scaled to match the design acceleration spectrum using the SeismoMatch program (SeismoMatch, 2023) (Fig. 6).

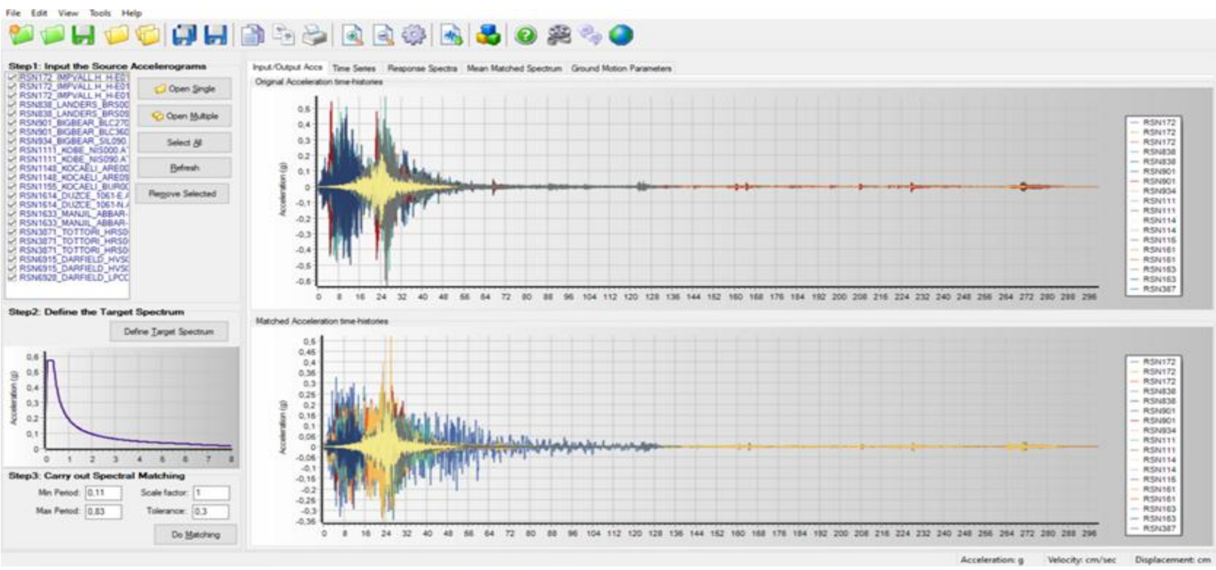

Fig. 6. Real earthquake records scaled in SeismoMatch

Upon reviewing the analysis results, it was observed that among 4562 hinges, 2259 points experienced slight damage, 18 points experienced moderate to extensive damage, and 3 points entered the collapse zone and suffered severe damage. Since the load on the element cannot be redistributed to other load-bearing elements once plastic deformation begins, initial yielding and collapse occurred simultaneously (Fig. 7).

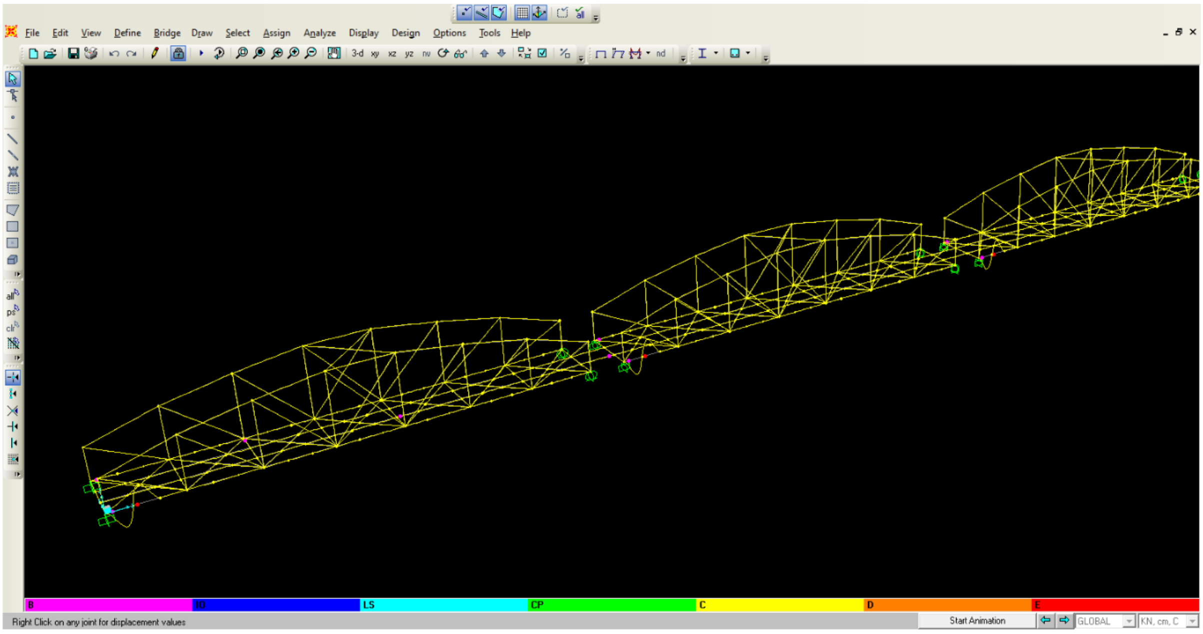

Fig. 7. Damage in the Y direction resulting from time history analysis in SAP2000

In structural analysis, the response of the finite element model to defined seismic loads is calculated through the modal analysis method. Fig. 8 shows the displacements occurring in the first eight modes of the Steel Bridge.

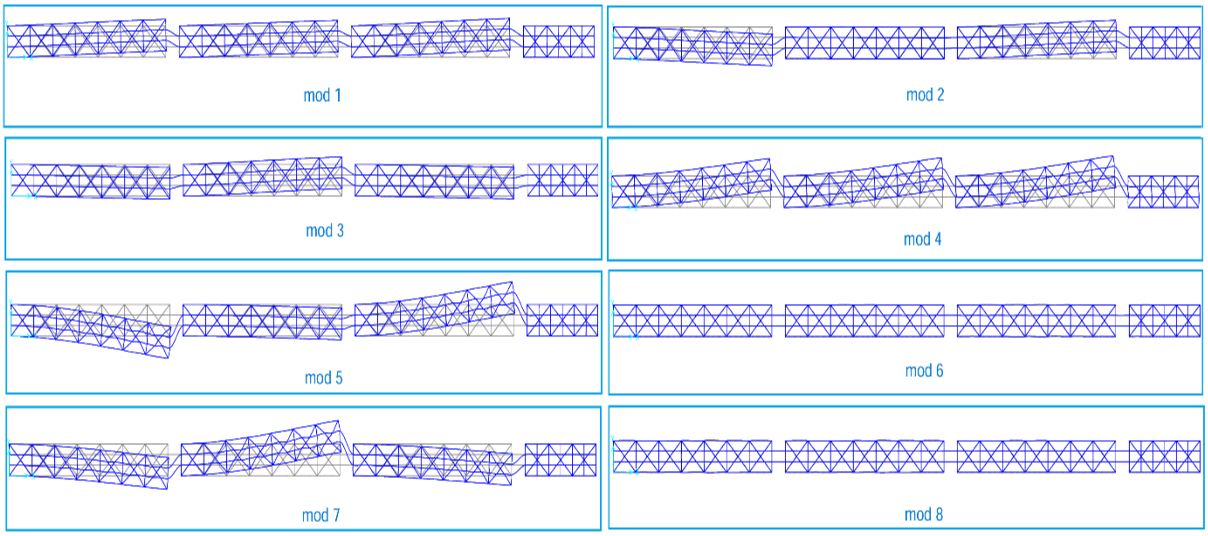

Fig. 8. Displacements in the first 8 modes of the Steel Bridge

As shown in Table 5, the maximum displacements in the Kırıkkale Steel Bridge were:

- 6.7 cm in the Y-direction in the second span during the 1st mode
- 10.1 cm in the first span during the 2nd mode
- 12.1 cm in the second span during the 3rd mode
- 25.27 cm in the third span during the 4th mode
- 28.61 cm in the third span during the 5th mode
- 0.47 mm in the third span during the 6th mode

- 33 cm in the second span during the 7th mode
- 38 mm in the first span during the 8th mode

Table 5. Displacements in the X and Y directions in the first 8 modes of the Kırıkkale Steel Bridge

Mode	Period	Displacements (cm)					
		1. span		2. span		3. span	
		x	y	x	y	x	y
Mode 1	0,5514	0,55	8,06	0,46	6,73	0,63	9,22
Mode 2	0,5511	0,68	-10,14	0,05	-0,75	0,64	9,41
Mode 3	0,5511	0,34	-4,99	0,82	12,10	0,30	-4,42

4. Conclusions

This study aimed to demonstrate the importance of earthquake analysis in historical structures, particularly from the perspectives of architecture and restoration, through the example of the historical Kırıkkale Demirköprü (Iron Bridge). In the restoration of historical structures—which inherently involves an interdisciplinary process—the identification of potential damage zones due to possible earthquakes is crucial for effective repair and strengthening interventions. Within the scope of this study, structural elements likely to incur damage during an earthquake and their corresponding mode shapes and displacement values were calculated using numerical analysis methods. The results underline the significance of earthquake analysis in the repair and strengthening of architectural structures. The findings specific to this bridge will serve as a foundation for seismic retrofit applications of other steel bridges in the Anatolian region with similar characteristics.

In future studies, the application of fragility curves—describing the probability of exceeding different damage states (collapse, severe, moderate, slight, and none) for a given ground shaking level—specifically to historical structures will be crucial for seismic risk assessment and loss estimation, contributing to the protection of cultural heritage.

Additionally, incorporating pre-existing structural defects into the numerical model and determining the structure's current dimensions using LIDAR technology will be vital for achieving realistic results. Employing non-destructive testing methods to assess material properties can help detect issues such as cracks due to corrosion or wear, internal voids, and section losses. The dynamic characteristics of the structural system identified through Operational Modal Analysis should be compared with the numerically derived properties, and the numerical model of the structure should be adjusted accordingly based on experimental data. Conducting nonlinear time history analysis with this calibrated model will make it possible to draw conclusions about additional measures required to minimize earthquake damage in the future.

Abstract. The integration of piezoelectric energy harvesting systems into building facades offers an innovative approach to addressing urban energy challenges. This article investigates the potential of such systems to harness wind-induced vibrations, shocks, and pressure. Using computational fluid dynamics (CFD) simulations by Eddy3d,the study analyzes wind dynamics on building facades in Istanbul,with meteorological data and wind power metrics informing the performance evaluation of piezoelectric sensors.These sensors are modeled through Simulink and the results are analysed to refine energy output predictions.The sensor selection is based on resonance frequency alignment with vibration frequencies derived from CFD simulations,ensuring effective harvesting from wind-induced facade motions.Eight scenarios across different facade locations were simulated using the proper piezo system, revealing that energy harvesting potential significantly varies with facade position. Simulation results show that the middle zone of the higher floors yielded the highest energy output, with a maximum battery-stored energy of 5.9 J in average and average voltage of 2.98 V,outperforming lower floors and corner positions. This highlights that harvesting potential is closely linked to local pressure intensity on tilted panels, rather than just wind pressure coefficients.Comparative analysis confirms that site specific tuning of sensor resonance and positioning can optimize harvesting performance.

Additionally,feasibility evaluations across different building heights emphasize that wind dynamics and harvesting efficiency shift notably with altitude.The findings suggest that energy harvesting from piezoelectric facades can be significantly optimized by tailoring system design to local environmental conditions and facade-specific dynamics.This approach offers a scalable strategy for enhancing building energy efficiency through energy conscious facade systems.

Keywords: Piezoelectric energy harvesting , Wind dynamics , Computational fluid dynamics (CFD) , Facade design, Renewable energy technologies

1. Introduction

The escalating demand for sustainable and resilient urban infrastructure has intensified research into advanced technologies capable of addressing both energy efficiency and structural performance. One emerging area of interest is the application of piezoelectric materials within the built environment. These materials possess the unique ability to convert mechanical strain, originating from dynamic loads such as wind, human activity, and seismic vibrations, into usable electrical energy. Their dual functionality as sensors and energy harvesters makes them particularly attractive for integration into building systems (Guangdong Sui et al., 2024).

Beyond energy harvesting, piezoelectric sensors have been extensively utilized for structural health monitoring (SHM), providing real-time feedback on material fatigue, crack propagation, and dynamic load behavior in both buildings and bridges (Abdulkadir Cüneyt Aydin and Oğuzhan Çelebi, 2023). In earthquake-prone regions, embedded piezoelectric transducers are also deployed for seismic sensing and early warning systems, enabling smart buildings to respond adaptively to tectonic disturbances (Pushan Kumar Dutta and Andhra Pradesh, 2024). Moreover, recent engineering prototypes have demonstrated the feasibility of incorporating piezoelectric dampers into non-load-bearing elements, such as floor voids, wall cavities, or ceiling panels, to harvest vibrational energy while simultaneously enhancing occupant comfort and structural damping (Zhengbao Yang et al., 2018).

This study focuses on the integration of piezoelectric energy harvesting systems into building façades, an area that remains underexplored despite the considerable mechanical energy potential from urban wind flows. By leveraging façade surfaces as dynamic interfaces exposed to wind-induced oscillations, these systems can generate

* Corresponding author, E-mail: bita.akhgar@gmail.com.tr

https://doi.org/10.31462/icearc2025_a_aen_528

supplemental electrical power while contributing to smarter building skins. Using Istanbul as a case study with its variable wind patterns, heterogeneous urban density, and mixed building typologies, the research evaluates how piezoelectric façade systems perform across different building heights and wind exposure scenarios. The findings aim to inform the engineering design of multifunctional façades that contribute to both energy generation and environmental responsiveness in high-density cities

2. Methodology

This study explores the potential of piezoelectric energy harvesting integrated into building facades by simulating and analyzing wind dynamics considering the vibrations, and energy outputs on the façade of the case building. The methodology combines computational and simulation approaches to evaluate the feasibility and performance of such systems in urban environments following the process shown in the research flowchart (Fig. 1).

2.1. Case Building

The case study investigates a prototype high-rise tower situated in Istanbul. The building has a total height of 170 meters and consists of 50 floors, each with a floor-to-floor height of 3.4 meters. The plan dimensions are 46.2 meters by 46.2 meters, forming a square footprint with four identical vertical facades. The facade utilizes a unitized structural curtain wall system (Fig. 2), made of single piece 1.4 m × 3.4 m structural glazing panels.

Each floor includes 36 panels horizontally on each facade side, 9 structural spans of 4 panels. The windward facade, aligned with the prevailing wind direction based on Istanbul's EPW weather file, is the primary subject of analysis. This prototype tower is considered to be in an isolated, conceptual scenario: no neighboring buildings, landscaping, or urban context are modeled. This allows a focused simulation of wind interactions on the facade surfaces, avoiding turbulence interference from surrounding structures.

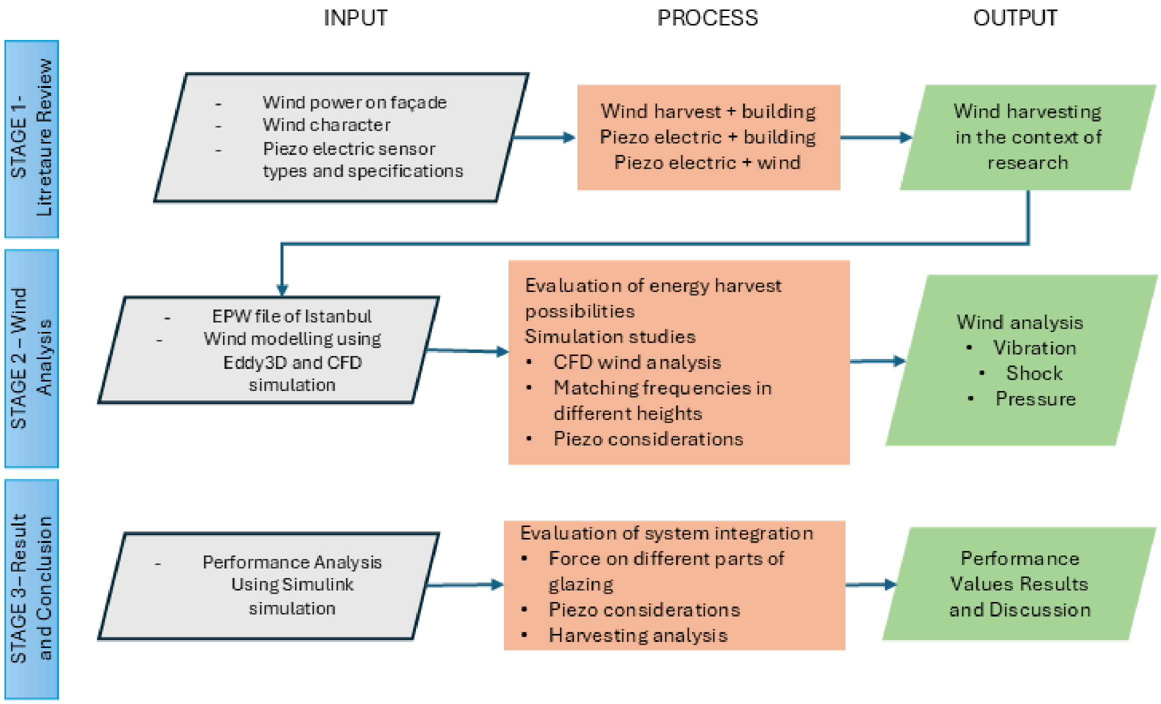

Fig. 1. Methodology approach

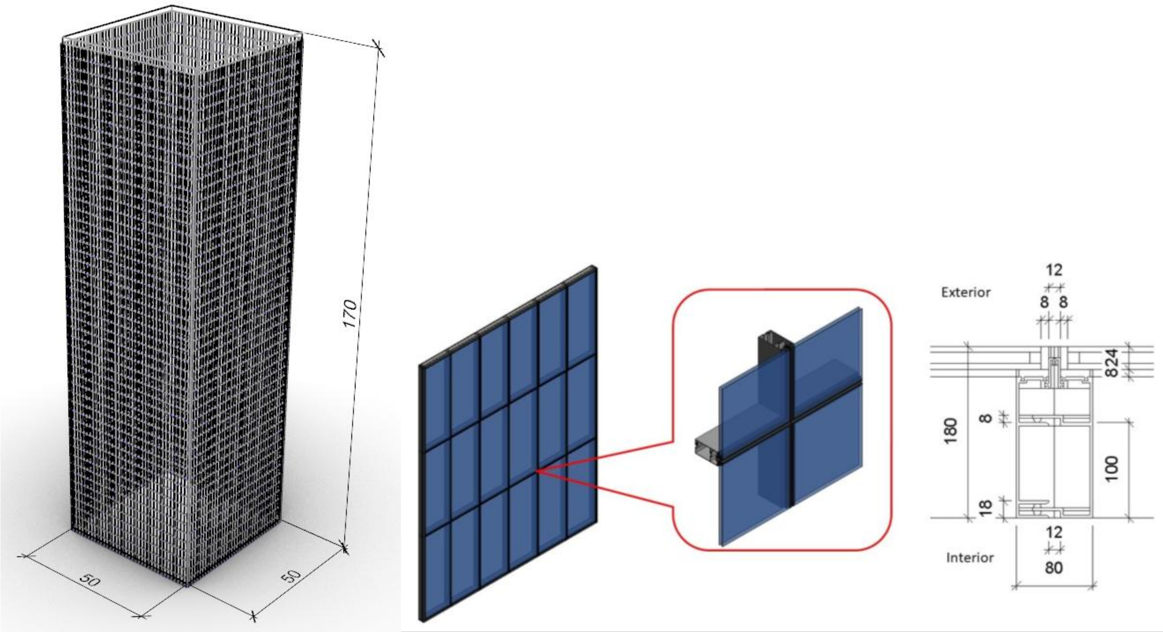

Fig. 2. Geometry and Façade Specifications of the Case building

2.2. Wind Simulation Setup and Zoning Strategy

Wind simulations were conducted using Eddy3D and OpenFOAM, linked through Rhino-Grasshopper for geometry and data control. To capture the dynamic behavior of wind-induced pressure and vibration across the facade, the entire windward surface is first analyzed as a whole using CFD in Eddy3D; color-mapped outputs such as pressure, velocity, and estimated vibration responses are then used to identify and differentiate facade zones (e.g., corner, edge, center) for subsequent piezoelectric simulation scenarios in Simulink.This zoning strategy captures the spatial variation of wind pressure due to height and lateral positioning, which is critical for understanding vibration amplitudes and frequency potential of piezoelectric harvesters.

High-resolution outputs provided by wind analysis, including wind velocity vectors, surface pressure (Pa), and pressure coefficient (Cpe) distributions across the façade, are interpreted to estimate vibration intensities on different facade sections, which are then converted into excitation parameters (e.g., frequency, amplitude) for piezoelectric simulation in Simulink.

To evaluate the energy harvesting potential of the windward facade, a piezoelectric energy harvesting system was modeled in Simulink using Simscape Multibody and Simscape Electrical blocks. The primary objective of this simulation was to determine the electrical output (voltage, current, and power) generated by piezoelectric benders under wind-induced vibration input, derived from the CFD outputs of Eddy3D and related calculations. Different settings were calibrated for the piezoelectric bender used to evaluate the electromechanical response. This cross-platform methodology bridges environmental simulation with energy harvesting system modeling, enabling an accurate assessment of real time wind induced vibrational energy potentials.

The integration of CFD results into Simulink facilitates a spatial feasibility analysis of the windward facade by highlighting zones with higher vibration activity and energy conversion efficiency. Based on the color-mapped output of wind pressure and velocity from Eddy3D, the facade is later subdivided into characteristic zones allowing scenario based simulations in Simulink without rerunning CFD. The Simulink model based on piezo bender energy harvest model (mathworks, 2023) and redefined according to research scenarios. These simulations yield comparative wattage outputs across zones, revealing the most optimal locations for energy harvesting using piezoelectric mechanisms.

3. Result and Discussion

The analysis employed the Reynolds Averaged Navier Stokes (RANS) equations, combined with a standard $k-\epsilon$ turbulence model, to solve for steady state wind flows around the building. Simulation settings used a refined mesh on the windward facade and immediate surroundings to capture local pressure and velocity variations across the curtain wall panels. The wind inflow direction was aligned perpendicular to the windward facade to amplify excitation forces.

3.1. Output Interpretation: Pressure, Velocity, and Facade Dynamics

The CFD simulation output includes spatial maps of wind velocity magnitude (m/s), pressure (Pa), and pressure coefficient Cp, which is a dimensionless value used to characterize wind pressure on building surfaces:

$$C_p = \frac{P - P_{ref}}{0.5\rho V_{ref}{}^2} \quad (1)$$

Where:

- P is the static pressure on the surface
- P_{ref} is the reference static pressure (often atmospheric)
- ρ is the air density
- V_{ref} is the reference wind speed

Fig. 3 illustrates the pressure coefficient (C_p) distribution across the windward facade. Higher positive C_p values are concentrated at the central core of the façade on the higher floors, while edges and corners exhibit greater negative suction due to flow separation and vortex formation.

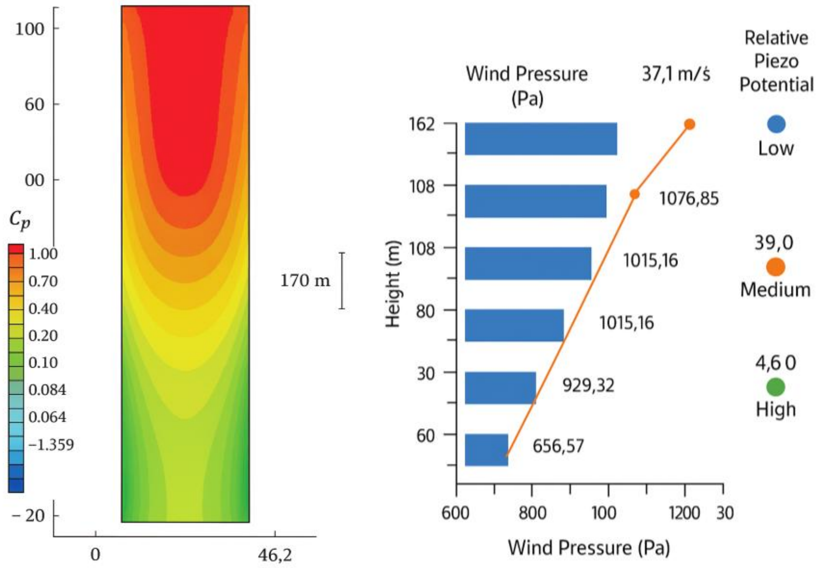

Fig. 3. C_{pe} on the Case Building and Wind Pressureon Façade analysis

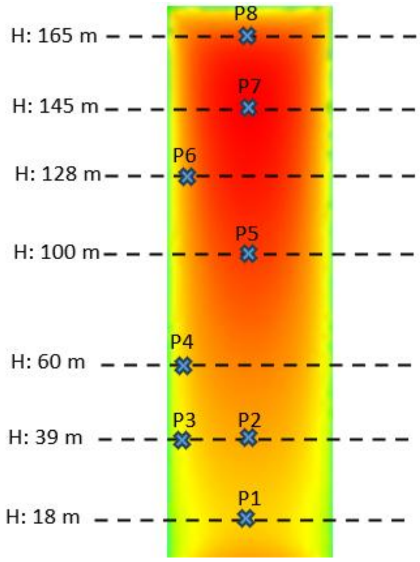

Fig. 4. Scenario Points Retrieved from previous step results

Considering the Cpe from the Eddy3D simulation, 8 points are defined to be analysis on the building façade. Fig. 4 shows these scenarios. Edge vortices and upward acceleration at the top of the tower result in significant dynamic variability, particularly in the corner panels.

From the spatial maps, pressure fluctuations and velocity gradients are further analyzed to derive dominant wind excitation frequencies on different zones of the facade. To calculate the frequency of vibration on a facade panel, we focus on the displacement, which is derived from the deflection limits for glass components for deformations class 2-SLS according to prCEN/TS 19100-2 (CEN, 2022). According to these standards, the deflection limit is typically set at L/60, where L is the length of the panel. In this case, with a panel length L = 3.4l meters, the maximum allowable displacement D would be 3.4 / 60 = 0.0567 meters. To enhance safety and ensure the displacement remains within acceptable limits, a safety coefficient is applied to reduce the displacement. Assuming a coefficient of 0.8, the adjusted displacement (0.0453(m)) will be considered in the façade engineering design and vibration frequency calculations. Using this adjusted displacement, the vibration frequency f can be calculated using equation(2). This calculation ensures both the safety and performance of the facade panel, particularly in the design of energy-harvesting systems like piezoelectric facades.

$$f = \frac{V_S}{2\pi D} \tag{2}$$

Where:

- f vibration frequency on each scenario panel
- V_s wind velocity on the surface
- D efficient displacement allowed by prCEN/TS 19100-2

Table 1 shows the results of calculating vibration frequency on each panel located in the scenario points shown in fig. 4.

The resulting vibration frequencies are calculated to be in the range of: $f \approx 118 \; to \; 152 \; Hz$

The values define the vibration frequency domain for piezoelectric energy harvesting simulations, showing that moderate to high-frequency excitations occur across the high-rise façade, especially near the top corners and leading edges. Despite the relationship between wind velocity and the natural vibration frequency of vortex shedding on this case façade is not direct, following equation 2, the vibration frequency on each panel has direct connection with the velocity on the surface of the panel. This means that contrary to common assumptions that higher wind speeds induce lower frequency motions (Zeng et al., 2023) in case the capacity of the façade can be utilized by correct façade engineering design, the relatively stiff façade panels exhibit high natural frequencies even under increased pressure. Instead, vibration amplitude may increase, while the frequency remains primarily dependent on the panel's structural characteristics rather than the wind velocity itself.

In addition, while wind velocity increases the force applied on the surface through dynamic pressure following equation 3, the structure's response is governed by its natural frequency, which depends on the stiffness, mass, and boundary conditions of the panels. The vibration frequencies of façade panels range between approximately 118 to 152 Hz, depending on the height and panel position as shown in table 1.

Dynamic pressure and velocity on the surface

$$V_s = \sqrt{\frac{2P}{\rho}} \tag{3}$$

Where:

- V_s : Velocity on the surface
- P : Static pressure on the surface
- ρ : the air density at sea level (1.225 kg/m³)

Table 1. Scenario points table

Scenario	Height (m)	Pressure (Pa)	Wind Speed (m/s)	Vibration Frequency (Hz)
1	18	700	33.8	118.75
2	39	820	36.6	128.52
3	39	738	34.7	121.93
4	60	810	36.4	127.74
5	100	1020	40.8	143.34
6	128	968	39.8	139.64
7	145	1100	42.4	148.86
8	165	1140	43.1	151.54

3.2. Energy Harvesting analysis through Simulink simulation

The energy harvesting mechanism is based on the conversion of mechanical vibration into electrical energy through the piezoelectric effect. The fundamental equations governing this process include:

Mechanical Input (Base Excitation - Sinusoidal Input) $$x(t) = A \,.\sin\,(2\pi f t) \tag{4}$$

Where:

- A : Vibration amplitude
- f : Vibration frequency (Hz)

Piezoelectric Constitutive Equations (1D approximation)

$$S = s^E T + dE \tag{5}$$
$$D = dT + \epsilon^T E \tag{6}$$

Where:

- S: Mechanical strain
- T: Mechanical stress
- D: Electric displacement
- E: Electric field
- s^E: Compliance at constant electric field
- d: Piezoelectric strain constant
- ϵ^T: Permittivity at constant stress

Generated Power $$P = \frac{V^2}{R} \tag{7}$$

Where:

- V: Voltage generated across load
- R: Load resistance

The energy harvesting potential of eight distinct points on the facade was evaluated through Simulink simulation. Each point was modeled using a piezoelectric bender element with a resonant frequency of 125 Hz, which falls within the observed vibration frequency range of the building facade (118–152 Hz). The simulations aimed to compare energy storage behavior under identical sensor and circuit conditions, isolating the impact of local vibration characteristics. The battery voltage output over time was recorded to observe the charging behavior at each point. As shown in Fig. 5, some scenarios exhibited faster charging rates, while others demonstrated delayed responses or lower voltage gains.

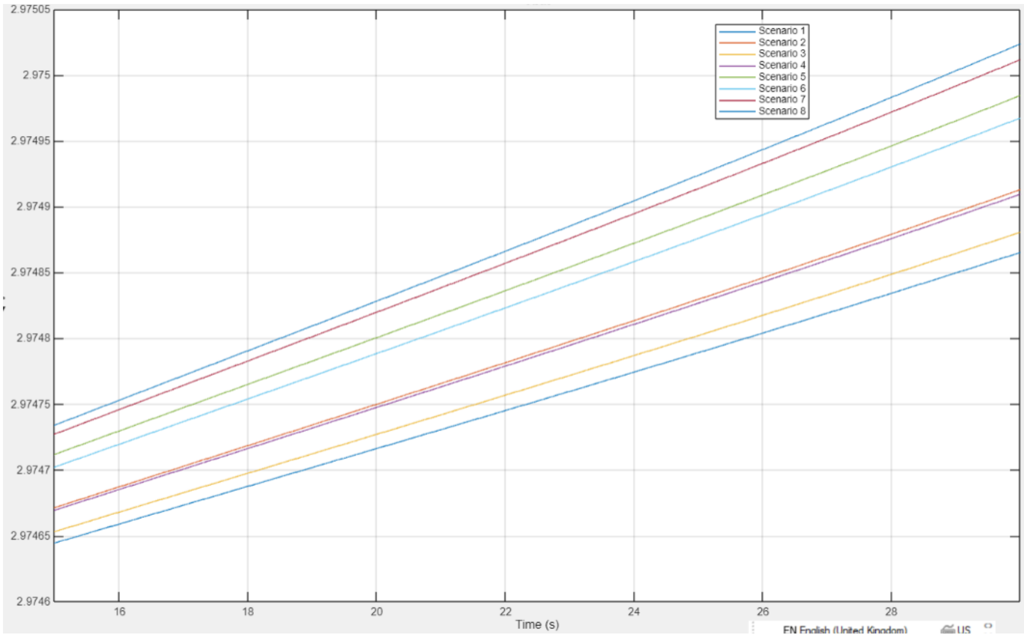

Fig. 5. Battery voltage (V_{bat}) over time for each facade point (Scenarios 1–8).

Despite identical piezo characteristics and circuit parameters, variations in local excitation amplitude and frequency content resulted in different energy outputs. To quantify the harvested energy, instantaneous power was calculated using equation 8 and this power signal was integrated integrated over the simulation period to obtain the cumulative energy stored considering equation 9.

$$P(t) = V_{bat}(t) \cdot I_{bat}(t) \quad (8)$$

$$E(t) = \int_0^t P(t)\ dt \quad (9)$$

where E(t) is the harvested energy in Joules, and T is the total simulation time (30 seconds in this case). The final energy values for each point are summarized in Table 2.

To understand internal energy losses, power dissipation in the circuit was monitored using a custom resistor model and power sensors. Results in Fig. 6 show varying dissipation levels, correlated with the vibration intensity and mechanical coupling efficiency of each point.

Further, dynamic behaviors like displacement (x1, xAH, xV1), charge (q), and piezo output voltage (Vp) were also tracked to validate the sensor's performance under harmonic excitation. The charge-to-voltage conversion follows equation 10.

$$V_p(t) = \frac{q(t)}{C_p} \quad (10)$$

where C_p is the piezoelectric capacitance. Charge oscillations differed significantly between points due to modal shape and local acceleration variations while no contrast observed among dynamic behaviours.

Table 2. *Simulated Energy Storage and Peak Power for Each Facade Point.*

Facade Point	Max V_{bat} (V)	Total Energy E (J)	Avg Power (W)	Max Power (W)
Scenario 1	2.97486	3.6	0.24	0.25
Scenario 2	2.97492	4.2	0.28	0.31
Scenario 3	2.97488	3.9	0.26	0.27
Scenario 4	2.97491	4.2	0.28	0.3
Scenario 5	2.97499	5.55	0.37	0.39
Scenario 6	2.97496	5.1	0.34	0.36
Scenario 7	2.97501	6.0	0.4	0.43
Scenario 8	2.97503	6.15	0.41	0.44

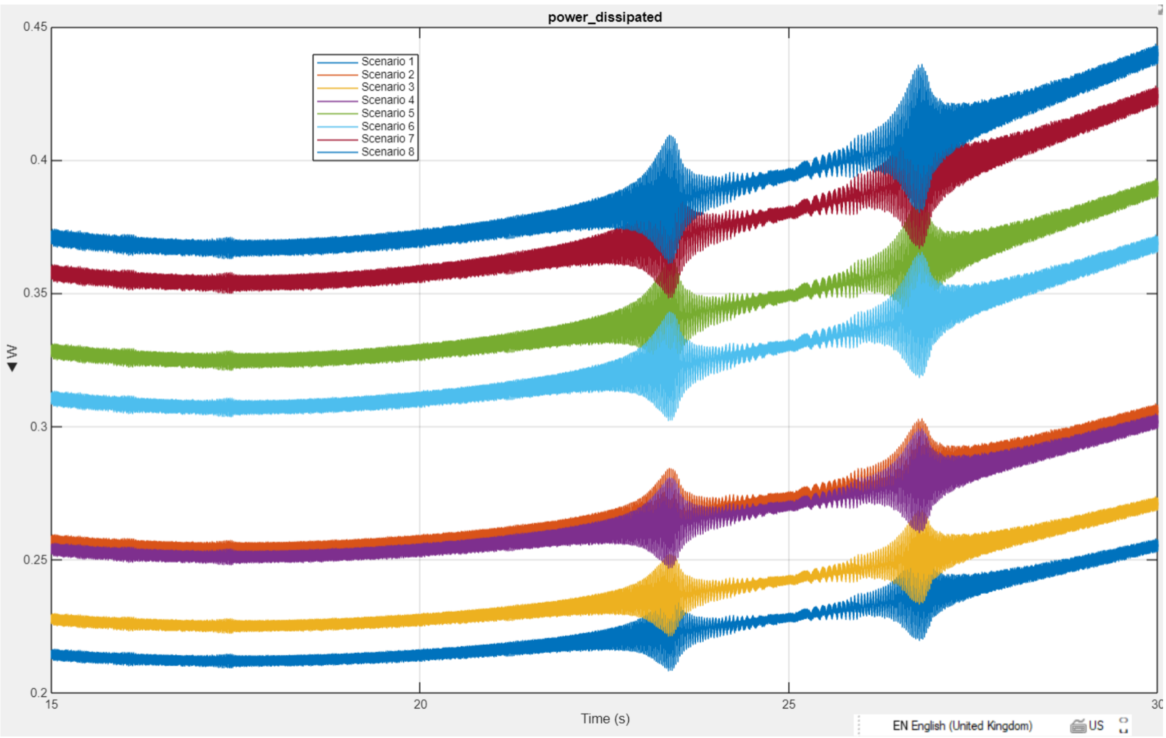

Fig. 6. Instantaneous power dissipation for each facade scenario.

3.3. Comparative Analysis

The results indicate that facade point scenario 8 demonstrated the highest energy storage, with a peak battery voltage of 804.2 V in 30 seconds and total energy output of 6.15 J. In contrast, point scenario 1 showed minimal energy capture, which does not seem feasible to be used for energy harvesting considering the piezoelectric technology costs, highlighting the importance of sensor placement in vibration energy harvesting systems.

The comparative results reveal that Scenario 5, which corresponds to the middle point of the lower floor, demonstrates a higher energy harvesting potential than scenario 6 which is located in higher floors but corner panels. This outcome contrasts with expectations that higher facade positions might always receive stronger wind loads regardless of corner or middle location. Instead, the results clearly suggest that harvesting potential is more strongly influenced by the pressure exerted on the tilted panel than by general parameters like the coefficient of pressure (CPe) across the facade.

As illustrated in Fig. 7, Scenario 5, 7 and 8 yielded a peak voltage of 8.92503 V and stored energy of 17.7 J (in total), surpassing all other locations sum up. Scenarios near the building's corners or on lower floors (e.g., Scenarios 4, 2 and 6) underperformed, likely due to local vibration mismatches and lower effective dynamic pressure at those locations.

This insight has significant implications for facade-integrated piezoelectric systems. It suggests that energy harvesting performance can be optimized not merely by geometric or aerodynamic modeling (e.g., using wind pressure coefficients), but by targeting specific pressure-intensive zones on the façade, particularly those where wind-induced vibrations align closely with piezo bender resonance characteristics. Fig. 8 visualizes the optimal harvesting zones, recommending a targeted installation strategy and motivating further research into location-specific energy harvesting system design.

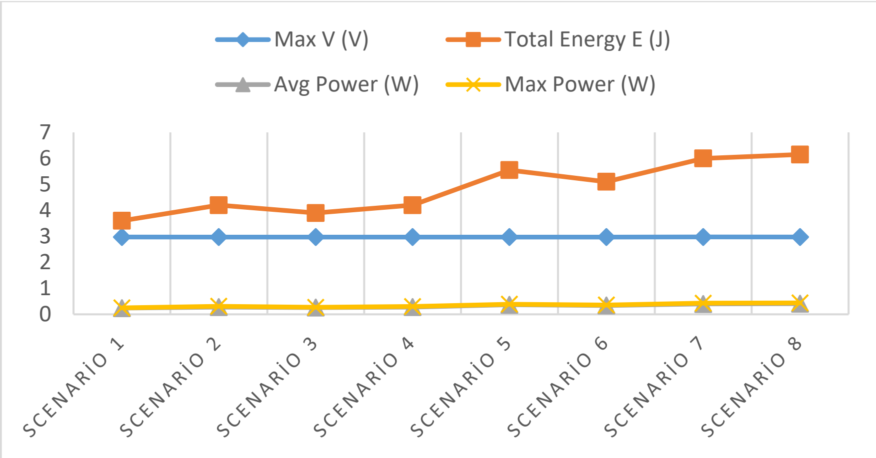

Fig. 7. Comparison of cumulative energy stored for all scenarios.

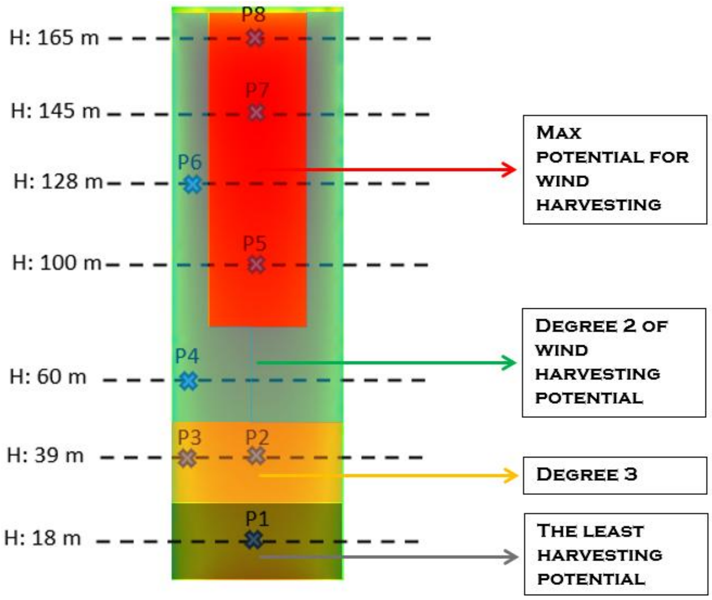

Fig. 8. Energy harvesting performance zoning comparison among 8 defined scenarios, highlighting the optimal harvesting location.

Furthermore, this analysis opens the door to using customized piezoelectric elements or resonant circuits tailored to the specific frequency content of each point, potentially enhancing total harvested energy. Rather than using a uniform 125 Hz sensor for all locations, sensors can be selected or tuned individually to match the dominant vibration frequencies observed at each facade segment. Therefore, optimal sensor placement guided by wind-induced vibration analysis is crucial for maximizing output in façade integrated piezo systems.

4. Limitation and Future gap

The current study assumes ideal mechanical-to-electrical conversion and neglects real-world nonlinearities such as aging, thermal drift, and load matching losses. The simulations presented offer valuable insights into point specific piezoelectric harvesting, but several limitations must be acknowledged:

The façade engineering design was assumed to be ideal, with simplified vibration input and linear behavior of piezo materials.

The harvesting circuitry does not account for advanced power conditioning, rectification losses, or dynamic load variation.

Economic feasibility, including the cost-benefit analysis of distributed piezo installation versus centralized strategies, remains unexplored.

Future research may focus on experimental validation of facade vibration and energy harvesting using scaled prototypes or full-size test beds, economic analysis of facade energy harvesting systems, particularly in high-potential zones, development of adaptive circuits and multi-frequency harvesters or sensor arrays, each matched to local vibration conditions for maximum efficiency and integration of realtime monitoring systems to manage harvesting performance and maintenance.

This study lays the foundation for a site-specific, performance-optimized harvesting strategy where design decisions can be driven by actual facade behavior under dynamic wind loads, paving the way for smarter and more energy wise building skins.

The impacts of Metaverse on architecture

Negin Khojasteh[*1], Sibel Macka Kalfa[1]

[1] Karadeniz Technical University, Department of Architecture ,61080 Trabzon, Türkiye

Abstract.The metaverse is a world that transcends our imagination, offering an online virtual space to create more experiences without considering geographic location. It is defined as a digital universe that surpasses the boundaries of the physical world. This digital realm, generated by computers, provides an experience beyond reality, enabling users to express themselves, communicate, and participate in various activities. The metaverse promises to be one of the cornerstones of future digital life by presenting innovative opportunities in areas such as business, education, architecture, engineering and entertainment. This universe, where physical spatial constraints become insignificant and a permanent virtual space for commercial interactions is provided, is regarded as the future of the internet. Over its nearly thirty-year history, the metaverse has continuously evolved through technological innovations, gaining broader recognition in 2021 when Mark Zuckerberg rebranded Facebook as "Meta." This development has enhanced the understanding of the metaverse's potential and increased interest in the digital world. In architecture and engineering, the opportunities offered by the metaverse are expected to be revolutionary. Predictions regarding its future impact suggest that the metaverse will drive significant transformation in these fields. Within this context, this study examines the potential contributions, advantages, and disadvantages of the metaverse in architecture. It has been observed that the metaverse facilitates virtual design and engineering processes, offering significant benefits in terms of time and cost. However, challenges such as infrastructure deficiencies and standardization processes have also been identified. Such evaluations are critical for better understanding the role of the metaverse in architecture.

Keywords: Metaverse, Architecture, Game Engines, Virtual World

1. Introduction

The concept of the "Metaverse" was first introduced by Neal Stephenson in his 1992 science fiction novel *Snow Crash*, where it was depicted as a virtual reality space used by characters to escape authoritarian control (Stephenson, 2003). This foundational idea inspired subsequent real-world applications aimed at creating immersive virtual environments.

In 2003, Linden Lab launched *Second Life*, an open-source, visually-driven social platform that allowed users to interact through three-dimensional avatars in an online world (Linden Research, Inc., 2022). As one of the earliest practical applications of the Metaverse, *Second Life* facilitated a wide range of activities, including socializing, commerce, and creative content generation. The evolution of the Metaverse continued with the rise of major social media platforms. In February 2004, Facebook was introduced as "TheFacebook.com," initially serving as a social networking site connecting individuals through online profiles and interactions (Phillips, 2007). It quickly expanded its user base and functionality, laying the groundwork for more integrated digital experiences.

A significant milestone in the development of the Metaverse occurred in 2021, when Mark Zuckerberg announced that Facebook would rebrand as "Meta," signaling a strategic shift toward building a comprehensive Metaverse ecosystem (Meta Platforms, Inc., 2021**).** The idea of immersive virtual worlds was further popularized by Ernest Cline's 2011 science fiction novel *Ready Player One*, which was adapted into a feature film in 2018 (Cline, 2012), (Spielberg et al., 2018). In 2014, Google launched *Google Cardboard*, a low-cost headset that made augmented reality (AR) and virtual reality (VR) experiences accessible to a wider audience (Smith, 2022), (Muensterer et al., 2014). In 2021, following Facebook's rebranding, two additional companies released eyeglass-like VR headsets—*Ray-Ban Stories* and *HTC Vive Flow*—alongside other wearable technologies, further enhancing the integration of virtual experiences into daily life (Rodriguez, 2022). These developments collectively reflect the rapid evolution and growing adoption of Metaverse-related technologies, underscoring their

[*] Corresponding author, E-mail: neginkhojasteh76@gmail.com

https://doi.org/10.31462/icearc2025_a_aen_548

transformative impact across various sectors. In Fig. 1, the metaverse evolution trajectory is displayed step by step, allowing for a detailed analysis of the progress of related technologies.

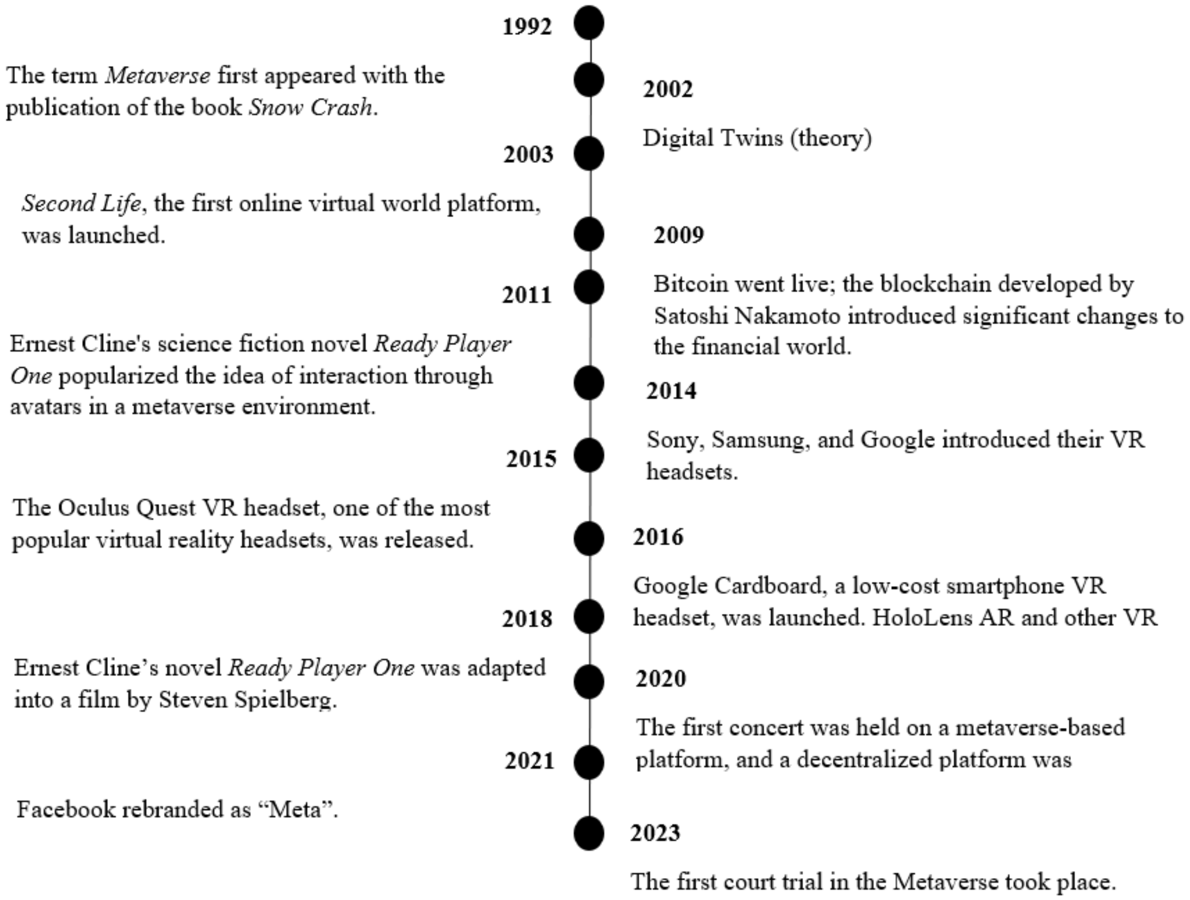

Fig. 1. Timeline of the development of the metaverse, with key events from 1992 to 2023.

When we examine the historical development of the internet, we see that with Web 1.0, the internet entered our lives. Later, with the development of Web 2.0, technologies such as Ajax, JavaScript, XML, DOM, REST, and CSS became integral to online experiences. Web 2.0 enabled users to engage in social activities and interact with one another (Tim Berners-Lee,1998). With the advent of Web 3.0, the concept of the metaverse was introduced and continues to evolve. The metaverse is defined as a three-dimensional virtual environment in which users can communicate and interact through digital avatars they create for themselves, engaging in various activities such as entertainment, commerce, gaming, and education (Kuş,2021), (Cheng et al., 2022). The metaverse enables and supports a wide range of technological advancements.

There are various software programs designed to enhance the understanding of this environment and to provide better services to users. These include applications used for 3D modeling, design, and other related tasks (Jovanovic et al., 2022), (Sparkes, 2021). Among the most commonly used programs are AutoCAD, SketchUp, Revit, Blender, Rhino, 3ds Max, ArchiCAD, SolidWorks, Unity, Unreal Engine, and Lumion. The metaverse is not a new concept; it has been a part of our lives for many years and continues to evolve and be updated to offer improved services (Duan et al., 2021), (Tlili et al., 2022), (Wu et al., 2022).

Given the growing number of users in the metaverse today, developers are making significant efforts to enhance the accessibility and attractiveness of this digital world. These efforts aim to draw a broader audience into this captivating virtual environment (Dwivedi et al., 2022), (Yu, 2022). Especially in recent years, the term metaverse has been used very frequently in the fields of engineering and architecture. However, due to the small number of applications on the subject, the inadequacy of the number of experts, and the fact that people working in the field do not know what the metaverse is for, its advantages and disadvantages, studies on the subject have been insufficient. Therefore, in this study, the advantages and disadvantages of the metaverse concept in the context of architecture have been examined, its potential contributions in architectural applications have been evaluated, and it has been tried to explain how this digital field can be integrated into architectural applications.

1.1. Metaverse Technologies

Metaverse technologies are illustrated schematically in Fig. 2. They contributes to the development of many technological innovations, from artificial intelligence to the Internet of Things

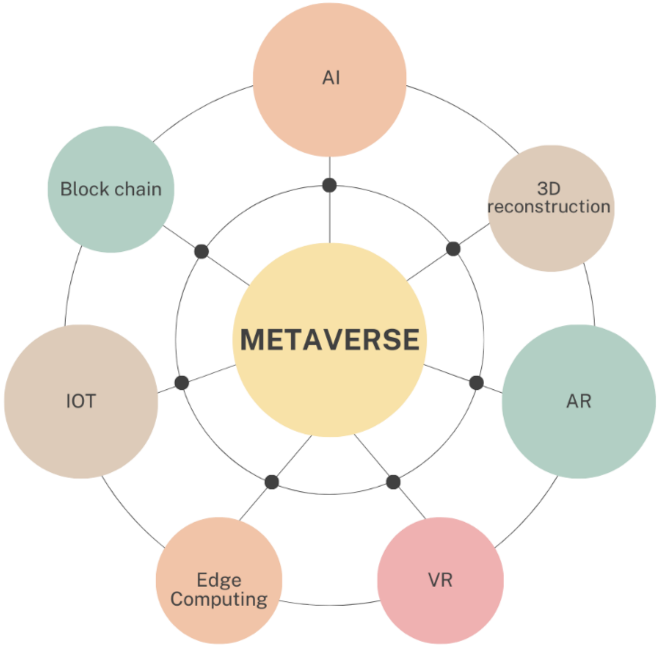

Fig. 2. The Metaverse and the technologies it works with

Artificial intelligence enhances performance in the metaverse by accelerating processes and delivering capabilities beyond human limits. Through intelligent algorithms, users can engage in decision-making and process automation. Additionally, under the guidance of content analysis, speech processing, and computer vision technologies, user experience and efficiency within the metaverse are significantly improved (Zhou et al.,2023).
Augmented Reality (AR) and Virtual Reality (VR) provide comprehensive three-dimensional experiences. AR integrates digital images and characters into the real world, making it accessible to broader audiences through smartphones and digital cameras. In contrast, VR offers opportunities to incorporate more realistic elements into the metaverse through physical simulations (Al-Ghaili et al., 2022).

Accessing and navigating the metaverse requires physical devices and accessories such as sensors, smart glasses, and headsets. Extended Reality (XR), or Cross Reality, is an umbrella term encompassing various immersive technologies that represent electronic and digital environments where data is displayed and projected. XR includes Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR). Across all dimensions of XR, individuals observe and interact within fully or partially synthetic digital environments generated by technology. These tools enhance user interaction with virtual spaces and offer more immersive and realistic experiences (Krütünlüoglu et al., 2022), (Yang et al., 2022).

1.2. Metaverse Layers

The metaverse consists of seven distinct layers, schematically illustrated in Fig. 3. This model, outlined by Jon Radoff in "Building the Metaverse," presents the "Seven Layers of the Metaverse," each representing a crucial aspect of the metaverse ecosystem. The layers are as follows:

1. Experience: Focuses on user activities and interactions in the metaverse, such as gaming, socializing, esports, theater, and shopping.
2. Discovery: Involves locating and organizing content within the metaverse, supported by advertising networks, social platforms, curation tools, ratings, marketplaces, and agents.
3. Creator Economy: Highlights tools and platforms for content creation, asset trading, workflows, and commerce that enable users to produce and monetize their contributions.
4. Spatial Computing: Covers technologies like 3D engines, VR/AR/XR, multi-user interfaces, and geospatial mapping that empower immersive environments.
5. Decentralization: Ensures openness and autonomy in the metaverse through distributed technologies such as edge computing, AI agents, microservices, and blockchain.
6. Human Interface: Encompasses hardware and tools such as mobile devices, smart glasses, wearables, haptic systems, gesture-based interfaces, voice controls, and neural interfaces that facilitate user interaction.

7. Infrastructure: Includes foundational technologies such as 5G, Wi-Fi 6, 6G, cloud computing, advanced materials, GPUs, and MEMS that support the entire metaverse framework.

In Fig. 3, the seven-layer structure of the metaverse is presented as a step-by-step process that illustrates its multi-dimensional framework.

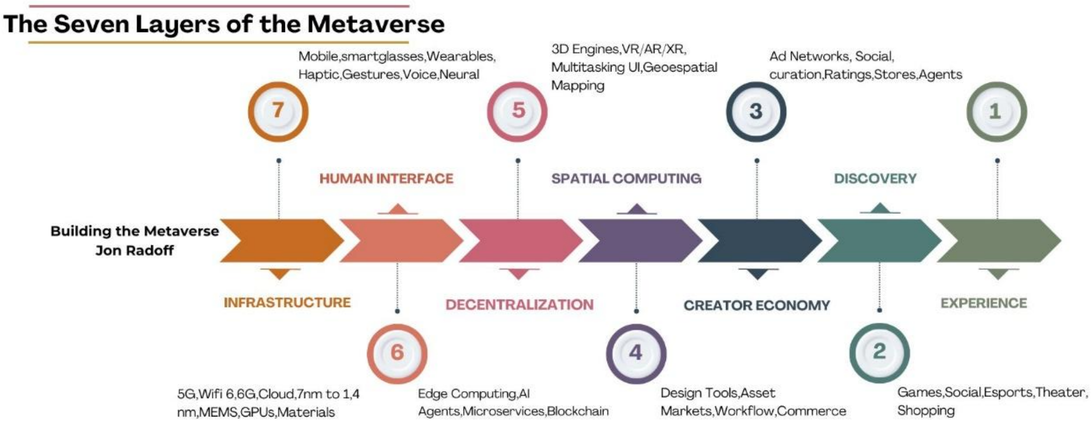

Fig. 3. Seven-layer metaverse platform (Radoff, 2021).

1.3. Literature Review

In the literature, numerous studies have been conducted on the metaverse in recent years. As a highly interdisciplinary subject that enables collaboration across diverse fields, the metaverse holds significant potential. A review of publications using the keyword “metaverse” in the Web of Science database over the past ten years is presented in Fig. 4.

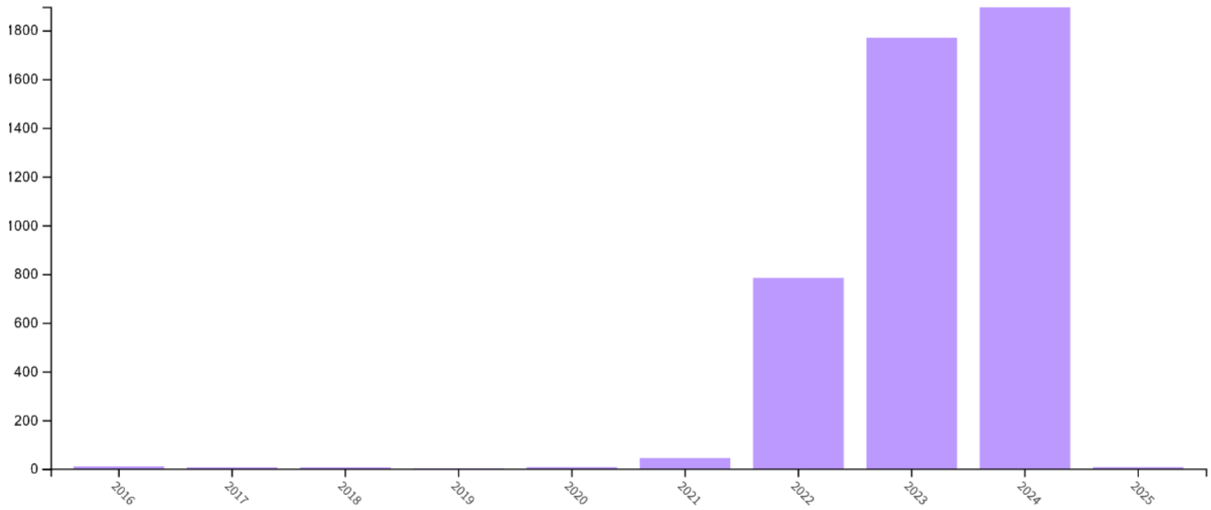

Fig. 4. Annual Growth of Metaverse Publishing

According to Fig. 4, the number of publications related to the metaverse remained quite low between 2007 and 2020. However, in recent years—particularly in 2023 and 2024—there has been a significant surge in publication numbers, reaching a peak, and this upward trend is expected to continue. This spike can be attributed to technological advancements and the growing interest of researchers and industries in the opportunities offered by the metaverse. As shown in Fig. 5, research on the metaverse to date has predominantly focused on the fields of computer science, engineering, and communications. This topic map also reveals how metaverse-related studies are distributed across other academic disciplines.

Fig. 5. The research areas where the concept of metaverse has been studied the most to date.

While studies on the metaverse are predominantly concentrated in the fields of computer science, engineering, and communications, the field of architecture does not rank among the top 25 categories and is represented by only 20 publications recorded in the Web of Science database (as summarized in Table 1) In addition, a review conducted on the Web of Science database regarding metaverse and architecture revealed a total of 20 publications, of which 13 were examined in detail. In the architecture category, only a limited number of studies were found within the selected years. This scarcity of research suggests that the topic is expected to gain significant importance in the near future, especially within the architectural field. It is clear that the present study addresses a critical gap in the literature. Table 1 below presents the publications identified within the scope of architecture.

Table 1. Overview of Recent Scholarly Works on Architecture and the Metaverse (2021–2024)

Line	Authors	Title	Publication Year	Type
1.	Yu Kongjian	From Slime Mold to Meta	2021	Editorial Article

Table 1. continued

10.	Ali Azizi Naserabad, Abdulhamid Ghanbaran	Computational approach in presentation a parametric method to construct hybrid girihs (hybrid Islamic geometric patterns)	2024	Research Article
11.	Marios Tsiliakos, Stefan Bassing, Dehui Tian, Jueqiu Gong, Qixuan Huang, Qiyue Huang, Huizhao Liu	EDUVERSE Exploring Gamification and the Metaverse in Architectural Pedagogy	2024	Research Article
12.	Yihan Lu, Zhouyu Zhang, Yaoping Zhang, and Li Li	Virtual Reality Architecture Teaching Application Based on Unity Platform-Taking a Small Architect's Metaverse Application as an Example	2024	Academic Chapter in a Book (Published in *CDRF 2023, Phygital Intelligence*)
13.	Beibei Zang, Tianjun Wang, and Dan Luo	The Embodied Interaction with XR Metaverse Space Based on Pneumatic Actuated Structures	2024	Academic Chapter in a Book (Published in *CDRF 2023, Phygital Intelligence*)

Inspired by the spatial abilities of slime molds and Facebook's rebranding to Meta, YU Kongjian reflects on human spatial cognition, while Dalibor Dzurilla and Henri Achten examine the role of traditional and digital sketching in human-computer interaction and client communication. In a related vein, Alice Bucknell explores the fusion of reality and the digital realm through game engines, enabling the creation of narrative environments shaped by both human and nonhuman intelligence. Kas Oosterhuis, drawing on digital technology and the concept of real-time architecture, envisions urban planning that adapts dynamically to its inhabitants. Elizabeth Wagemann analyzes urban discontent and utopian visions as imagined by students during lockdown workshops, while Flavio Martella and Marco Enia investigate the intersection of material and virtual dimensions in emerging spatial conditions. Simultaneously, Ali Azizi Naserabad and Abdulhamid Ghanbaran identify and generate systematic and non-systematic hybrid girih patterns rooted in historical Islamic geometry. Claudia Bernasconi and Libby Balter Blume explore virtual social spaces in architecture through multidisciplinary concepts of space, place, and context. Marios Tsiliakos and colleagues introduce Eduverse, a gamified metaverse platform for architectural education, leveraging game engines and user experience design. Yihan Lu and collaborators focus on architectural education for children through prefabricated blocks and PC-based tools. Meanwhile, Walaiporn Nakapan and colleagues develop a metaverse platform centered on Singapore, blending real and imagined architecture to enhance user engagement. Beibei Zang and team break sensory boundaries between the physical and the metaverse using XR systems with pneumatic wearables. Finally, Micaela Mantegna and Marcelo Rinesi argue that virtual spaces are as real as physical ones, urging architects to extend their intellectual and visual skills beyond the discipline to democratize spatial agency and counter neoliberal control. As can be seen from the studies that have been done in literature, the metaverse has begun to affect architecture. It is clear that this effect will spread to a larger area in the coming years.

2. Advantages and Disadvantages of the Metaverse

It is important to evaluate the advantages and disadvantages of the Metaverse in order to determine whether it offers significant benefits and to identify the areas in which it may have positive or negative impacts. For example, among its advantages are the ability to engage in realistic interactions with other users and the potential for implementing educational scenarios. On the other hand, disadvantages include the high cost of required hardware and the risk of users becoming dependent on the virtual world. Table 2 provides detailed advantages and disadvantages of the metaverse.

Table 2. Advantages and Disadvantages of Metaverse

Advantages	Disadvantages
• Provides users with the ability to interact with other users, real-world objects, and any emerging virtual scenarios. • Physical laws are applied in the virtual environment just as in the real world (physics-based simulations) . • Through digital twins in the metaverse and blockchain-supported logistics, transparency and visibility among stakeholders are enhanced, facilitating processes such as product traceability, smart contracts, and payments. • Manufacturers should collect data from processes, aggregate it, and use interoperability protocols to connect it across the supply chain. • It will have its own virtual economy enabled by digital currencies or NFTs.	• Prolonged use of the metaverse may lead to mental health issues similar to those caused by social media and gaming addiction, and can blur the line between the real and virtual worlds. • Internet speed is still very low • VR headsets need to be more ergonomic and lightweight . • As more data is collected in the metaverse, concerns regarding privacy, security, and identity management become significant challenges—exacerbated by the decentralized nature of the environment . • The advanced VR equipment required for the best metaverse experience is not yet widely available or affordable. The high cost of necessary devices limits widespread adoption. • This process requires a significant amount of energy.

Table 2 provides a comprehensive overview of both the opportunities and risks within the metaverse ecosystem. The findings indicate that, alongside innovations such as realistic interactions in virtual environments, digital twin applications, and NFT-based economies, limitations such as high costs, ergonomic concerns, and the potential for dependency must also be considered. To examine the advantages and disadvantages of the metaverse and to analyze its architectural aspects, several tables have been prepared. The following tables present these elements in a comprehensive and categorized manner.

2.1. Advantages and Disadvantages of Metaverse in terms of Architecture

Table 3 summarizes the advantages and disadvantages of architectural applications within metaverse environments, highlighting key aspects related to the design, use, and experience of virtual spaces. It also addresses the opportunities and limitations encountered across a broad spectrum—from student projects to professional applications—offering a comprehensive evaluation that can inform future architectural design processes.

Table 3. Advantages and Disadvantages of Metaverse in Architecture

Advantages	Disadvantages
• Since students are not required to physically visit construction sites, they avoid the risks associated with such visits, including safety hazards.	• Students reported difficulties in understanding scale, materiality, and the real-world experience of construction sites.
• The ability to navigate through different stages of the construction process in a virtual environment enhances students' understanding .	• Students reported experiencing dizziness and discomfort after prolonged use of smartphone headsets.
• Technologies such as Augmented Reality (AR) provide rich and immersive educational experiences that help students comprehend complex architectural concepts in an interactive and dynamic manner.	• Virtual environments, including metaverse platforms, often lack haptic feedback, making it difficult for students to fully understand material properties and the real scale of building elements.
• They offer continuous access to learning environments and enable students to revisit various stages of construction projects without the need for travel.	• Public and professional awareness of the topic remains limited; seminars and educational outreach are needed to address this gap.
• By integrating AR, VR, and digital interaction, metaverse environments cater to diverse student learning preferences.	• There is still limited understanding of this subject among individuals, and acquiring proficiency in it requires familiarity with a wide range of platforms.
• For architects and urban planners, the metaverse represents a new trend and opportunity for 3D visualization, 3D design, and their further development.	

This table reveals that while the metaverse architecture offers innovative design and educational opportunities in virtual environments, it creates various difficulties in users' interaction with the real world. The findings show that, despite the enrichment of the spatial experience, more research is needed on issues such as technological infrastructure, ergonomics and sustainability. In this way, the architectural dimension of future metaverse applications can become more functional and user-friendly.

3. Examination of Metaverse Applications in Architecture

In recent years, the number of architectural applications designed on metaverse platforms has been increasing. World-famous architectural offices are creating different designs on metaverse platforms. The most effective of these designs are Liberland city, José Cuervo Metadistillery and Metaserai. In this study, these designs were detail analysed. Liberland city that the digital city project was designed by Zaha Hadid Architects,. This design aims to create autonomous living spaces in the metaverse environment and allow users to experience digital interactions within sustainable urban structures. The Liberland Metaverse, where residents can buy vacant plots centered around a curated urban core, and access them as avatars. The community features hyper-realistic districts that encourage urban self-governance and zones where the absence of urban planning "allows for a spontaneous order via a free-wheeling discovery process". The project also comes as a response to the world's transformative and emerging notion to end stagnation and push for universal prosperity. The metaverse's open and transparent decentralized autonomous organization will have much greater demand and appeal over centralized corporate ventures, further accelerating this urban transformation. In Fig. 6., visuals of Liberland city are given.

Fig. 6. Liberland Metaverse City

Rojkind Arquitectos has ventured into the metaverse with the José Cuervo Metadistillery, a virtual experience center designed to foster social interaction and brand engagement. Inspired by the roots of the agave plant, the structure symbolizes connectivity and cultural heritage. Located within the Decentraland platform, the Metadistillery offers immersive activities such as a barrel maze, a floating volleyball pool, and a luminous agave garden, all culminating in a virtual bar to enhance communal experiences. This project exemplifies the potential of digital architecture to create inclusive, interactive spaces that transcend physical limitations. To create the Metadistillery, Rojkind Arquitectos collaborated with a group of experts and designers specializing in digital experiences: the agency Ache, specialized in creative development; the expert study in the Metaverse, Tangible; the largest video game district, Decentraland, the developers of the experience, Vegas City, Mekanism as a marketing agency; and the UK based dining experience experts, Bompass & Parr, tasked with creating the aesthetic and consumer experience. Within the infinitely diverse paths of "unique experiences," the digital world has permeated the imagination of millions of young people and created common environments with intuitive languages of interaction that pose digital challenges, where any subject can acquire an alternate identity through avatars in a new social context. In Fig. 7., visuals of José Cuervo Metadistillery are given.

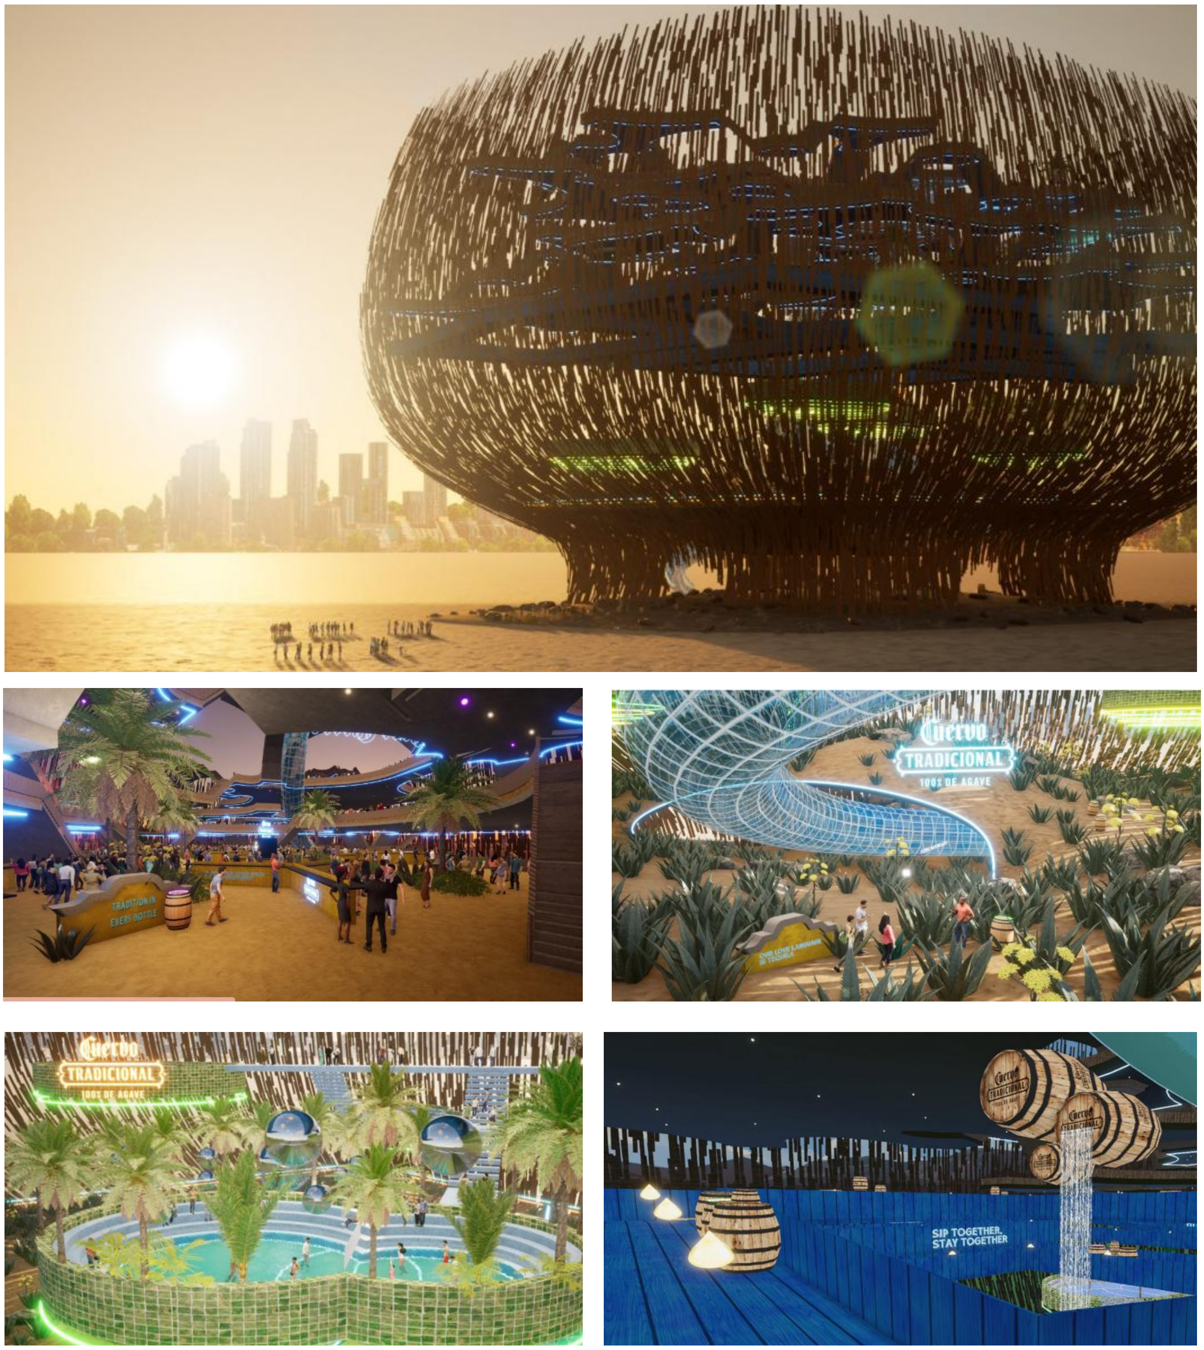

Fig. 7. José Cuervo Metadistillery

The metaverse platform pax.world has collaborated with renowned architecture firms Grimshaw, HWKN, Farshid Moussavi, and WHY to create "Metaserai," a series of virtual social hubs inspired by the Silk Road's caravanserais. These hubs are designed to host cultural, social, and educational events such as concerts, theater performances, digital art exhibitions, markets, lectures, and festivals. Each architectural firm offers its unique interpretation of the Metaserai concept, aiming to foster community interaction and cultural exchange within the metaverse. The project envisions a decentralized virtual society governed by a Decentralized Autonomous Organization (DAO), with Metaserai hubs serving as communal centers amidst privately owned virtual lands. The structure takes its cue from the architectural features of the caravanserai, a simple structure surrounding a central courtyard and watering point. The cuboid shape appears to levitate in its location. As it has no physical connections to the ground, visitors can enter through spherical follies or gates. The interactions between users will trigger a flow of data which will, in turn, influence the bespoke spaces, all generated from a kit-of-parts. This constantly shape-shifting architecture aims to reflect human interaction at a scale, speed, and scale impossible in a physical environment. In Fig. 8, visuals of Metaserai are given.

Fig. 8. "Metaserai," a series of virtual social hubs

4. Conclusions

Metaverse architecture offers innovative opportunities for design and education in virtual environments, it also presents various challenges in terms of users' interaction with the real world. The findings indicate that although spatial experiences are enriched, further research is needed in areas such as technological infrastructure, ergonomics, and sustainability. Addressing these aspects may lead to more functional and user-friendly architectural applications of the metaverse in the future.

Based on the previously discussed advantages and disadvantages, it is clear that the metaverse has existed in our world for several years, yet remains in continuous development. Like today's virtual platforms, the metaverse continues to evolve in response to user demands, offering increasing convenience in daily life. As a result, it holds the potential to further facilitate interactions and provide more immersive experiences.

However, like earlier technological advancements, the metaverse presents both opportunities and challenges. While it enhances flexibility and accessibility in learning, it is also limited by sensory constraints and technical issues—especially those critical to the accurate understanding of material perception and architectural scale. Addressing these challenges is essential to fully realize the potential of the metaverse in design and architecture.

Fire risk assessment of atrium-planned shopping centers: The case of Ceylan Karavil Park Shopping Mall

Sevilay Akalp *1, İdil Ayçam 2

1 Harran University, Department of Architecture, 63050 Şanlıurfa, Türkiye
2 Gazi University, Department of Architecture, 06570 Ankara, Türkiye

Abstract. Shopping centers are multifunctional public buildings designed to address a wide range of ergonomic needs, serving as spaces where various requirements of daily life are met and different user profiles converge. In the 21st century, shopping centers can be characterized as sheltered spaces with stabilized comfort conditions, designed to efficiently meet diverse needs within a short time frame while offering resilience to climatic conditions. In this context, given that users spend a significant portion of their time in these spaces, it is crucial to prioritize the design of transitional elements that connect indoor and outdoor spaces during the planning stages of such projects.The layout types aimed at increasing user potential must address fundamental requirements such as natural lighting, ventilation, and illumination. Among these design strategies, the atrium layout has emerged as a frequently preferred approach in shopping centers, particularly for its role in enhancing energy efficiency. However, ensuring fire safety in shopping centers with high human density is a critical concern. Within this framework, the study employs a case study method to evaluate the fire risk associated with atrium-planned shopping centers, focusing on Ceylan Karavil Park Shopping Mall located in Diyarbakır. The evaluation was conducted in accordance with the national fire precaution regulation**,** ensuring regulatory compliance in the assessment of fire safety components.The methodology incorporates on-site observations and regulatory compliance assessments to analyze fire escape routes, staircases, and both active and passive fire safety measures. The study concludes by proposing various recommendations to enhance fire safety in atrium-planned structures and emphasizes the need for broader research to support the safety performance of such buildings.

Keywords: Shopping Mall; Life Safety; Emergency; Fire; Diyarbakır; Emergency Action Plan (EAP)

1. Introduction

Shopping malls are not merely venues for fulfilling individuals' economic shopping needs but also multifunctional spaces for entertainment and social interaction. Shopping malls have become integral components of a widespread cultural phenomenon across all segments of society, regardless of age, economic status, or social class. Based on this phenomenon, stakeholders in the construction sector have been developing shopping mall projects to meet market demands. However, building designs must be prepared — starting from the early design stages and continuing through the operational period — within the framework of criteria such as fulfilling functional requirements, reliability, and usability (Marantika et al., 2020). In this context, shopping mall structures should not be designed solely on functionality or accessibility; the fact that these structures present a high fire risk must also be considered. In other words, ensuring fire safety in buildings with high occupant density constitutes an essential design strategy. Proper management of fire safety not only reduces the risk of fire and ensures the rapid and safe control of flames during a fire incident (Rubaratuka, 2013; Ahmad Sabri et al., 2023). The high fire loads characteristic of shopping malls necessitate the development of specific fire safety regulations. However, since fire safety measures and awareness are often not effectively communicated to the users of these spaces, the occurrence of related issues becomes inevitable (Othuman Mydin, 2013; Abdul Rahim et al., 2014).

Shopping mall structures are also considered gathering spaces that accommodate commercial, entertainment, and food and beverage functions. In particular, the upper floors, which house cinema halls and food courts, exhibit significantly high fire loads. Examining shopping mall unit plan typologies reveals that they often feature wide structures with atriums. While atriums contribute to energy-efficient solutions by providing natural lighting and illumination, they pose a significant fire risk, as fires can spread rapidly through these spaces. Therefore, atriums must be carefully evaluated as critical components of fire risk mitigation strategies.

* Corresponding author, E-mail: sevilayakalp@harran.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_552

According to the literature, fire causes are often linked to gas leaks, negligence, and short circuits (Hafiz Mohd Noor and Hussien, 2020). In this context, the restaurants, cafes, and fast-food chains operating within shopping malls — which utilize large-scale gas-operated kitchen equipment — present substantial fire risks due to potential gas leaks or insufficient maintenance of exhaust systems. Another significant fire hazard in shopping malls is the extensive network of electrical systems, including lighting fixtures and escalators. Short circuits within these systems can be significant sources of fire risk (McGrath, 2020; Uluç et al., 2022). Furthermore, human errors and a general lack of fire awareness among users contribute to fire risks in shopping mall structures. Thus, developing and implementing effective fire prevention systems are imperative for these highly vulnerable building types.

Fire protection systems are generally categorized into active and passive measures. Active fire protection systems respond to and suppress fires manually or automatically once a fire is detected. In contrast, passive fire protection systems aim to limit fire spread through architectural design features such as material selection, compartmentalization, and insulation, offering protection without requiring active intervention (Drysdale, 2011). An integrated approach combining active and passive fire protection systems is essential to ensure fire safety in shopping mall structures. Creating fire compartments can help confine fires to limited areas, particularly in buildings with high fire loads. In other words, using fire-resistant building materials and establishing fire-rated cells are key passive strategies. Another important passive fire protection measure involves the creation of refuge areas, especially necessary in shopping malls where the evacuation of large crowds can be challenging. Refuge areas are temporarily safe zones isolated from smoke and flames (Tabassum et al., 2014; Yunus, 2021). Among the active fire protection systems employed in shopping malls are fire alarm systems, fire suppression systems, sprinkler systems, and smoke control systems (Della-Giustina, 2014; Kodur et al., 2019). Critical components include emergency lighting, illuminated exit signage, and unobstructed evacuation routes (Marantika et al., 2020). Additionally, provisions for fire brigade access, such as designated parking areas for fire engines, must be incorporated into the design to facilitate emergency response operations (Kikwasi, 2015; Taylor et al., 2019).

In conventional large-scale urban fire analyses, shopping malls are often treated as anonymous structures within standard datasets, with individual spatial differences being overlooked. However, each shopping mall exhibits unique characteristics in terms of atrium design, spatial organization, and user density, necessitating that the fire safety performance of each structure be assessed within its own specific context. Particularly in buildings with atrium plans, the dynamics of fire spread differ significantly, rendering evaluations based on general assumptions inadequate. Therefore, site-specific, field-based analyses are required. By considering real usage conditions, user habits, and spatial changes that occur over time, the fire safety performance can be presented in a more realistic manner. This study was conducted to identify deficiencies in current practice and to provide scientific data support for the development of safety-oriented design and operational strategies in public buildings with high human circulation, such as atrium-planned shopping malls. In particular, following the devastating earthquakes that struck southeastern Türkiye on February 6, 2023, shopping malls have come to be regarded not only as commercial facilities but also as designated emergency gathering areas. This shift in perception has significantly increased the importance of ensuring that such buildings are safeguarded not only against earthquakes but also against other potential disasters, such as fires. In this regard, considering the high fire risks associated with atrium-planned shopping malls, a case study was conducted on Ceylan Karavil Park Shopping Mall — the largest shopping mall in Diyarbakır, located in the Southeastern Anatolia Region of Türkiye — to propose preventive strategies and recommendations for fire safety both before and during fire incidents. Through on-site observations, photographic documentation, and spatial analyses, fire escape routes, emergency staircases, and the active and passive fire protection systems utilized in the structure were identified, and recommendations for enhancing fire safety in atrium-planned shopping malls were developed.

2. Materials and methods

Within the scope of this study, the fire safety of shopping mall structures, categorized among atrium-planned commercial buildings, was investigated using the case study method, one of the qualitative research approaches. Ceylan Karavil Park Shopping Mall, one of the largest shopping centers in Diyarbakır, Southeastern Anatolia Region of Türkiye, was selected as the study area. Both spatial characteristics and fire safety equipment were examined through on-site observations following active and passive fire protection methods. Additionally, archival research was conducted within the records of the Diyarbakır Metropolitan Municipality, and relevant architectural and engineering documents of the building were analyzed.

The study's methodology includes comprehensive on-site investigations of fire doors, staircases, escape routes, and fire safety systems, in accordance with the provisions of the national fire regulation (Regulation on the Protection of Buildings from Fire, 2009). Fig. 1 presents the overall framework of the study's methodology.

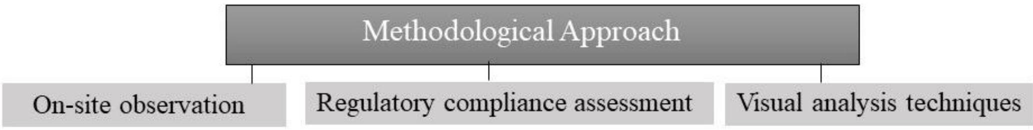

Fig. 1.Methodology of study

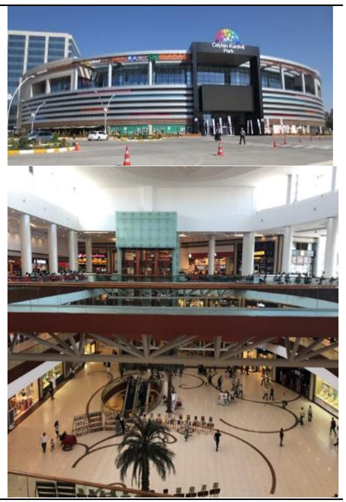
3. Results and discussion

The construction of Ceylan Karavil Shopping Mall, located in the Kayapınar district of Diyarbakır, commenced in 2008 and the mall was opened to the public in 2014. The project, designed by A Tasarım Architecture Office founded by Ali Osman Öztürk, stands among the significant commercial spaces in the Southeastern Anatolia Region of Türkiye.

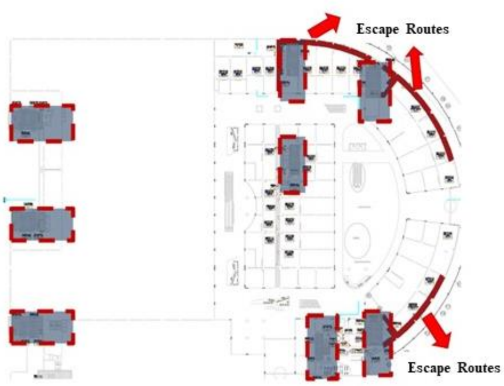
Table 1. General Information and Main Entrance View of Ceylan Karavil Shopping Mall (A Tasarım Mimarlık, 2025)

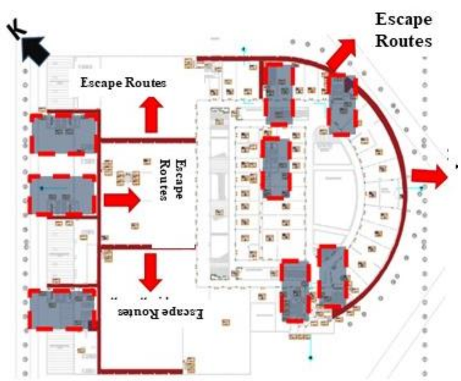
Project Type:	Shopping Mall
Project Location:	Diyarbakır/Turkey
Project Category:	Commercial
Architectural Design:	A Tasarım Architecture Office
Project Architect:	Ali Osman Öztürk
Construction Completion Year:	2014
Total Construction Area:	160,000 m²



The structure, located along Şanlıurfa Boulevard, which is recognized as the main arterial road of Diyarbakır, is also situated at a nodal point connecting the city's rapidly developing residential and commercial areas. The building features an atrium plan typology, and atriums and terraces have been designed to ensure the fluidity between interior and exterior spaces (A Tasarım, 2025).

Table 2. Locations of Escape Routes and Staircases (Compiled by the author from the Diyarbakır Yenişehir Municipality Archives)





Ground floor plan	First floor plan

Table 2 continued

	Second floor plan	Third floor plan

The building contains a total of 13 fire escape staircases. According to the Fire Protection Regulation (Resmi Gazete, 2009), the riser height of fire escape stairs must not exceed 18 cm, and the tread width must not be less than 20 cm. In the examined structure, it was determined that the tread width is 23 cm and the riser height is 17 cm. Therefore, it was confirmed that the staircase dimensions comply with the fire safety regulation requirements. The building also features three designated fire escape corridors. The escape route located on the southeastern façade curves to serve multiple fire staircases. Additionally, on the northwestern side of the building, vertical escape routes are connected to fire staircases through horizontal escape corridors. On the third floor plan, three independent fire escape corridors were identified. For fire staircases that are not directly connected to an escape corridor, fire lobbies equipped with a pressurization system have been designed to prevent the spread of fire into the staircases. The fourth floor serves as the roof level, where vertical shafts (ducts) are extended upward. In compliance with fire safety regulations, escape routes must be free from any obstructions. However, field observations revealed that in some floors, objects such as boxes and shopping carts were present on the escape paths, posing significant risks to the safe evacuation of occupants during a fire incident.

According to the provisions of the regulation, the minimum clear width of fire escape doors must be at least 80 cm, and the minimum door height must be at least 200 cm (Resmî Gazete, 2009). To ensure the safe evacuation of sufficient occupants during a fire emergency, the door dimensions along escape routes must be designed following these requirements. Furthermore, there must be no thresholds or obstacles in the areas where fire exit doors are located, allowing level and unobstructed passage.

In the evaluated structure, the fire exit doors' width was 100 cm, and no thresholds were observed. Exit doors leading into internal escape corridors or passageways must have fire resistance equivalent to main escape doors and be equipped with self-closing mechanisms. It was determined that all fire exit doors in the building had panic bars.

Fig. 2. Emergency exit doors of fire escape routes

In complex structures such as shopping malls, where multiple exits are available, it is essential to guide occupants correctly toward the appropriate exit doors during a fire emergency. In case of an emergency, the locations of exits to be used for evacuation must be clearly indicated within the building, and planned evacuation routes must be adequately displayed to occupants from every point inside the structure. Additionally, emergency exit signs must be installed at the height of 200 to 240 cm from the floor level (Resmî Gazete, 2009).

The emergency evacuation signs within the building are not positioned at a height between 200 and 240 cm as required. Instead, these signs were found to be installed at the ceiling height of each floor. However, when the building was evaluated as a whole, it was determined that the emergency wayfinding signs, lighting, and markings along the escape routes were implemented in accordance with the relevant regulations. Active fire safety measures consist of all precautions taken to detect a fire at its earliest stage and to automatically or manually intervene in order to limit potential damage and to facilitate rescue operations. These measures are categorized into two main groups: fire detection and alarm systems, and fire prevention and suppression systems (Resmî Gazete, 2009).

Fig. 3. Emergency evacuation signs

Fire detection and alarm systems must be activated through manual intervention, automatic detection, or signals received from a suppression system. Manual activation is provided via fire alarm buttons installed along fire escape routes. According to the relevant regulation, the accessibility distance to a fire alarm button from any point on a floor must not exceed 60 meters; in areas where disabled and elderly individuals are present, this distance must be reduced. Furthermore, all fire alarm buttons must be clearly visible, easily accessible, and mounted at a height between 110 and 130 cm from the floor (Resmî Gazete, 2009). Upon examination of the shopping mall structure, it was observed that some fire alarm buttons were obstructed by barriers. Although the accessibility distances were designed appropriately to accommodate individuals with disabilities and elderly users, the visibility of the alarm buttons was compromised by lighting fixtures or advertising panels belonging to individual stores.

Fig. 4. Sprinkler Systems

According to the regulation, fire alarms must be accessible, and no obstacles should be placed in front of them that would impair their visibility. However, in the examined building, it was observed that some fire alarms were obstructed by advertising panels (Fig. 5). Fire pumps are pumps that supply pressurized water to water-based fire suppression systems and are defined by their rated flow and rated pressure values (Resmî Gazete, 2009). In the event of a fire, water reservoirs must be provided to meet the water demand of the sprinkler systems. It was confirmed that the current building is equipped with water reservoirs.

Fig. 5. Fire alarm systems

According to the Fire Regulation, fire hose cabinets must be installed in healthcare, hotel, and commercial buildings with a construction area exceeding 3,000 m². In addition, electrical cabinets must remain closed, and the cables must be maintained without wear in order to prevent potential leakages. Upon examination of the building, it was determined that the fire hose cabinets and electrical cabinets were designed in accordance with the regulatory requirements.

Fig. 6. Fire Pumps and booster systems

4. Conclusions

Fire constitutes a significant risk factor, particularly in large-scale structures. In this context, it is essential to correctly implement fire safety measures in multifunctional building types, such as shopping malls, where occupant density is considerably high, to minimize potential losses. Accordingly, Ceylan Karavil Shopping Mall, recognized as one of the significant commercial structures in the Southeastern Anatolia Region, was selected as the case study area, and the fire safety aspects of the building were examined using qualitative research methods. The passive and active fire protection measures implemented in the structure were evaluated and compared in accordance with the Fire Regulations. It was determined that the fire hydrants, hoses, and reels intended for use during fire emergencies were designed in compliance with the regulatory standards.

It was determined that the fire suppression systems, sprinkler systems, fire hose cabinets, and water reservoirs were constructed following the relevant standards. However, during an emergency, the approach distance required for fire trucks was obstructed by various barriers, preventing efficient access. Moreover, although emergency signage and lighting are present within the building, their installation heights and placements do not comply with the prescribed standards.

Regarding passive fire protection measures, the examination revealed that the widths and dimensions of the escape corridors were initially designed in compliance with the regulations; however, due to improper usage, escape paths have been partially obstructed by waste materials and temporary barriers. It was also confirmed that the panic bar-equipped doors along fire escape routes comply with the required height and width standards and that the emergency lighting systems along escape and exit routes are actively functioning.

Additionally, the inspection of electrical cabinets and wiring revealed worn and aged cables throughout the building. Table 3 summarizes the existing active and passive fire protection measures, along with the identified deficiencies.

Table 3. General evaluation of active and passive fire protection measures in Ceylan Karavil shopping mall

Active Fire Protection Measures		Passive Fire Protection Measures	
Fire hydrants / Hose reels	√	Obstacles such as waste and trash present in escape routes	✖
Manual fire alarm call points partially obstructed by barriers		Directional signage and lighting along escape routes installed	√
Fire suppression systems	√	Stair risers designed according to regulations; however, non-slip bands were not applied	√
Sprinkler systems	√	Panic bars installed on fire escape doors	√
Fire boosters (hydrophores)	√	Fire escape corridor widths designed in accordance with regulations	√
Fire pumps	√	Presence of exposed installations in escape corridors that may cause electrical leakage	✖
Water reservoirs for fire systems	√	Lighting systems along escape and emergency exit routes functioning actively	√
Fire hose cabinets and extinguishers	√	Exit signage is functional and operational	√
Fire truck access to the building is difficult due to various obstructions	✖	Smoke doors designed with proper sealing as per regulations	√
		Directional signage and lighting are available, but installed at ceiling height rather than 200–240 cm	✖

Based on the findings, it was concluded that the building was initially designed in compliance with the Fire Regulations; however, improper use and lack of user awareness over time have significantly increased the fire risk. Consequently, the following recommendations are proposed for improving fire safety in shopping mall projects:

- Escape routes within the building must always be kept clear, and elements that may obstruct evacuation, such as waste, stands, and temporary exhibition units, should be regularly monitored and removed.
- Fire-resistant curtain systems or automatic smoke curtains should be installed on floors opening into atrium spaces to prevent the spread of smoke and flames during a fire incident.
- A continuous fire access road and sufficient maneuvering space should be provided around atrium-type shopping malls to ensure that fire trucks can rapidly and unobstructedly access the building. These areas must be kept free of obstructions at all times.

- To increase fire safety awareness, regular fire drills and emergency response training should be organized for shopping mall employees and visitors.
- Directional and emergency exit signs must be placed at locations that are easily visible both horizontally and vertically, considering the building's spatial volumes, and must comply with regulatory standards.
- A regular maintenance and repair program must be established to address the deterioration and aging of the building's electrical wiring.
- Implementation of Natural Smoke Ventilation Shafts: Automatic operable roof windows or natural ventilation shafts should be integrated into the upper sections of atrium spaces to ensure the vertical discharge of smoke during fire incidents.
- Installation of Fire Curtains Around Atrium Openings: To prevent the horizontal spread of smoke and hot gases, automatic fire curtain systems should be installed around atrium openings to create compartmentalized zones.
- Use of High-Discharge or Water Mist Sprinkler Systems: In addition to standard sprinkler installations, high-throw or water mist sprinkler systems should be employed to ensure effective fire suppression in large-volume atrium spaces.
- Regular Fire Evacuation Simulations with Computer-Based Tools: Performance-based fire evacuation simulations should be conducted periodically using specialized software to assess and optimize evacuation strategies based on user density and building configuration.
- Enhancement of Emergency Public Address Systems: In wide and tall atrium areas, emergency public address systems should be designed to deliver clear and audible evacuation instructions throughout the entire space, ensuring effective user guidance during emergencies.

Fire safety in shopping malls must not only be considered during the design stage but also actively maintained throughout the operational life of the building. Continuous monitoring, user awareness, and regular inspections are crucial to sustaining fire safety measures. The findings of this study highlight that fire safety requires ongoing user discipline and cannot be ensured solely through structural solutions. Awareness-raising initiatives and training programs aimed at employees and visitors are vital to ensuring the continuity of fire safety. Through such efforts, it is possible to eliminate human-related risks that hinder rapid intervention during a fire event, thereby minimizing potential loss of life and property.

Structural system interventions in adaptive reuse of industrial buildings: The case of Ayvalik Rahmi Koc Museum

Esma AVCIL*[1a], Necdet TORUNBALCI[2]

[1] *Istanbul Technical University, Graduate School, Department of Architecture, 34367 Istanbul, Türkiye*
[2] *Istanbul Technical University, Faculty of Architecture, Department of Structural and Earthquake Engineering, 34367 Istanbul, Türkiye*

Abstract. Industrial buildings reflect the changes and developments of the Industrial Revolution in both technology and social life. Furthermore, these buildings have gained a place in the social and economic memories of cities. However, such buildings have lost their functions over time and left idle within the developing urban fabric, facing the danger of extinction. The concept of 'Industrial Heritage' has emerged due to this. With this well-known worldwide concept, the principles of adaptive reuse, intervention methods, and function selection have also gained importance. In addition, the structural systems, architectural features, and values of these buildings have begun to be considered.

In this study, an industrial building located in Ayvalık, Balıkesir, which has an essential place among the industrial heritage examples in the Aegean Region, is examined. Although the structure preserved its original plan scheme, it has deteriorated significantly over time, and therefore, comprehensive repair and improvement were needed. In this research, the structural system requirements and interventions made to the structural system of this masonry structure which was previously used as an olive oil factory -later reused as a museum, were examined within the framework of national and international standards. In this context, the structural system types used in both cases of the structure were determined and categorized, and a structural system conformity assessment was evaluated based on the Turkish Building Earthquake Code (TBDY 2019), European Standards (Eurocode), and American Standards (ASCE/SEI).

This study aims to document the adaptive reuse applications of industrial buildings in Turkey, minimize errors in similar applications, and encourage the preservation of such structures.

Keywords: Industrial heritage; Structural system; Adaptive reuse; Conservation; Structural codes

1. Introduction

The Industrial Revolution began in England in the 18th century and quickly became one of the most crucial turning points affecting the world. With this revolution, production methods and production processes radically changed, as the production methods previously carried out in small-scale workshops using traditional techniques gave way to production in large spaces where mechanization was available. This transformation brought about the updating of the architectural and structural system designs of the buildings with the change of spatial requirements such as the need for wide open spaces. In the 20th century, while production methods continued to develop, the industrial zones that were previously located outside of the city center remained within the urban fabric. With the loss of their functions, the necessity and need for the preservation and adaptive reuse of industrial buildings emerged. While implementing these phenomena in industrial buildings, the structural system features, current status, and structural requirements of the buildings should also be taken into consideration. Since the industrial heritage buildings had not been designed according to modern-day engineering principles and regulations or had several damages because of wear and tear, lack of maintenance, problematic interventions on the structural system, exposure to atmospheric conditions, and earthquakes after long years of use, structural interventions may be required in the adaptive reuse processes of these buildings. Industrial heritage buildings should also be evaluated in spatial and socio-cultural contexts, and it is of great importance that new functions are selected by the original character of the structures and that the interventions are reversible, sustainable, and by conservation principles. In this context, the main purpose of the study is to analyze the structural system conditions of industrial heritage buildings before and after reuse implementations and to make an evaluation within the framework of national and

international standards (TBDY 2019, Eurocode 8, and ASCE/SEI 7-22) and general engineering principles in this process. In addition, the development of structural strategies for the sustainable transformation of existing structures and the promotion of cooperation between the disciplines of architecture, engineering, and conservation are also significant goals of the study.

2. Methodology

Firstly, in the structural documentation and information collection process, reports, photographs, historical building survey projects, restitution projects, and restoration projects of the case study were obtained from the architectural design team. The current condition and before the adaptive reuse process of the building, the structural system components also were cataloged in this step. Secondly, in the standard analysis phase, three different regulations from different regions (TBDY2019, Eurocode 8, and ASCE/SEI 7-22) and general engineering principles were examined, and an analysis table was prepared for the structural system requirements. The requirements of each standard and, in matters not specified by the standards, general engineering principles have been systematically identified. This table has also made it possible to analyze and compare the approaches of different regulations and general principles to structural requirements. In these analysis tables, basic structural design principles and structural system requirements for each type of structural system have been evaluated. Each parameter has been separately evaluated for each regulation and general engineering principle, and the results have been marked in the table. During the visualization phase, the irregularities were defined using a specific coding system that comes from the analysis table marked on the project drawings. The structural system, plan layout, and irregularities have been visualized using different line types and colors. In the results evaluation phase, the pre- and post-conditions of the building were evaluated in terms of the requirements of different regulations, and the similarities and differences between the standards were specified. This evaluation was made only in terms of compliance criteria, without any performance analysis. This four-step methodology allows for the systematic analysis of structural systems in adaptive reuse industrial buildings and the comparative evaluation of different regulations and standards.

3. Results and Findings

The olive oil factory, located in the Sakarya Neighborhood of Ayvalık District, Balıkesir province, between Government Street and the sea, was built by Anastasyos Yorgolos of Greek origin in 1910 and was transferred to the Emvali Metruka Administration during the exchange period. The ownership of the factory passed to Kahraman Bahadır, the Güldenoğul Family, and the Ertem Family, respectively (Yıldız, 2017). In the first land registry records, there was the phrase “masonry factory with oil house, soap house, machine and boiler room, and house” (EMR Architecture, 2024). In addition, it was determined that there was a building next to the factory building, which was in the use of the family, but this building was demolished by the Ertem Family in 1954 (Yıldız, 2017). General information about the structure is provided in Table 1 while, the condition of the building before adaptive reuse is shown in Fig. 1, and after reuse in Fig. 2.

3.1. Analysis of the Structural System Before and After Adaptive Reuse

3.1.1. Assessing the Condition and Structural System of the Building Before Adaptive Reuse

The structural system of the original building, which consists of two floors, the ground floor and the first floor, is a masonry carcass construction system supported by a timber frame system in order to increase the durability of traditional masonry buildings. The building in consideration is comprised of two rectangular sections, with common walls, and has an L-plan geometry. There is also a single-storey reinforced concrete structure with a rectangular plan measuring 4.69 m x 19.72 m attached to the building. The masonry stone has been used for the ground floor's exterior walls, and the first floor also had masonry stone and brick on the exterior walls. The thickness of exterior walls varies from 40 to 50 cm at the ground floor and approximately 25 to 35 cm at the first floor. The common walls between two partitions on the ground and first floors of the building had shifted from their axis over time, and also reinforced concrete structural elements added later had caused the wall to deteriorate on the ground floor. In addition, while the building's integrity was mostly preserved on the ground floor, the first floor was greatly damaged due to the collapse of the roof elements and part of the wall in the long direction (EMR Architecture, 2024). It was determined that the masonry brick wall on the middle axis of the longest facade of the first floor, which is 38.75 m long, had collapsed, most of the window openings on this facade had been covered with bricks, and some of the windows had disappeared. The most deteriorated/changed facade that had suffered in the building was that facade because of these reasons. There were ten circular-section timber posts, two rectangular-section timber posts, and one stone column on the ground floor, and eight nearly rectangular timber posts on the first floor. The cross-sectional dimensions of the vertical load-bearing elements on both floors varied, and the elements were not placed in a regular way. The two main rectangular sections of the building were covered with two hipped roofs at different levels, which were mostly damaged or collapsed. In this context a conformity assessment chart for the basic principles is given in Table 2, and structural system is Table 3.

Table 3. Continued.

8	Ratio of door/window opening lengths to wall length along the unsupported wall length	✓ Most favorable wall window/wall 1.7 m/8.32m= 0.25<0.40	✓ 1.7 m<8.32 m / 4=2.08m	– No criteria are specified in the standard.	✓ There is a wall in accordance with general principles.
		X Most unfavorable wall 16.37 m/23.15 m = 0.70>0.40	X 16.37 m>23.15 m/4	– No criteria are specified in the standard.	X Load-bearing walls should have low opening ratios
9	Distance between building corner and door/window opening	X Shortest wall: 0.92 m < 1.00 m (1st floor).	✓ Min. length > Wall height / 5 0.92 m > 0.64 m	X Min. length > 3 x wall thickness, 0.92 m < 1.50 m	X It is not suitable.
10	Wall length between door/window openings	X Shortest wall length 0.52 m<1.50 m (first floor)	✓ Total of opening heights/wall thickness 4,02 /10<30	X Min. length>6 x wall thickness, 0.52 m<3.00 m	X It is not suitable.
11	Perpendicular intersecting walls and openings	X Shortest wall length 0.64 m<1.00 m	– No criteria are specified in the standard.	X Min. length>3 x wall thickness, 0.64 m<1.50 m	X It is not suitable.
12	Length of solid wall between openings	✓ Longest wall opening 1.65 m<3.00 m	– No criteria are specified in the standard.	– No criteria are specified in the standard.	✓ Longest wall opening 1.65 m<3.00 m

It is seen that the condition of the building was quite problematic due to the fact that the loadbearing walls were not designed in a balanced way and the timber elements had an irregular and almost random placement. There is a presence of recesses and protrusions in the plan irregularity in all regulations and general design principles. This irregularity also corresponds to the creation of earthquake joints in empirical structural design principles. The fact that the two sections of the first floor of the structure have a height difference of approximately 30 cm from each other and the floors are not in the same plane/level also creates horizontal discontinuity. It is thought that the vertical elements/timber posts on which these floors were supported would be subjected to shear stress. The fact that the timber load-bearing elements were not orthogonal in the plan became largely compatible with all three standards. The load-bearing elements were not continuous between the floors and have different heights. Despite attempts to ensure proper load transfer from timber beams and roof trusses to masonry walls, irregular load transfer through these insufficient support elements caused damages to walls, slabs, and roofs. This discontinuity and the unbalanced placement of the loadbearing elements increased the tendency for torsional irregularity in the building. Thus, this design was negative according to all standards and general principles. There was no dilatation between the sections of different parts. This is also a reason for creating a seismic joint because two rectangular sections need to be separated by dilatation in order to move independently of each other under seismic loads and not affect each other negatively in the framework of modern regulations. Although the limit values regarding the arrangement of joints are clear in the context of empirical principles, these limit values are not clearly mentioned in modern regulations, but this separation is recommended in all three standards. According to the report, building height complies with TBDY2019 and ASCE-SEI 7/22 limits for both sections and general principles, despite no criteria in EC8. Ground floor height exceeds TBDY2019 and EC8 limits but remains within ASCE/SEI 7/22 values. The northeast facade's loadbearing wall, has thinned compared to other walls and decreased to 25 cm; it has a weak feature in terms of statics due to the lack of support elements for 38 m and having 33 window openings. In addition, the destruction that occurred in the middle axis of this wall is a result of the wall being weak in terms of statics. The largest unsupported length of the walls did not comply with all three standards and general principles. Although there is no limit specified in the standards regarding the total length limit of the load-bearing walls, according to general principles, the ratio of the load-bearing walls to the gross area of the structure in both directions is less than 0.25 on the ground floor, and this causes the loads to be unbalanced. When examining openings in load-bearing walls, the ratio of door/window opening lengths along the unsupported wall length to the wall length reduces the load bearing capacity; this ratio should not be less than 0.40 in TBDY2019 and 0.25 in EC8, while ACI 530-13 provides no specific ratio. The minimum length between openings is not suitable according to all standards and general principles. No criteria are specified in EC8 regarding the length between the wall and the opening that intersect each other perpendicularly. However, there were negative walls below the limit values given in TBDY2019 and ACI 530-13. The longest opening ratio in the plan is determined only in TBDY2019, the most negative wall, which is 165 cm long, is smaller than the limit criterion of 300 cm and remains within the limits. Irregularities identified through structural assessment are marked in Fig. 3 and Fig. 4.

3.1.2. Assessing the Condition and Structural System of the Building After Adaptive Reuse

The plan boundaries of the main factory building were preserved with the restoration applications, and the reinforced concrete building, which was added to the building later, was removed. In addition, the demolished building's location of the foundation walls was revealed with excavation works, and then the reconstruction of the building was carried out in the same area. A partial basement floor was built under the entire short section and a part of the long section to meet the museum's requirements, such as providing technical space and storage. When adding a basement floor, it was planned to preserve the original masonry wall up to the foundation level and to create an additional reinforced concrete wall around the basement floor (Emr Architecture Archive). The closed window openings were opened throughout the building; also, the damaged/lost doors and windows were remade based on the original ones. However, the door size was modified on some walls according to the museum's requirements. In addition, while the level differences of the ground floor's stone coated slab were corrected, the floor was also renewed. Applications such as completing the damaged wooden coverings and closing the gaps in the slabs that had occurred over time were implemented. Furthermore, the 30 cm level difference between the slabs was preserved while providing access between these two main parts on the first floor by a wooden ramp. Some restoration applications were implemented such as integration, renovation, and repair elements to the roof structure which was damaged and partially collapsed. Besides, these applications covers the preservation of the original timber beams and truss elements, and the reproduction of the structural elements with insufficient cross sections, which were determined to have been added later, in their original dimensions (Emr Architecture Archive). The reinforcement of the walls was done by applying injection to the stone and brick walls on the ground floor and by supporting the walls with sheet metal moldings added to the window openings in the short rectangular section in the plan on the first floor. However, since the opening dimensions in the long direction doubled and the wall thickness decreased to 25 cm, additional reinforcement methods had to be applied in this section. The demolished sections of the walls were completed with the original brick and bonding method. Furthermore, the areas that lost their quality were integrated with bricks after the decay process. In addition, some walls on the first floor were wrapped with fiberglass from the inside, and an additional brick layer was laid on the mesh in order to increase the thickness of the wall section. Also, the demolished chimney was integrated with the original height and bracelet detail in the approved restitution project. In this context a conformity assessment chart for the basic principles is given in Table 4, and structural system is Table 5.

The steel elements designed for system reinforcement purposes in the structure were mainly balanced, and the existing structural problems were tried to be eliminated. The irregularity of the recesses and protrusions in the plan that existed before of the building continued to exist because the architectural design could not be interrupted. It is thought that the applied structural reinforcement design was beneficial in reducing the negative impact of this situation. The fact that the level differences of the slabs continued after reuse, a horizontal discontinuity situation occurred within the framework of all standards and general principles. However, it is thought that the negative impact was eliminated by the steel frame system implementations. The steel frame system elements were designed orthogonally; it has become compatible according to all three standards in this aspect. Besides, continuity was provided in the vertical structural elements. It is thought that adding a partial basement floor to the building in line with the architectural need might have triggered different torsional and vertical settlement possibilities. It should not be overlooked that the partial basement floor, which rises on a reinforced concrete raft foundation and is completed with reinforced concrete shear walls around it and a reinforced concrete slab on top, creates a structural difference in terms of rigidity between it and the section without a basement. During the restoration, because of the necessity of preserving the original design, no dilatation was designed between two masses. This separation is recommended for the different behavior of the two sections under seismic loads in all three standards, just as it was before the adaptive reuse. According to the structural analysis report, the height of the structure complies with the TBDY2019 and ASCEI-SEI 7/22 limits for both sections and the general principles, although no limit is specified in EC8. The height of the ground floor is above the floor height limit values determined in TBDY2019 and EC8 and remains within the limit values in ASCEI-SEI 7/22. With the support of the structure with a steel frame system after the adaptive reuse, this issue improved for all three standards. The 100 cm long cantilever is considered reasonable since it is below 150 cm according to general engineering principles. The problematic long facade of the first floor, was supported with steel frame elements and reinforced by adding a row of brick with CFRP/Glass Fiber Reinforced Polymer to its section and increasing the section size. Thus, the wall thickness has become compliant with all three standards, EC6 and ACI 530-13 determined as sub-standards and general principles. The largest unsupported length of the loadbearing walls has become compliant with EC8 and ACI 530-13 with the applications made after the adaptive reuse. The 7.87 m unsupported wall on the ground floor exceeds the 7.50 m limit of TDBY19 but is at an acceptable level. Regarding the total length limit of the load-bearing walls, the ratio of the load-bearing walls to the gross area of the building in both directions of the building is less than 0.25 on the ground floor. It is thougth that the steel frame system, glass fiber polymer reinforcement, and increased wall thicknesses positively contribute to this situation. When the criteria for door/window opening lengths along the unsupported wall length are examined, the 3.97 m long wall on the first floor of the building shows negative characteristics according to all standards and general principles. The minimum length between window/door openings is also not suitable. As identified through structural assessment, the irregularities are marked in Fig. 5 and Fig. 6.

4. Conclusions

After the Industrial Revolution, production methods changed in the world, and over time, small workshops were replaced by industrial buildings with wide open spaces using new building materials. However, these buildings were abandoned with the further development of technology and remained idle in the city. The idea of adaptive reuse of the industrial buildings, which are significant witnesses of the city's memory, has gained importance with the emergence of phenomena such as industrial heritage and conservation. The adaptive reuse concept aims to reintroduce these buildings to the city without losing their value.

Since most industrial heritage buildings have not received engineering services and have been exposed to many dangers over time, their structural systems can also be damaged. However, in the adaptive reuse processes of these industrial buildings, the applications should be reversible and should be carried out in a way that the buildings do not lose their authenticity. When the interventions made to the structural systems of industrial heritage buildings are also affected by the standards and regulations of the regions where the buildings are located. In this context, the building in research, which was previously used as an oil factory but is now used as a museum building, was evaluated with the approach of different regions of the world to structural system design and to what extent the building in question meets the principles of these regulations.

The original condition of the building presents many negativities in terms of TBDY2019, EC8, and ASCEI-SEI 7/22 standards and general engineering design principles. It is seen that some of these negativities continued after the adaptive reuse due to the necessity to remain as loyal as possible to the original structure and the inability to make extensive changes in the plan contours in order not to deteriorate the original architectural design.

The structural problems in the building have been mostly corrected and the building has become compliant not only with TBDY2019 but also with international standards by the steel frame applied to the building after the adaptive reuse. Although some irregularities and dimensional inconsistencies partially persist after the adaptation, the weaknesses have been largely eliminated with the addition of a steel frame system and glass fiber reinforcement to reduce the load on the masonry walls of the building, and it can be said that the overall performance of the building has been positively affected by strengthening the system statically and dynamically.

Acknowledgements

We would like to thank EMR Architecture for sharing their project drawings that were essential to this study, along with related archival materials. We also appreciate Koc Group for their efforts in conservation and reusing the industrial heritage building, facilitating its transformation and continued existence.

Seismic characterization and vulnerability of stone masonry buildings in Urla

Yavuz S. Karavin*[1], Uğur Demir[1]

[1] *Izmir Institute of Technology, Department of Architecture, 35433 Izmir, Türkiye*

Abstract. Stone masonry is one of the oldest structural materials used by humanity. Although the development of new building materials has reduced the use of stone masonry construction, in some regions it still constitutes a significant part of building stock. However, due to low tensile strength, high weight and the lack of maintenance, stone masonry buildings are known to be weak against earthquake loads. Furthermore, the use of different construction techniques and materials causes the seismic performance of the buildings to vary widely. Urla, located in the middle of Urla Peninsula, hosts many stone masonry buildings. The active seismicity and the high earthquake risk in the region pose a threat to stone masonry buildings. Therefore, it is crucial to evaluate seismic characterization and vulnerability of those buildings in Urla. To assess the seismic risk level in a region, rapid seismic assessment methods play the initial role since they allow to determine risk distribution quickly. In this study, the seismic performance of 30 stone masonry building in Urla is evaluated according to two rapid seismic assessment methods: FEMA P-154 and RBTE-2019. The performance scores of the buildings and the reasons behind the risk levels are presented in this paper.

Keywords: Building Stock; Rapid Assessment; Seismic Behavior; Stone Masonry; Urla

1. Introduction

Stone masonry buildings (SMBs) stand as one of the earliest building typologies used by humanity (Quelhas et al., 2014). Since the main material of SMBs, stone, is abundant across many regions in the world and these structures are characterized by ease of construction, SMBs can be broadly found throughout the world. It is also noteworthy that SMBs are known to have significant architectural and historical value and encountered mostly as cultural heritage buildings. Therefore, conservation approaches are common for these buildings (Gonen & Soyoz, 2021).

Stone masonry is composite structural materials consisting of stone and adhesive mortar in general, however, masonry walls without any adhesive materials (dry-joint masonry) are also seen in considerable numbers (Shantanu, 2020). Despite this simple definition, there is an extensive variability in the construction of masonry in terms of stone shape and size, bond pattern of the wall and presence of additional structural materials (Tomazevic, 1999). Construction traditions of nations, environmental and economic conditions have a great influence on wall construction. Stone type, used materials, and the typologies of flooring and roofing systems are shaped by the most abundant materials in the local conditions. Another aspect of variability is observed in wall construction, where stone walls can be built as single-leaf walls or as multi-leaf walls with infill materials. On the other hand, urban settlements and rural areas generally exhibit notable differences in the architectural characteristics of SMBs. Stone masonry structures are typically found as residential buildings in rural areas, whereas in urban settlements, they are more commonly seen as monumental and religious structures. Furthermore, SMBs in urban settlements are predominantly three or four stories high, whereas in rural areas, they are usually one or two stories (Tomazevic, 2014). Additionally, the size, complexity, and quality of construction in SMBs are generally greater in urban settlements compared to rural areas (Bothara & Brzev, 2012).

Stone masonry walls are known to be non-tensile structural elements due to their heterogeneous nature (Borri et al., 2020). Furthermore, diversity in construction of masonry walls leads seismic performance of these buildings to vary in a wide range, and complicates the understanding of its global behavior. Considering the characteristics of these buildings exhibits differences between region to region, inventory studies regarding classification of architectural and structural features of SMBs hold great significance (Tunc, 2024; Demir 2024). To better understand the seismic risk level of the buildings, rapid seismic assessment methods play the initial role. For large-scale of buildings stocks, it is not efficient and possible to analyze each building in detail, in terms of cost and time limitations. At this point, rapid seismic assessment methods allow prioritizing risk levels of buildings in short-time

*Corresponding author, E-mail: yavuzkaravin@iyte.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_566

period. In this context, FEMA P-154 Rapid Visual Screening (RVS) (FEMA, 2015) stands out as one of the most commonly applied methodologies across the world, for various types of buildings. The method mostly focusses on the vertical and plan irregularities observed in the buildings. The method provides two levels of scoring scheme, requiring different information levels. Although this methodology is not oriented to masonry buildings and includes only a few parameters specific to masonry buildings, it includes a scoring section for unreinforced masonry buildings (URM) which estimates probability of collapse for masonry buildings. RBTE-2019 method (Provisions for the Seismic Risk Evaluation of Existing Buildings under Urban Renewal Law) has been published as a rapid approach to prioritize seismic risk levels of reinforced concrete and masonry buildings in certain regions of Türkiye. The section for masonry buildings in this method includes more parameters specifically regards possible deficiencies that can be observed in masonry buildings. Several rapid seismic assessment methods specifically related to masonry buildings can be found beyond the literature (Gatti, 2024; Islam et al, 2024; Ortega et al., 2019; Borri et al., 2015; Restrepo-Velez & Magenes, 2004). Application of these methods simplifies and accelerates risk mitigation efforts for urgent scenarios in seismically active regions.

Aegean shores of Türkiye is known to be one of the most seismic-active regions across the world. Almost 700 earthquakes bigger than Mw>4.0 have occurred in this region since 1900 (Çınar et al., 2021). In a narrower sense, series of significant earthquakes were felt in Izmir, which is the biggest city in Aegean shores, including Seferihisar 2005 earthquake Mw=5.7, Karaburun earthquake 2017 Mw=6.2, Samos earthquake Mw=6.6 (Binici et al., 2022). The increasing seismic activity gave rise to the need of studies regarding estimating the risk level of building stock across the city. Consequently, a comprehensive inventory study has been conducted in collaboration with Izmir Metropolitan Municipality and Bogazici University, results were presented in the report named Izmir Earthquake Master Plan (IDMP). The study was conducted in the central districts of Izmir, to clarify buildings typologies and related risk levels for those buildings. IDMP report have indicated that %11 of the examined 217824 buildings were masonry buildings, and also it was stated that the group of masonry buildings constitutes the most vulnerable buildings among all building typologies. Kahraman et al. (2013) conducted another comprehensive inventory study in Balçova and Seferihisar districts of Izmir, including 10550 buildings, indicating similar results with IDMP. Although these studies include numerous buildings, no inventory study has been conducted in Urla district, which is known to be with its diverse historical background. Furthermore, remarkable numbers of SMBs can be found in Urla, both in rural and urban areas of the district. Considering the diversity of SMBs in Urla, and low earthquake performance of these building typology, vulnerability assessment studies hold a significance. In relating to that, 30 SMBs in Urla were examined through site surveys in scope of this study. Subsequently, architectural and structural features of these buildings were classified, and their seismic performance were assessed through two rapid seismic assessment methods: FEMA P-154 and RBTE-2019, results are discussed and presented in this paper.

2. Site Surveys and General Observations

Urla is located in the center of Urla Peninsula, the south part of Izmir. It is the biggest district of Urla Peninsula with its population of 77599 and surface area of 704 km² (TUIK, 2023). Although its population is not as high as the population of central districts of Izmir, Urla constitutes a notable part of Izmir's geography. Including the central neighborhoods, a total of 37 villages and neighborhoods are involved in Urla (IDA, 2014). In scope of this study, several neighborhoods in Urla were visited and a total of 30 SMBs were examined on-site, including not residential ones but also educational, religious and commercial purposed buildings. The geographical distribution and occupancy classes of 30 examined buildings is shown in Fig. 1. Data regarding the buildings' occupancy classes, age, wall texture, stone and mortar type, diaphragm type, presence of bond beams and lintels, situation of restoration and presence of existing damage were collected using a data collection sheet prepared in scope of this study. Furthermore, a measurement survey was also conducted, and plan and elevation drawings were also drawn during site visits.

The SMBs in Urla were found to be box-type, simple buildings. Examined buildings were mostly 1 or 2 floors, except a three-storey building in Gülbahçe village. Data related to construction data of the buildings was obtained through oral conversations with building owners, and it was found that the buildings were considerably old, with an average age of 78. Religious buildings, three mosques in this study, were found as oldest structures with most eligible architectural and structural features. It was observed that stones were obtained from local quarries by the self-effort locals of the villages in rural areas. However, it was noted that stones of the buildings in central settlements of the district were obtained from industrial quarry located in Balıklıova. Stone masonry walls were generally found to be constructed as rubble in texture and thick in size. Mud and lime-based mortars were common in these buildings. One critical observation was that the SMBs in this region were mostly constructed with timber floors. Rigid diaphragms, reinforced concrete slabs, were found only in 4 buildings. Bond beams (*hatıl*) were found to be present %26 of the 30 buildings. While buildings are mostly in detached position in rurals, buildings attached to neighboring buildings were rather common in central neighborhoods of Urla. Examples of examined SMBs are shown in Fig. 2.

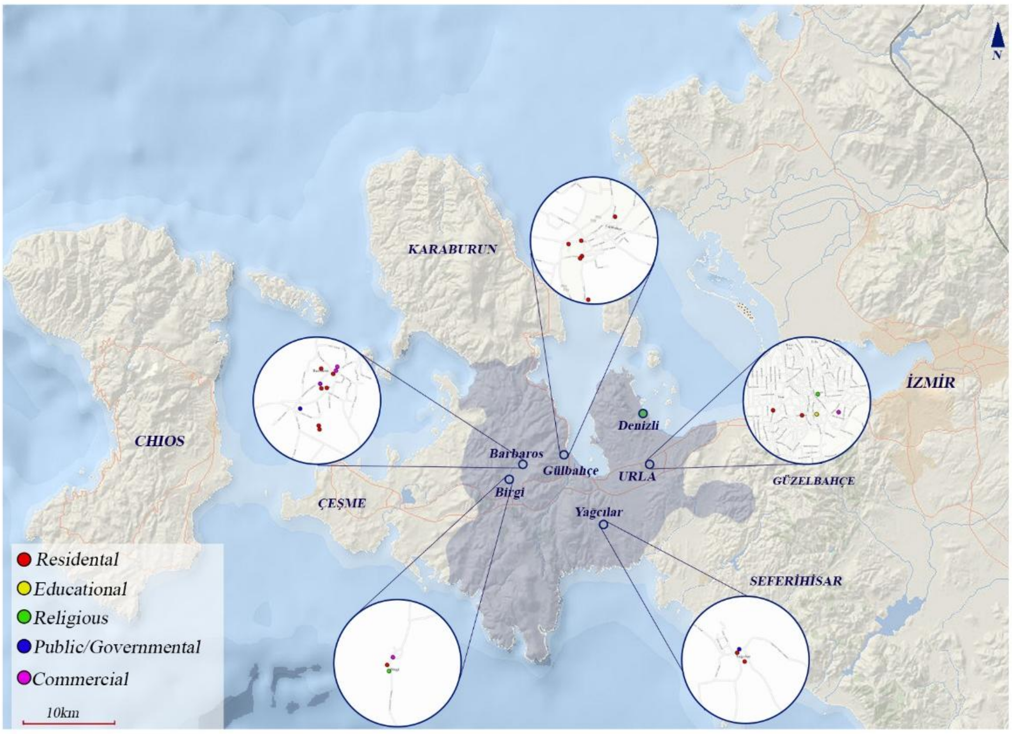

Fig. 1. Distribution of examined buildings with occupancy classes.

Fig. 2. Examples of examined buildings, a) Gülbahçe, b) Barboros, c) Birgi villages.

3. Rapid Seismic Assessment

Vulnerability scores of 30 SMBs were evaluated through the methods of FEMA P-154 and RBTE-2019, using the data collected from buildings, plan and elevation measurements and photographs taken on-site. Assumptions, scoring process and results are presented in the related subtitles of the paper.

3.1. FEMA P-154

FEMA P-154 Rapid Visual Screening method (FEMA, 2015) has been published by Federal Emergency Management Agency, to estimate seismic hazard for large numbers of buildings. The method only requires visual on-site inspection of a screener, which is not expected to exceed 15 minutes. The method mostly considers the possible architectural irregularities in buildings and does not require measurements. Two levels of scoring schemes are provided in this method, Level 1 and Level 2 scoring, and each can be applied for 17 types of structural system. Considering that all of the examined buildings are unreinforced stone masonry, scoring for only unreinforced masonry buildings (URM) was used in this study. However, scoring schemes vary depending to the seismicity level of the region. The method divided seismicity regions into five levels, and different scoring forms are provided for each seismicity level. Determination of seismic level for the building site is made according to short-period spectral acceleration (S_S) and 1-second spectral acceleration (S_1) values expected for the region. These values were obtained from Turkish Seismic Hazard Map published by Disaster and Emergency Management Authority of Türkiye (AFAD, 2018), using the occupancy classes of each building and soil type of the building sites. Since the data related to soil type could not be obtained, it was assumed that all soil types are "D" class, as it is directed in the FEMA P-154 handbook (FEMA, 2015). Although RVS forms provides nine different occupancy classes, this classification was made according to Turkish Building Earthquake Code (TBEC, 2018), since the hazard map follows this code. The determination of seismicity level using the S_S and S_1 values are shown in the Table 1.

According to provided classification, 28 buildings were found to be in High seismicity region, while the remaining two buildings were found to be in Very High seismicity region.

In each scoring, Level 1 and Level 2, basic scores are assigned to buildings, according to the seismicity level of the buildings' region. Final Level 1 score (S_{L1}) is calculated by summing the basic score and modifiers, which represent negativeness parameters in buildings. One of these parameters is that vertical irregularities might occur in URM buildings. Vertical irregularities (V_{L1}) are estimated in two conditions, severe or moderate. If the ground floor of the buildings is higher than the upper floors, this condition is considered to be presence of soft storey, a type of severe V_{L1}. Less amount of wall in ground floor leads to weak storey, another type of severe V_{L1}. Out-of-plane setbacks are also considered as severe V_{L1}. Sloping sites create a one-storey level difference between two facades of the building, level differences of slabs in a building and in-plane setbacks are considered as moderate V_{L1}. If load-bearing walls in two directions are not well-distributed in plan layout, this situation may lead to a torsional weakness for the building and considered as plan irregularity (P_{L1}) in FEMA P-154 Level 1 scoring. The presence of reentrant corners and diaphragm opening exceeding half of the whole diaphragm are also considered P_{L1}. Since the soil types are assumed to be "D" class, modifiers relating A-B and E type were not applied to any buildings. Post benchmark and pre-code modifiers are not considered for Level 1 scoring in High and Very High seismicity zones. Basic scores and values of modifiers for High and Very High seismicity regions are shown in Table-2.

Base score for Level 2 scoring is determined by subtracting V_{L1} and P_{L1} modifiers from S_{L1}, since these parameters are considered again in Level 2 scoring. Level 2 scoring estimates vertical and plan irregularities in separated subtitles. Additionally, presence of gable walls, pounding effect for attached buildings and retrofitting implementations are also considered in Level 2 scoring. Evaluating of 30 buildings in Level 2 scoring are applied as directed in FEMA P-154 handbook (FEMA, 2015). RVS provides minimum scores for both Level 1 and Level 2 scoring, which is 0.2 for URM buildings. However, to estimate the vulnerability level of each building and establish a comparative result, the minimum score guidance was not applied in this study, for each scoring of RVS.

Table 1. Determination of seismicity level according to FEMA P-154.

Seismicity Level	**S_S**	**S_1**
Very High	$S_S \geq 1.500g$	$S_1 \geq 0.600g$
High	$1.000g \leq S_S \leq 1.500g$	$0.400g \leq S_1 \leq 0.600g$
Moderately High	$0.500g \leq S_S \leq 1.500g$	$0.200g \leq S_1 \leq 0.400g$
Moderate	$0.250g \leq S_S \leq 0.500g$	$0.100g \leq S_1 \leq 0.200g$
Low	$S_S \leq 0.250g$	$S_1 \leq 0.100g$

Table 2. Basic scores and modifiers in Level 1 Scoring (Adopted from FEMA, 2015)

Parameters	**Basic Score and Modifiers**	
	High	**Very High**
Basic Score	1	0,9
Severe V_{L1}	-0.7	-0.6
Moderate V_{L1}	-0.4	-0.3
P_{L1}	-0.4	-0.3
Post-Benchmark	NA	NA
Pre-Code	0	0
A-B Soil Type	0.3	0.1
Soil Type E (1-3 Floors)	-0.2	0

3.2. RBTE-2019

Provisions for the Seismic Risk Evaluation of Existing Buildings under Urban Renewal Law (RBTE-2019) was published by Turkish Ministry for Environment and Urban Planning to range buildings according to seismic hazard level, including masonry buildings. This method is also known as rapid, first stage screening for buildings, however, it includes more parameters and requires basic measurements for masonry buildings. As it is directed in FEMA P-154, the first step of RBTE-2019 is determining the seismicity zone of the building site. Differing from FEMA P-154, seismicity level of the building site is determined according to spectral design acceleration (S_{DS}), which is the multiplied version S_S with soil type coefficient. The values of S_{DS} are obtained, again, from the Turkish Seismic Hazard Map (AFAD, 2018). All of the soil types are assumed to be "ZD" (refers to D in FEMA P-154) to ensure consistency between to methods. Occupancy classes are determined as it is directed in TBEC (2018). The method has similar approach with FEMA P-154, assigns each building a base point (BP) according to the seismicity level of the building site. BP for soil type ZD and S_{DS} values are given in Table 3.

Table 3. Determination of base point according to soil class and S_{DS}, for RBTE-2019.

Seismicity Zone	Soil Class	S_{DS}	Base Point		
			1-Storey	2-Storey	3-Storey
1	ZC/ZD/ZE	≥1.0	110	100	90
2	ZC/ZD/ZE	$1.0 \geq S_{DS} \geq 0.75$	120	110	100
3	ZC/ZD/ZE	$0.75 \geq S_{DS} \geq 0.50$	120	110	100

Masonry buildings are divided into four typologies in RBTE-2019 guideline and different structural system points (SP) are assigned to these typologies. Since the examined buildings consist of only URM buildings, SP was assigned as 0 for all buildings. Fifteen negativeness parameters are provided in RBTE-2019. Conditions for parameters are related with numeric values, parameter values ($_i$). Positive conditions are linked to 0 parameter value, while moderate and bad conditions are linked to 1 and 2 parameter values, respectively. Additionally, parameter points (NP_i) are also assigned to each parameter. All parameters, numeric representations for parameters and parameter points are shown in Table 4. Certain parameter points varies according to the number of floors of the buildings. Performance Point (PP), which is the final assessment score for this method, is calculated by Equation 1.

While assessing the material quality, masonry walls built with rounded, riverside stones and small uncoursed stones were assumed to be bad quality. Walls constructed with partially coursed stones are assumed to be average and walls with cut-stones are assumed to be good quality of material. Determining masonry workmanship quality is also defined with three conditions. Masonry walls constructed with staggered vertical joints and continuous horizontal joints are assumed to be good quality. If load-bearing stone masonry walls are totally irregular in terms of vertical and horizontal joints, this situation is considered to be bad quality, and all other cases are assumed to be average workmanship quality. It was assumed that slab levels of attached buildings are different, which means pounding effect is assumed to exist for all attached buildings. The remaining parameters are evaluated as it is directed in the RBTE-2019 guidelines.

$$PP = BP + SP + \sum(N_i \times NP_i) \quad \textbf{(1)}$$

Table 4. Parameters,

Parameters		Numeric Representations of Parameter Values			Parameter Point for Number of Floors		
		0	1	2	1	2	3
Building Alignment		Detached	Attached	-	-	-	-
Material Quality		Good	Avg.	Bad	-10	-10	-10
Masonry Workmanship		Good	Avg.	Bad	-5	-5	-5
Existing Damage		No	Yes	-	-5	-5	-5
Plan Geometry		Regular	Irregular	E. Irregular	-5	-10	-10
Bond Beam (*hatıl*)		Presence	Absence	-	-5	-5	-5
Amount of Wall		High	Avg.	Low	-5	-5	-10
Opening Regularity		Regular	Partially R.	Irregular	0	-5	-5

4. Results and Discussions

Final scores obtained from FEMA P-154 Level 1 and Level scoring are shown in Fig. 3a. The results indicates that notable part of the buildings were not punished by negativeness parameters. Another notable part of the buildings were modified with severe V_{L1}, as a result these buildings were clustered in 0.3 points. Results of Level 2 scoring differ notably from Level 1 scores. More detailed estimation revealed the deficiencies in the buildings as clustering buildings' scores under zero points. The parameter related to pounding effect, which is included in Level 2 scoring but not in Level 1 scoring, led buildings to get less points in Level 2 scoring. The presence of gable walls were not considered in Level 1 scoring, however, this parameter also caused buildings to get less points in Level 2 scoring.

Performance scores obtained from RBTE-2019 are mostly clustered in the mid-ranges, shown in Fig. 3b. The most impactful parameter is material quality in this method, and it was seen that buildings with "bad" material quality could not exceed 60 points. Another crucial parameter is out-of-plane behavior of the masonry buildings. The condition which led buildings to have bad out-of-plane response is mostly the absent of rigid diaphragm. Buildings with rigid diaphragm were found to have performance points not falling below 80 points. It should be noted again that that number of buildings with rigid diaphragms are scarce in this building stock. Pounding effect stand as another crucial parameter, as it is observed in FEMA P-154. Attached buildings, where pounding effect exists, is failed to exceed 70 points, since this parameter is one of the most impactful parameters in the RBTE-2019 methodology. However, it should be noted that the buildings carrying the risk of pounding effect are rather scarce in these buildings.

In order to compare the final assessments scores obtained from each method, Final Level 1 and Final Level 2 scores from FEMA P-154 and Performance Points obtained from RBTE-2019 are normalized to a 0-100 scale. Normalized final assessment scores of each building is shown in Fig. 4. It is observed that Final Level 1 scores are beyond any correlation with both Final Level 2 scores and RBTE-2019 scores. Final Level 2 scores and RBTE-2019 scores are partially correlated with each other, however, average RBTE-2019 score is clearly higher than FEMA P-154 Level 2 scores. This situation can be explained with the plurality of the parameters in RBTE-2019 provide to estimate positive features of these buildings such as sufficient amount of walls, regular plan and opening layout.

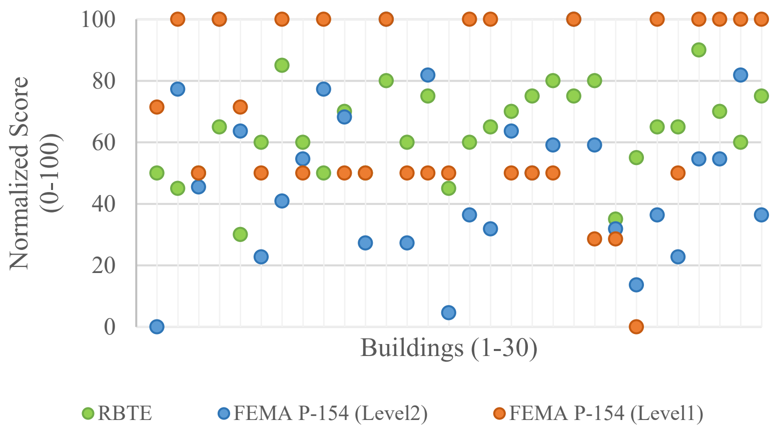

Fig. 4. 0-100 Normalized final assessment scores obtained from each method.

5. Conclusions

In this study, a total of 30 SMBs in Urla were examined on-site and their general architectural/structural features are presented. In the subsequent phases of the study, seismic risk level of these buildings were evaluated using two rapid seismic assessment methods: FEMA P-154 and RBTE-2019. SMBs in Urla are mostly observed to be small, box type, one or two floors and relatively old buildings. Masonry walls are generally constructed as rubble masonry with partially coursed stones. Rigid diaphragms and bond beams were barley found in this building stock.

Seismic performance of these buildings exhibited variety in a wide range according to each method. Final Level 1 score of FEMA P-154 was not distributed in a meaningful range, while Final Level 2 scores showed the vulnerability of these buildings more clearly. The reason behind lower Level 2 scores can be explained with the parameters included in Level 2 scoring but not in Level 1 scoring, such as pounding effect and presence of gable walls. RBTE-2019 scores clustered in the mid-range. The results of this method indicate the importance of masonry wall quality, diaphragm typology and building adjacency. It is suggested that the risk mitigation efforts have to specifically prioritize the buildings with the following character:

- SMBs with rounded, uncoursed, totally irregular masonry walls
- SMBs where there is a possible pounding effect
- SMBs without any rigid floor diaphragm

It is also expected that the inventory and risk estimation studies will be enlarged with extensive numbers of buildings spreading across larger regions.

Abstract. Village Institutes were institutions established in the first years of the Republic, with the aim of building a nation-state, as well as aiming to develop and raise awareness of the people in the country where most of the population lived in villages, aimed at their socio-economic progress, and also provided the education of village children. For this purpose, these institutes have been established in almost every region throughout Türkiye, in places where several cities are combined.One of these institutes that left its mark on a period and still maintains its importance on the agenda is Van Ernis Village Institute. Van Ernis Village Institute campus is the 21st Village Institute to be opened recently. It is 80 km from Van, 18 km from Erciş district, 24 km from Muradiye district, in the form of a peninsula surrounded by Lake Van on three sides, in an area of approximately 150 decares. Like other village institutes, Van Ernis Village Institute is a campus that includes many structures such as dormitory, dining hall, workshops, classrooms, library, bathhouse and administrative units. This campus, which was in active use since 2011 in accordance with its educational function, was abandoned after the 2011 earthquake in Van and its surroundings. Determining the structural damage of the surviving buildings in this campus today constitutes the purpose and scope of this study. Field observation, on-site measurement and documentation systems were used as the study method. This study aims to contribute to the documentation and transfer of the Van Ernis Village Institute campus, one of the first institutions of the Republic in Van, to the future.

Keywords: Village institutes; Van Ernis Village Institute; Van Earthquake; Structural damages

1. Introduction

Village Institutes were institutions established in the early years of the Republic to build a nation-state, and also to develop the people, raise their awareness, and ensure their socio-economic progress in a country where most of the population lived in villages, and to provide education for village children. For this purpose, these institutes were established in almost every region of Turkey, in places where several cities meet. In these institutes, the aim was to provide students with the ability to solve problems they would encounter in real life, as well as to contribute to the development of the villages they were in, and the education program was organized and implemented in the form of learning by applying on-site. These village institutes, which were opened in 21 units throughout the country, were later closed by the decision of the political structure of the period. One of these institutes that left its mark on a period and still maintains its importance on the agenda is the Van Ernis Village Institute. The Van Ernis Village Institute is the 21st institute that was recently opened (Figure 1). Village Institutes were institutions that were generally organized as a campus and included many structures such as dormitories, dining halls, workshops, classrooms, libraries, baths and administrative units. The locations chosen on the campuses, the local materials they were made of and their dimensions varied according to the function of each structure.

The Ernis Village Institute, like other village institutes, is a settlement that contains many structures. The institute, which contains many large and small buildings for education, accommodation and other needs, was left dysfunctional and to its own fate for many years, and when it was defeated by time, most of the structures were demolished, and the ones that remained standing were damaged and managed to survive to the present day. In recent years, a section of the campus was allocated to a tourism business, and nine of the remaining structures were registered.

Fig. 1. Village Institutes in Türkiye

This campus, which is considered to be transferred to the Ministry of Youth and Sports, was taken as a subject of study because it is one of the architectural heritages of the Republic period and because it is an important place in terms of education. The aim is to both draw attention to the institute by determining the architecture and existing damages of the structures in this campus, document them and create a basis for possible future plans.

The Village Institutes, established in Turkey in the 1940s, aimed to provide teachers with the theoretical and practical training they needed to solve various problems in the villages where they would work and to increase the productivity of the village. The Village Institute Project was part of a populist ideology that aimed to eliminate the inequality of opportunity between urban and village life. In other words, the Village Institutes were considered a tool to create and spread the national culture of the newly established Republic of Turkey (Aytemur, 2007).

In Turkey, while 75% of children living in cities attended primary school between 1933-1934, only 20% of village children could benefit from primary school education, efforts to expand education gained momentum between 1936-1939 and four Village Teacher Training Schools were established. These four schools were the first steps of the Village Institutes Project developed and put into practice by the Minister of National Education at the time, Hasan Ali Yücel, and the General Director of Primary Education, İsmail Hakkı Tonguç. With the new laws put into effect for the new education system, Village Institutes began to be established, and it was aimed to create a new organization in education suitable for the village structure and to give a new task definition to the village school and its teachers. Thus, the "village revitalization policy" adopted by the Village Institutes was legally secured, and by the end of 1948, the number of village institutes throughout Turkey had reached 21. The last institute to open was the Van Ernis Village Institute. Among these, the Ernis Village Institute, established 80 km away from Van in 1948, started education with the logic of learning by doing in order to train teachers for the surrounding provinces.

Following the transition from a single-party system to a multi-party system in 1946, within the framework of Law No. 6234 dated January 27, 1954, it was accepted that Village Institutes would be called 'primary teacher training schools', and students in these closed educational institutions, such as the Van Ernis Village Institute, continued their education in these campuses, which were transformed into schools implementing a different education system, or in different schools.

1.1. Purpose

Within the scope of this study, it was aimed to make an ecological assessment of the three surviving structures in the Van Ernis Village Institute, and also to examine and examine the architectural projects and damage status of these structures. As a study method, observation, examination and on-site measurements were made in the field, and literature data on the subject was examined. One of the study purposes is to bring to light one of the main sources related to the Village Institutes, one of the most original projects in the history of the Republic in Turkey. Another purpose is to address the current problems of this campus, which is a beautiful example of the architecture of the Republic period, and to ensure that precautions are taken against possible damage to the structures in the future.

2.2. Method

In the study, in addition to literature review, observation and in-depth examination and project design methods were applied in the field. In terms of content, first the village institutes and then the Van Ernis Village Institute were examined. Then, ecological data were taken from 5 buildings in this institute. Again, structural damage and problems in these buildings were determined by on-site observation in the field. In the research conducted on village institutes, it is possible to come across many literatures. Many theses, articles and studies have been conducted on 21 village institutes in Turkey. However, the studies conducted on Van Ernis Village Institute are extremely limited and currently, they are mostly seen in the form of news in the media.

There are many master's and doctoral theses conducted on Village Institutes in different disciplines and architecture. Some of these, especially in the discipline of architecture;

Baysal, E. (2006), “View of village space in the Early Republican Period and spatial experiences in village institutes”; Aladağ, A. (2019) “Preservation of village institutes as cultural heritage sites in the Early Republican Period; The example of İvriz Village Institute”; Yeşiltepe, A. (2022), “Traces of modernization in rural areas: A study on the heritage values and protection of village institute campuses”.

Another study on village institutes is the study of Figen Kıvılcım and Çakıcı (2013) titled “History and Values of Hasanoğlan Village Institute and High Village Institute Campus” published in an architecture journal.

It is possible to list many more publications on this subject. However, the studies on the Van Ernis Village Institute are extremely limited and are first included in a few pages in the book titled “Village Institutes in Turkey” prepared by Fay Kirby (1962).

One of the studies on this institute was presented by Subaşı Direk (2023) under the title “Van Ernis Village Institute Campus” in Local Expansions of Modernism in Turkish Architecture XIX (Docomomo 2023).

Village institutes included buildings made mostly by students using local materials from the region and environment in which they were located. These materials were generally stone, wood and soil. Within the scope of the study, three structures were examined in the Van Ernis Village Institute, and it was determined that these structures and other structures used throughout the campus were also made of these natural materials.

2. Van Ernis Village Institute

Van Ernis Village Institute is a settlement that started to be used as a Village Institute in 1948, but in fact the structures inside were built and used much earlier. The settlement is located on the northern tip of Lake Van, 80 km from Van, 18 km from Erciş district, and 24 km from Muradiye district, on an area of approximately 150 acres. It is located on a peninsula surrounded by Lake Van on three sides.

The settlement, which contains around 30-40 large and small structures, was first used as a Russian shipyard and then as a military barracks. No information has been found regarding the architects or engineers of the structures in the campus.

It was opened in 1948 as a Village Institute, under the Ministry of National Education at the time, and was soon converted into a Village Teachers' School, then into Ernis Primary Teachers' School, Alpaslan Primary Teachers' School, Muradiye Alpaslan Anatolian High School and finally Muradiye Alpaslan Science High School, and was used as an educational campus until 2011. The campus was abandoned after the 2011 earthquake in Van and its surroundings, when the buildings on the campus were damaged and some of them collapsed (Fig. 2-3).

Fig. 2. General situation of Van Ernis Village Institute Campus (Recreated by the author via Google Earth, 2023)

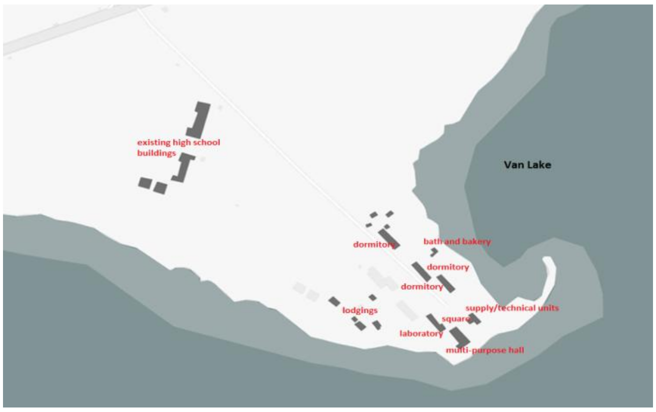

Fig. 3. Sketch of the location of buildings in Van Ernis Village Institute Campus

Some of the campus structures were built by the Russians as shipyards and service buildings until 1915. Later, it was used as a military barracks and some dormitories and service buildings were added during this process. When it was opened in 1948 as the last and 21st of the Village Institutes, the students of the Institute first built the oven and bathhouse with their own means. This bathhouse structure, made of Ahlat stone, a building material of the region, is important not only because it is the only structure that still stands almost undamaged, but also because it is one of the first structures built by the students of the institute with their own means (Fig. 4).

Another building on the campus, which was used as a workshop for a while and later as a dormitory when the number of students increased, and a multipurpose hall are also made of stone. These structures are discussed separately. Ahlat stone, scientifically known as "ignimbrite", is extracted from the foothills of Mount Nemrut in the Ahlat district of Bitlis. Ahlat stone is a volcanic rock. Due to its durability, ease of processing and prevalence, it has been used in many structures in the region, especially historical monuments. Ahlat stone, which usually has different colors such as white, cream, gray and coffee, is a building material still used in structures in the region. The surface of this stone is rough and is known for its high durability. Ahlat stone has a specific gravity of 2.6-2.64 and a compressive strength of around 14 Mpa (Işık, 2007).

Fig. 4. Location of buildings in Van Ernis Village Institute Campus

2.1.Van Ernis Village Institute Bath Structure

The bath structures of village institutes were buildings built to meet the cleaning and hygiene needs of users in these schools. Baths were used to meet the cleaning needs of students and staff, to provide a hygienic environment and to prevent health problems. The bath structures of village institutes generally had a simple and functional design. They were mostly built as stone or brick structures. Hamams usually consisted of a changing room (cold) and a washing room (warm). Hamams were used to provide health education as well as meeting the hygiene needs of students and staff. Cleaning habits, body care and hygiene were taught in hamams.

However, after the end of the village institute period, many village institutes were closed or used for different purposes. Therefore, today, village institute baths are generally dysfunctional or unrestored.

Van Ernis Village Institute Bathhouse is located in the northwest part of the peninsula-shaped settlement surrounded by a lake on three sides, which started to be used as a Village Institute in 1948. It is important as it is one of the first structures built by the students of Ernis Village Institute, the 21st and last of the Village Institutes, with their own means. It is also one of the structures that managed to survive the last major earthquake in the region. While other structures were severely damaged and most of them were destroyed, the bathhouse, which was built with a masonry system and the local material Ahlat stone, is still standing solidly (Fig. 5). It is possible to see the different colors of Ahlat stone, which is a volcanic stone, on this bathhouse.

The Van Ernis Village Institute Bathhouse structure consists of two sections. The first section is the dressing and preparation (cold) section, with a clean opening of 5 m x 7 m, four windows on each side, and a door in the middle of the southeast section to enter the space. The second section of the bathhouse structure is the washing (warm) section. There are toilets on both sides between the hot section and the preparation section of the bathhouse (Fig. 6).

The cold section, which is passed through a hipped roof, is accessed through a door that is exactly in the middle, to the hot section. The square hot section, which has an interior opening of 6.4 m x 6.4 m, has arches on its four sides. There are three basins inside each arch (Fig. 7). In the very center of the bath, there is an eight-sided navel stone and a dome on it that is as wide as the bath. There are lighting holes called elephant eyes on the dome that provide illumination to the interior. In order to heat the bath, which was built with extremely neat workmanship, a section called the furnace was built between the bath and the oven. The oven is located in the northwest part of the bath. It is thought that the heat in the furnace was also used for the oven.

Fig. 5. Van Ernis Village Institute Bath

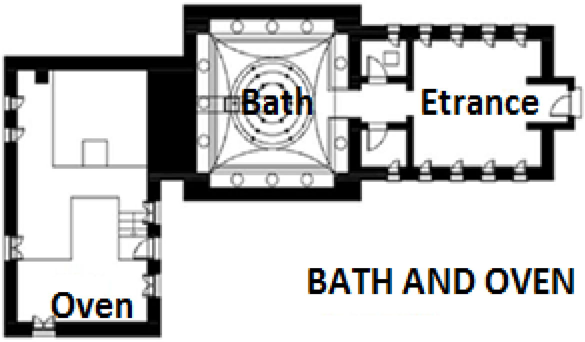

Fig. 6. General plan of Van Ernis Village Institute Bath

Although no serious damage was observed in the measurements made on the bath structure, there are some deteriorations in places due to plant growth, lack of maintenance due to long-term disuse and gradually water-humidity and lack of maintenance in the materials. It is known that the Ahlat stone used in the structure has low durability and wears out a lot due to its soft spongy feature, therefore temperature differences, frost and humid environments affect this situation and cause fragmentation and breakage. Freezing and thawing, which is effective cyclically especially in cold periods, is one of the most important factors in the deterioration of the building stones in the region.

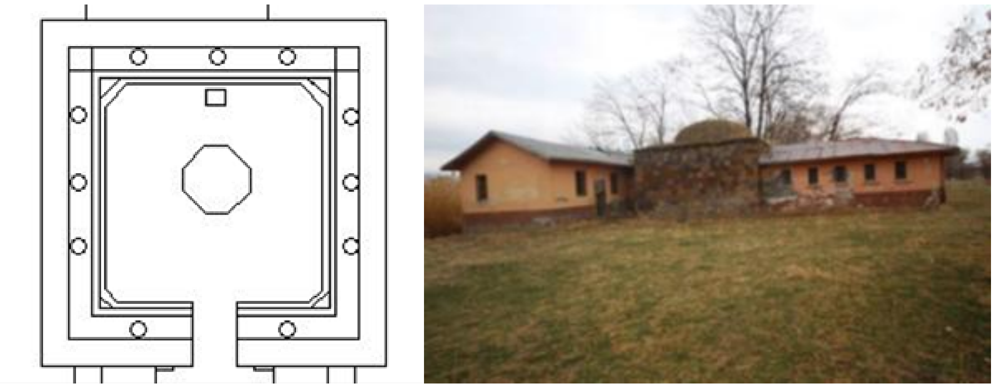

Fig. 7. Van Ernis Village Institute Bath Hot Section Plan and View

2.2. Van Ernis Village Institute Dormitory

The dormitory has a rectangular plan in the east-west direction. The entrance to the building is provided by a rectangular door in the middle of the south facade. There is a two-step staircase in front of the door. A square hall was created at the entrance, and the hall divided the two areas built in the same arrangement in the east and west of the building in the middle. There is a square-plan room on the north of the hall on the entrance axis (Fig. 8). The east wing and west wing of the building are accessed by one door in the hall. After passing through the door, there are large dormitory areas on both wings and two rooms in the corners of the dormitory. In the dormitory sections, there are two pillars located on the same axis to support the upper cover.

A total of twelve supporting piers were used, six on each of the north and south facades of the building. The piers continue from the ground to the ceiling level and support the upper cover. There are thirty-eight window openings in the building, sixteen on each of the north and south facades and two on each of the east and west facades. In this way, the building has a very spacious appearance (Fig. 9). Stone material was used as construction material in the building. The building is covered with a hipped roof covered with metal sheet.

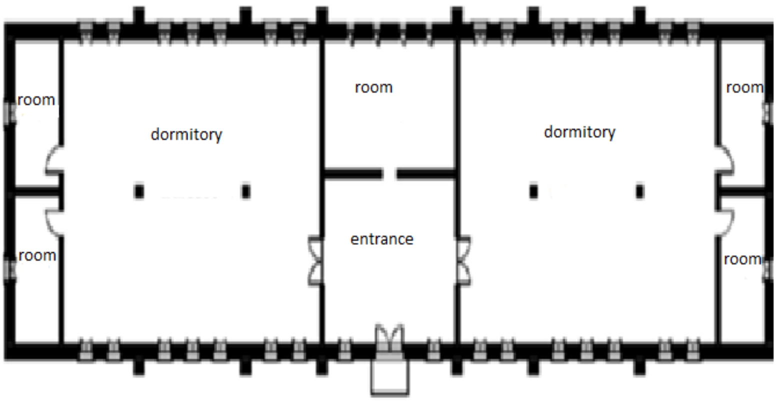

Fig. 8. Van Ernis Village Institute Dormitory plan

Fig. 9. Van Ernis Village Institute Dormitory view

This building, which was thought to have been used as a workshop and then as a dormitory, shows peeling paint and plaster, some deterioration due to water from the ground, and some damage to the windows and walls due to not being used for a long time when viewed from the exterior. However, this building, which has an intact facade, is in disrepair due to writings on the walls, broken plaster, and water problems. On the other hand, serious damage to the floors, walls, and ceiling inside the building is noticeable (Fig. 10). The wooden ceiling covering of this building has mostly collapsed, while the floor covering has also deteriorated and has collapsed in places. There is some material loss due to the removal of plaster on the walls and exposure to water, and especially large cracks at the joints. As a result of the current use of the building as a warehouse or animal shelter outside of its function, there is deterioration in the interior architecture in the form of neglect, dirt and ruins.

Fig. 10. Van Ernis Village Institute Dormitory Interior view

2.3. Van Ernis Village Institute Multi-Purpose Hall

The building has a rectangular plan in the east-west direction. Adjacent to the building is a rectangular plan building in the north-south direction in the southeast. The entrance to the building is provided by a rectangular plan door in the middle of the west facade (Fig. 11).

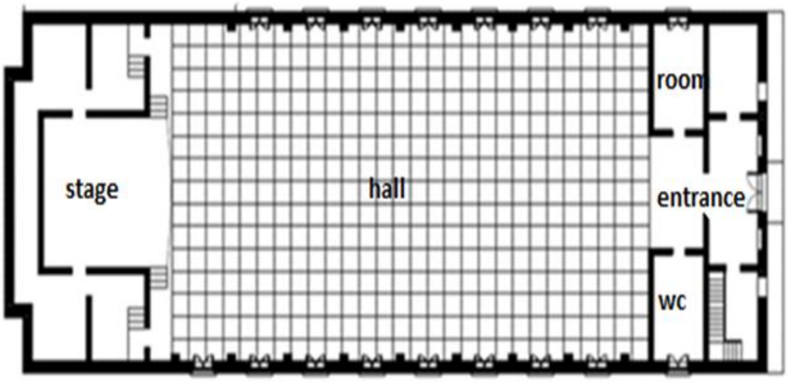

Fig. 11. Van Ernis Village Institute Multi-Purpose Hall plan

A hall was created after the entrance. There are one square-plan room in the north and south of the hall. Above these rooms, a slightly protruding area was created on the side facing the hall and a staircase was used to access this area from the room in the north. After passing through the hall, a second rectangular-plan hall was created and there are one rectangular-plan room in the north and south of this hall. The space in the north was used as a toilet. After the second hall, there is a large living room. There is a stage raised from the ground in front of the east wall of the building. The stage is accessed by a staircase with three steps from the north and south. There is a rehearsal room (backstage) on the north and south of the stage. These rooms can be accessed both from inside the hall and from the stage. There are nine window openings in the building, nine on the north facade, eight on the south facade and two on the entrance facade (Figs. 12-13). Regular cut stone was used as construction material on the walls of the building. The walls were plastered from the inside. The building was covered with a four-way inclined hipped roof covered with wood from the inside and metal sheet from the outside.

The Van Ernis Village Institute multipurpose hall was used for events such as cinema, theatre and concerts during the education period, and it is a very modern and functional structure for its time. However, this structure is also in a very worn-out state due to neglect and neglect due to not being used for many years. Although the integrity of the exterior has been preserved, especially the writings and paints on the doors and walls on the entrance facade, broken and damaged windows and doors, and also the bad appearances on the walls due to water and weather conditions are noticeable. However, the real damage in this structure is seen inside the structure. It is noteworthy that the ceiling coverings, which show the fine workmanship of the period it was built, have fallen off, the vertical plasters thought to be made for acoustic purposes on the walls have broken and material losses, large cracks and plaster removal at the wall, window and corner joints.

The area where Van Ernis Village Institute is located is in Muradiye district of Van province and is located in the 1st degree earthquake zone in the 2023 "Turkey Earthquake Zones Map" divided into 5 regions (URL-1, 2024). Van Province is one of the most important earthquake regions in Eastern Anatolia due to its location in the compression zone of the Eurasian and Arabian plates in terms of tectonics, at the intersection of the North Anatolian Fault Zone and the East Anatolian Fault Zone. The last two major earthquakes occurred in 2011.

Fig. 12. Van Ernis Village Institute Multi-Purpose Hall entrance facade

Fig. 13. Van Ernis Village Institute Multi-Purpose Hall entrance interior view

There are sandy, gravelly and clayey soil layers in Van, which is located on alluvial layers and is around the lake. Due to underground waters that approach the ground surface to a depth of 2 meters in some places, subsidence occurs in the foundations of some structures. Van Ernis Village Institute Campus is also in a 1st degree earthquake zone and all structures are located on such ground. It is thought that the cracks seen in the structures on the campus, especially in the dormitory and multipurpose hall, are after the earthquakes. Again, it is inevitable that there will be problems caused by ground water in the structures of the campus, which is surrounded by a lake on three sides. However, the greatest damage occurred because the structures were left alone for many years without being used or maintained. These empty structures were sometimes used as animal shelters or warehouses for nearby settlements, but in a rude manner, and it was observed that windows, doors, ceilings, walls and floor coverings were damaged by human hands. Damage and deterioration in structures increased due to climatic cycles, hot-cold temperature differences, precipitation, and also factors such as ground-based water, humidity and earthquakes.

3. Conclusions

Village institutes were one of the important elements that contributed to the development of both villages and cities and carried the society to the level of civilization. The Van Ernis Village Institute, which was opened last and unfortunately short-lived, includes a group of structures that made up the architectural heritage of the Republic, which contributed greatly to the environment it was located in despite its short life and still has a high symbolic value today. Some of the buildings made of stone of this institution are original structures that have survived from the Institute and maintain their façade integrity when viewed from the outside.

Within the scope of this study, three structures built of stacked stone located in a 1st degree earthquake zone and on alluvial ground were taken into consideration and the current status of the Van Ernis Village Institute structures was tried to be determined. Although there was no visible damage in the heating section of the bathhouse structure, which is the first of these structures and is even more important because it was built by the students themselves, it is noteworthy that damage formations started due to non-use, groundwater, rainfall and other environmental effects. Mass losses, abrasions and breaks are seen in the stones of the structure, which has not been used for a long time and has been abandoned to its fate. Lichens that have formed over time have started to damage the stones, especially in the dome. Due to the effects of water, humidity effects have also occurred in the walls and some other parts of the bath structure.

The greatest damage among the structures is seen in the dormitory building. Separation in the carrier system, material loss in the roof and walls, and abrasion in the floors constitute the main damages. Again, although there is no visible damage other than the pictures made outside the multipurpose hall, there are damages on the walls, floors and ceilings inside the structure due to long-term disuse. It is necessary to carry out studies to repair these damages, to prevent the structures from being damaged too much in the future and to protect them, and these processes should be continuous. The loss of properties and damages of the stone material used in the three structures considered over time due to natural processes may affect the load-bearing properties of the structures.

The stone structures on the Van Ernis Village Institute campus, like other buildings within the Institute, have preserved their authenticity since they were used until 2011. Today, it is seen that the settlement, which is completely idle, is prone to further destruction by people due to uncontrolled entries. Taking security measures within the campus and opening this area to use by assigning different functions is extremely beneficial in terms of both national wealth and national value. In particular, interventions to be made in the damages incurred in the Van Ernis Village Institute buildings, which are considered within the scope of the architectural heritage of the Republic period, in a way that preserves their authenticity and their use with the functions to be assigned will be important in terms of transferring these structures to the next generations.

A review of applications of Monte Carlo Simulation in construction risk management

Oguzcan N. Kuru*[1], Fahriye H. Halicioglu[2]

[1] Dokuz Eylul University, Graduate School of Natural and Applied Sciences, Department of Architecture, 35390 Izmir, Türkiye
[2] Dokuz Eylul University, Faculty of Architecture, Department of Architecture, 35390 Izmir, Türkiye

Abstract. Effectively managing uncertainties and risks in construction projects is a critical factor influencing project success rates. Monte Carlo simulation, in particular, is a versatile method used in risk management to model possible scenarios and quantitatively predict their impacts on projects. This method enables project managers to understand potential risk effects better through hundreds or thousands of iterations and make informed decisions. Identifying, analyzing, and prioritizing risks is crucial in achieving project objectives related to cost, time, and quality. In this context, Monte Carlo simulation is a robust analytical tool that enhances risk management processes by enabling probabilistic analysis and scenario evaluation. This study provides an extensive literature review on applying Monte Carlo simulation to construction project risk management. Existing studies emphasize its contributions to risk analysis and prioritization, its capacity to measure uncertainties, and its transformative impact on project planning. The effectiveness of Monte Carlo simulation in generating probabilistic scenarios and evaluating their effects on project objectives has solidified its value in both theoretical and practical domains. The findings consolidate diverse perspectives from the literature, highlighting the pivotal role of Monte Carlo simulation in advancing risk management practices. This review is a comprehensive reference for understanding the method's practical benefits and theoretical foundations. It aims to encourage its broader adoption in construction risk management by addressing its advantages and potential challenges in various project scenarios.

Keywords: Monte Carlo Simulation; Risk Analysis; Risk Management; Construction Projects

1. Introduction

Construction projects are complex processes involving multiple stakeholders, variable parameters, and unpredictable conditions. The timely completion of projects, adherence to budget constraints, and achievement of desired quality standards are often influenced by multifaceted factors such as disruptions in material supply, fluctuating weather conditions, variations in labor productivity, and economic uncertainties (Chan et al., 2004). For instance, a sudden flood during bridge construction or an unexpected surge in steel prices in a skyscraper project can significantly jeopardize project objectives. Such uncertainties make the construction sector a high-risk domain, necessitating effective management of these risks. Unmanaged risks lead to financial losses, resulting in broader consequences such as reputational damage and operational disruptions (Akintoye & Macleod, 1997).

In this context, risk management emerges as a fundamental discipline that directly impacts the success of construction projects. The systematic identification, analysis, and prioritization of risks enables project managers to anticipate potential threats and develop proactive solutions (Iqbal et al., 2015). For example, the early detection of ground subsidence risk in a tunnel project allows for the design of appropriate support systems, providing significant advantages in terms of safety and cost efficiency. However, when risk management processes are neglected, even a minor disruption can trigger a domino effect, leading to delays, budget overruns, and, in extreme cases, complete project failure. Consequently, risk analysis has become an integral part of modern project planning and is recognized as an indispensable element for achieving sustainable success in the construction industry (Khodabakhshian et al., 2023).

Monte Carlo simulation is a powerful tool for quantitatively modeling risks and uncertainties (Arunraj et al., 2023). By employing random variables to simulate hundreds or even thousands of possible scenarios, this method goes beyond traditional deterministic approaches by providing a probabilistic distribution of project outcomes. While deterministic methods typically focus on a single "most likely" scenario, Monte Carlo simulation reflects

*Corresponding author, E-mail: oguzcannazmi.kuru@ogr.deu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_634

real-world complexity by assessing the interactions of variables and the cumulative effects of risks (Bouayed, 2016).

This paper aims to review the applications of Monte Carlo simulation in the construction risk management process. By exploring the theoretical foundations and practical benefits of the method, it seeks to enhance the effectiveness and data-driven nature of risk management in the construction sector. This review study focuses on how Monte Carlo simulation can be utilized across a wide range of applications, from cost estimation to time scheduling, while addressing the challenges that may limit its applicability and strategies for overcoming these challenges. In this regard, the paper aspires to serve as a comprehensive guide for academics and industry professionals, encouraging the broader adoption of the method in construction risk management.

1.1. Concept of Risk

Risk can be defined as events or conditions that emerge under uncertainty and have the potential to positively or negatively impact a project's objectives. In the project management literature, risk often focuses on adverse outcomes; however, risks can also present opportunities. Nonetheless, risks are typically perceived as threats that may hinder the achievement of project goals (Aven, 2017).

Risk consists of two key components:

- Probability: The likelihood of a risk occurring.
- Impact: The risk's consequences on the project if it occurs.

These two components determine the severity of the risk. For instance, high-probability and high-impact risks present the greatest threats to a project, while low-probability and low-impact risks are less significant (Duijm, 2015).

1.2. Risk Management

Risk management is a systematic process aimed at identifying, analyzing, and developing strategies to address risks that may arise during project processes, ultimately ensuring the achievement of project objectives (Thamhain, 2013). Risk management originated in the insurance industry in the early 20th century and has since been applied in various fields, including project management, finance, and engineering. Particularly after the 1980s, risk management processes became standardized within project management (Smith & Merritt, 2002). Risk management plays a critical role in project success because, as the complexity and uncertainty of projects increase, the impact of risks also escalates (Taroun, 2014).

Risk management is critical in complex and large-scale projects (Qazi & Dikmen, 2019). Construction projects inherently involve high uncertainty and risk. These risks can lead to delays, cost overruns, or a decline in quality. Risk management offers a proactive approach to prevent or minimize such adverse outcomes (Akintoye & Macleod, 1997).

In particular, risk management becomes even more critical in sustainability-focused projects (e.g., energy-efficient building projects). These projects typically involve more significant uncertainty and complexity than traditional projects (Nawaz et al., 2019). For instance, the availability of green materials, challenges in achieving energy efficiency goals, or problems from implementing new technologies can increase project risks.

PMBOK (2018) addresses risk management under seven core processes. These processes follow the Plan, Define, Analyze, Respond, and Monitor/Control framework.

- *Risk Identification*: Risk identification involves identifying all potential risks that may arise during the project lifecycle. In this step, the project team, stakeholders, and experts provide their insights to identify project-specific risks more comprehensively. Stakeholders can anticipate risks at different project stages and assess their potential impacts (Hillson, 2002). The risk identification process uses brainstorming, expert opinions, historical project data, and risk checklists (Thamhain, 2013).
- *Risk Analysis*: Risk analysis assesses the likelihood and impact of identified risks. In this step, the potential effects of risks on the project are analyzed either quantitatively or qualitatively. Quantitative analysis involves numerically evaluating risks, while qualitative analysis involves classifying risks based on their relative importance (Ward & Chapman, 1991).
- *Risk Prioritization:* Risk prioritization involves ranking risks based on their potential impact on the project. This step creates a risk matrix using the likelihood and impact values of risks. The risk matrix allows for classifying risks as high, medium, or low priority (Dandage et al., 2019).
- *Risk Response Planning*: Risk response planning involves developing strategies to reduce or eliminate the effects of risks. This step defines risk prevention, mitigation, transfer, or acceptance strategies. For example, additional measures may be taken for a high-risk situation, or the risk can be transferred through insurance (Zhang, 2016).
- *Risk Monitoring and Control*: Risk monitoring and control is tracking risks throughout the project and taking necessary actions. In this step, the status of risks is regularly reviewed, and as new risks emerge, the risk management process is updated (Levene & Lewis, 2015).

1.3. Monte Carlo Simulation

Monte Carlo simulation is a statistical technique that employs random sampling to model and analyze complex systems affected by uncertainty, making it a vital tool for construction risk management. By generating thousands of possible scenarios, it quantifies the impacts of risks on project objectives such as cost, schedule, and quality, surpassing the limitations of deterministic methods (Labeau & Zio, 2002; Peleskei et al., 2015).

Grounded in probability theory, Monte Carlo simulation leverages principles like the law of large numbers and the central limit theorem to represent a system's potential states through random sampling. It addresses high-dimensional computations, optimization challenges, and stochastic processes, particularly when deterministic approaches are impractical or computationally intensive. In construction, it enables project managers to assess risks arising from material price volatility or schedule delays by modeling variable interactions (Cheng & Guo, 2024; Rubinstein, 1981).

The simulation process follows a structured sequence. Initially, the system, such as a construction project's cost or schedule, is defined, along with desired outputs. Probability distributions for input variables (e.g., labor productivity, material costs) are established using historical data, expert opinions, or theoretical models. Random samples are then generated from these distributions using random number generators, and the system is modeled for each sample set to produce outputs. Finally, results are statistically analyzed using metrics like mean, variance, and confidence intervals to evaluate uncertainty impacts, often supplemented by sensitivity analysis to identify critical inputs (Paxton et al., 2001; Wei et al., 2013).

The accuracy of the Monte Carlo simulation hinges on several factors. A sufficient number of iterations—typically thousands—ensures statistically reliable results, improving accuracy as sample size increases. The model's fidelity to the real system, validated through experimental data or analytical solutions, is crucial. Additionally, the quality of random number generators influences outcome reliability. In construction, inaccurate input data, such as incomplete cost records, can undermine results, necessitating robust data collection (Ramírez-Márquez & Coit, 2005; Kwak & Ingall, 2007).

Simulation outputs should be calibrated against real-world data to enhance result validity, with model parameters adjusted as needed. Conducting scenario and sensitivity analyses further tests the model's performance across diverse conditions, ensuring its applicability to complex construction projects. These steps are critical for mitigating risks in large-scale infrastructure or sustainable construction initiatives (Khodabakhshian et al., 2023).

Monte Carlo simulation is a cornerstone of modern risk management, with origins in nuclear physics and widespread applications in finance, engineering, and construction. Providing probabilistic insights into uncertainties empowers project managers to make informed decisions, develop proactive risk mitigation strategies, and optimize resource allocation, thereby enhancing project success in the dynamic construction industry (Brandimarte, 2014; Peleskei et al., 2015).

2. Research Methodology

This study adopts a literature review methodology to examine the use of Monte Carlo Simulation in construction risk management. This review aims to synthesize findings from existing academic sources to understand how Monte Carlo Simulation has been applied in various contexts within the construction sector. Specifically, the study explores the methodological contributions of Monte Carlo Simulation to risk analysis, highlights the advantages and limitations associated with its use, and identifies the industry-specific domains where it has been most effectively implemented, such as cost estimation, schedule forecasting, and resource planning.

3. Results and Discussion

Table 1 presents the literature review results. These results reveal the Monte Carlo Simulation's capacity to model uncertainties, conduct probabilistic risk analyses, and predict the effects of risks on project objectives. This section synthesizes the key results from the literature review and discusses the significance of these findings in construction risk management.

Monte Carlo simulation is commonly employed in the construction sector, where project management and cost estimation are processes characterized by high uncertainty. Ildarabadi et al. (2021) demonstrated that using a Monte Carlo simulation for financial risk assessment in construction projects made cost estimates more reliable. Similarly, Sadeghi et al. (2010) developed a more flexible analytical method by combining fuzzy logic with Monte Carlo simulation for risk analysis in the construction sector. Qazi et al. (2021) examined the effectiveness of Monte Carlo simulation in risk prioritization for sustainable construction projects and showed that it scientifically grounded the ranking of risk factors. Another study by Peleskei et al. (2015) explored how Monte Carlo simulation could improve the accuracy of cost estimates in construction projects.

(2025)	***"Risk Consideration and Cost Estimation in Construction Projects Using Monte Carlo Simulation"***	Risk analysis and cost estimation in construction projects	Low accuracy of cost estimates in construction projects	Construction cost management with Monte Carlo simulation	Monte Carlo Simulation, Financial Modeling	To improve risk-based cost estimates in construction projects	Monte Carlo simulation can increase the accuracy of cost analysis in construction projects.

As seen in Table 1, the literature review shows that Monte Carlo simulation is widely used in various areas of construction risk management, such as cost estimation, scheduling, and contingency planning. For instance, Peleskei et al. (2015) and Allahi et al. (2017) demonstrated that the method significantly enhances the accuracy of cost estimates by accounting for uncertainties such as material price fluctuations, labor efficiency, and unforeseen events. Similarly, Wang and Huang (2009) and Wali and Othman (2019) showed that Monte Carlo simulation, when combined with techniques like the Critical Path Method (CPM) and Program Evaluation and Review Technique (PERT), improves the reliability of project completion time predictions. These findings validate the method's ability to overcome the limitations of deterministic approaches and provide probabilistic result ranges that better reflect the complex and variable nature of construction projects.

The role of simulation in risk prioritization is another important finding that contributes to the improvement of resource allocation and strategic planning. Baumgertel et al. (2016) used the method in flood defense projects to identify critical cost risks and ensure more accurate contingency reserves. Similarly, Tong et al. (2018) applied a Monte Carlo simulation to evaluate occupational health risks caused by construction dust, revealing higher exposure risks in certain site areas and facilitating the implementation of targeted mitigation measures. These applications showcase the method's versatility in addressing financial and non-financial risks and provide project managers with actionable insights for reducing significant uncertainties. Probabilistic outputs such as histograms or cumulative distribution functions present the likelihood and magnitude of risks in an accessible manner, facilitating decision-making processes.

The integration of Monte Carlo simulation with complementary techniques enhances its effectiveness. Sadeghi et al. (2010) combined fuzzy logic with Monte Carlo simulation to obtain more robust cost risk assessments with incomplete or uncertain data. Similarly, Rezaie et al. (2007) introduced a cyclical algorithm to model interdependencies among uncertainties, improving the method's accuracy compared to traditional Monte Carlo approaches. These developments demonstrate that the natural limitations of Monte Carlo simulation, such as neglecting inter-variable dependencies highlighted by Wall (1997), can be overcome through hybrid methodologies. These findings emphasize the importance of adapting the method according to specific project contexts and data suitability.

However, applying a Monte Carlo simulation in construction risk management faces some challenges. The accuracy of simulation results heavily depends on the quality of input data and the appropriateness of the selected probability distributions. Studies like Kwak and Ingall (2007) warn that poorly defined inputs or insufficient sample sizes can jeopardize the reliability of results. Additionally, the computational complexity of the method and the need for specialized software such as @Risk or Crystal Ball can pose obstacles, particularly in small-scale projects or teams with limited technical expertise (Taylor & Brown, 2021). These limitations indicate that while Monte Carlo simulation has transformative potential, successful application requires robust data collection processes and skilled personnel.

The discussion of these findings highlights the transformative impact of Monte Carlo simulation in construction risk management. Providing a probabilistic framework allows project managers to move beyond point estimates and fosters a more proactive and informed approach to risk mitigation. This aligns with a broader shift toward data-driven decision-making in the construction industry, as evidenced by its increasing adoption in large-scale infrastructure projects (Yeung, 2001) and sustainable construction initiatives (Qazi et al., 2021). However, the identified challenges suggest that the method requires ongoing refinement. Improving data quality through historical project records, integrating artificial intelligence for real-time uncertainty modeling, and developing user-friendly tools could overcome these barriers and make the method more accessible across different project scales.

Monte Carlo simulation is a crucial tool in advancing construction risk management by providing a detailed understanding of uncertainties and their impacts. Its ability to generate reliable cost and time estimates, prioritize risks, and support contingency planning is a cornerstone of modern project management practices. However, maximizing its benefits depends on addressing implementation challenges through education, data management, and technological innovation. These findings reinforce the method's theoretical and practical value and pave the way for future research to optimize its application in the evolving landscape of construction projects.

Monte Carlo simulation offers a range of advantages and some limitations. According to Raychaudhuri (2008), this method excels at handling uncertainty by incorporating random variables into the modeling process. Bonate (2001) highlights its versatility across various application areas, while Kwak and Ingall (2007) emphasize its effectiveness in generating accurate forecasts within decision support systems. Recent studies further underscore its strengths in construction risk management. For instance, Khodabakhshian et al. (2023) note that Monte Carlo simulation enhances decision-making by providing probabilistic outputs that account for complex interdependencies among project variables, such as material costs and labor productivity, thus enabling more robust contingency planning. Additionally, Martinez et al. (2022) demonstrate its value in renewable energy construction projects, where it facilitates precise risk assessments by modeling uncertainties in energy production and cost estimates, contributing to sustainable project outcomes.

On the other hand, Harrison (2010) notes that the method can be computationally intensive, particularly in large-scale implementations. Silver and Tesauro (2009) argue that the accuracy of the simulation heavily relies on the quality and appropriateness of the probability distributions used for input variables. Recent literature reinforces these limitations and identifies new challenges. For example, Taylor and Brown (2023) highlight that integrating Monte Carlo simulation with emerging technologies, such as artificial intelligence, can increase computational demands, requiring advanced hardware and skilled personnel, which may be prohibitive for smaller construction firms. Furthermore, Peleskei et al. (2015) point out that inconsistencies in historical data, often due to incomplete project records in developing regions, can undermine the reliability of simulation results, necessitating rigorous data validation processes. Despite these challenges, advancements in cloud-based simulation platforms and automated data preprocessing, as discussed by Cheng and Guo (2024), are beginning to mitigate computational and data-related barriers, making the method more accessible across diverse project scales.

4. Conclusion and Recommendations

This study has investigated the use of Monte Carlo simulation in the risk management processes of construction projects, emphasizing its role in modeling uncertainties, evaluating risks, and ensuring alignment with project goals. Based on the literature review, methodological analysis, and discussion of findings, it is evident that the Monte Carlo simulation serves as a valuable and practical tool within the construction industry. The study's key findings confirm the method’s ability to improve the reliability of cost and time estimates, prioritize risks, and frame decision-making processes within a data-driven context.

The main results show that the method goes beyond deterministic approaches, providing probabilistic scenarios that allow project managers to understand the complex nature of uncertainties better. Additionally, integrating complementary techniques (e.g., fuzzy logic or cyclic algorithms) has enhanced the accuracy of analyses, further strengthening the method's practical value. However, challenges such as data quality, technical expertise requirements, and software dependencies were identified as limiting factors in the method's applicability.

Monte Carlo simulation fosters a proactive approach to construction risk management, addressing the shortcomings of traditional methods. Forecasting the range of potential values for project duration or cost with a certain probability provides managers with a solid foundation for developing risk mitigation strategies and optimizing resource allocation. Especially in large-scale and complex projects, the advantages offered by this method can potentially increase project success. However, fully realizing this potential depends on improvements in data collection processes, staff training, and the development of user-friendly technologies.

The results of this study lay the groundwork for encouraging broader adoption of Monte Carlo simulation in construction risk management. By systematically addressing uncertainties, the method increases the likelihood of achieving project objectives in terms of time, cost, and quality. However, several recommendations can be made to maximize the method's effectiveness. First, construction companies should systematically archive historical project data and incorporate it into simulation models to improve the quality of input data. Second, sector-specific training programs should be developed to enhance the competence of project teams in applying Monte Carlo simulation. Third, integrating innovative technologies such as artificial intelligence and machine learning with the simulation could enhance accessibility and accuracy by enabling real-time risk analysis and faster computation. Lastly, developing low-cost and user-friendly software tools should be encouraged to facilitate the method's adoption.

Future research presents significant opportunities to implement these recommendations and further enhance the application of Monte Carlo simulation in the construction industry. For example, creating risk models specific to different project types (e.g., infrastructure, residential, industrial facilities) could broaden the method's sectoral applicability. Additionally, studying the impact of simulation on sustainability-focused projects could provide new insights into how eco-friendly construction practices can be supported through effective risk management. Such research could strengthen the theoretical foundations of Monte Carlo simulation while making its practical application more accessible and effective.

A roadmap for preliminary assessment of energy performance in traditional houses: The case of Ayvalık

Gülten Manioğlu[1] , Halime Firdevs Taşkın[*1], Eda Köse Murathan[2]

[1] *Istanbul Technical University, Department of Architecture, 34367, Istanbul, Türkiye*
[2]*Artvin Coruh University, Department of Architecture, 08200, Artvin, Türkiye*

Abstract. Ayvalık traditional houses, located in the province of Balıkesir, Turkey, represent the rich cultural and architectural heritage of the region. The conservation of these houses includes not only preserving their architectural and environmental features but also ensuring the continuity of life within them. In this context, maintaining thermal comfort conditions for users is essential. This study aims to carry out a preliminary assessment of Ayvalık traditional houses in terms of energy performance and to propose a roadmap for energy-oriented research in historic settlements. The assessment, developed through on-site investigations, involves the systematic collection and organization of data. The study also intends to serve as a foundation for future research on the energy performance of traditional houses. Within this scope, a preliminary assessment was carried out on six traditional houses located in the traditional urban pattern of Ayvalık through on-site investigation and documentation, focusing on their architectural characteristics and environmental context. Subsequently, the strengths and weaknesses of the houses were analyzed both quantitatively and qualitatively in terms of climate and energy performance. The study demonstrates that it is possible to assess the energy performance of traditional houses while preserving their historical value. Based on the results, it can also be stated that energy performance assessments should be integrated with conservation practices to ensure sustainability in traditional houses. Accordingly, a roadmap has been developed to guide future energy-oriented studies on traditional houses, while respecting their historical values.

Keywords: Ayvalık; Traditional Houses; Energy Performance; On-site Investigation

1. Introduction

Traditional houses represent significant heritage assets with their architectural features, as well as their socio-cultural, economic, and environmental sustainability values. They are the products of local construction techniques that have been shaped by the climatic conditions, natural resources, and social lifestyles of their geographic context (Kuban, 1995). In this regard, traditional houses should be considered as dynamic resources that not only embody the aesthetic and historical heritage of the past but also transmit knowledge of sustainable building culture to the present. The preservation and continued use of these houses are essential for safeguarding cultural continuity. Today, conservation approaches have taken on a multidimensional character, focusing on both the preservation of the original form of the structures and the maintenance of their usability through adaptation to contemporary needs (ICOMOS, 2021; Onecha et al., 2021). In this context, integrating sustainability principles into the conservation of cultural heritage buildings has become increasingly important. Assessing traditional houses in terms of both their cultural significance and environmental performance provides a contemporary perspective for sustainable conservation practices.

Today, global challenges such as increasing energy consumption, climate change, and environmental sustainability have made it necessary to re-evaluate building performance through a performance-oriented approach. This has brought renewed attention to the potential of traditional houses in terms of energy efficiency (Eres & Güler, 2022). The use of local materials, thick stone walls, shading elements such as overhanging structures, narrow street layouts, and spatial configurations that promote natural ventilation all reveal that traditional houses were designed based on passive climate control strategies. In this context, assessing the energy performance of traditional houses is essential both to align conservation strategies with contemporary environmental goals and to ensure the sustainable adaptation of the existing building stock (Gou et al., 2015; Özbalta et al., 2021; Kaoua et al., 2022).

* Corresponding author, E-mail: taskinha@itu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_652

Numerous studies have been conducted at both national and international levels on the energy performance of traditional houses. Different climatic conditions, geographical features, and cultural lifestyles have been fundamental factors shaping the design of these structures. This diversity has enabled the development of passive design strategies aimed at enhancing energy efficiency. For instance, studies on “Machiya” traditional houses in Japan have shown that these houses adapted to high humidity and seasonal temperature variations, enhancing indoor comfort through sliding panels that promote natural ventilation and shading (Iba & Hokoi, 2022). Similarly, “Hanok” traditional houses in Korea emphasize energy efficiency through ondol, a floor heating system that minimizes heat loss in winter, and wide eaves that provide cooling in summer (Lee et al., 2020). In Nepal, material choices vary according to climatic zones: stone and adobe with high thermal mass are preferred in colder regions, while lightweight timber walls are more common in subtropical areas (Gautam et al., 2019). In Spain, particularly in the Andalusia region, courtyard-integrated house plans are widely used, creating a cooling effect by facilitating natural ventilation within indoor spaces (Torres-González, 2025). As in other countries, studies on traditional house typologies across different climatic zones in Turkey have quantitatively demonstrated the adaptive capacity of these structures to local environmental conditions. For instance, research on Safranbolu traditional houses revealed that indoor temperatures remain more stable compared to outdoor conditions during both the hottest and coldest days of the year, achieving a certain level of thermal comfort without the use of active heating or cooling systems (Ulukavak Harputlugil & Çetintürk, 2005). Likewise, measurements conducted on the traditional timber-framed "Düğmeli" houses in the İbradı-Ormana region of Antalya showed that, while outdoor temperatures exceeded 35°C during the hottest summer days, the interior temperatures of stone-walled houses remained consistently between 27–29°C throughout the day (Tüfekçi Topkaya, 2022). A comparative study between the traditional “Mungan” house and the modern “Demir” house in Mardin further revealed that the Mungan house, with its thick stone walls, maintained indoor temperatures 4–5°C lower and more stable than those of the modern house (Manioğlu & Yılmaz, 2008).

The literature highlights the necessity of on-site investigation in understanding the energy performance of traditional houses. In this context, the *Preliminary Assessment of Energy Performance in Traditional Houses* method developed in this study was applied to Ayvalık. The research involves a systematic process of data collection and organization at the settlement, building, and building component scales. In the initial stage of on-site investigation and documentation, the historical and cultural background of the examined settlement was studied. In subsequent stages, evaluations related to the energy performance of the traditional houses were conducted, ranging from the settlement scale to the material scale. The outcomes of this study are expected to provide a roadmap for future energy-oriented research on traditional houses.

2. The architectural and cultural significance of Ayvalık traditional houses

Ayvalık is a distinctive settlement both for its natural landscapes and its traditional houses, which have developed through a long historical process and have significant architectural and cultural value. The traditional settlement pattern, particularly concentrated in the town center, holds a special position in terms of the conservation of cultural heritage. The first official step toward protecting the settlement was taken in 1976, when the High Council of Immovable Antiquities and Monuments designated Ayvalık as a "site area to be preserved as a whole with its natural and historical assets" under decision number A-160 (Erdem et al., 2007). Following this designation, conservation plans and registration efforts were implemented, and today two separate urban conservation areas have been defined, covering Ayvalık and Alibey (Cunda) Island. Fig. 1 illustrates the boundaries of urban conservation and natural protected areas designated with varying protection levels, together with a satellite image that shows the general morphology of the settlement.

The traditional houses within the urban conservation area, with their architectural diversity, offer insights into the historical transformations of the settlement. Despite changing user needs and spatial demands over time, many buildings have preserved their original identity, although in some cases, traditional spatial arrangements have been replaced by new functional interventions. This transformation has shaped both the historical and structural development of the settlement, influencing the architectural and cultural values of Ayvalık. In this context, the historical and structural development of the traditional settlement pattern is addressed under separate subheadings.

2.1. Historical Development

Ayvalık, located in the Balıkesir province, is a coastal settlement on the northern shore of the Aegean Sea, historically distinguished by its economic activities and geographical characteristics. The spatial and cultural development of the town was shaped by a rural economy based on olive production, the conditions of the natural environment, and its multi-layered social structure. Under these influences, Ayvalık evolved into an important Greek settlement under Ottoman rule starting from the 17th century. In the 18th century, the town gained notable momentum in local urbanization with the growth of the olive oil and soap industries in Western Anatolia (Uçar, 2013; Özker, 2020).

Fig. 1. Urban conservation and natural protected areas with satellite imagery of the study area

By the 19th century, Ayvalık had developed into a settlement predominantly inhabited by a Greek population, characterized by its educational institutions, religious buildings, and examples of civil architecture. This socio-cultural development played a decisive role in shaping the housing pattern and the overall morphology of the settlement (Niğdelioğlu Çamkaya, 2023). However, social unrest in 1821 and a major earthquake in 1865 led to the destruction of a significant portion of the building stock, necessitating the reconstruction of the town. During the reconstruction process, traditional planning principles were preserved, although Western architectural influences also began to appear in the settlement (Kıyak, 1997; Akın, 2007). Ayvalık continued its architectural and cultural development until the beginning of the 20th century. The 1923 population exchange between Türkiye and Greece marked a profound transformation in the socio-cultural structure of the town. Although the user profile changed with the exchange, the original architectural character of many buildings was largely preserved in the following years (Niğdelioğlu Çamkaya, 2023). In 1976, Ayvalık was designated as an "urban conservation area" by the High Council of Immovable Antiquities and Monuments, initiating the implementation of conservation policies within the settlement. Nevertheless, these conservation efforts could not entirely prevent the spatial transformations that occurred over time (Özker, 2020). From the 1980s onward, increasing population pressure and the impact of tourism led to the deterioration of some structures, while others were restored in ways that were incompatible with their original authenticity.

2.2 Structural Development

The traditional settlement pattern of Ayvalık was shaped by its relationship with street orientations, parcel organization, and topography, gradually developing a natural character over time (Kıyak, 1997). The streets were oriented perpendicular to the prevailing winds from the north and northeast, known locally as the "Poyraz", facilitating the penetration of cool airflows into the settlement during the summer months (Aslan, 2018). Narrow and shaded design of the streets limited direct solar radiation throughout the day, helping to prevent overheating and creating a microclimate that enhanced passive cooling. While a more regular, grid-like parcel organization is observed in flatter areas, the streets on sloped terrains adapt organically to the topography, changing direction in response to the landform. This adaptation not only maintains visual connections with the surrounding landscape but also supports natural air circulation across the settlement (Kıyak, 1997; Akın, 2015).

The building-scale approaches that developed in parallel with this settlement pattern also define the structural characteristics of Ayvalık traditional houses. This architectural identity emerged at the intersection of geographical conditions and cultural accumulation, blending the use of local materials, climate-adaptive solutions, and construction techniques of the period to create a distinct regional character. Typically constructed in a row-house arrangement, these houses are generally two or three stories high (Erdem et al., 2007). The ground floors were built using load-bearing stone masonry, while the upper floors employed a timber frame system. In this composite construction method, the ground floors were often built with Sarımsak Stone, a local material prized for its ease of carving and its aesthetically pleasing pinkish hue. This material contributed significantly to both the structural integrity and the architectural expression of the buildings. On the upper floors, a lighter and more flexible system known as the "bağdadi" technique was applied (Niğdelioğlu Çamkaya, 2023). In this technique, the timber frame was covered with reeds or wooden laths, then finished with lime-based plaster (Fig. 2) (Asımgil & Erdoğdu, 2013). Thanks to this construction method, the upper floors, often featuring oriel window, are visually and physically separated from the stone-built ground floors. With their pastel-colored plastered surfaces, these facades make a characteristic contribution to the distinctive street silhouette of the settlement.

Fig. 2. An example of the "bağdadi" construction technique in Ayvalık traditional houses

The use of wood in Ayvalık traditional houses was not limited to structural elements; it also contributed to the aesthetic and characteristic identity of the buildings through details such as window shutters and ceiling decorations. Iron was also widely used, serving both functional and decorative purposes in window grilles, balcony railings, and door knockers (Uztuğ, 2006; Efe, 2019). Architectural features formed by the use of these materials, such as oriel window, wide eaves, doors, and windows, are the distinctive elements that define the aesthetic expression of Ayvalık traditional houses. These features introduce both horizontal and vertical articulation to the facades, thus collectively shape the silhouette of the settlement within the street pattern (Akın, 2015).

Following the settlement pattern and structural features previously described, an examination of the spatial organization of Ayvalık traditional houses reveals that the ground floors were predominantly organized for commercial purposes, incorporating service areas such as storage and kitchens, along with rooms opening onto the courtyard (Tibet, 2013). The upper floors, on the other hand, functioned as the main living spaces of the houses. In most examples, two separate external entrances provided direct access to both the ground floor, typically used for storage, and the upper floor, where the living spaces were located. Additionally, internal access between the ground and upper floors was often provided by an interior staircase (Efe, 2019). Another important space on the upper floor that connected the rooms was the "sofa". Generally designed in an inner sofa layout, this space functioned not only as a circulation area but also as a place for sitting, resting, and daily living activities. The rooms were mostly arranged along the long sides of the sofa, while balconies, staircases, or external openings were often located at the short sides in some examples (Erdem et al., 2007). The sofa was intentionally designed to promote natural ventilation and daylight and served as a livable central space within the house. A schematic floor plan example of Ayvalık traditional houses is presented in Fig. 3.

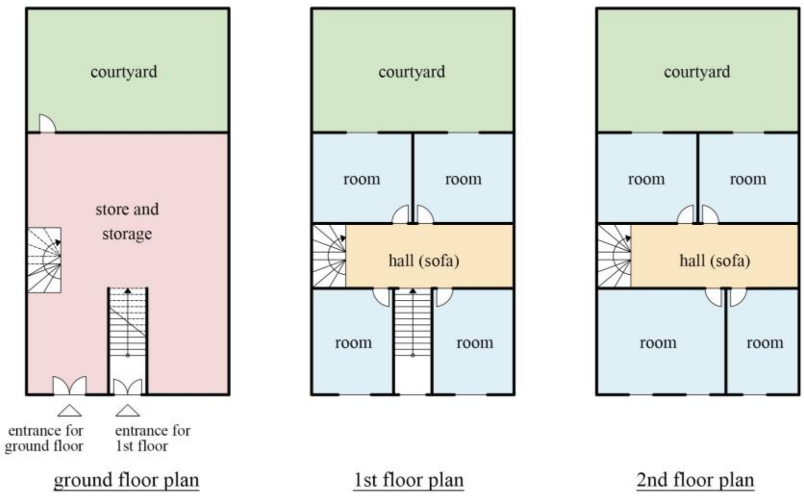

Fig. 3. A schematic floor plan example of Ayvalık traditional houses

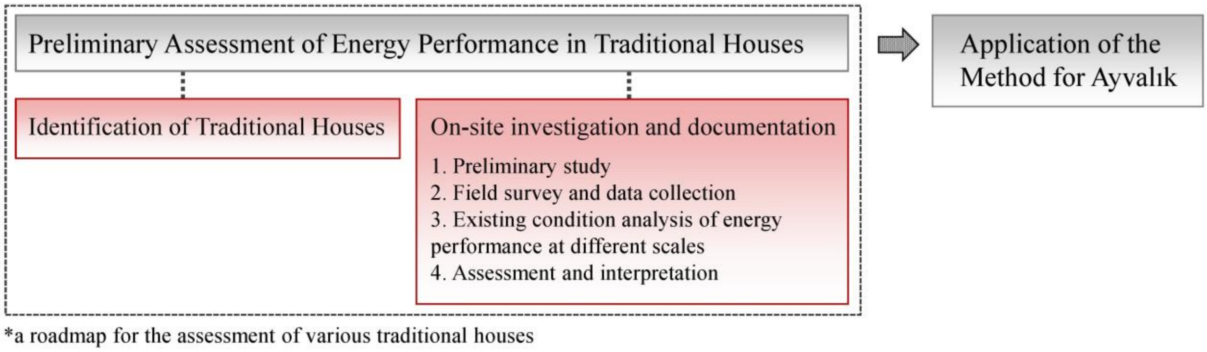

Fig. 4. Stages of the proposed method

3. Preliminary assessment of energy performance in traditional houses

In this section, a preliminary assessment method is proposed to provide a foundation for studies focusing on the energy performance of traditional houses. The method aims to systematically examine the building and settlement characteristics and to document the findings, thereby establishing a basis for future energy analyses. Furthermore, the method is designed to be applicable to traditional houses located in different climatic regions, and in this study, it is exemplified through its application to Ayvalık traditional houses. The methodology comprises the identification of traditional houses to be evaluated in terms of energy performance, followed by on-site investigation and documentation. Within this framework, a comprehensive and systematic preliminary assessment method has been developed through observations and analyses conducted at the settlement, building, and building envelope scales for Ayvalık traditional houses. Fig. 4 summarizes the stages of the proposed method.

3.1 Identification of traditional houses to be assessed in terms of energy performance

The settlement of Ayvalık traditional houses is characterized by a compact urban pattern formed by narrow streets, organic parcel structure, and stone-timber structures. Within this settlement, six traditional houses with different locations and orientations were selected based on their ability to reflect the region's unique architectural character and their relevance for representing energy performance through passive design strategies. The selection process was guided by specific criteria. These included the spatial arrangement of buildings, distances between structures, and orientation at the settlement scale, as well as the internal spatial organization and façade properties at the building scale. These houses were then examined on-site according to the defined criteria. Their locations and parcel information are shown on the Ayvalık settlement map in Fig. 5.

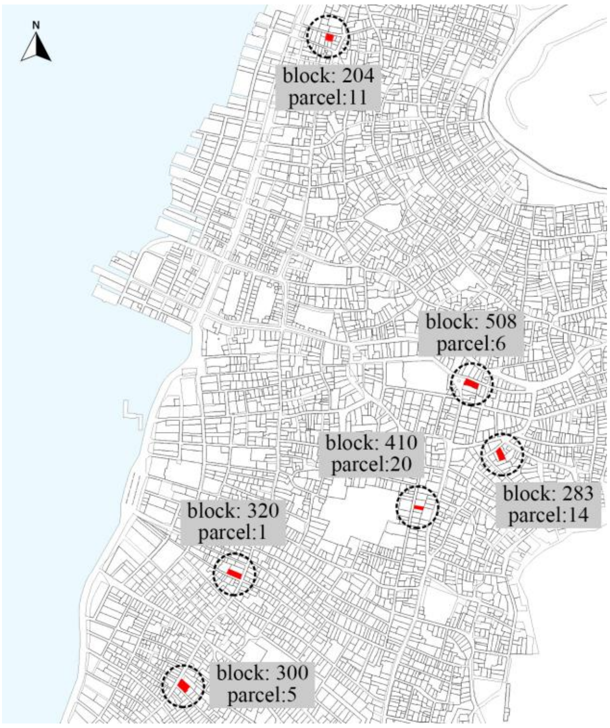

Fig. 5. Location and parcel information of the traditional houses assessed within the scope of the study

3.2 On-site investigation and documentation

On-site investigation and documentation is among the fundamental stages of the restoration process in historical buildings, enabling the analysis of their existing conditions. The data gathered during this process is also critical for conducting energy performance analyses aimed at ensuring the sustainable use of historic structures. Based on this approach, the present study proposes a systematic preliminary assessment method for evaluating the energy performance of traditional houses, inspired by on-site investigation practices commonly employed during restoration works (Yazgan, 2023; Ahunbay, 2016; Kudeb, 2009; Republic of Türkiye Ministry of Culture and Tourism, 1983a; 2012b). The proposed method defines systematic data collection steps that can guide future studies focused on the energy performance of traditional buildings. These on-site investigation and documentation stages were applied to the Ayvalık traditional houses and are presented in Table 1. It was observed that the ground floors of the houses consisted of load-bearing stone walls, utilizing Sarımsak Stone, a material specific to the region. In the upper floors, a timber frame system was employed, and the "bağdadi" technique was applied.

4. Application of the method for Ayvalık

In this section of the study, Ayvalık traditional houses were analyzed in terms of energy performance based on on-site investigation and documentation stages. Accordingly, the six traditional houses identified in Section 3.1 were examined and observed in detail during the site visit. The details of the building components in the selected Ayvalık traditional houses were determined through project documentation and field survey.

Table 1. On-site investigation and documentation stages for assessing the energy performance of traditional houses

On-site investigation and documentation	
1. Preliminary study	Site selection
	Initial review based on the location and orientation of traditional houses within the settlement plan
	Literature and archival review to document the historical background of the traditional houses
	Examination of official records related to traditional houses, such as registration and conservation status
2. Field survey and data collection	During the survey: recording the overall condition, surroundings, and architectural details of the selected traditional houses through photography and preliminary measurements
	Requesting existing restoration project documentation of the selected houses from relevant institutions
	In the absence of such documentation, prepairing measured drawings (plan, section, elevation) and identifying material details
3. Existing condition analysis of energy performance at different scales	At the settlement scale: environmental and climatic assessment including building surroundings, distances to neighboring buildings or obstacles, adjacency relationships, building orientation, solar exposure, and ventilation conditions, etc.
	At the building scale: spatial and typological analysis including floor plan layout, spatial organization, functional distribution, relationships between spaces, ceiling heights and number of floors, etc.
	At the building component scale: identification of materials used in building components (external walls, roof, groundfloors, and windows) through project documents or field surveys; calculation of overall heat transfer coefficients (U-values) in accordance with the TS 825 standard; determination of transparent component details (glazing type, frame type), and assessment of shading devices, etc.
	Identification of areas requiring intervention in terms of energy performance and detection of physical damages
4. Assessment and interpretation	Assessment of the transmissivity of the building's opaque and transparent components according to TS 825
	Development of improvement proposals for the building's opaque and transparent components

All of the roofs were designed as either hipped or gabled roofs. In this context, the overall heat transfer coefficients (U-values) of the building components were calculated to evaluate the energy performance of the selected traditional houses. These U-values were compared with the recommended maximum U-values for the second climatic zone (characterized by a mild-humid climate) as specified in the TS 825 "Thermal Insulation Requirements for Buildings" standard (TS 825, 2024) (external walls: 0.4 W/m²K, roofs: 0.3 W/m²K, ground-contact floors: 0.35 W/m²K, and windows: 1.8 W/m²K). The data obtained contribute to a better understanding of the architectural characteristics of traditional houses and their potential for user-centered sustainability. In addition, these findings aim to provide a foundation for developing new strategies for the contemporary built environment. A detailed analysis of on-site investigation and documentation for the assessment of energy performance in the selected Ayvalık traditional houses is presented in Table 2.

The Ayvalık traditional houses addressed in terms of energy performance were examined and analyzed according to the on-site investigation and documentation stages proposed within the scope of the study. In the first stage, the locations of the traditional houses were identified on the settlement plan. In the second stage, the selected houses were examined on-site through observation, and an archive was created by photographing their general conditions, surroundings, and architectural details. Subsequently, the restoration projects of the houses were requested from the relevant institutions. The examination revealed that restoration projects had been completed for five of the houses, while information was obtained indicating that one house (House 5) was scheduled for restoration. In the third stage, the existing condition of the selected traditional houses was analyzed at different scales (settlement, building, and building component) in terms of energy performance.

At the settlement scale, the location of the selected traditional houses, their relationship with neighboring buildings, street layout, orientation, solar exposure, and ventilation conditions were examined. Three of the houses are located on corner plots, while the other three follow a row-house typology. This distinction affects the surface area directly exposed to external climatic elements. The analysis also focused on the main façade -where the entrance is located- and its exposure to climatic factors such as sun and prevailing winds (northeast and southeast). Regarding solar exposure, it was found that the main façades of five houses were either directly or partially exposed to sunlight, while one house (House 1), whose main entrance faces north, benefited only from reflected solar radiation. As for ventilation conditions, plan-based analysis showed that three of the six houses were oriented to benefit from both northeast and southeast winds, two houses received ventilation primarily from northeast winds, and one house was not directly exposed to the prevailing winds. These findings demonstrate that the influence of external climatic elements such as sun and wind may vary from house to house. Narrow streets were also observed within the settlement. These streets facilitate natural ventilation by channeling prevailing winds and create shaded areas through surrounding buildings, thereby reducing solar heat gains. Such spatial configurations contribute not only to improved pedestrian comfort but also indirectly enhance the cooling energy performance of the houses.

At the building scale, the selected traditional houses were examined in terms of spatial organization, functional distribution, and the relationships between interior spaces. It was observed that the ground floors of the houses are used as storage areas, while the upper floors serve as living spaces. This functional division is also evident in the entrance configuration: one of the two doors at the front opens to the ground-floor storage area, while the other leads to the living space above. In the analyzed houses, the upper floors generally have higher ceiling heights than other levels. This design strategy likely allows hot air to rise, preventing heat accumulation in the main living areas. As a result, thermal discomfort caused by warm indoor air is reduced, and a cooler indoor environment is maintained. Additionally, the placement of living spaces on the upper floors may have been preferred to take greater advantage of natural ventilation. This planning approach corresponds with the typical layout scheme widely observed in the traditional settlement pattern of Ayvalık (Fig. 3). Other planning strategies observed in Ayvalık include the use of oriel windows (cumba) and courtyards, both of which are commonly found in the analyzed houses. Through oriel windows, the number of openings increases, allowing for improved natural lighting and the creation of shaded areas on the façade. Courtyards also provide shaded areas throughout the day, offering users a chance to cool down. Thus, these traditional planning strategies contribute significantly to both indoor and outdoor thermal comfort, as well as to the overall energy performance of the houses. In terms of current use, three of the houses function as hotels, two are used as residences, and one remains unused, as it has not yet been restored.

At the building component scale, information on the materials used in the selected traditional houses was obtained through field surveys and architectural project documents. Based on this data, the heat transfer coefficients (U-values) of the components were calculated in accordance with the TS 825 standard. In the selected houses, Sarımsak Stone was commonly used on the ground floor, particularly in external walls and floors in contact with the soil. In contrast, the upper floors featured timber frame systems in both external walls and roofs. Due to these material differences, U-value calculations were carried out separately for each floor. As shown in Table 2, the results indicate that the U-values of the components exceed the recommended threshold values defined by TS 825. However, the wall construction technique (stone + infill + stone) results in a high thermal mass in the building envelope. This may help maintain indoor comfort during both heating and cooling seasons, regardless of the U-value. Due to the material and technological limitations of the period these houses were built, the thermal resistance of the building envelope is relatively low. This is a common characteristic observed in cooling-dominant regions.

In such climates, passive cooling strategies such as shading devices, narrow wind-ventilated streets, high ceilings, oriel windows, and courtyards tend to be prioritized. As for transparent components, their thermal performance was also found to be limited, primarily due to the common use of single glazing. To support thermal performance, most of the windows are equipped with wooden shutters, which function as shading elements that help reduce overheating in summer and limit heat loss during winter.

In summary, the analysis indicated that the opaque and transparent components of the selected traditional houses do not meet the performance criteria defined by TS 825. Therefore, it is necessary to develop improvement strategies to enhance their energy performance under the climatic conditions of the region. These strategies should focus particularly on opaque components and be designed in a way that preserves the original material use and construction techniques of traditional architecture. This approach would support both the conservation of architectural authenticity and the improvement of indoor comfort conditions for users.

5. Results

In traditional houses, it is essential not only to preserve their architectural and environmental characteristics but also to ensure indoor user comfort for the sustainability of life in these buildings. Based on this necessity, the study adopted a multi-scalar approach to assess Ayvalık traditional houses in terms of energy performance and proposed a roadmap to support design decisions that enhance thermal comfort. In this context, a systematic preliminary assessment method was developed for future research on energy performance, incorporating on-site investigation and documentation stages. Accordingly, a preliminary assessment was conducted on six traditional houses located within the urban conservation area of Ayvalık. The architectural characteristics of the houses and their relationship with the environment were examined, ranging from the settlement scale to the material scale.

In Ayvalık, it has been observed that cooling strategies are prioritized due to the region's climatic characteristics, directly shaping planning strategies at both the settlement and building scales. At the settlement scale, the analysis of energy performance revealed that the location and orientation of the houses, their relationship with neighboring buildings, and the presence of narrow streets affect solar heat gains and natural ventilation potential. It was also observed that houses located on corner plots are more exposed to external climatic conditions compared to those built in a row-house typology. However, the orientation of façades and the spatial organization should also be considered key design features for maximizing the benefits of sunlight and wind. At the building scale, the analysis focused on features such as floor plan layout, spatial organization, functional distribution, relationships between spaces, ceiling heights and number of floors. These features provide insights into both user comfort and the energy performance of the houses. For example, higher ceilings may support cooler indoor conditions, while courtyards can provide shaded outdoor areas. Oriel windows contribute not only to shading but also improve daylight access through an increased number of windows. The current functions of the houses also influence their energy consumption. At the building component scale, the analysis was based on the heat transfer coefficient (U-value) thresholds recommended in the TS 825 Standard. Accordingly, it was found that the U-values of wall and floor components constructed with Sarımsak Stone and timber frame systems exceed the recommended limits. This indicates that, under current conditions, these houses have potential for energy performance improvement. In addition, wooden shutters on the windows can be considered another climate-responsive strategy at the component scale, as they help reduce overheating in summer and minimize heat loss in winter. In light of these findings, it was concluded that assessing the energy performance of traditional houses is essential. However, in future studies, the thermal mass performance of the building envelope can be quantitatively determined through measurements and supported by modeling and simulation tools to estimate annual energy loads of the buildings.

In conclusion, the preliminary assessment method developed and exemplified through the case of Ayvalık traditional houses has provided a foundation for future research. The sustainability of traditional houses depends on both the preservation of their historical features and the improvement of their energy performance. Accordingly, this study offers a basis for advanced simulation-based analyses and emphasizes the importance of energy performance-oriented approaches in traditional settlements. Therefore, it will be possible to create sustainable and energy-efficient living environments for the future while preserving the valuable heritage of the past. Future studies may focus on proposing alternative building component improvement strategies and innovative material solutions in accordance with restoration principles. Simulation tools can also be used for a more detailed analysis of indoor thermal comfort conditions. Finally, assessing the energy performance of traditional houses under future climate scenarios could be considered another important research topic.

An examination of the illumination levels of vertical circulation elements in historical buildings: Stair towers of the old Edirne Train Station building

Elif Polat*[1], Şule Yılmaz Erten[2]

[1*] *Trakya University, Institute of Science, 22020 Edirne, Türkiye*
[2] *Trakya University, Department of Architecture, 22020 Edirne, Türkiye*

Abstract. Circulation elements are building elements that serve the purpose of connecting spaces either horizontally or vertically, facilitating the movement between spaces located at different places or levels. One such element is stairs, which, while being the most fundamental circulation component in architecture, can have various designs and details depending on the architectural style and period. In this context, stair towers, especially those designed as part of public buildings or historical structures, not only give monumental character to the buildings but also include window openings that allow natural light to penetrate into the interior spaces. This study will evaluate the natural lighting conditions of the stair towers in the historic train station building, designed by Architect Kemaleddin and currently used by the Faculty of Fine Arts at Trakya University, which is an example of early 20th-century Republican era civil architecture. The arrangement of the existing window openings and the level of daylight will be analyzed. In this scope, using the Dialux Lighting Simulation program, the distribution of natural light within the space and, where necessary, the effectiveness of artificial lighting will be assessed, and the functional and practical applications of past design dynamics will be discussed.

Keywords: Circulation Elements; Natural Lighting; Dialux; Train Station Buildings; Stair Towers.

1. Introduction

The luminous atmosphere created in both interior and exterior spaces plays a significant role in maintaining individuals' circadian rhythms, influencing circadian systems that regulate daytime cycles and endocrine secretions (Öney & Balcı, 2021). In architectural structures, various luminous functions and requirements exist depending on different spatial functions. These are established through a combination of factors such as appropriate lighting design, correct use of light sources, adjustment of color temperature, and control of light intensity.

Circulation areas are spaces that facilitate movement and establish connectivity between different interior and exterior parts of a building. These areas are designed to ensure that users can move safely and efficiently. Although they are not typically spaces where individuals spend extended periods of time, the provision of physical and visual comfort in these transitional zones is crucial to support purposeful actions. Therefore, lighting in these areas must be functionally appropriate and accurately implemented. Within architectural terminology, horizontal circulation areas refer to corridors, while vertical circulation areas include staircases, elevators, ventilation shafts, lighting wells, and certain open spaces such as gardens, courtyards, or plazas located outside buildings.

This study focuses on stair towers, which historically served both as vertical circulation elements and as prominent architectural features.

2. Materials and Methods

In this study, the architectural lighting simulation software Dialux Evo 4.0 was utilized. DiaLux, a program used for both interior and exterior lighting design, allows for spatially based simulations of both natural and artificial lighting data. It was employed to determine the levels of natural and artificial lighting within the stair towers of the Old Railway Station (currently the administrative building of Trakya University Faculty of Fine Arts), which is characterized by insufficient natural illumination. Initially, the amount of daylight-based illumination was measured independently from artificial lighting; subsequently, the existing artificial lighting levels were assessed.

golden light publishing

The study proposes a lighting scenario addressing the necessary number and type of lighting fixtures required to meet the minimum illuminance levels as defined in lighting standards.

3. Architectural Circulation Spaces and Daylight Requirements From Past to Present

Circulation elements in architectural structures facilitate both horizontal and vertical movement, ensuring connectivity between spaces. These elements not only enable transitions between different levels but also hold architectural significance in terms of aesthetics and functionality. From antiquity to the present, the form and characteristics of these elements have evolved according to architectural periods. The historical development of vertical circulation elements, particularly staircases, can be categorized into six distinct periods.

In ancient times, staircases emerged as functional necessities, as seen in Mesopotamian ziggurats and Egyptian pyramids. During the Greek and Roman periods, stairs acquired aesthetic value, with Romans constructing larger and more ornate staircases using arch and vault systems. In the Middle Ages, spiral staircases became common in castles and cathedrals for defense and spatial efficiency. Renaissance stair design gained artistic expression, which was further enriched with decorative elements during the Baroque and Rococo periods. The 19th century introduced steel and reinforced concrete, leading modernist architects to design functional, minimalist stairs inspired by industrial architecture and nautical themes. Le Corbusier, through his concept of the "architectural promenade," favored ramps and sculptural stair designs (Templer, 1992; Arığ, 2023; Canbakal-Ataoğlu, 2024).

In 20th-century modern architecture, circulation elements were primarily shaped by principles of functionality and efficiency. Staircases and elevators were designed not only for vertical transport but also as integral components of spatial aesthetics. They were strategically positioned to interact with environmental factors—especially natural light—enhancing the luminous and spacious quality of interiors and enriching spatial experience. Thus, circulation areas were carefully planned to fulfill functional needs while also contributing to architectural aesthetics. Stair lighting plays a crucial role in both safety and visual enhancement. A well-designed lighting scheme ensures safe usage while improving the overall spatial appearance. Despite the widespread use of elevators in the postmodern period, staircases remain essential architectural elements for guiding circulation, especially in public buildings (Templer, 1992; Canbakal-Ataoğlu, 2024).

3.1. Lightning Requirements for Staircases

To ensure safe use, staircases must be equipped with appropriate lighting conditions. Both national and international standards emphasize lighting requirements for stairs in terms of user safety, comfort, and energy efficiency. A well-designed lighting system not only promotes safety but also enhances the spatial atmosphere.

Stair lighting must meet requirements for safety, functionality, and aesthetics. Adequate illuminance levels should ensure clear visibility of steps and edges; a minimum of 100 lux per step is recommended. Uniform and consistent light distribution is essential to prevent shadows and dark areas, thus enabling secure movement (TS EN 12464-1:2012).

Motion sensor technologies may be employed to improve energy efficiency and user experience, activating lihgts only when needed and reducing unnecessary energy consumption, particularly in dark environments. Aesthetic and functional considerations should guide lighting design; decorative fixtures, wall sconces, or chandeliers may be used in alignment with the architectural style, but functionality must remain a priority.

Today, LED lighting is one of the most preferred methods for stair illumination due to its energy efficiency and long lifespan, offering both economical and environmentally friendly solutions. Various color temperatures can be used to influence spatial ambiance. In narrow or spiral staircases, a sensitive lighting design is crucial. Properly planned lighting systems enhance both safety and architectural harmony. Moreover, smart technologies enable lighting levels to be adjusted according to user needs, optimizing energy use

3.2. Illuminance Standards for Vertical Circulation Elements

Stair towers and other circulation components have become essential in architectural design for facilitating natural lighting. The admission of natural light enhances user experience and positively influences spatial ambiance. The positioning, facade orientation, and structural features of staircases are key factors in directing light into the space. In particular, glass surfaces used in stair tower design play a critical role in introducing daylight into interiors. These applications offer advantages in terms of both aesthetics and energy efficiency. As a result, circulation spaces become brighter and more spacious while also ensuring visual comfort.

Additionally, illuminance reference values for the safe and effective use of vertical circulation elements are specified by both national and international standards. In Turkey, stair lighting is regulated by TS EN 12464-1:2012 and the Regulation on Fire Protection of Buildings (Ministry of Environment and Urbanization). According to these:

- TS EN 12464-1:2012 requires a minimum of 100 lux for staircases in enclosed spaces.
- The Fire Protection Regulation mandates at least 1 lux for emergency routes and escape stairs.
- Steps must be lit to prevent shadows, glare, and ensure visual comfort.

Internationally, standards such as ISO 8995-1, CIE 60, BS 5489, NFPA 101 (Life Safety Code), and IEC 60598 address stair lighting:

- ISO 8995-1 (CIE 60): Minimum 100 lux for interior stairs, 20 lux for exterior stairs.
- BS 5489: Recommends 5 lux for outdoor stairs and 15 lux for frequently used areas.
- NFPA 101: Requires at least 1 lux for emergency exits and stairways.
- IEC 60598: Regulates the electrical safety and energy efficiency of stair lighting fixtures.

Table 1 provides a comparison of national and international standards regarding stair lighting and associated energy efficiency criteria. Both TS EN 12464-1 and ISO 8995-1 mandate a minimum of 100 lux for enclosed stairs. NFPA 101 and Turkish regulations require at least 1 lux in emergency exits. While the UK and other countries have additional requirements for exterior stair lighting, such regulations are not clearly specified in Turkish standards.

Below is a table comparing national and international standards (Table 1).

Table 1. Comparison of National and International Standards

Criteria	**Türkiye (TS EN 12464-1:2012)**	**ISO 8995-1 (CIE 60)**	**BS 5489 (United Kingdom)**	**NFPA 101 (USA)**
Indoor Staircase Lighting	100 lux	100 lux	-	-
Outdoor Staircase Lighting	Not specified	20 lux	5-15 lux	-
Emergency Lighting	1 lux	1 lux	-	1 lux
Energy Efficiency and Safety	Compliant with IEC 60598	Compliant with IEC 60598	Compliant with IEC 60598	Compliant with NFPA 101

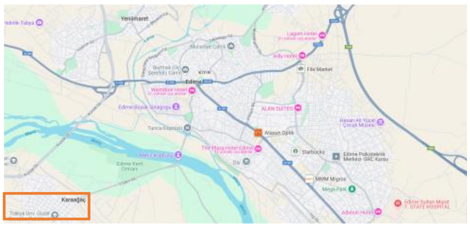
4. Field Study: Stair Towers of Trakya University Faculty of Fine Arts

To emphasize the importance of natural lighting in railway station buildings, the historical railway station located in Karaağaç, in the central district of Edirne, was selected as a case study. Within the scope of the study, the current condition of the building will be examined in detail, and its adequacy in terms of natural lighting will be assessed. Where necessary, artificial lighting scenarios will be proposed to supplement deficiencies.

4.1. Location and Characteristics of the Building

The Karaağaç Train Station, formerly known as Edirne Railway Station (Fig.1, Fig. 2) is a historical structure located on Karaağaç Street in the Karaağaç neighborhood of Edirne. The original station, constructed during the Ottoman period by the Chemins de fer Orientaux / Rumelia Railway (CO) Company, was inaugurated on April 4, 1873. However, due to increasing demands for passenger and freight transport over time, it was decided to construct a larger and more monumental station building. The new station, designed in a neoclassical style by the prominent architect Kemaleddin, was inspired by the design of the Sirkeci Railway Terminal in Istanbul. The resulting structure is an impressive, three-story, rectangular building measuring 80 meters in length. It served as one of the most important stops on the railway line connecting Istanbul to Europe. Today, the station remains a significant cultural and historical landmark and is considered one of the key elements of Edirne's architectural heritage (URL1, Başar & Erdoğan, 2009; Hasanbat, 2018).

Before being allocated to the Faculty of Fine Arts, the building served various functions throughout its history. Between 1872 and 1977, it operated as the Edirne Train Station; from 1977 to 1982, it housed the Edirne State Academy of Engineering and Architecture; from 1982 to 1994, it served as the Trakya University Edirne Vocational School; and between 1998 and 2011, it functioned as the Rectorate and Administrative Offices of Trakya University (Meral, 2016). In 2011, the building was transferred to the Faculty of Fine Arts, where it underwent restoration and adaptive reuse. Today, the ground floor accommodates the administrative offices and exhibition halls of the Faculty of Fine Arts. The upper floor, where the stair towers under study are located, currently functions as a guesthouse for the university.



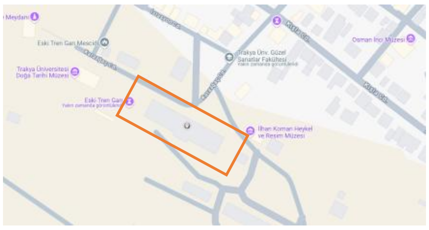


Fig. 1, Fig. 2. The Location and Urban Context of the Faculty of Fine Arts, Trakya University, Edirne

4.2. Architectural Features of the Building

The Edirne Railway Station was constructed as a three-story building, including a basement, aligned parallel to the railway tracks. As with earlier railway station buildings, it reflects the typical characteristics of railway station typology. The building is symmetrically organized along the axis of the central ticket hall entrance. The central and end volumes are emphasized by projecting them beyond the main facade plane and raising them above the roofline, highlighting the symmetrical layout. This emphasis is further accentuated by a pair of cylindrical towers capped with pointed wooden domes, symmetrically placed on either side of the central block, facing the entrance to the station (Fig. 3).

The station building, measuring 80 meters in length and 16 meters in width, was constructed using a brick masonry wall system (Fig. 4, Fig. 5). The exterior walls of the central section, which includes the three-story ticket hall, as well as the window and door arches, moldings, and the upper parts of the towers, were built with ashlar stone. Volta flooring system was used for the floors, and the building is covered with a hipped roof made of asbestos sheets supported by steel trusses (Edirne Inventory of Immovable Cultural Assets, 2013).

On the facades of the building, the basement floor windows are designed with segmental arches, while the ground and first-floor windows feature pointed arches. The windows on the ground floor are wider and taller than those on the upper floors, allowing for increased daylight penetration and contributing to a balanced visual composition. The main entrances on both the city-facing and platform-facing sides of the station are marked by large, pointed arches extending across the entire height of the structure, glazed to allow natural light in. These arches are framed with wide moldings, giving them the appearance of monumental portal gates. The upper ends of the towers—also accessible from the exterior—feature enclosed balconies defined by twelve pointed-arched openings, each supported by short columns. The building's facade composition is further enhanced by buttresses at specific points and wide-banded eaves, which together create a harmonious architectural expression.

Approaching the building from the city side, two cylindrical towers with circular plans and pointed domes—considered symbolic elements of the Edirne Railway Station—can be observed. These cylindrical towers are positioned on either side of the main hall and are set back from the main entrance block. Their placement within the architectural plan was made possible by the inclusion of single-storey service areas with terrace roofs and parapet railings.

Inside the towers, access to the terrace is provided by a helical staircase (Fig. 6), illuminated by natural light through four pointed-arched windows—two on the front facades and two on the side facades—of two different sizes. As the tallest structural elements of the building, the towers are fully visible from the northeastern facade adjacent to the main entrance block. When viewed from the southwestern facade (towards Greece), only the domes of the towers are discernible.

Designed with a circulatory function, the towers house spiral staircases that allow access to the first floor, attic, and the terrace level of the tower. The domes feature enclosed terraces made more prominent by twelve arched openings supported by columns.

The tower masses of the station building extend from the chamfered corners of the structure up to the first-floor level, and the form transitions at the parapet level are shaped by the repetition of various geometric forms and stone moldings along the facade, giving the tower a cylindrical surface. The towers, iconic symbols of the station, are topped with onion-shaped, lead-covered domes. Today, only one of the staircases—located in the left tower and leading to the Dean's Office—remains in use. This staircase can be accessed both from the interior and the exterior. Upon reaching the first floor, one arrives at the administrative staff level; at the start of the second floor, access to the main building's attic space is provided; and at the top level, the tower's terrace is reached—although it has been observed that the area leading to the terrace has been closed off.

Based on the data obtained regarding the building, the natural illumination levels of the staircase towers and the entrance hall have been identified and evaluated in detail.

Fig. 7, Fig. 8, Fig. 9 Interior Photographs of the Stairwell Tower of the Administrative Building, Faculty of Fine Arts, Trakya University (Elif Polat Archive, 2025

4.3. Evaluation of the Natural Daylight Levels of the Towers

Within the tower, a helical staircase that provides access up to the terrace level is illuminated by natural light through four pointed-arched windows (Fig. 7, Fig. 8, Fig. 9, Fig. 10, Fig. 11, Fig. 12), consisting of two on the front facades and two on the side facades, in two different sizes (Fig. 13, Fig. 14). The pointed-arched windows of smaller height are used at the lower levels of the tower, whereas the larger-sized windows are employed from the first floor up to the terrace level. This difference in window size results in a perceptible increase in the level of natural illumination in the upper sections of the tower.

As stated in Section 2.2, the required illuminance level for staircases, ramps, and escalators is specified as 100 lux (TS EN 12464-1:2012; URL2) (Fig. 15, Fig. 16). The same illuminance value of 100 lux shall also be adopted for the towers located within the workspace.

A daylighting analysis was conducted using the Dialux lighting simulation software for the main entrance hall of the building and the stairwell towers located on either side (Fig. 17, Fig. 18, Fig. 19).

In the ground floor plan of the structure, due to the absence of windows in the stair towers and the fact that this level is illuminated solely by natural light entering through the large windows of the main entrance hall, the measured illuminance level was found to be 25 lux. On the first floor of the towers, daylight enters through four pointed-arch windows, yielding an illuminance level of 500 lux in areas adjacent to the windows, while the surrounding areas recorded values ranging between 100 lux and 300 lux (Fig. 19).

An analysis of false-color lighting distribution in the main entrance hall revealed illuminance levels of 250 lux in areas near the windows and 100 lux in zones farther from them. Since these levels comply with the prescribed standards and provide sufficient lighting, no additional artificial lighting has been deemed necessary for this section. In the following section, a proposed artificial lighting scenario is presented for the ground floor, where natural illumination proves insufficient.

Ambient conditions for 'Room 1' are normal

Fig. 19. Natural Illuminance Measurement Results of the Stairwell Tower Located on the Left Side of the Building (Room 1) (DiaLux Evo)

4.4. Proposed Lighting Model for Stair Towers

Artificial lighting is required in zones where natural daylight fails to provide adequate illumination, and it serves to enhance brightness levels through controlled energy consumption. Accordingly, for the ground floor of the structure under study, the proposed model incorporates lighting fixtures along the ceiling and sidewalls of the tower entrance, as well as within the transitional section connecting the tower to the main volume. This strategy aims to enhance energy efficiency in general lighting while also creating a safer and more effective circulation zone.

Whereas the current design includes only a single artificial lighting fixture on the ground floor, the proposed model utilizes a total of three artificial lighting units—specifically, the LAMP brand's Moody G2 800 WW FL Triac BK fixtures—to achieve optimal and sufficient illumination. A false-color representation of the proposed model is illustrated in Fig. 20.

According to Fig. 21, the months with the highest demand for lighting are identified as January and December, with 17:00 being the time of day requiring the most illumination. (The calculations were made based on a five-day work week and operating hours between 07:00 and 18:00.)

In the proposed lighting scenario, user comfort in circulation areas has been ensured, and a direct, zonal, and energy-efficient lighting strategy has been implemented. The scenario supports the specific illuminance needs of each zone. As a result of this lighting proposal, the interior lighting levels of the towers have reached the 100 lux standard as cited in the literature and mandated by regulations for circulation areas. This configuration meets the minimum illumination requirements necessary for efficient circulation, in accordance with relevant standards.

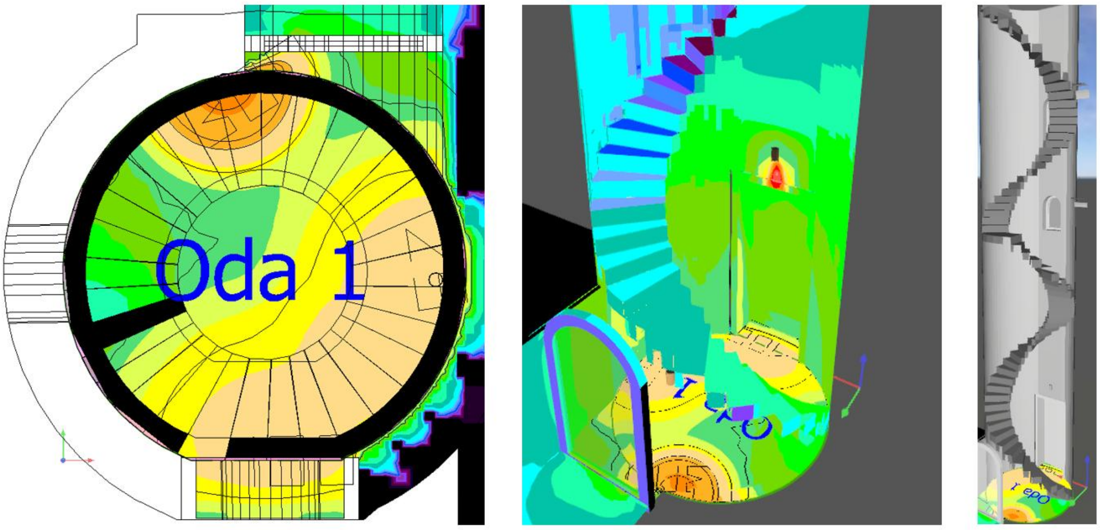

Fig. 20 Analysis of Incorrect Colors in the Stairwell Tower Located on the Left Side of the Building (Room 1) (DiaLux Evo)

An energy consumption analysis has been conducted using the fixtures employed in the study, and the variation of the analysis results by month is presented in Fig. 21.

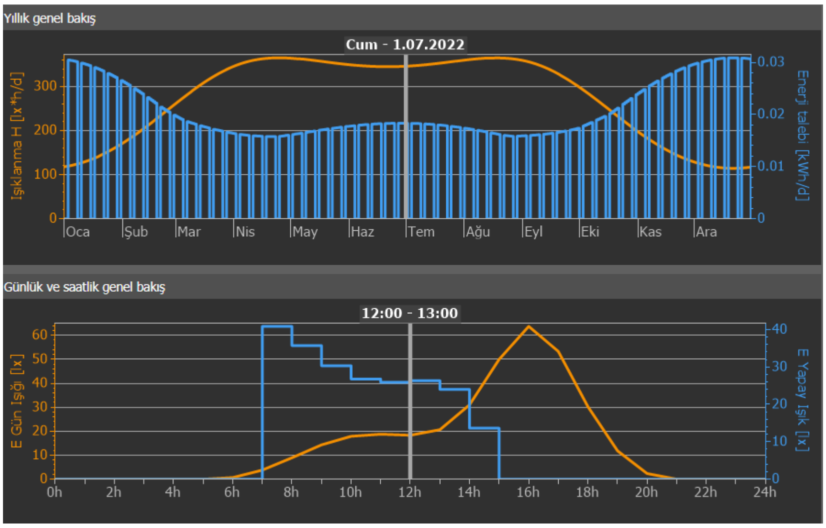

Fig. 21 Annual Energy Demand Measurement Results of the Stairwell Tower Located on the Left Side of the Building (Room 1) (DiaLux Evo)

5. Conclusions

Since daylight is insufficient to provide adequate illumination in certain areas of the stairwell towers, lighting proposals suitable for circulation zones have been developed in accordance with the findings of this study. In the proposed scenario, the illuminance level required for circulation functions has been achieved based on the relevant standards, ensuring adequate lighting for operational needs. Furthermore, both direct and indirect artificial lighting have been evaluated in terms of their impact on energy consumption. Proper and adequate illumination of staircases—which play a crucial role in facilitating vertical circulation—and the spaces housing them, is also critical for accident prevention.

This study focuses on the illuminance levels of the main entrance hall and the stairwell towers of the historical Edirne Train Station, which currently serves as the Faculty of Fine Arts building at Trakya University. The adequacy of lighting in these areas has been assessed. It was found that the natural lighting levels in the main hall, considered the entrance foyer, and the upper floor hall connected via the stairs, are sufficient during working hours. However, while the first-floor stairwell lighting level is adequate for functional use, the ground floor level is insufficient. Therefore, a scenario incorporating artificial lighting fixtures for the ground floor was proposed to achieve the required illuminance levels. The energy consumption of the proposed artificial lighting is observed to increase, particularly during the winter months (December and January).

In the case of historical buildings, evaluations regarding daylight levels are made based on the original facade and spatial design at the time of construction. Structural interventions that may alter the building's authenticity are typically restricted, aside from necessary conservation-related modifications. Thus, existing openings have been preserved in their current form, and an artificial lighting scenario was developed accordingly. Furthermore, the change in the building's function does not necessitate alterations in lighting requirements for the circulation areas addressed in this study. The requirements of staircases, as vertical circulation elements, remain consistent across different periods and functions. Therefore, the continued functional integrity of the stairwell towers, and their role as the sole means of vertical circulation within the building, underscore the significance of this study. The outcomes of this research aim to guide future studies concerning the assessment and proposal of both natural and artificial lighting strategies in historical buildings.

Birecik Bridge in the context of long span reinforced concrete bridges: An architectural and structural analysis

Fatma Şebnem Kuloğlu Yüksel*[1], Sevilay Akalp[1], Yahya Melikoğlu[1]

[1]*Harran University, Department of Architecture, 63000 Şanlıurfa, Turkey*

Abstract. Birecik Bridge is considered as an important structure that stands out in the process of Turkey's rural development policies in the 1950s and the construction of modern engineering structures in Anatolia. In addition to exhibiting Turkey's engineering capacity in terms of the period in which it was built, it also had a strategic importance in terms of facilitating the transportation of the surrounding agricultural rural area with the urban area. Located over the Euphrates River in the Southeastern Anatolia Region, the bridge is one of the longest reinforced concrete bridges in Turkey with a length of 720 meters. The structural systems used in the design of Birecik Bridge, which is an indicator of the development of reinforced concrete bridge technologies in Turkey, made it possible to cross large spans in an economical and durable way. The main purpose of this study is to examine and document the architectural and structural features of Birecik Bridge, an important architectural heritage for Turkey. The data obtained through literature review and fieldwork were systematically evaluated to analyze aspects of the bridge such as design, material use and durability. The study and documentation of the bridge sheds light on the history of engineering and architecture in Turkey and provides a scientific reference for the conservation and restoration of similar structures in the future. Thus, the bridge is considered in its historical context as a structure that demonstrates the role of modern engineering and architecture in regional development.

Keywords: Birecik bridge, Reinforced concrete bridge, Long span bridges, Architectural heritage, Sanliurfa

1.Introduction

Bridges are not merely structures that facilitate transportation; they are also critical architectural and urban planning elements that support the spatial continuity of cities, integrate with the landscape, and contribute aesthetically to urban identity. Located in Turkey's Southeastern Anatolia Region, the district of Birecik has historically served as a strategic center, enabling crossings over the Euphrates River and standing out as a key junction point within local and international trade networks (Paydaş & Narin, 2022; Bilici, 2024).

Due to the natural barrier formed by the Euphrates River, transportation in the region faced considerable challenges throughout history, and crossings were for a long time conducted using primitive methods (Onüçyıldız et al., 2016; Öğün & Başı, 2016). Within this context, the Birecik Bridge, inaugurated in 1956, was regarded not only as an engineering achievement but also as a tangible manifestation of the modernization initiatives, rural development policies, and transportation strategies of the Republic of Turkey.

As part of the development programs initiated in the 1950s, the integration of rural areas with urban centers was targeted, with investments in highways and bridge constructions aiming to enhance rural-urban interaction (İnan & Konyalı, 2022). In this regard, the Birecik Bridge contributed to regional development by connecting Southeastern Anatolia's production hubs to industrial and foreign trade routes, assuming a symbolic role in reducing the infrastructural disparities between the eastern and western parts of the country (Yurddaş, 2019).

From an engineering perspective, the Birecik Bridge represents a significant milestone in the development of long-span reinforced concrete bridge technology in Turkey. Featuring wide arch spans and hybrid structural systems, the bridge successfully combined durability with economic solutions, reflecting the technical capabilities of its time (URL-1).

Globally, long-span reinforced concrete bridges came to prominence in the late 19th century with advancements in materials and engineering, as the compressive and tensile strengths of reinforced concrete enabled large spans to be crossed economically (Billington, 1979). By the mid-20th century, innovations such as prestressed concrete technology and segmental construction methods further expanded spans and redefined the balance between aesthetics and engineering requirements in bridge design.

*Corresponding author, E-mail: kyuksel@harran.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_703

In Turkey, the widespread use of reinforced concrete bridges accelerated during the post-World War II period (Tanrıverdi and Gürel, 2019). While early examples featured small to medium-span arch systems, the Birecik Bridge, completed in 1956 with an approximate span of 180 meters, became one of the most significant crossings realized using reinforced concrete in the country (Bayraktar et al., 2013). This process paved the way for the widespread adoption of long-span bridge construction across Turkey, particularly with the later embrace of prestressed concrete technologies.

Today, many long-span reinforced concrete bridges are being constructed in Turkey using contemporary techniques such as segmental casting, prestressed concrete, and hybrid systems. The viaducts of the Northern Marmara Motorway, the approach viaducts of the 1915 Çanakkale Bridge and the major crossings along the Ankara-Niğde Motorway exemplify the advanced state of concrete bridge engineering in the country.

This study aims to examine the Birecik Bridge from both architectural and structural perspectives and to reveal the socio-spatial impacts of infrastructure investments during Turkey's modernization process. Supported by a literature review and field observations, this analysis seeks to demonstrate that the bridge serves not only as a transportation structure but also as a multilayered architectural heritage reflecting the ideological, technological, and societal vision of its era.

2.Materials and methods

The primary material of this study is the Birecik Bridge, located in the district of Birecik in the province of Şanlıurfa, within the Southeastern Anatolia Region of Türkiye. A multi-stage methodology was adopted in order to comprehensively analyze the architectural and structural features of the bridge. The research process consists of three main phases: a literature review, archival investigation, and fieldwork.

In the first phase, the historical development of reinforced concrete bridge technology, the evolution of long-span bridges, and academic studies related to the Birecik Bridge were systematically examined. In the second phase, project documents belonging to the Şanlıurfa Regional Council for the Protection of Cultural Assets Archive, the General Directorate of Highways, and the 9th Regional Directorate of Highways were analyzed; data regarding the construction process, technical specifications, and conservation efforts of the bridge were collected. Furthermore, by utilizing photographic archives from previous years, the physical changes of the bridge were assessed.

In the final phase, the fieldwork involved on-site observations of the bridge, where the load-bearing system components, material properties, and current structural condition were documented in detail. The on-site examinations contributed to both the evaluation of the bridge's conservation status and the verification of the findings derived from the literature and archival research.

3.Results and discussion

The Birecik Bridge stands among the significant engineering achievements of its time, brought to life through detailed and meticulous work. With decision No. 549 dated 15.11.2007, the bridge was registered as an immovable cultural asset requiring protection by the Şanlıurfa Regional Council for the Protection of Cultural Assets under the Ministry of Culture and Tourism. Subsequently, with decision No. 657 dated 30.06.2008, the same Council granted permission for minor repairs. In this context, practices such as the renewal of the railings, asphalt resurfacing, lighting, and expansion joint repairs were carried out. On 09.07.2014, decision No. 1122 approved the prepared survey, restitution, and restoration projects by the Şanlıurfa Regional Council for the Protection of Cultural Assets.

The bridge is located between the Birecik Dam upstream and the Karkamış Dam downstream. The waters released from the Birecik Dam are stored in the Karkamış Dam Lake, with the bridge situated within the boundaries of this lake basin. During the construction of the Karkamış Dam, ground improvement works were carried out using the jet grouting method to protect the foundations of the bridge and ensure impermeability. In 2009, an accident occurred on the bridge: a fuel-carrying vehicle fell from the 12th span and caught fire, causing damage to the bridge's load-bearing elements. The maintenance and repair works on the expansion joints and guardrails of the bridge mentioned above were carried out by the 9th Regional Directorate of Highways in 2008. As of 2014, a comprehensive project was prepared and presented for the repair and reinforcement of the bridge.

3.1. Architectural features of the Birecik Bridge

Throughout history, humans have sought to live near water; in particular, freshwater sources such as streams and rivers have been favored as settlement sites. The historic city of Birecik, shaped by settlements along the Euphrates River, played a role that was heavily dependent on the river for the development of transportation and trade. In particular, small boats and rafts remained the primary means of transportation for crossings from the city center to the western side for many years. However, with the increasing volume of trade and evolving transportation needs, the necessity for a permanent structure became apparent. In this context, the Birecik Bridge, inaugurated in 1956, represented a strategic step that supported the region's economic and social development.

One of the longest reinforced concrete road bridges in Türkiye, the Birecik Bridge is located on the E-90 highway and forms a critical transportation corridor, particularly for the Şanlıurfa-Gaziantep axis (Fig.1). The bridge was designed with a total length of 694.6 meters and a width of 10.54 meters, utilizing 44,000 bags of cement and 921 tons of iron (The Şanlıurfa Regional Council for the Protection of Cultural Assets Archive, 2025). On either side of the deck, there are pedestrian sidewalks constructed with reinforced concrete blocks, integrated with metal railings and lighting poles.

In terms of architectural design, segmental arch systems were employed on the eastern side (towards Birecik), while beam systems were used towards the west (Gaziantep side). Progressing from east to west, the initial span is crossed with a flat deck, followed by five segmental arches each with a span of 55 meters over the main riverbed (Sert et al., 2015). The deck, supported by square-sectioned columns following the curvature of the arches, is carried by 24 columns under each arch span.

Fig.1. Early construction period of the Birecik Bridge (The Şanlıurfa Regional Council for the Protection of Cultural Assets Archive, 2025)

On the eastern bank, a retaining wall extends along the Euphrates River, providing support to the bridge. The segmental arch section spans approximately 300 meters. After the seventh pier, the bridge transitions into a beam system supported by 13 rectangular piers towards the west (Fig. 2.). The beam section of the deck measures approximately 400 meters in length. In the structural design of the bridge, plain steel reinforcement was used, with the piers reinforced by triangular-sectioned cutwaters and toe details on both the upstream and downstream sides. Recognized as an original example of Republican-era bridge engineering in Türkiye, the Birecik Bridge was registered by the Şanlıurfa Regional Council for the Protection of Cultural and Natural Assets in 2007 and continues to serve two-way vehicular and pedestrian traffic today.

Fig. 2. View of the bridge’s reinforced concrete beam section from the west bank; the reinforced concrete beam system supporting the deck slab; view of the bridge’s reinforced concrete arch section from the east bank (Personal Photograpy Archieve of Author, 2025)

3.2. Structural features of the Birecik Bridge

The Birecik Bridge is located in the Birecik district of Şanlıurfa province, oriented in an east-west direction over the Euphrates River, along the Şanlıurfa-Gaziantep route (Fig 3). Opened in 1956, this bridge is an important engineering work from the Republican Era, with a total length of 720 meters and a width of 10 meters. At the time of its construction, it held the title of Turkey’s longest reinforced concrete highway bridge and today it is classified as a registered cultural heritage (URL-2).

Two different load-bearing systems were used together in the bridge. On the eastern side (Şanlıurfa direction), where the main bed of the Euphrates River is deeper, a reinforced concrete arch system was implemented. On the western side (Gaziantep direction), a variable cross-section reinforced concrete beam system was preferred. Additionally, the first span on the eastern side near the Birecik city center was designed as a flat-deck transition.

Fig. 3. Views of the bridge from the north side toward the south, and from the east side toward the west side (General Directorate of Highways Archive)

The distribution of the load-bearing systems along the east-west direction, span by span, is as follows:
1st Span: With a span of 20 meters, constructed with a variable cross-section reinforced concrete beam. It is used as a pedestrian and vehicle underpass (Fig. 4.). The piers are clad with cut limestone, and the beam height measured from the black elevation is approximately 5.10 meters.

Fig. 4. View from 1st Span of the Birecik Bridge, which is used as a pedestrian and vehicle underpass (Personal Photograpy Archieve of Author, 2025)

Spans 2–6: Each consists of segmented reinforced concrete arches with a span length of 55 meters. (Bayraktar etal., 2013).The radius of the arches is approximately 52.43 meters. The bridge arches are rigidly connected in the middle parts and at the side piers, and are constructed with joints at the upper points of the right and left parts of the middle points of the arches.The heights from the black level (reference elevation) to the crown points are measured as 5.15 m for span 2, 13.05 m for span 3, 15.65 m for span 4, 14.45 m for span 5, and 12.30 m for span 6. In addition, there is a flood protection wall constructed by the State Hydraulic Works (DSİ) at span 3.

7th-20th Spans: Consist of variable cross-section reinforced concrete beam systems, each with a 26-meter span. Gerber beam system with hinged expansion joints are located at the 8th, 11th, 14th, and 17th spans (Fig. 6.). A pedestrian staircase detail is present at the 12th span. The foundation piers, columns, beams, and decks of the bridge's arch and beam systems were entirely constructed of reinforced concrete. However, the support details at the end points of the arch and beam sections could not be fully determined from existing documents.

When examining the deck heights relative to the black elevation in the beam system spans, the following values were recorded: 8.70 meters at the 7th span, 10.60 meters at the 8th, 8.70 meters at the 9th, 8.15 meters at the 10th, 6.80 meters at the 11th, 5.60 meters at both the 12th and 13th, 4.10 meters at the 14th, 4.70 meters at the 15th, 4.30 meters at the 16th, 5.40 meters at the 17th, 4.60 meters at the 18th, 5.50 meters at the 19th, and 5.30 meters at the 20th span (The Şanlıurfa Regional Council for the Protection of Cultural Assets Archive (2025). *Archival documents on Birecik Bridge)*.

According to the technical report prepared during the restoration and repair works carried out in 2014, it was determined that BÇI type plain reinforcement steel was used in the bridge. Tests performed on concrete cores revealed that the concrete strength class was between C25-C30 in the arch sections and between C20-C30 in the beam sections.Today, the Birecik Bridge is open to both pedestrian and vehicular traffic, allowing the passage of normal vehicles, passenger buses, and heavy-duty trucks.

The Euphrates River, over which the Birecik Bridge stands, is the longest and most water-rich river in Turkey. With a total length of about 2800 kilometers, 1263 kilometers of the river lies within Turkey's borders. The flow regime of the Euphrates River is quite regular; water levels rise between March and June, and a gradual decrease is observed from July to January. Large-scale hydroelectric dams such as Keban, Karakaya, Atatürk, Birecik, and Karkamış have been constructed on the river, making these structures strategically important for the region's energy production and water management.

4.Conclusions

Within the scope of this study, the structural and architectural features of the Birecik Bridge, located in the Southeastern Anatolia Region of Turkey and built in 1956, have been comprehensively examined. The analyses show that the bridge serves not only as a means of facilitating transportation but also plays a decisive role in the region's economic development and socio-economic transformation. Especially by strengthening the connection between the east and west, this bridge has indirectly contributed to the increase in agricultural and livestock activities observed around the Euphrates River.

From a structural point of view, the Birecik Bridge incorporates advanced engineering solutions for its time. Considering that reinforced concrete and girder systems were only beginning to be used in the early 20th century, the bridge's design — combining both reinforced concrete arch and girder systems to balance the pressure and tensile forces caused by water — stands out as a significant approach that enhances structural durability.

Over time, corrosion-related deterioration has occurred on the bridge piers submerged in water, and wear on the load-bearing elements has been observed due to increased vehicular load. In this context, the registration of the Birecik Bridge as a cultural asset in 2007 has further emphasized the importance of its preservation.

In order to ensure the bridge's transmission to future generations as a long-lasting cultural heritage element, several restoration and conservation strategies have been developed. Within this framework; detailed material analyses of the original load-bearing elements should be conducted, intervention methods specific to different types of deterioration should be determined, and the principle of minimum intervention should be adopted during restoration to preserve the original structural character of the bridge. In addition, the heavy vehicle load on the bridge should be reduced, and alternative transportation routes should be planned for this purpose. It is also recommended to establish structural health monitoring systems to monitor the bridge's future performance and to take early precautions against potential risks.In conclusion, it is expected that the conservation and restoration proposals developed for the Birecik Bridge will form a methodological framework for the sustainable preservation of historic reinforced concrete bridges and contribute to the academic literature.

Graphite's multifunctional effects on thermal properties in construction materials

Cansel Özkan*[1], Leyla Tanaçan[1]

[1] *Istanbul Technical University, Department of Architecture, 34367 Istanbul, Türkiye*

Abstract. Management of thermal energy plays an important role in reducing energy consumption to provide an optimum environment within the building. It is known that approximately 30-40% of the total energy consumption worldwide originates from the construction sector and a large amount of this energy is wasted for heating and cooling purposes. Therefore, improving the thermal insulation properties of the buildings is of great importance in order to save energy by reducing energy losses. The thermal conductivity and volumetric heat capacity of a wall are two properties that greatly affect building's energy performance. The heat storage capacity of the material relies on its high specific heat and density, with high thermal conductivity facilitating rapid heat transfer during storage, while thermal insulation is achieved through a low thermal conductivity component or surrounding material. Graphite, a black and gray carbon mineral, is sourced from nature and increasingly produced synthetically by recycling lithium-ion batteries, driven by the rapid rise in battery production. Consequently, its availability has spurred widespread use in industries like electronics and energy storage, with its potential applications in architecture, such as thermal management now under research. The high thermal conductivity of graphite can be used to increase the heat storage capacity of materials, and in applications such as when it is included in expanded polystyrene, its radiation scattering property contributes to reducing thermal conductivity, thereby improving insulation performance. As a result, the use of graphite in architecture offers great potential in terms of increasing energy efficiency. In this study, the existing literature on the classification, properties, usage and potential of graphite in architectural materials within the scope of thermal energy management is reviewed and evaluated.

Keywords: Graphite; thermal conductivity; radiation; material; architecture.

1. Introduction

The demand for increasing the energy efficiency of buildings has increased significantly since energy use in the building sector constitutes a significant portion of total energy consumption and greenhouse gas emissions worldwide (Jelle, 2011). Considering the exhaustible nature of energy resources, global warming and increasing economic costs, energy efficiency in the construction sector has become a priority. According to the International Energy Agency (2024), a large portion of global energy consumption originates from the construction sector; a significant portion of the sector's energy use consists of heating and cooling needs, which are affected by climate conditions and economic development trends. In particular, the fact that a large part of the existing building stock has been constructed without considering energy efficiency increases energy losses, and these losses lead to both economic resource waste and environmental carbon emissions. In this context, the Building Energy Performance Directive (BEPTR) in force in Turkey also makes energy classifications of buildings mandatory and encourages energy saving through thermal insulation.

Effective thermal insulation in buildings is of great importance in meeting demands for improved energy efficiency. The increasing energy demand on a global scale and the need to combat climate change have accelerated the search for sustainable and high-tech materials in the construction sector.

One of the basic ways to minimize heat losses is to provide effective thermal insulation in the building envelope. Heat transfer in buildings occurs through three basic mechanisms: conduction, convection and radiation. Thermal insulation is the set of materials or systems used to delay or reduce the heat flow that occurs through these means. Thermal insulation systems can be generally examined under three headings according to the mechanisms by which they are effective against heat transfer:

https://doi.org/10.31462/icearc2025_a_aen_722

In conduction-based insulation, materials with low thermal conductivity coefficients are preferred. These materials minimize conductive heat transfer thanks to their inert air cells. Materials such as stone wool, glass wool, polyurethane foam and expanded polystyrene (EPS) are examples of this group.

Reflective insulation provides protection against heat transfer through radiation. By using materials such as aluminum foil with high reflectance and low emissivity, heat transfer through radiation can be significantly reduced. Radiant barrier systems are practical examples of this approach.

Thermal mass is based on the principle that building elements store heat and transmit it to the interior space in a time-spread manner. Materials such as reinforced concrete, brick and natural stone with high specific heat capacity reduce energy needs by balancing temperature fluctuations and contribute to passive heating/cooling strategies.

Insulation materials contribute to maintaining indoor temperature thanks to their high thermal resistance (R-value) and low thermal conductivity (k-value). Such materials generally limit convection by containing microscopic air gaps (dead air cells); they also reduce the effect of radiation thanks to their low emissivity. Thus, the total effectiveness of the insulation is explained by creating a structure that is not only conductive but also resistant to radiation and convection. The basic principle of thermal insulation is to slow down the heat flow and stabilize the indoor temperature against external factors. In this context, research in the field of building physics has brought to the agenda the development of materials that not only have insulation properties but also have heat storage capacity. Accordingly, optimizing low thermal conductivity and high specific heat capacity in building materials plays a critical role in achieving energy efficiency targets. While low conductivity limits the transfer of temperature fluctuations to the interior; high heat capacity allows the energy to be stored for a long time and reduces the energy consumption of HVAC systems. In this direction, graphite has a remarkable potential due to its unique physical and chemical properties. Thanks to its high thermal and electrical conductivity, resistance to high temperatures, chemical stability and low density compared to metals, graphite is widely used as an industrial raw material in a wide variety of areas such as metallurgy, refractory production, electrochemical devices, sealing elements and lubricants (Çuhadaroğlu & Kara, 2018). In addition to these traditional areas of use, it is thought that properties of graphite such as optical reflectivity can be evaluated in radiation-controlled insulation systems.

On the other hand, graphite is not only a material obtained from natural reserves, but can also be supplied by recycling wastes originating from the use of lithium-ion batteries as anode material and graphite production processes. The study conducted by Liu et al. (2024) shows that graphite production wastes can exhibit photocatalytic activity under visible light and these wastes can be converted into environmentally friendly building materials. Similarly, Kumari & Samadder (2024) conducted studies on the recovery of graphite from end-of-life lithium-ion batteries and its conversion into graphene derivatives. These developments strengthen the contribution of graphite to the sustainable material cycle. Although the effects of graphite on the mechanical strength, electrical conductivity and piezoresistive properties of cement-based composites have been extensively studied in the existing literature, research on its effects on thermal properties is still limited. In particular, studies that address the role of graphite in architectural applications aimed at increasing energy efficiency in building envelopes with a holistic approach are lacking.

This study aims to evaluate the application areas and advantages offered by graphite within the scope of thermal energy management in buildings.

Accordingly, the structure of the study is as follows:

- In the first section, the classification, types and basic properties of graphite will be examined.
- In the second section, the potential use of graphite in architectural applications in the context of thermal insulation, radiation control and thermal mass properties will be discussed.
- In the last section, current limitations and future research and development areas will be evaluated.

2. Graphite: classification and properties

Graphite is one of the four allotropic forms of pure crystalline carbon; the others are diamond, fullerene, and carbon nanotubes (Fig 1). Formed by the arrangement of carbon atoms in a planar honeycomb structure, graphite is a gray-black, opaque mineral with a metallic or earthy luster. Its Mohs hardness varies between 1-2, its density varies between 2.1-2.3 g/cm³, and it has a high melting temperature (3.927°C). With these properties, graphite is a unique material that offers many technical properties such as high temperature resistance, chemical inertness, excellent electrical and thermal conductivity (Olson, 2020; T.C. Enerji ve Tabii Kaynaklar Bakanlığı MTA, 2023; Kaya, 2006; Pierson, 1993). Given these properties, graphite is used in many areas both as a naturally obtained mineral and as a synthetic material produced by industrial processes.

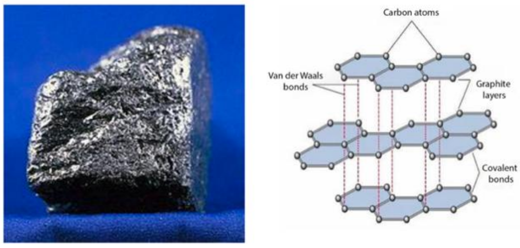

Fig 1. Graphite and structure of graphite (Çuhadaroğlu & Kara, 2018)

Natural graphite is formed in metamorphic rocks through geological processes, while synthetic graphite is obtained by carbonizing carbon sources such as petroleum coke and anthracite at temperatures of 3000–4000°C (IMIB, 2020). Natural graphite is classified into three basic forms: amorphous (microcrystalline), flake and vein type. Amorphous graphite is the most common and low-quality form with a microcrystalline structure and low carbon content. All graphite deposits in Turkey fall into amorphous class and are generally used in metallurgical processes, pencils and brake pads (Kaya, 2006; Jara et al., 2019; T.C. Enerji ve Tabii Kaynaklar Bakanlığı MTA, 2023). Flake graphite has a high carbon content (approximately 85–98%) and is generally found in metamorphic rocks formed under high temperatures and pressures. This type is especially preferred in high-tech fields such as lithium-ion batteries, nuclear reactors and refractory materials. Vein-type graphite is the rarest, highest purity and most valuable type of graphite. It is usually found in Sri Lanka and provides the best thermal and electrical performance with high crystal perfection (Olson, 2020; T.C. Enerji ve Tabii Kaynaklar Bakanlığı MTA, 2023). The physical and chemical properties of the three primary types of natural graphite are summarized in Table 1.

Synthetic graphite has a different environmental profile than natural graphite due to the high energy requirement in the production process. While approximately 4.9 kg of CO_2 is released per kg in synthetic graphite production, this rate is at the level of 1–2 kg CO_2 in natural graphite. In addition, other pollutants such as NOx, SOx and particulate matter are also emitted into the atmosphere during synthetic graphite production (T.C. Enerji ve Tabii Kaynaklar Bakanlığı MTA, 2023). In contrast, synthetic graphite is preferred especially in electrode production, coatings and as a carbon additive due to its advantages such as high purity, controlled structure and chemical stability (IMIB, 2020). A comparison between synthetic and natural graphite is presented in Table 2.

Some intermediate products obtained from graphite reveal the versatile structure of this material. For example, graphene is a single-atom-thick, hexagonally arranged carbon layer obtained from graphite and is called today's "miracle material". Graphene has a current carrying capacity a thousand times greater than copper, 200 times greater strength than steel, and excellent heat conduction. In addition, with its transparent, flexible, and lightweight structure, it has the potential to revolutionize areas such as electronics, defense industry, automotive, and sports equipment (Olson, 2020). Another intermediate product, expanded graphite, is formed by opening its layers like an accordion as a result of high-temperature treatment. This material is used especially in insulation, flame retardant additives, gaskets, and battery technologies with its properties such as low density, high surface area, and electromagnetic protection. Expandable graphite is another form that gains sudden expansion when heated by being subjected to an intercalation process with certain chemicals. Thanks to these properties, it contributes to the development of systems with high energy efficiency (T.C. Enerji ve Tabii Kaynaklar Bakanlığı MTA, 2023).

The physical properties of graphite are also among the factors that determine its areas of use. These properties are presented in Table 3. Its density is low, its hardness is low, but its heat and electrical conductivity properties are quite high. It can be easily flaked due to the weak Van der Waals bonds between the layers, which makes it a natural solid lubricant (Kaya, 2006; Pierson, 1993; Olson, 2020). It is also chemically stable and resistant to most acids, bases and salts. These versatile properties of graphite have made it used in a wide range of applications, from pencils to nuclear reactors, from electrodes to heat-resistant refractory materials. Natural and synthetic forms offer different advantages in different sectors. Natural graphite is mostly used in refractory, casting, pencil and battery production; synthetic graphite stands out in electrode and carbon additive applications where it is required in a purer form (IMIB, 2020).

Table 1. Comparative properties of natural graphite types (Kenan, 1993, as cited in Kaya, 2006)

	Amorphous	**Flake**	**Crystalline**
Carbon (%)	81.00	90.00	96.70
Sulfur (%)	0.10	0.10	0.70
Density (g/cm³)	2.31	2.29	2.26
Graphite Content (%)	28.00	99.90	100.00
Morphology	Granular	Flaky	Layered

Table 2. Comparison of synthetic and natural graphite (MTA, 2023; IMIB, 2020)

Properties	Natural Graphite	Synthetic Graphite
Production method	Natural formation (metamorphism)	High temperature carbonization
Carbon Footprint	1–2 kg CO_2/kg	4,9 kg CO_2/kg
Purity	Low–medium	High

It is stated that the visible graphite reserves in the world are approximately 300 million metric tons, and this figure can reach 800 million metric tons with potential reserves. Turkey has 30% of the world reserves with approximately 90 million tons of reserves. However, since the graphite deposits in Türkiye are amorphous, they are imported for applications requiring high purity (IMIB, 2020; Kaya, 2006).

Finally, although various studies are carried out in the world on graphite recycling, there is no effective application in Turkey yet. Recycled graphite can be reused as brake pads, thermal insulation materials and carbon additives, which provides both economic and environmental benefits. In particular, the recovery of graphite content in lithium-ion batteries will have strategic importance in the coming years (MTA, 2023; Liu et al., 2024).

3. Applications of graphite within the scope of thermal energy management in buildings

Graphite is used as an additive in many insulation systems due to its high thermal conductivity, low emissivity and stable physical properties (Çuhadaroğlu and Kara, 2018); thus, it provides performance improvements for different heat transfer mechanisms. The effects of graphite additive on the methods developed against the three basic heat transfer mechanisms affecting thermal insulation offer a remarkable research area. In the literature, it is seen that graphite-containing materials affect these three heat transfer paths (conduction, radiation and heat storage/release (thermal mass)) in different ways. Therefore, the effects of graphite on these transition paths will be evaluated under separate headings; analyzes specific to each heat transfer mechanism will be presented according to the materials to which graphite is added. In this context, the effects of graphite additive on thermal performance will be examined on three different building material groups, namely EPS, mortars and pastes and phase change materials (PCMs). In Table 4, the heat transfer mechanisms affected by graphite, the roles it undertakes in these processes and the thermal performance changes that occur accordingly are summarized.

3.1 Effect of graphite on thermal conductivity

Graphite is a carbon allotrope with high thermal conductivity (Pierson, 1993). Therefore, it can have an effect on increasing conductivity in the materials it is used in, and this situation can vary depending on factors such as the binder matrix used, the amount of graphite, particle size and distribution homogeneity. The effects of graphite added to EPS and mortar mixtures, respectively, are as follows.

3.1.1. EPS with graphite

When micron-sized graphite particles were added to expanded polystyrene (EPS), significant decreases in thermal conductivity were observed (Blazejczyk et al., 2020; Lakatos & Csík, 2022). This decrease is explained by two main mechanisms: (i) reduction of radiative heat transfer due to the high infrared radiation absorption capacity of graphite, (ii) suppression of conductive heat transfer by interrupting the phonon conduction paths in the polymer matrix by graphite (Blazejczyk et al., 2020). Lakatos et al. (2018) measured the thermal conductivity values in the range of 0.030–0.032 W/m K in graphite-added EPS materials from five different manufacturers, and obtained results that were close to the manufacturers' data but with 5–10% deviation. These differences were attributed to graphite distribution and porosity. Blazejczyk et al. (2020) reported a 17.2% reduction in thermal conductivity in 'gray' EPS panels containing up to 7.3% graphite, compared to low-doped 'speckled' EPS; the thermal conductivity of the 'gray' panels was measured at 0.0312 W/m·K. Micro-Raman analyses showed that the phonon spectrum was suppressed and there was a deterioration in the polymer chain structure. These graphite microparticles reduce the phonon conduction of the polymer matrix, reducing heat conduction.

Table 3. Physical properties of graphite (Olson, 2020; MTA, 2023; Kaya, 2006; Pierson, 1993)

Properties	Value
Density	2.1–2.3 g/cm³
Hardness (Mohs)	1–2
Melting Point	3.927 °C
Electrical Conductivity	20 times more than copper (specific)
Thermal Conductivity	398 (W/mK)*
Specific Heat	0.690 - 0.719 (kJ/kgoK)

*For commercial pyrolytic graphite, the thermal conductivity is 390 W/m·K in the ab directions.

Table 4. Effects of graphite addition to different materials.

Material	Heat Transfer Mechanism Affected by Graphite	Role of Graphite	Performance Improvement	References
EPS	Conduction	Phonon scattering, formation of micro heat paths	15–30% reduction in thermal conductivity	Blazejczyk et al. (2020); Rydzkowski et al. (2020); Lakatos et al. (2018)
EPS	Radiation	Infrared absorption and scattering	15–25% improvement in total U-value	Rydzkowski et al. (2020); Zhou et al. (2024)
Mortar	Conduction & Thermal Mass	Microstructure densification, porosity reduction	Up to 97% increase in thermal conductivity; Increase on specific heat capacity. Reduction on thermal flux 6% -54%;	Medina et al. (2018); Barbero-Barrera (2017a), Silva & Gachet (2024)
PCM	Conduction & Thermal Mass	Acceleration of phase change, leakage prevention	0.2 → 0.48 W/m·K increase in conductivity; Increase in heat storege capacity 13.86 → 47.36 kJ	Chen et al. (2024); Belete et al. (2024); Zhang et al. (2006); Cui et al. (2015)

This shows that it has a strong effect not only on radiation but also on matrix conductivity. In addition, a non-standard experiment with aluminum foil in heat flow meter (HFM) tests was carried out by Blazejczyk et al. (2020) to measure the total thermal conductivity and separate the radiation and conduction components from each other. As a result, it was found that graphite-doped samples almost completely block the radiation, and Graphite microparticles (GMP) not only suppress the radiation but also prevent the propagation of acoustic and optical phonons by disrupting the order of the polymer chains. Phonons (heat-carrying vibrations) are strongly scattered in the boundary regions between the graphite and the polystyrene matrix, less frequently reflected, and delayed by being absorbed and scattered in random directions within the graphite. In addition, the interaction between the graphite and the polymer chains in the matrix disrupts the matrix, which slows down the heat conduction. All these processes hinder the movement of phonons, thus seriously reducing heat conduction (Blazejczyk et al., 2020). In the study conducted by Rydzkowski et al. (2020), the thermal conductivity decreased to the range of 0.024–0.025 W/m K with graphite nanoparticles added to EPS (reference EPS: 0.038–0.040 W/m K), which means a 35–40% decrease. It was stated that this improvement was due to the graphite particles being embedded in the walls of the EPS granules and limiting the radiation effect.

These studies show that graphite added to EPS not only reduces heat conduction but also increases the thermal stability and fire resistance of the structure. A summary of various studies investigating the use of graphite in EPS materials, including details such as graphite type, content, particle size, and corresponding thermal conductivity, is presented in Table 5.

3.1.2 Mortars and pastes with graphite

Studies have been conducted to research the effect of graphite on thermal conductivity by adding it to cement and lime based mortar systems. The graphite used is usually in the form of isostatic graphite powder, expanded graphite (EG) or synthetic flake and the particle size is mostly at the micron level. In the research of Medina et al. (2016), series of gypsum pastes with 0–5–10–15–20–25% of graphite filler by weight replacement of gypsum, decreased porosity and water absorption rates and increased compressive strength up to 275%. According to Medina et al. (2018), the incorporation of industrial waste isostatic graphite powders into cement pastes and mortars (as 10–30% cement replacement) resulted in an increase in thermal conductivity up to 171% despite the decrease in bulk density. This increase was paralleled by the increase in mechanical strength. It may encourage its use in conductive flooring for heating purposes and solar energy storage materials.

Barbero-Barrera et al. (2017a) studied on the gypsum-based systems, by adding 0-25%, gypsum replacement resulted in increases of up to 19% in bulk density, up to 97% in thermal conductivity and up to 10.3% in emissivity, while in radiant building applications, thermal flux was reduced by 54% towards the outside. This showed that graphite gypsum composite material is particularly suitable for use in radiant systems.

Table 5. Summary of EPS studies with graphite

Reference	Type of Graphite	Graphite Content	Graphite Particle Size (μm)	Thermal Conductivity (λ or R)
Blazejczyk, 2020	Graphite Microparticles (GMP)	Product B: low GMP Product C: high GMP	1–15 μm	λD: ~0.0305 W/m·K at 10°C
Lakatos et al., 2018	Nano/micro graphite flakes	Not specified quantitatively	Not specified	λ ≈ 0.031–0.033 W/m·K
Lakatos & Csík, 2022	Microscale & nanoscale graphite powder	Not specified quantitatively	Nano size (heat mirror effect)	λ < 0.039 W/m·K (better than white EPS)
Rydzkowski, 2020	Graphite nanoparticles	Added during granule formation	Dispersed in cell walls, <5 μm wall thickness	Best thermal conductivity among tested variants
AIA Platinum GPS	High-purity graphite (IR absorber/reflector)	<1% of total mass	Not specified	R-value: ~5.0 ft²·h·°F/BTU per inch (~0.028 W/m·K)

Barbero-Barrera et al. (2017b), in another study, tested samples containing different hydraulic lime replacements with graphite ranging from 0% to 50% and reported an increase of up to 80% in thermal conductivity. In the same study, the best results were obtained in mechanical strength with 25% graphite addition. Again, it was concluded that it became useful in high-temperature products and also in radiator floors, ceilings or walls thanks to the graphite addition. Filazi et al. (2023) studied alkali-activated mortars with 0.5–4% graphite addition and 24.6% increase in electrical conductivity was achieved with 4% addition, and no tests were performed on thermal conductivity. Silva & Gachet (2024), in their study aiming to evaluate the electrical and mechanical properties of mortars produced using Portland cement, sand and powdered graphite at 0%, 5%, 10% and 15% by mass of cement, found that electrical impedance decreased by 259.42% with 15% graphite addition, i.e. high electrical conductivity was achieved. No tests were performed on thermal conductivity.

In general, the range of 10–15% is recommended as the optimum additive ratio in terms of thermal conductivity and workability balance. In addition, when the additive ratio exceeds 25%, mechanical strength decreases and serious deterioration in workability can occur (Barrera et al., 2017b). It can be said that graphite creates conductive networks in the mortar matrix, not only increasing thermal conductivity but also providing electrical conduction, which offers great potential for smart building materials. Table 6 summarizes various studies on mortar and paste incorporating graphite, highlighting differences in binder types, graphite sources, contents, particle sizes, and reported thermal conductivity values.

3.1.3 PCMs with graphite

Phase change materials (PCM) play an important role in increasing the passive heat storage capacity for structures; however, their heat transfer rates are generally limited due to low thermal conductivity. In order to overcome this deficiency, the use of graphite additives in PCM systems has been intensively investigated in recent years. In general, graphite has been integrated into cement-based phase change material systems in different morphologies (e.g. expanded graphite, graphite sheets, microencapsulated graphite-added PCMs) in order to eliminate the problem of low thermal conductivity, accelerate heat storage and release processes, prevent possible leaks in paraffin-based PCMs through physical adsorption, and optimize both thermal and mechanical performances of building materials. In this context, graphite has functioned as both a conductivity-enhancing additive and a supporting matrix that stabilizes the phase change medium. High thermal conductivity enables composites to be used more efficiently as resistance heating elements due to the increase in heating rate; It increases the storage efficiency of paraffin, so it is desirable for heat storage capacity because the heat storage and release time is reduced (Fraç, 2021). Zhang et al. (2006) reported a 221% increase in thermal conductivity of paraffin-SBS based shape-stable PCM with 20% flake graphite addition. However, mechanical weakening and paraffin leakage were observed with additions above 15%. Zhang & Fang (2006) found that 85.6% paraffin-based PCM impregnated with expanded graphite shortened the heat storage time by 27% and the cooling time by 56% compared to conventional paraffin. Zhang et al. (2013) added 0.5–2.5% n-octradecane/expanded graphite-based PCMs to cement mortar and achieved a 8.7 °C decrease in indoor temperature, a 15% decrease in thermal conductivity, and an increase in heat storage capacity.

Table 6. Summary of mortar and paste studies with graphite

Reference	Binder	Type of Graphite	Graphite Content (%)	Graphite Particle Size (μm)	Thermal Conductivity (λ or R)
Medina et al., 2016	Gypsum	Recycled isostatic EDM graphite	5–50	1–10 (peak), 35–150 (agg.)	0.341–0.739
Barbero-Barrera et al., 2017b	Hydraulic Lime	Waste graphite powder	5–50	Not specified	0.05–0.30
Filazi et al., 2023	BFS-based AAM	Commercial graphite powder	0.5–4	≤75	Not reported
Medina et al., 2018	Portland Cement	Isostatic graphite	Up to 30	~10	Up to +171%
Barbero-Barrera et al., 2017a	Gypsum	Revalorized graphite	Not specified	Not specified	0.329–0.725
Silva & Gachet, 2024	HES Portland Cement	Commercial powdered graphite	5, 10, 15 by weight of cement	75	Not reported

Cui et al. (2015) observed a 40% decrease in thermal conductivity with 20% addition in mortar systems containing graphite-added microencapsulated paraffin (GM-MPCM). Frąc et al. (2021) incorporated expanded graphite (EG) impregnated paraffin into the cement matrix at a ratio of 10–30 wt% of cement and found that the composites exhibited a high degree of thermal conductivity despite the high paraffin content with low thermal conductivity. This high thermal conductivity was attributed to the inclusion of expanded graphite, which is characterized by this property. Xiong et al. (2022) added graphite flakes to increase the thermal conductivity of microencapsulated PCM-cement composites, aiming to improve the heat storage and release rates by forming conductive networks in the matrix. As a result, the incorporation of 5 wt% graphite powder (GP) into CP-MPCM composites increased the thermal conductivity by up to 50.1%, improved the heat storage and release rates by over 25%, and improved the overall heat storage coefficient of the cement paste by 55.8%. Chen et al. (2024) applied graphite as a coating on porous Al_2O_3 ceramic, which is widely used in PCM packaging due to its advantages of controllable porosity and high thermal conductivity. Graphite coating was used to significantly increase the very low thermal conductivity of Lauric Acid/Myristic Acid (LA/MA), a phase change material (PCM). It was increased by approximately 20.7 times by compensating for the low conductivity of Al_2O_3. Belete et al. (2024) incorporated graphite into cement-based plaster mortar as part of a shape-stable phase change material (SSPCM) together with graphite, sodium sulfate decahydrate and calcium chloride hexahydrate. Thus, the thermal conductivity of the composite increased from 2.81 to 3.86 W/m °C. Both sensible and latent heat storage capacity of PCM increased with graphite addition, and the total heat storage capacity reached from 13.86 kJ to 47.36 kJ. Table 7 provides a summary of studies on the incorporation of graphite into PCM systems, outlining their material compositions, graphite types and contents, particle sizes, and the intended functions of graphite in enhancing thermal performance.

High thermal conductivity allows composites to be used more efficiently as resistive heating elements by increasing the heating rate. It is also preferred in terms of heat storage capacity; because it increases the heat storage efficiency of paraffin and shortens both heat storage and release time (Fraç et al., 2021). These findings show that graphite acts as an active heat transfer promoter and thermal stabilizer in PCM systems, not as a passive additive. Graphite improves both the energy performance and structural integrity of PCM-containing building materials by providing both impermeability and increasing thermal conductivity. However, as the additive amount increases, the risk of loss in mechanical strength increases, and the optimum graphite additive rate remains in the range of 5–15%.

3.2 Effect of graphite on radiation

Graphite has the capacity to limit not only conductive heat transfer but also radiative heat transfer. Lakatos et al. (2018) stated that graphite has very good infrared radiation absorption and also has a radiation scattering behavior. Especially compared to traditional insulation materials with low emissivity, graphite's radiation absorption and scattering properties are remarkable. Thanks to its low emissivity, graphite is an effective additive material in limiting heat transfer by radiation.

Table 7. Summary of PCM studies with graphite

Reference	**Material Composition**	**Type of Graphite**	**Graphite Content**	**Graphite Particle Size (µm)**	**Purpose of Use of Graphite**
Reference	Material Composition	Type of Graphite	Graphite Content	Graphite Particle Size (µm)	Purpose of Use of Graphite
Zhang et al., 2006	Paraffin + SBS + additives	Exfoliated graphite	0–20 wt%	Not specified	Enhance thermal conductivity of shape-stabilized PCM
Zhang & Fang, 2006	Paraffin + Expanded Graphite (EG)	Expanded Graphite (EG)	85.6% paraffin loading, 14.4% EG	300 µm, 200 mL/g expansion ratio	Support structure and enhance heat transfer in PCM
Zhang et al., 2013	n-octadecane + EG + Cement mortar	Expanded Graphite (EG)	0.5–2.5% composite PCM in TESCM	500 µm, 300 mL/g expansion ratio	Prevent PCM leakage and improve heat storage in cement mortars
Cui et al., 2015	Paraffin + Microcapsule + Flake Graphite + Cement	Flake graphite	5–20% GM-MPCM (graphite portion not specified)	800 mesh (~20 µm)	Enhance thermal conductivity of MPCM in cement composites
Zhang, 2006	Shape-stabilized paraffin PCM + additives	Graphite	0–20 wt%	Not specified	Improve thermal conductivity of shape-stabilized PCM
Fraç et al., 2021	Cement + 20–25% EG/Paraffin composite	Expanded Graphite (EG)	20–25% (composite form)	142–168 kg/m³ bulk density	Enable self-heating and storage in electric cement composites
Bi et al., 2020	Diatomite + EG + Paraffin + Cement mortar	Expanded Graphite (EG)	1–2 vol%	d50 ≈ 505 µm	Improve water resistance and thermal storage in steam-cured mortar
Cui et al., 2015	GM-MPCM (Paraffin + Flake Graphite) + Cement mortar	Flake graphite (800 mesh)	5–20% (graphite portion in GM-MPCM not specified)	150–350 µm (GM-MPCM size)	Enhance mechanical and thermal performance in cement mortar
Belete et al. 2024	$Na_2SO_4 \cdot 10H_2O$ + $CaCl_2 \cdot 6H_2O$ + Graphite + Cement mortar	Graphite (shape-stable)	Not specified	Not specified	Stabilize PCM and improve composite thermal management

3.2.1 EPS with graphite

Lakatos & Csík (2022) stated that in graphite-doped EPS plates, nanosized graphite particles act as heat mirrors by scattering and partially reflecting infrared radiation, while graphite powders on the cell walls absorb and significantly reduce radiative heat transfer. Blazejczyk et al. (2020) stated that the addition of graphite to EPS also reduces heat transfer by radiation, but to a lesser extent than conduction. Graphite absorbs and reflects infrared radiation, which reduces radiative transfer. By integrating graphite flakes into the polystyrene matrix, thermal conductivity is reduced by graphite particles that reflect and absorb radiation energy (Nowoświat et al. 2021).

These studies reveal that graphite is an active additive material in EPS systems that also acts as a phonon reflection and radiation suppressor.

3.3 Effect of graphite on thermal mass

Thermal mass refers to the ability of a material to store heat and delay and balance ambient temperature changes. This feature is of great importance in terms of increasing indoor comfort and reducing energy consumption. Thanks to its high thermal conductivity and specific heat capacity, graphite significantly contributes to thermal mass by increasing sensible and latent heat storage capacities in various building materials.

Graphite can affect heat storage and release processes in systems where it is included as an additive. It can have an effect on the absorption and delayed release of heat, especially when used in plasters, concrete-like mixtures or PCM systems. In addition, it can provide optimizing effects on time lag depending on the distribution, density and location of graphite in the material.

The use of materials with high thermal conductivity is critical for efficient energy transfer to interior spaces. In addition, materials with high or medium specific heat capacity are needed to support energy accumulation and overall thermal stability of the system (Barbero-Barrera et al., 2017a).

3.3.1 Mortars and pastes with graphite

In mortar systems, the thermal mass value depends on density, specific heat and temperature change capacity. Graphite, in these systems, spreads heat faster thanks to its distribution in the microstructure, and also contributes to the extension of thermal balance by providing an increase in specific heat. Barbero-Barrera et al. (2017a) achieved an increase of in specific heat capacity with 25% graphite addition in gypsum-based systems, and a decrease in thermal flux of 6–54% according to simulations. This can be said to be an indirect thermal mass effect that reduces indoor temperature fluctuations.

3.3.2 PCMs with graphite

The most intensive and directly observed contribution of graphite to thermal mass is seen in PCMs. PCMs, by their nature, can store heat as sensible and latent. Adding graphite to PCMs both accelerates this storage and increases the capacity. Belete et al. (2024) increased the heat storage capacity from 13.86 kJ → 47.36 kJ in PCMs containing sodium sulfate decahydrate and calcium chloride hexahydrate with 8% graphite, increased the specific heat capacity from 0.92 → 1.33 kJ/kg °C and the diffusion coefficient from $1.40 \times 10^{-6} \rightarrow 1.68 \times 10^{-6}$ m^2/s. These data directly reveal the increase in thermal mass. Chen et al. (2024) showed that the latent heat capacity of the FSPCMs30 system was 73.93 J/g, high specific heat and low diffusivity, long-term heat retention and late release were achieved. In the study of Zhang & Fang (2006), the heat discharge time in PCM systems with EG additives was 56% shorter than in conventional paraffin; this enabled the PCM to operate in a sharper temperature range and improved energy management. Cui et al. (2015) reported that the inner surface temperature in mortar systems with GM-MPCM additives was reduced by 4.1 °C, and the formation of the heat peak was delayed by 12 minutes. This is a thermal buffering effect that directly contributes to the thermal mass. In line with these data, it was clearly demonstrated that the graphite additive significantly improved the thermal mass in PCM systems by storing heat more efficiently, releasing it later and slowing down the heat fluctuations

4. Conclusions

Within the scope of this study, the effects of graphite additive on building materials were examined through three basic heat transfer mechanisms (conduction, radiation and thermal mass); evaluations were made specifically for EPS, mortar and PCM systems. The findings are summarized under the following headings:

4.1 Effects on thermal conductivity

- In EPS systems, graphite particles provide a conductivity decrease of 15–40% by preventing phonon conduction within the polymer matrix.
- In mortar systems, especially at 10–15% additive rates, graphite formed conductive networks within the matrix and provided a thermal conductivity increase of up to 171%. However, workability and mechanical strength were weakened at additives above 25%.
- In PCM systems, thermal conductivity increased up to 221% with flake or expanded graphite additives. Especially with graphite-coated Al_2O_3 structures, a value of 3.73 W/m K was reached.

4.2 Effects on radiation

- The effect of graphite on heat conduction is twofold: It both blocks radiation (infrared absorption of graphite) and reduces phonon transmission within the matrix.
- The radiative absorption capacity of graphite in EPS and its distribution within the matrix suppressed the total heat transfer, providing low temperature stabilization and fire safety.

4.3 Effects on thermal mass

- In PCM systems, specific heat capacity, diffusion coefficient and total heat storage capacity have increased significantly with graphite addition.
- In mortar systems, especially in gypsum-based systems, increase in specific heat capacity and up to 54% decrease in thermal flux indicate that indoor temperature oscillations are balanced.

Table 8. Effects of Graphite Properties on Thermal Conductivity, Radiative Heat Transfer, and Thermal Mass in Building Materials

Material	Property Range Obtained	Thermal Conductivity Reduction	Radiative Heat Transfer Reduction	Enhancing Thermal Mass
EPS	Graphite content: <1–7.3% by weight. Particle size: Nano (<5 µm) to micro (1–15 µm). Types: Nano/micro flakes, microparticles, high-purity graphite.	15–40% reduction (λ: 0.038–0.040 W/m·K to 0.024–0.033 W/m·K). Examples: 7.3% graphite: -17.2% (λ = 0.0312 W/m·K); Nanoparticles: 35–40% reduction.	Nearly blocks radiation (HFM tests). Graphite particles scatter/reflect IR; cell wall graphite absorbs IR. Significant but secondary to conduction.	Limited impact. Indirectly improves heat retention via thermal stability.
Mortars/Pastes	Graphite content: 0.5–50% by weight. Particle size: Micro (1–75 µm). Types: Isostatic, expanded, synthetic flake, waste graphite.	Typically increases λ. Up to 171% increase in thermal conductivity.	Reduces thermal flux by 54% in radiant systems. Increases emissivity (+10.3% in gypsum). Less focus than conductivity.	Increases specific heat. Reduces thermal flux (6–54%), stabilizing temperatures.
PCMs	Graphite content: 0.5–25% by weight. Particle size: Micro (20–500 µm). Types: Expanded graphite, flakes, microencapsulated.	Often increases λ, (e.g., +221% paraffin-SBS, +50.1% CP-MPCM, +20.7x Al_2O_3-PCM, 2.81 to 3.86 W/m·K SSPCM). Exceptions: -40% (20% GM-MPCM mortar); -15% (0.5–2.5% EG-PCM). Optimal: 5–15%.	Reduces IR transfer, stabilizes PCMs (e.g., prevents paraffin leakage). Less emphasized than conductivity/thermal mass.	Boosts heat storage (e.g., 13.86 kJ to 47.36 kJ at 8% graphite). Increases specific heat. Delays heat peaks.

Table 8 summarizes the effects of graphite additives on different building materials. For EPS, mortars and phase change materials (PCM); the effects of the properties such as graphite content percentage, particle size and type on thermal conductivity (λ), radiative heat transfer and thermal mass are presented comparatively. In EPS, nano and micro sized graphite additives reduce thermal conductivity by 15–40%, while effectively reflecting infrared radiation and largely preventing radiative heat transfer. In mortars, low graphite amounts can provide a limited decrease in λ, while high amounts generally increase the λ value; however, they provide significant gains on thermal mass. In PCM systems, graphite generally increases thermal conductivity. In addition, graphite additives improve system stability by increasing thermal storage capacity and temperature compensation performance in these systems. The trends observed in thermal behaviors according to the amount and type of graphite additive for each material group are clearly presented in the table.

Graphite additive has the potential to provide an effective and sustainable solution in making building materials multifunctional. In EPS, the same thermal insulation performance is achieved with much thinner layers; PCM and mortar systems offer striking advantages in terms of heat management, energy saving and thermal comfort. However, optimization of the additive ratio is critical in terms of preserving mechanical and workability properties.

4. Further studies

The findings obtained within the scope of this study showed that the addition of graphite to building materials provides significant changes in heat conduction, a decrease in EPS and an increase in mortars, in contrast to each other; suppression of heat conduction by radiation, as in the case of EPS, and an increase in thermal mass. However, the full potential of graphite in architectural materials has not yet reached its limits. The following suggested research directions may guide future studies:

Although the effects of flake, expanded and synthetic powder graphite types in various material systems have been studied in the existing literature, a comparative evaluation of these graphite types under the same conditions has not been made. In future studies, the effects of different graphite types on heat transfer, mechanical strength and long-term stability can be examined in detail.

Graphite has been observed to affect not only thermal insulation but also properties such as electrical conductivity, fire resistance and surface emissivity. In this context, it has high potential in designing multifunctional materials, especially for applications such as smart building components, radiant heating systems and heat storage panels.

The effects of graphite-added materials on annual energy consumption, indoor thermal comfort and carbon emissions can be considered a subject worth investigating.

Although there are studies on the response of graphite to UV radiation, humidity and temperature cycles, it is not yet sufficiently understood. Especially in exterior facade applications, whether graphite materials experience a loss of performance over time can be revealed with long-term aging tests.

The environmental footprint, energy recovery potential and recyclability of end-of-life materials of graphite-added building materials should be investigated.

The high performance of graphite-added EPS panels against low thermal conductivity and radiation resistance suggests that such behaviors can be transferred to other matrix systems. Future studies may aim to develop new composite materials that mimic the microporous structure of EPS but contain cement, lime or geopolymer-based binders. In such systems, improvements in thermal insulation performance can be achieved by utilizing both graphite's ability to block radiation and create conductive paths.

Sustainable concrete with reduced environmental impact as a building material

Fatma S. Kuloglu Yuksel*[1]

[1] *Harran University, Department of Architecture, 63300 Şanlıurfa, Türkiye*

Abstract. Concrete is one of the most widely used construction materials worldwide due to its durability, ease and speed of production, and design flexibility. The production of concrete requires aggregate, water, cement, and various mineral and chemical admixtures. The environmental impact of concrete is determined by multiple factors, including the extraction and production of its constituent materials, the manufacturing process, transportation to the construction site, placement into formwork, curing, usage, and end-of-life disposal. With the increasing global demand for concrete, its environmental impact has become a critical concern. Numerous scientific studies have been conducted to reduce CO2 emissions during concrete production and use, as well as to minimize raw material consumption. These studies can be classified into two main approaches: direct benefits, which involve selecting appropriate concrete compositions during the production phase, and indirect benefits, which focus on the potential reductions in CO2 emissions throughout the service life of concrete. The primary goal of these studies is to mitigate CO2 emissions associated with concrete production and utilization. This study provides a comprehensive review of global research and advancements in the production and application of sustainable concrete with reduced environmental impact as a building material. It also discusses relevant practical implementations that align with these developments.

Keywords: Concrete; Sustainable concrete; Environmental impact of concrete

1. Introduction

Concrete is defined as a composite construction material produced by homogeneously mixing cement, water, aggregates, and admixtures in specified proportions. Initially exhibiting a plastic consistency, it hardens through the process of cement hydration and solidifies by taking the shape of the formwork in which it is placed.

Among all construction materials, concrete is the most widely produced and used within the building industry. It stands out due to its cost-effectiveness, the ability to achieve the required compressive strength, long service life, and ease of production.

The fact that concrete production mainly relies on raw materials such as cement, aggregates, water, and chemical or mineral admixtures indicates a high level of natural resource consumption. Furthermore, it is well known that the concrete production industry has a significant carbon footprint (Scrivener, 2018).

The construction sector is responsible for a considerable portion of global greenhouse gas emissions. Concrete production, in particular, is subject to criticism due to its high energy demand and CO2 emissions, which pose challenges in terms of environmental sustainability goals. As a result, various alternative solutions have been developed (Arıoğlu etal, 2004).

In this context, the concepts of low-impact concrete, green concrete, and sustainable concrete have emerged. Within the construction industry, the notion of sustainability must be addressed through environmental, economic, and social dimensions. Various criteria have been established for assessing sustainability based on these dimensions. The sustainability criteria formulated for building materials are outlined below.

Sustainable building materials are those that consume minimal energy during their service life and do not pose harm to the environment or human health throughout the stages of raw material extraction, processing, usage, maintenance, or disposal. Also referred to as "green" materials, sustainable building materials are produced in a way that minimizes environmental damage and utilizes non-renewable resources responsibly and efficiently.

In the selection of building materials, alongside conventional criteria such as performance, quality, aesthetics, and cost, compliance with sustainability principles is also expected.

Sustainable materials are characterized by the following features (Tufan & Özel, 2018) (Table 1):

- They do not contain toxic components and therefore are not harmful to human health.

* Corresponding author, E-mail: kyuksel@harran.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_767

- They are recyclable or reusable.
- They do not adversely affect the natural environment after their functional life ends.
- They are sourced from local materials and producers.

Table 1.Sustainability criterias (Tufan and Özel, 2018)

Sustainability Dimension	Criteria
Environmental Dimension	Is there a reduction in waste?
	Can air pollution be prevented?
	Is the produced material toxic to the environment?
	Does it reduce CO_2 emissions?
	Does it help preserve biodiversity in nature?
	Is the material harmful to soil quality?
	Can it absorb odors from the environment?
	Is the material recyclable?
	Does it have high reusability potential?
	Does it help prevent visual pollution?
	Does it help prevent noise pollution?
	Is the energy consumption low?
	Can it be sourced from local and natural resources?
	Can water pollution be prevented?
Economic Dimension	Is it possible to reduce energy consumption during raw material transport?
	Can transportation costs be minimized?
	Is maintenance and repair easy?
	Is the material durable and long-lasting?
	Does it reduce material use in the provision of goods and services?
Social Dimension	Is the material compatible with the social fabric of the region?
	Does it promote a healthy environment?
	Does it ensure safety for human use?
	Does it meet the housing needs of people?
	Does it support social needs such as education, cultural activities, appropriate jobs and housing?
	Does it support the local workforce?

2. Materials and methods

This study conducted a literature-based review using articles, technical reports and international case studies. The sources are categorized into two main sections:

- Direct reductions in CO2 emissions through material substitutions and low-clinker cement production.
- Indirect reductions through improved durability, maintenance strategies and smart use of concrete in energy-efficient buildings (Orhon, 2012).

2.1. Direct benefit approaches

Direct benefit approaches refer to sustainability strategies aimed at reducing CO2 emissions during the concrete production process. A key concept in these approaches is "embodied CO2", which represents the amount of CO2 emitted into the atmosphere during the manufacturing of construction materials. This term is derived from "embodied energy," which describes the energy consumed during production, and is adapted to reflect CO2 emissions. It is often abbreviated as EC or ECO2 (Embodied CO2).

To reduce the ECO2 value of concrete, sustainability strategies during the production phase include the selection of appropriate constituents and optimized concrete mix design.

Cement production ranks third among global anthropogenic sources of carbon dioxide (CO2) emissions. Therefore, to produce more innovative and sustainable concrete, one or more of the following strategies should be employed:

1. Replacing a higher portion of cement with supplementary cementitious materials (SCMs) such as mineral additives in the concrete mix.
2. Improving concrete strength and durability by substituting cement with combinations of mineral additives.
3. Reducing the amount of cement by using water-reducing admixtures.

4. Utilizing reactive local aggregates in place of non-reactive aggregates sourced from distant locations by applying suitable binder combinations, even in cases where the aggregates may be sensitive to alkali-silica reactions.

5. Producing concrete with locally sourced crushed stone aggregates to reduce transport-related emissions and enhance material efficiency (Justnes and Martius-Hammer, 2016).

Concrete with High Volume Mineral Additions: The most effective and rapid method for reducing CO2 emissions generated during cement and concrete production is to partially replace cement in concrete with mineral additives or to use blended cement where a portion of clinker is substituted with these additives(Özcan and Güngör).

Typical mineral additives include pozzolans that react with calcium hydroxide, such as ground granulated blast furnace slag and fly ash, both of which have latent hydraulic properties. Pozzolans can also be used in combination with other materials like silica fume, rice husk ash, and metakaolin. Due to the relatively high cost of using these additives in quantities sufficient to significantly reduce CO2 emissions, research on alternative materials is ongoing.

Concrete with Low Binder Content: Limestone is a widely available natural material used both as a raw material in clinker production and as a filler in cement or concrete. Fly ash, a by-product of coal-fired thermal power plants, is available in large quantities in many countries, including China and India. The synergistic chemical interaction resulting from the combined use of fly ash and finely ground limestone can enhance compressive strength (Brito and Kurda, 2021).

The theoretical basis for this synergy is built upon a delicate balance among ettringite, monosulfoaluminate hydrate, and calcium monocarboaluminate hydrate. This balance improves water-binding capacity by enhancing hydration. Since conventional cement does not provide enough aluminates to maintain this balance, the additional aluminates from supplementary materials like fly ash are required. Thus, a ternary binder system using cement, ground limestone, and fly ash can be formed.

Use of Water-Reducing Admixtures: Many concrete producers utilize water-reducing chemical admixtures to reduce cement content for economic reasons, while also achieving environmental benefits in terms of sustainability. According to a practical standard, 1 kg of modern polycarboxylate-based water-reducing admixture can reduce the water content of 1 m^3 of concrete by 20 kg.

For instance, in a concrete mix containing 350 kg of cement and 1.8 kg of polycarboxylate admixture per m^3 with a water-to-cement ratio of 0.6, the cement content can be reduced to 290 kg while maintaining the same performance (Justnes and Martius-Hammer, 2016).

Alkali-Silica Reaction (ASR) Resistant Concrete: Silica fume (microsilica), either added directly to the concrete mix or found in the cement, reacts with hydration products to rapidly transform alkali hydroxides into silicate phases. This mitigates the risk of alkali-silica reactions. Through such methods, it becomes possible to use local aggregates instead of sourcing high-quality aggregates from distant regions, thereby promoting a more sustainable solution by extending the availability of local resources.

Locally Produced Aggregates: The depletion of traditional aggregate sources, such as natural sand and gravel, increases the need for alternative sources and technologies. Norway has taken steps in this direction by producing aggregates from hard rocks through crushing.

Sustainability in the context of aggregate access and processing presents challenges, particularly for industries managing large stockpiles of non-saleable fines (process dust).

Key principles include resource efficiency, zero waste production, recycling, and effective logistics. While manufactured sand and aggregate may require more energy than natural or untreated aggregates, when sourced close to markets, the reduction in transport emissions makes them more environmentally favorable.

Selection of Appropriate Constituents: Selecting appropriate concrete constituents is a viable strategy to reduce the embodied CO2 of concrete. Cement is a particularly strategic component due to its high embodied CO2 resulting from intense energy use and chemical processes during production. For example, 1 ton of cement production results in approximately 1 ton of CO2 emissions.

A key strategy for reducing the ECO2 of concrete is to incorporate industrial by-product pozzolans such as fly ash, silica fume, ground granulated blast furnace slag, rice husk ash, and metakaolin. As these materials are typically industrial residues with no direct application but display pozzolanic activity, they can be used both in blended cement and to partially replace cement in concrete mixes.

Due to their low embodied CO2 as by-products, their inclusion in concrete effectively lowers the overall embodied CO2 of the mix.

2.2. Indirect benefit approaches

Indirect benefit approaches aim to reduce CO2 emissions associated with the operational phase of a structure by ensuring that concrete is used in a way that leverages its inherent properties. Key characteristics to consider include durability, thermal mass, use of recycled materials, and photocatalytic functionality (Kuloğlu Yüksel and Karagüler, 2017).

From a sustainability perspective, the most effective solution is one that optimally aligns material properties with the various stages of a building's life cycle. Beginning at the design stage, the adoption of energy-efficient architectural approaches and careful selection of materials can lead to more sustainable outcomes across the entire lifespan of a building. This contributes not only to the preservation of the built and natural environment but also ensures the continued availability of finite resources.

Thermal storage capacity: In indirect benefit approaches, the key point is that concrete has a high thermal storage capacity. In other words, by using the "thermal mass" of concrete—especially in structural elements like reinforced concrete slabs—it is possible to reduce the need for heating and cooling during the building's use phase, leading to energy savings. In addition to passive solar energy applications—such as the use of Trombe walls—various active strategies are also commonly employed today to harness the thermal mass of concrete and reinforced concrete structural elements. These include techniques such as night-time ventilation and heat transfer through water circulating in facade-integrated systems for heating or cooling. In such approaches, the thermal mass of the structure is managed and optimized through building automation systems (BAS) equipped with dynamic components, enabling more efficient energy control and indoor thermal comfort throughout the building's operational phase (Orhon, 2012).

Photocatalytic properties: Concrete is a versatile material whose properties can vary significantly depending on the characteristics of its constituent materials. Among these advanced properties, photocatalytic activity is of particular interest in the context of sustainability and environmental performance. For instance, when cement containing titanium dioxide (TiO_2) is used in concrete production, the resulting material exhibits photocatalytic behavior.

Titanium dioxide, a semiconductor material, enables the concrete surface to initiate oxidation reactions under exposure to ultraviolet (UV) light. These reactions facilitate the breakdown of airborne pollutants such as nitrogen oxides (NO_x), volatile organic compounds (VOCs), and other harmful substances. Consequently, photocatalytic concrete contributes to improved air quality in urban environments.

In addition to its environmental benefits, this type of concrete also offers self-cleaning capabilities, as the photocatalytic reactions help decompose organic materials on the surface, reducing the need for maintenance and cleaning. As such, photocatalytic concrete is increasingly considered a promising innovation in the development of sustainable and smart construction materials (Kuloğlu Yüksel and Karagüler, 2017).

3. Results and discussion

This section synthesizes the findings from both the literature and case studies concerning the environmental performance of sustainable concrete technologies. The results are presented in two major categories aligned with the methodology: direct CO_2 reduction strategies and indirect CO_2 mitigation approaches.

3.1. Direct strategies

- The incorporation of supplementary cementitious materials (SCMs) such as fly ash, slag, and silica fume led to measurable reductions in clinker content and associated CO_2 emissions.
- The use of low-binder concrete mixes and water-reducing admixtures improved resource efficiency without compromising strength.
- Case studies demonstrated that localized aggregate sourcing not only reduced transportation emissions but also contributed to a circular material economy.

3.2. Indirect strategies

- Concrete's thermal mass was effectively utilized in passive design systems (e.g., Trombe walls), reducing energy loads for heating and cooling.
- Active control of thermal mass through building automation systems (BAS), including nighttime ventilation and facade-integrated hydronic systems, resulted in enhanced operational energy performance.
- The application of photocatalytic concrete was found to support air purification and self-cleaning surfaces, contributing to long-term sustainability.

These findings underscore the multifaceted role of sustainable concrete not only as a structural material but also as a tool for climate-responsive architecture. The integration of both material innovations and performance-based design enables a comprehensive reduction in environmental impact across the building life cycle.

4. Conclusions

The environmental impact of concrete is increasingly under scrutiny as the global demand for construction materials grows. While concrete remains essential for infrastructure development, its production and usage must evolve to align with sustainability goals. Direct reduction strategies, such as using SCMs and reducing clinker content, offer immediate improvements in CO_2 performance. Indirect strategies like enhancing durability and incorporating recycled materials contribute to long-term environmental benefits throughout the structure's life cycle.

Moreover, the emergence of self-healing concrete technologies represents a promising innovation in enhancing the durability and service life of concrete structures, thereby contributing significantly to long-term sustainability goals in the construction industry.

The integration of these approaches, supported by scientific research and field implementations, marks a significant step toward a low-carbon construction industry. Future work should focus on regional material optimization, life-cycle assessment tools, and policy frameworks that support greener concrete practices (Arkitera, 2025).

Green building evaluation in historical buildings: The case of Sveti Stefan Church (Bulgarian Church)

Aylin Aras*1, Berfin Ergin[2]

[1] Bursa Technical University, Department of Architecture, 16330 Bursa, Türkiye
[2] Architecture, Independent Researcher İstanbul, Türkiye

Abstract. The increase in energy consumption today has also influenced architecture. Factors such as the materials used in buildings, the planning and layout of structures, the impact of environmental conditions, geography, and the social context are all parameters affecting energy use. In light of the energy consumption of buildings, studies have been developed to reduce energy demand, leading to the emergence of concepts such as 'sustainable architecture' and 'green building.' Within this framework, new strategies and methods have been introduced to align with sustainable architecture and green building practices.
Historical buildings are also crucial to consider within the scope of sustainability. As cultural heritage assets, these buildings should be preserved and transferred to future generations. From this perspective, historical structures should also be evaluated in terms of sustainable architecture and green building certification systems.
The Sveti Stefan Church is the world's only 'fully prefabricated iron church,' making it unique and noteworthy. This study aims to evaluate the Sveti Stefan Church through the lens of sustainable architecture and green building certification systems. A new Green Building Evaluation Model will be developed for the historical structure, and the building will be assessed using this model. In this context, the evaluation will focus on parameters such as the materials used, the planning and layout of the building, the impact of environmental factors, and the geographical and social context.

Keywords: Sustainable Architecture; Green Building Evaluation Systems; Historical Buildings; Sveti Stefan Church.

1. Introduction

The energy performance of buildings is shaped by a range of factors, such as material selection, architectural planning and spatial organization, environmental conditions, geographic setting, and socio-cultural context. In recent decades, there has been a marked increase in energy consumption, a trend that has become increasingly evident within architectural practice. This growing concern has led to the development of strategies focused on energy efficiency, ultimately giving rise to the concept of sustainable architecture. Within this framework, numerous methods and design approaches have been introduced, contributing to the evolution of "green buildings."

Green buildings refer to architectural designs that seek to minimize energy usage and maximize the efficiency of natural resource utilization. Many nations have implemented certification frameworks to promote sustainable building practices. Among the most prominent of these are BREEAM, LEED, Green Star, SB-Tool, and CASBEE.

This study proposes a novel Green Building Assessment Model tailored for historic buildings, with the aim of evaluating them through the lens of green building standards. The case study selected for this research is the Sveti Stefan Church.

As the world's only fully prefabricated iron church, the Sveti Stefan Church holds significant architectural and historical value. In this research, the church is analyzed in line with sustainable design principles and established green certification criteria. Based on the evaluation outcomes, a set of recommendations is presented to enhance the building's environmental performance.

Drawing from internationally recognized green building assessment frameworks and building upon the model introduced in Elif Gizem Yetkin's 2020 study, this research develops a tailored evaluation tool for historic structures. The proposed model aims to contribute to the sustainability and preservation of heritage buildings by identifying strategies for their improvement.

2. Historical and Architectural Background of Sveti Stefan Church

The Sveti Stefan Bulgarian Orthodox Church, also known as the Iron Church, is the only fully prefabricated iron church in the world that has survived to the present day. It is situated between the Fener and Balat districts of Istanbul. The church was designed with a lightweight skeleton, and its components were manufactured in Vienna under the technological conditions of the period, with final assembly carried out in Balat. Due to its unique prefabricated structure, the Sveti Stefan Church was selected for analysis in this study. This section presents basic information about the church and carries out a green building assessment.

2.1. Construction and Architectural Features

The church is constructed on a stone base with a 210 cm-high masonry basement (Fig. 3), which is placed on wooden piles, and a steel column-beam system is built above it. The steel structure (Fig. 2) consists of a truss system, which is covered with cast elements on the exterior and flat sheet metal on the interior. The relief-decorated panels used in the façade are made of cast iron. Accessory profiles are mounted to the frame with rivets, while the sheet metal and cast iron panels are welded to it. The exterior walls are painted with oil-based paint, whereas the interior walls of the ground floor, along with the plastered surfaces and square-sectioned columns, are clad with marble panels in green, beige, and cherry-red colours (Çiçekliyurt, 2020).

Due to the unstable ground conditions, a steel-framed structure was proposed, and architect Aznavur designed the internal load-bearing system in 1892. The current plan of the Iron Church (Fig. 1) was developed by the Waagner company, following modifications to the load-bearing structure and decorative elements. The company initially assembled the structure in its own garden to identify and address any potential construction errors (Çiçekliyurt, 2020).

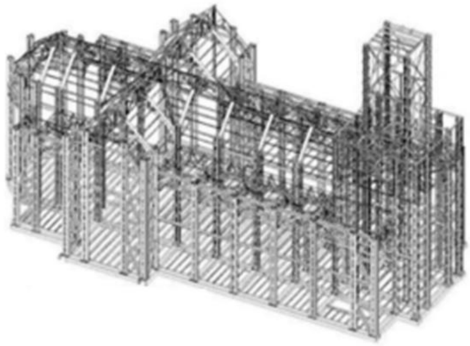

Fig. 2. The iron skeleton designed by architect Aznavur (Çiçekliyurt, 2020).

Fig. 3. Basement floor

2.2 Historical Significance
In 1849, Bulgarian Prince Stefan Bogoridi, an Ottoman State official, donated the land on which the church stands today for the needs of the church. On 17 October 1849, a special decree was issued allowing Bulgarians to have their own churches. On 9 October 1849, a small church was officially built. Later, the church was expanded and became the independent church known today as the Wooden Church (**Hata! Başvuru kaynağı bulunamadı.**). Due to damage sustained from numerous fires, permission was granted to build a new church. The project for the church, proposed to be constructed using prefabricated panels due to the unstable ground, was selected through a competition. Following the competition, it was decided to implement the design by Architect Aznavur. The assembly of the church was completed on 14 July 1896 (Bujaşka, 2016).

Fig. 4. Timber Church (Kuruyazıcı & Tapan, 2019)

3. Green Building Principles and Their Adaptation to Historical Structures
The rapid growth of technology and population during the Industrial Revolution disrupted the balance between the natural and built environments, resulting in significant damage to the natural ecosystem. Environmental degradation leads to the depletion of energy resources and creates increasingly challenging living conditions. In response to these threats, the concept of "sustainability" emerged as a preventive approach.

Global warming, climate change, pollution, and the depletion of water and energy resources—factors that mutually reinforce one another—have evolved into common challenges that transcend national boundaries. In short, human activities and their consequences are placing increasing pressure on the Earth's carrying capacity (Sev, 2009).

The construction and building sector creates the built environment. The built environment affects and degrades the natural environment. The concept of sustainable architecture emerged to mitigate this damage and to ensure that resources are preserved for future generations.

The objectives of sustainable architecture are:

- To reduce the carbon footprint
- To meet basic human needs by enhancing psychological and physical well-being and contributing positively to the social environment

Sustainable architecture is based on three fundamental principles

- Conservation of Energy and Natural Resources
- Building Life Cycle Design
- Biological Building Design (Osmançelebioğlu, 2015)

3.1. Sustainability in Heritage Conservation

The environment evolves from simplicity to complexity, creating variations based on cultural development. The environment is born, grows, develops, and diversifies through experience. During this process of development and diversification, urban elements create remnants and traces of cultural structures (Yılmaz, 1992). "These traces symbolize the economic, social, and cultural characteristics of societies, thereby forming the historical environment." (Çelimli, 2022)

Historical structures are key elements for understanding the social, cultural, and technological developments of a society. Conservation efforts are conducted to ensure that these structures are preserved for future generations. Following conservation, some structures maintain their original function, while others are repurposed. Today, environmentally sensitive and sustainable conservation practices ensure the preservation of the values of historical structures. (Eldek, 2014).

3.2. Challenges in Applying Green Building Standards

There are several established reasons for the limited implementation of green building strategies today. These factors create significant obstacles to the widespread adoption of green building practices. Some of these obstacles include:

- High cost of available products,
- Insufficient policy implementation efforts,
- Technical challenges during the implementation process,
- Lengthy planning and approval processes in green building certification systems,
- Lack of information and awareness regarding green building certification systems,
- Increased costs driven by customer demand,
- Delays caused by unfamiliarity with green technologies,
- Conflicts of interest among stakeholders (Zhang, X., Shen, & Wu, 2010).

4. Methodology for Green Building Evaluation

Green buildings are a product of sustainable architecture, which emerged alongside the concept of sustainability. Sustainable architecture aims to meet criteria such as compatibility with the building’s surroundings, the sustainability of functions, the use of renewable energy sources, energy efficiency, energy conversion, and material recycling. As a result of these criteria, green buildings emerge as structures that reduce carbon emissions, show respect for both the built and natural environments, and ensure the sustainability of the building life cycle.

Some benefits provided by green buildings include:

- Reduced energy consumption.
- Protection of ecosystems.
- Improvement in user health.
- Increased efficiency.
- Reduction in greenhouse gas emissions.
- Conservation of resources.
- Lower building operating costs (Osmançelebioğlu, 2015).

Green building assessment systems originated in the United Kingdom with the BREEAM Certification. Over time, numerous additional systems have been developed, contributing to the global growth of green buildings and the reduction of carbon emissions.

4.1. Evaluation Criteria

Green building certification systems and assessment practices were established by various countries following the identification of the need for concrete assessment and rating of green buildings through academic and sectoral studies. Today, numerous green building assessment systems have been developed and are used worldwide (Fowler & Rauch, 2006).

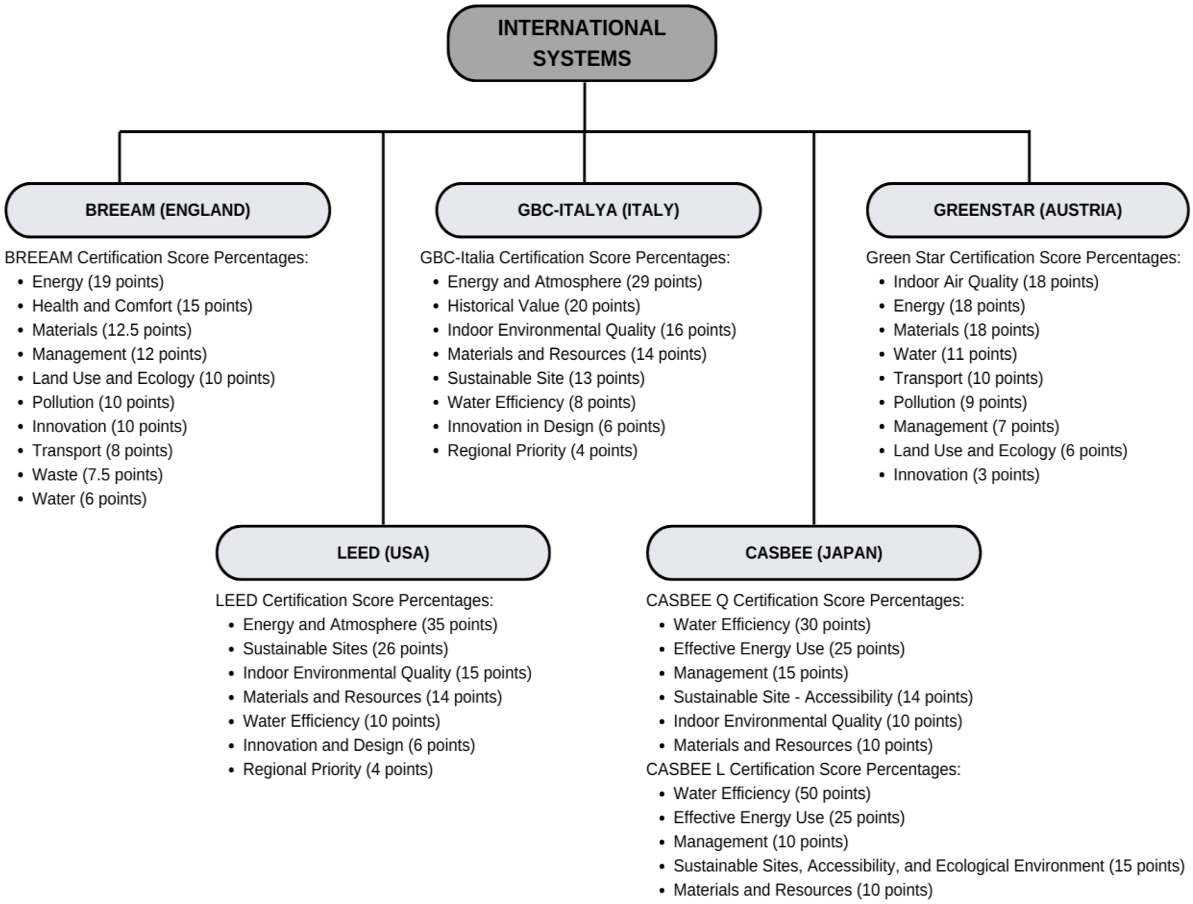

Fig. 5. International Systems (Modified from Yılmaz (2012) and rearranged by the author)

"Some of the certification systems recognized by countries that are members of the World Green Building Council (WGBC) include:

- United Kingdom - BREEAM: Developed to establish design standards, technical specifications, construction-operation phases, and building performance criteria (Global, 2016).
- United States – LEED: The LEED Certification System aims to raise awareness of environmental impacts throughout the building life cycle and improve the performance of stakeholders in the building sector (Sev & Canbay, 2009).
- Italy – GBC-ITALIA: GBC-Italia was developed based on the LEED certification and has been specifically adapted to focus on historic buildings. Buildings eligible for certification must have been constructed before the industrialization of construction (1945). This system establishes assessment guidelines tailored to Italy (Yetkin, 2020).
- Australia – GREEN STAR: Established in 2003 by the Green Building Council of Australia (GBCA), it was designed to evaluate the building life cycle, similar to BREEAM (Osmançelebioğlu, 2015).
- Japan – CASBEE: This system evaluates building design, construction, post-construction monitoring, and maintenance practices. CASBEE is more complex than other systems, with its assessment based on the formula: BEE (Building Environmental Efficiency) = Q (Built Environmental Quality) + L (Built Environmental Load) (Dullinja, 2017).
- Canada – LEED CANADA
- Germany – DGNB" (Yılmaz B. , 2012). (Fig. 5**Hata! Başvuru kaynağı bulunamadı.**)

4.2. Data Collection and Analysis

As a result of research conducted within the scope of sustainable architecture, a new evaluation system has been developed, drawing on the GBC-ITALY Green Building Evaluation System. The doctoral thesis titled "Proposal for a Green Building Evaluation Model for Historical Buildings in Our Country in the Context of Sustainable Architecture" by Elif Gizem Yetkin (2020) served as a reference in the creation of this new evaluation model.

The eight categories from the GBC-ITALY Green Building Evaluation System have been retained as main headings, with modifications made to their criteria (Table 1). The historical nature of the structure being evaluated is the most significant factor influencing the evaluation criteria. Additionally, the relationship between the structures and their sites is considered essential in maintaining the integrity of the building’s usage. It is crucial to incorporate these changes in the evaluation as technology continues to develop and evolve. In light of this, it is deemed necessary to include these factors among the criteria.

Table 1. Criteria of a Green Building Assessment System Model for Historical Buildings

Energy and Atmosphere Category Criteria
Criterion 1: Commissioning of energy systems
Criterion 2: Minimum energy performance
Criterion 3: Optimisation of energy performance
Criterion 4: Use of renewable energy
Historical Value Category Criteria
Criterion 1: Energy use assessment of existing conditions
Criterion 2: Diagnostic assessment and structural monitoring of the building
Criterion 3: Reversibility of conservation measures
Criterion 4: Assessment of conservation measures
Criterion 5: Ensuring the sustainability of the conservation area
Criterion 6: Preparation of a maintenance plan
Criterion 7: Compatibility of architectural and landscape works with the structure
Criterion 8: Functionality of the structure
Criterion 9: Relationship between the structure and the land
Interior Environment Quality Category Criteria
Criterion 1: Minimum performance for air quality
Criterion 2: Environmental control of tobacco smoke
Criterion 3: Monitoring of indoor air
Criterion 4: Evaluation of minimum outdoor air supply
Criterion 5: Indoor air quality management plan
Criterion 6: Selection of low-emission materials
Criterion 7: Control of indoor air pollutants and chemical sources
Criterion 8: Management and control of systems
Criterion 9: Ensuring spatial hierarchy
Material and Resource Category Criteria
Criterion 1: Collection and storage of recyclable materials
Criterion 2: Management of demolition and construction waste
Criterion 3: Maintenance of carrier systems and non-structural elements
Criterion 4: Use of recycled materials
Criterion 5: Optimisation of the environmental impact of materials used
Criterion 6: Materials extracted, processed and produced within a limited distance
Criterion 7: Reuse of the building
Sustainable Area Category Criteria
Criterion 1: Prevention of pollution from construction site activities
Criterion 2: Reclamation and improvement of used land
Criterion 3: Transportation
Criterion 4: Recovery of open spaces
Criterion 5: Rainwater: quantity and quality control
Criterion 6: Heat island effect: exterior surfaces and roofs
Criterion 7: Reduction of light pollution
Water Efficiency Category Criteria
Criterion 1: Reduction of water consumption
Criterion 2: Reduction of landscape water consumption
Criterion 3: Measurability of water consumption
Criterion 4: Rainwater utilisation systems
Innovation in Design Category Criteria
Criterion 1: Innovation in application
Criterion 2: Innovation in materials
Regional Priority
Criterion 1: The area has regional priority

According to Yetkin, historical structures are evaluated across three categories. Based on Yetkin's example, the point distribution for each category was analyzed according to the importance levels outlined in Table 2, leading to the creation of a new point distribution (Table 3, Table 4).

Table 2. Score Distribution by Categories in the Green Building Assessment Model for Historical Buildings (According to Yetkin)

Evaluation Categories	1st Class	2nd Class	3rd Class
Regional Priority	7	3	2
Energy and Atmosphere	17	32	40
Indoor Air Quality	11	21	18
Materials and Resources	20	13	10
Health and Safety	3	3	3
Water Management	4	4	8
Sustainable Land	4	4	6
Historical Value	30	16	9
Innovation in Design	4	4	4
Total	**100**	**100**	**100**

Table 3. Category-Based Score Distribution in the Green Building Assessment Model for Historical Buildings (According to the Developed Model)

Evaluation Categories	1st Class	2nd Class	3rd Class
Regional Priority	7	3	2
Energy and Atmosphere	17	34	42
Indoor Air Quality	11	22	19
Materials and Resources	21	13	10
Water Management	4	4	8
Sustainable Land	4	4	6
Historical Value	32	16	9
Innovation in Design	4	4	4
Total	**100**	**100**	**100**

Table 4. Score Distribution by Sub-Criteria of Categories in the Green Building Assessment Model for Historical Buildings (According to the Developed Model)

Energy and Atmosphere Category Criteria	1st Class	2nd Class	3rd Class
Criterion 1: Commissioning of energy systems	9	7	2
Criterion 2: Minimum energy performance	2	3	5
Criterion 3: Optimisation of energy performance	2	3	2
Criterion 4: Use of renewable energy	4	21	33
Historical Value Category Criteria	**1st Class**	**2nd Class**	**3rd Class**
Criterion 1: Energy use assessment of existing conditions	4	2	1
Criterion 2: Diagnostic assessment and structural monitoring of the building	9	2	1
Criterion 3: Reversibility of conservation measures	4	2	1
Criterion 4: Assessment of conservation measures	5	2	1
Criterion 5: Ensuring the sustainability of the conservation area	2	1	1
Criterion 6: Preparation of a maintenance plan	3	3	1
Criterion 7: Compatibility of architectural and landscape works with the structure	3	2	1
Criterion 8: Functionality of the structure	1	1	1
Criterion 9: Relationship between the structure and the land	1	1	1
Interior Environment Quality Category Criteria	**1st Class**	**2nd Class**	**3rd Class**
Criterion 1: Minimum performance for air quality	0	1	1
Criterion 2: Environmental control of tobacco smoke	1	1	2
Criterion 3: Monitoring of indoor air	1	1	3
Criterion 4: Evaluation of minimum outdoor air supply	1	1	0
Criterion 5: Indoor air quality management plan	0	1	1
Criterion 6: Selection of low-emission materials	3	6	4
Criterion 7: Control of indoor air pollutants and chemical sources	3	8	5
Continuation of Table 5			
Criterion 8: Management and control of systems	0	1	1
Criterion 9: Ensuring spatial hierarchy	2	2	2

Table 4. continued

Material and Resource Category Criteria	1st Class	2nd Class	3rd Class
Criterion 1: Collection and storage of recyclable materials	1	1	1
Criterion 2: Management of demolition and construction waste	0	0	1
Criterion 3: Maintenance of carrier systems and non-structural elements	4	1	1
Criterion 4: Use of recycled materials	1	2	1
Criterion 5: Optimisation of the environmental impact of materials used	4	4	3
Criterion 6: Materials extracted, processed and produced within a limited distance	1	2	1
Criterion 7: Reuse of the building	10	3	2
Sustainable Area Category Criteria	**1st Class**	**2nd Class**	**3rd Class**
Criterion 1: Prevention of pollution from construction site activities	1	1	0
Criterion 2: Reclamation and improvement of used land	0	0	0
Criterion 3: Transportation	0	0	0
Criterion 4: Recovery of open spaces	0	0	0
Criterion 5: Rainwater: quantity and quality control	1	1	1
Criterion 6: Heat island effect: exterior surfaces and roofs	1	1	5
Criterion 7: Reduction of light pollution	1	1	0
Water Efficiency Category Criteria	**1st Class**	**2nd Class**	**3rd Class**
Criterion 1: Reduction of water consumption	1	1	4
Criterion 2: Reduction of landscape water consumption	1	2	3
Criterion 3: Measurability of water consumption	1	0	0
Criterion 4: Rainwater utilisation systems	1	1	1
Innovation in Design Category Criteria	**1st Class**	**2nd Class**	**3rd Class**
Criterion 1: Innovation in application	3	3	3
Criterion 2: Innovation in materials	1	1	1
Regional Priority	**1st Class**	**2nd Class**	**3rd Class**
Criterion 1: The area has regional priority	7	3	2

Table 5. Certification Types and Scoring Methodology

Certificate Type	Point
One Star	40-49
Two Stars	50-59
Three Stars	60-79
Four Stars	80 and above

As a result of the developed scoring system, the certificate types and their corresponding scores (Table 5) are provided for the evaluation of the structure.

5. Assessment of Sveti Stefan Church in Terms of Green Building Criteria

The Sveti Stefan Bulgarian Church is analyzed and scored according to a table developed based on Yetkin's (2020) study. In the model evaluation, it is classified as a first-class structure due to its materials and construction technique.

5.1. Energy Efficiency and Renewable Energy Use

There are no energy-saving or renewable energy initiatives in the historical development or current use of the structure. Therefore, it has not been scored in the evaluation.

5.2. Historical Value

The structure continues to function in its current state through restoration work conducted in accordance with conservation criteria for historical buildings and their surroundings. The church, built on filled ground, has been lightened using iron structural elements, thereby establishing a relationship between the building and its land. The iron structural elements and the church's foundation are continuously monitored, and restoration work is carried out when damage is detected. The building receives 20 points in the current evaluation based on the following criteria: ensuring the building’s active use, preserving its function, extending its lifespan through restoration techniques, conducting structural analysis and monitoring, ensuring the reversibility of conservation efforts, evaluating the conservation process, maintaining functionality, and ensuring the relationship between the building and the land is maintained.

5.3. Indoor Environmental Quality

Due to its religious nature, there is a there is a spatial hierarchy between the spaces. Spatial orientation, varying floor heights, gallery spaces, and both interior and façade decorations contribute to this spatial hierarchy. While the presence of a spatial hierarchy earns the structure 2 points, the lack of studies addressing indoor air quality highlights a shortcoming in the evaluation criteria.

5.4. Material Sustainability and Conservation Techniques

The iron used throughout the structure is environmentally friendly because it is recyclable. As an environmentally friendly material, it also contributes to social and economic sustainability. The building's reuse includes its restoration and continued use for its original purpose. The church continues to serve its original function. The church received 14 points in the materials and resources category.

5.5. Sustainable Area

Light pollution is minimized due to the building's function. Natural lighting is essential. The building receives 1 point for this criterion.

5.6. Water Efficiency and Management

There are no studies on water efficiency or sustainability in the structure.

5.7. Inovation in Design

The use of iron materials, iron throughout the entire structure, prefabricated construction, and, consequently, new construction techniques have led to innovation in both application and materials. The church received 4 points in the innovation in design category.

5.8. Regional Priority

The building has regional priority due to its location, interaction with the sea, proximity to public transport, location between the two central districts of Fener and Balat, and its location in the historic district of Fatih in Istanbul. The church has been awarded 7 points in the regional priority category.

When analysed in terms of Energy Efficiency and Renewable Energy Use, Building and Historical Value, Indoor Environmental Quality, Material Sustainability and Conservation Techniques, Sustainable Areas, Water Efficiency and Management, Innovation in Design and Regional Priority, the church receives a total of 48 points on the model. Sveti Stefan Church has been evaluated through the model created in line with the principles of sustainable architecture and green building certification systems. In line with the results obtained, it was concluded that the level should be increased. In this direction, suggestions are presented in the following sections.

6. Discussion

6.1. Strengths and Limitations in Green Adaptation

The need for sustainable energy sources in terms of Turkey's energy production and consumption, as well as the country's potential, are identified within the framework of its strengths and limitations.

Strengths:

- The fact that sustainable energy sources mostly do not require high technology facilitates resource utilisation.
- Turkey has significant potential for various sustainable energy sources due to its geopolitical location.
- Using sustainable energy sources for electricity generation will be effective in maintaining ecological balance by reducing fossil fuel consumption.
- Energy imports will be significantly reduced, leading to economic improvement.

Limitations:

- The current economic situation results in limited investment in energy sources.
- Global climate issues.
- The lack of awareness among the population hinders the use of sustainable energy sources (Doğan, 2015; Gürcün & Petek, 2021; Yılmaz, 2018).

6.2. Potential Improvements and Best Practices

- Within the scope of the identified strengths and limitations, training programs on sustainability and green energy-green building certifications should be organized to raise user awareness.
- Governments should implement incentive programs to promote green building certification systems and increase their adoption.
- Factories producing materials should be established with measures ensuring easy access to materials without negatively impacting human health.

- Governments should ensure energy production through ecological means and support the use of green energy in buildings as a result.

Sustainable architecture is an issue that needs to be popularised because we are located in a geography with high historical value and geopolitical location that is suitable for sustainable designs. First of all, when it is started to be applied in the historical environment, it has the potential to increase the value of the historical environment and provide support for restoration works.

7. Conclusion and Recommendations

Owing to the site's coastal context, seawater and prevailing winds are identified as critical environmental parameters in this analysis. The building currently receives no credit under the Energy and Atmosphere category; however, it is proposed that a wave energy conversion system be integrated by installing capture chambers along the shoreline (Fig. 6). This renewable energy system could be located in the basement of the church and designed as a publicly accessible exhibit, thereby demonstrating the integration of contemporary energy technologies within a historical structure. This solution not only enables on-site energy generation but also contributes to optimizing the building's energy performance and reducing overall consumption. As a result, the building fulfills all criteria within the Energy and Atmosphere category, adding 17 points to its green building assessment.

In addressing the third criterion under the Materials and Resources category—related to the maintenance of both structural and non-structural components—it is essential to implement a scheduled maintenance program. This program should outline routine inspections and the systematic upkeep of building elements at defined intervals. Such proactive management ensures the ongoing preservation of the structure and satisfies criterion 3, thereby contributing an additional 4 points to the overall sustainability evaluation.

In the case of the church, rainwater is collected from the roof and directed through vertical downpipes integrated within the structural columns, channeling the water to the ground and into perimeter drainage systems surrounding the building. To enhance water efficiency, it is proposed that this rainwater be stored in a subterranean reservoir to be constructed within the church garden, specifically for irrigation purposes. This system enables the reuse of rainwater for landscape maintenance, effectively reducing the building's overall water demand. By fulfilling Criteria 1, 2, and 4 under the Water Efficiency category, the building earns an additional 3 points.

As a result of the proposed interventions, the building receives a total of 24 additional points under the green building assessment framework for historical contexts. This improvement elevates the church's score from 48 to 72 points, advancing its certification from one star to three stars.

The study and the assessment model developed herein underscore the potential for integrating sustainability principles into the conservation and evaluation of heritage buildings through the application of green building certification systems. This approach highlights how historical structures can actively contribute to sustainable architectural practices when assessed with context-sensitive criteria.

Deterioration in buildings: A study on failure analysis and solutions

Merve Özdoğan*[1], Nilay Coşgun[1]

[1] Gebze Technical University, Department of Architecture, 41400 Kocaeli, Türkiye

Abstract. Buildings are exposed to various effects over time from the first day they are built. As a result of the impacts, deterioration may occur at different points such as building elements and materials. This situation negatively affects the functionality, safety, health, and aesthetic value of buildings, while increasing repair and maintenance costs. Understanding the causes of building deterioration and developing solutions to these problems is important for the design, construction, and use of the building. The study prepared in this direction aims to understand the main causes of deterioration in buildings through the example of a residential building and to offer solutions for the deterioration detected. The study aims to develop measures for long-lasting and durable structures by revealing the interaction of environmental and human-induced factors related to the deterioration of buildings. Environmental factors focus on physical, chemical, biological, climatic, and mechanical factors, while human-induced factors are discussed under the subheadings of design errors, material selection errors, workmanship/ application errors, inadequate supervision, and usage errors. The effects of these factors on building elements were identified and classified through a literature review. In the context of the information obtained, a comprehensive observational study was conducted on a residential building. In the study, the deterioration of the building was determined, the causes of the deterioration were analyzed in the context of environmental and human-induced factors, and solution suggestions were presented. As a result, it was observed that the main causes of deterioration were physical factors, workmanship/application errors, and inadequate supervision. It is thought that the study will be an example of raising awareness on the prevention of building deterioration and designing durable and long-lasting structures.

Keywords: Structure; Deterioration; Error; Causes of deterioration; Structure analysis

1. Introduction

Individuals expect the places they live in to be safe, healthy and comfortable. However, deterioration can occur in different areas in structures during the design, construction and usage periods. Deterioration can be caused by physical, chemical and biological environmental factors such as heat, water, humidity and climate, and in addition to these, human factors such as usage error, workmanship/application errors, inadequate supervision etc. Some deteriorations cause visual discomfort while others can cause danger to the structure. Therefore, it is important to be informed about the causes of deterioration, to be able to detect the source of the errors and to be able to suggest solutions for the repair of deterioration.

2. Materials and methods

Within the scope of the study, the factors causing deterioration were examined under two main headings as environmental and human-induced factors. The causes of deterioration and possible solution suggestions were shared. In line with the data obtained through the literature review, a residential structure was selected in order to analyze the errors it contains. When selecting the structure, criteria such as access to sufficient information about the structure, the presence of different functions in the structure, the variety of materials in the interior and exterior spaces, and access to all open-to-use areas in the structure were taken into consideration. The structure constituting the field research was introduced by providing information about the way it was settled on the land, its identity, its purpose of use, the types of apartments it contains, and its other functions. Although there are many studies in literature examining different structures and sharing sample errors; it is thought that the detection of deteriorations that occurred in a structure completed in 2019 with current construction techniques within six years will contribute to the addition of current data and examples to the research field. 10 different deteriorations in the residential structure were determined to be examined in the study. The causes of the selected deteriorations were determined

*Corresponding author, E-mail: mozdogan@gtu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_840

through observation, and solution suggestions for detecting errors and correcting the deterioration were shared. In this way, it is aimed to bring to literature sample methods that can be used in structures with similar deteriorations and errors.

3. Factors causing deterioration in structures

When structures are designed, they are expected to respond to the needs and desires of users. However, deterioration may occur at various times and in different places during the life of the structure. There are many different reasons for these deteriorations. However, if it is generalized, it can be said that faulty decisions and practices are the basis of deterioration. In this study, the factors that cause deterioration in the structure were discussed. Although the factors in question are related to each other, they were examined under two main headings as environmental and human-induced factors. While physical, chemical, biological, climatic and mechanical factors were examined under the main heading of environmental factors; design errors, material selection errors, workmanship/application errors, inadequate supervision and usage errors were discussed under human-induced factors (Fig . 1) (Coşgun, İpekçi, & Yılmaz, 2002). Although the factors were examined under separate headings, it is known that the causes of deterioration may affect each other and that the errors made may cause other errors.

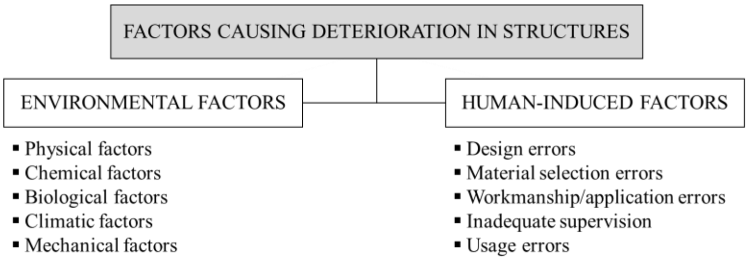

Fig. 1. Factors causing deterioration in structures

3.1. Environmental factors

During the construction and usage processes, structures that are open to external effects in terms of material, component and element dimensions are exposed to different environmental factors. Environmental factors are generally the result of atmospheric effects such as wind, sun, temperature, precipitation and humidity. Physical factors such as heat, water, humidity and climate; chemical factors such as sun rays, corrosion etc.; biological factors that occur due to the effect of bacteria/fungi/insects/worms; mechanical factors that occur depending on the properties of the material can be counted in the environmental factors group. In the structural elements exposed to these factors, deteriorations such as cracking, shedding, efflorescence, moss formation, corrosion and color change can be observed over time (Öztürk, 2017). If precautions are not taken against these factors and deterioration is not detected quickly when it occurs, it can cause major deteriorations inside and outside the structure.

3.1.1. Physical factors

The physical properties of the material are expressed with properties that can be measured by experiments such as size, volume, mass, conductivity, and expansion coefficient (Toydemir, Gürdal, & Tanaçan, 2000). Therefore, it is possible to define physical factors as effects that can change the properties of the material that can be measured by experiments. Factors such as heat, water, humidity, and fire can be included in the group of physical factors.

- Heat effect: Due to the temperature difference between two materials, heat passes from a hot object to a cold object. When the materials used in the structures are not selected according to this situation, problems occur in the structures. Thermal problems are among the most important issues that should be given importance in terms of the comfort of the individuals living in the structure, the physics of the structure and energy saving (Eriç, 2002). The heat changes experienced can cause shrinkage and expansion in the materials. Since the volume of the material increases when expanding and decreases when contracting, it can cause deterioration such as cracking, breaking and separation in the material unless precautions are taken (Fig. 2) (Croci, 1998; Esener, 2018). In order to prevent this situation, it is necessary to know the properties of the materials, choose the right material and solve the necessary details.

Fig. 2. Coatings falling off the facade of the building due to heat change (Güzelçoban Mayuk, 2007)

- Water and humidity effect: When the laws of physics are examined for the humidity and movement occurring in the building material, it is seen that it is caused by the pressure difference. Water vapor moves according to the partial pressure and passes from the area where the pressure is high to the area where it is low. During this transition, the vapor turns into water and sweats on the material (Eriç, 2002). Water and humidity can cause the heat retention properties of building materials to decrease, the material to disintegrate and swell, the formation of efflorescence, the occurrence of deteriorations such as corrosion and decay in the building elements, and the formation of mold and fungus (Fig. 3) (Yıldız & Dal, 2016). Therefore, taking precautions against water and humidity such as covering the building with a roof with wide eaves, choosing water-resistant paints and coatings on the building surface, using sills with drips in the joinery, and using drainage in the building will reduce the occurrence of problems in the building (Ekinci, İşçi, & Alyavuz, 2007).

Fig. 3. Swelling and flaking seen in the ceiling paint as a result of the effect of water and humidity in the building (Özdoğan, 2023)

- Fire effect: Fire can occur due to human error or environmental factors. As a result of fire, some or all of the structures burn. In partial fires, the elements of the structure are damaged, and the damaged parts need to be repaired or renewed. Selecting the materials used in the structure that are resistant to high temperatures can be a precaution against fire and can minimize damage.

3.1.2. Chemical factors

Chemical factors cause changes in the chemical properties of the materials used in the structures. As a result of sun rays and atmospheric effects, deterioration and aging occur on the surface or internal structure of the material. Sunlight can cause conditions such as color fading and hardening. In order to be protected from the effects of sun rays; choosing the color according to the place, designing wide eaves, designing sunshade elements, positioning the space and joinery layouts according to the sunlight needs can protect the structure from deterioration. Corrosion: is the situation where metal elements undergo dissolution or chemical change and wear as a result of various effects in the environment (Fig. 4). In order to be protected from corrosion, eliminating the factors that cause corrosion, coating the metal used with materials such as oxide, silicate or organic-based oil, bitumen and plastic can be offered as a solution (Eriç, 2002).

Fig. 4. Corroded column reinforcement (left), corroded railing (right) (Dal & Yılmaz, 2015; Peter, 2025)

3.1.3. Biological factors
Biological factors that cause deterioration in structures can be considered as plants, animals, insects, bacteria and fungi. When the roots of plants such as trees or ivy start to interfere with the elements of the structure, they cause deterioration in the building foundations and walls. In addition, the branches of the plants can hit the structures and cause physical damage to the structure. Animals can damage the structure by gnawing and dismantling the materials in the structure. Insects and fungi pose a major problem in wooden structures and structural elements. Fungi formation can be seen in wooden materials due to high humidity and insufficient ventilation. Bacteria, fungi and algae can cause decay and color change in the joints and internal and external surfaces of the structure (Fig. 5) (Öztürk, 2017; Zakar, 2013). To protect the structure from biological factors, regular checks should be provided, the building should be ventilated, and cleaning, maintenance and repair should be done in the structural elements/materials.

Fig. 5. Fungus and mold formation in the building (Interior, 2023)

3.1.4. Climatic factors
Climate, which affects a large area for many years and consists of elements such as sunlight, pressure, temperature, precipitation, and wind, is another factor that causes deterioration in structures (MGM, 2023). If the design and detail solution are not carried out according to the climate characteristics of the region where the structure is located, deterioration will occur in the structure as long as it is exposed to these elements. On the facade, which is the most exposed to external effects, wear, shedding, color changes, breaks, and cracks can occur due to rain and wind, and this can cause various deteriorations in the structure. In order to prevent deterioration, the material selection should be made correctly, and the structure should be maintained regularly.

3.1.5. Mechanical factors
The characteristics of the structure and the materials in the structure under mechanical loads such as pressure, tension, flexibility, elasticity and ductility are called mechanical factors (Eriç, 2002). Before the construction of the structures, the loads affecting the structure are made through static calculations. However, due to movements and loads that are not taken into account or that occur over time, deterioration may occur in the structures. Due to mechanical effects, wear, cracks, rounding of material edges and reduction in element cross-section may occur as a result of friction in the structure (Fig. 6) (Erdoğan, 1982; Öztürk, 2017). In order to eliminate mechanical effects, regular checks should be carried out in the structure and the deteriorated elements or materials should be repaired/replaced.

Fig. 6. Cracks caused using different materials in the building floor and wall (Özdoğan, 2023)

3.2. Human-induced factors
Many human deteriorations are observed in structures. Unconscious use of structures, lack of periodic maintenance and repair, wrong decisions made during the design phase, wrong material selection, workmanship/application errors and inadequate supervision can be shown as human-induced factors (Coşgun et al., 2002; Erdemir M., Erdoğan N. Ş., & Korkmaz S.Z., 2023).

3.2.1. Design errors
Deterioration in the structure can occur not only during the usage phase of the structure but also as a result of wrong decisions taken during the design phase. Design errors usually result from the lack of knowledge and care of the architect who designs the structure and the engineer who carries out the static solutions. Errors made during the design phase cause decisions to be made during the implementation phase and details to be resolved, and sometimes wrong choices cause deterioration in the structure. In addition, due to the lack of sufficient communication with the user during the project design phase of the space, dysfunctional and unusable spaces can emerge for the user.

3.2.2. Material selection errors
From the carrier system to the countertop material in the kitchen, even the smallest element/material in the structures must be selected after detailed research and its application must be done with the details solved in the appropriate place. At this point, it is important to know the chemical, physical and mechanical properties of the materials sufficiently. In the use of different materials together, the materials must be visual and mechanically compatible with each other. If qualified material selection is not made, deterioration occurs earlier and affects the quality of the structure. In addition, choosing materials in accordance with the location of the structure, climate characteristics and cultural data is one of the important points of a correct design.

3.2.3. Workmanship/application errors
The production sector of structures is an area that requires different disciplines to work together. Therefore, it is important to ensure sufficient coordination between the design and construction teams. As a result of unprovided coordination, communication gaps during the implementation phase cause problems in structures. In the architectural project, decisions may need to be made during the construction phase due to insufficient details that are not explained as necessary for the implementation to be carried out. This deficiency in the project attempts to be completed incorrectly or incompletely during the implementation. As a result, workmanship is carried out incompatible with the decisions in the project and faulty applications occur. Application errors resulting from unqualified workmanship cause damage that may cause discomfort during the life of the structure.

3.2.4. Inadequate supervision
Inspection of the structure should be carried out by the people responsible for the design, production and usage processes. Municipalities should examine the architectural project in detail when approving it, and during the construction of the structure, construction sites should be inspected by site managers and building inspection companies. During usage, regular inspections by users and authorized people will reduce the number of deteriorations that are at risk of occurring in the structure. To create long-lasting and healthy structures, inspections should be carried out at regular intervals on the structure's carrier system, materials and details. It is important for the life of the structure that the deteriorations detected during the inspections are conveyed to the necessary people and the problem is repaired/solved before it grows.

3.2.5. Usage errors

While individuals in the structure are using space, they can perform actions such as decreasing or increasing the load-bearing system elements of the structure, reducing the element dimensions and removing the filling elements. Since the calculations are made in accordance with the architectural project in the static projects where the load-bearing capacity of the structure is calculated, these interventions made at the time of use cause the static calculations to change. Changes in the loads of the structure can cause the load-bearing capacity of the structure to decrease. As a result of this situation, deterioration, collapse, collapse occur in the structure and cause loss of life. Not using the structures for a long time, leaving them unmaintained or abandoning them can lead to a decrease in the life of the structure. Building materials also have a certain life and it is necessary to perform maintenance on the building elements at different periods depending on their material. It is important for the user to show sufficient care in this matter to extend the life of the building elements and the structure. The maintenance and repairs to be made must also be carried out by qualified persons (Coşgun, İpekçi, Yılmaz, 2002).

4. Results and discussion

It can be said that two basic methods are mainly used in the detection of deterioration in the structure. The first of these methods is based on obtaining data through observation on the structural element where the deterioration occurs. When the cause of the deterioration is understood, error detection is made, and solution suggestions are presented, and the element/material is repaired or replaced. However, since the detections are made depending on the experience of the person, it can sometimes be ignored that there may be other errors that cause deterioration (Baytop, 2001). In the other method, errors are handled with the performance approach. In the performance approach, detection is also made based on observation, but unlike the other method, deterioration and errors are evaluated depending on performance requirements, criteria and measures. In this context, since the obtained data are obtained through analyses, the origin of errors that indirectly cause deterioration can be determined more clearly (Utkutuğ, 2006).

In this study, it was aimed at analyzing the deteriorations in a selected multi-storey housing site. While determining the deterioration, observation-based photography studies were carried out in the structure. In line with the collected data, the cause of the deterioration was tried to be determined. In this context, solution suggestions were presented based on the information obtained from the literature and experience in the repair or elimination phase of the deterioration.

4.1. Building information

The housing site determined to be examined was completed in 2019 and consists of eight blocks (four buildings in a detached order) and 155 flats placed in the northwest direction of the land. The flats in the blocks vary in normal and duplex forms as 4+ 1, 3 +1, 2+1 and 1+1. The structure consists of a basement, ground floor, three normal floors and an attic. The load-bearing system is reinforced concrete skeleton, and the floor type is designed as slab and hollow-tile slab. The wall filling material is brick, aerated concrete and plasterboard. The structure can be reached on foot from the main entrance and by vehicle from the three parking lot entrances. Due to the elevation difference in the land where the structure is located, the blocks sit on different elevations. In the landscape areas, there is a security cabin, open adult and children's pool, ornamental pool, children's park, sports area, cafeteria and green areas.

4.2. Deterioration detected in the field study and their analysis

In the study, 10 of the deteriorations observed in the structure for field research are presented in a table under the titles of deterioration detection, causes of deterioration, error detection and solution suggestions for deteriorations. While detecting errors that cause deterioration, the basic error that may cause deterioration is written in the first place. In addition, in the stage of presenting solution suggestions, suggestions are presented starting from the easiest and fastest solution for the problem. The detected deteriorations are shared in each line. The examination of 10 deteriorations including the mentioned stages is given in Table 1.

Table 1. Deterioration analysis

No	Deterioration Detection	Causes of Deterioration	Error Detection	Solution Suggestions
1	 Swelling, flaking and discoloration on the wall	Swelling, flaking and color change are effects of water and humidity in structures. Plaster and paint that swells by taking in water show shrinkage in volume when dry. This is why flaking occurs.	▪ Workmanship/ application errors ▪ Material selection errors	The waterproofing application in the wet area behind the damaged wall can be checked and re-done. In case the water flow path is an electrical channel to which the lighting is connected, the channel can be insulated.
2	 Crack in the wall	Incompatibility may occur between the reinforced concrete load-bearing elements of the structure, the infill wall located between the columns and beams, due to material differences. Settlements may occur between the infill wall elements over time. In the infill wall application, the connection of the wall to the load-bearing system may not be provided.	▪ Workmanship/ application errors	The part where the crack is located can be scraped. After applying filler/plaster to the scraped area, the surface is sanded and plastered by placing plaster wire on it. Then, a layer of paint can be applied.
3	 Deflection and water accumulation in the winter garden cover	Roofs must be designed and implemented in a way that allows rain/snow water to drain off the surface as quickly as possible, depending on climatic conditions. In the detected example, the intermediate joint lines were not applied parallel to the slope. This situation caused water accumulation on the surface and deflection of the surface of the affected material over time.	▪ Design errors ▪ Workmanship/ application errors ▪ Inadequate supervision	By opening channels between horizontal logs and providing the necessary waterproofing, water can be ensured to flow in the direction of the slope and pour into the gutter. The system can be disassembled and re-configured to be parallel to the roof slope.

Table 1 continued

4	 Paint and plaster peeling off in the area where the expansion joint is located on the wall	The top of the expansion joint in the project was not covered with a flexible element but was covered directly with plaster and paint. Movement occurred in the joint due to the movements that occurred as the building settled on the ground over time. Since the plaster is a brittle material, it cracked and the flaking on the surface grew larger over time.	▪ Design errors ▪ Material selection errors ▪ Workmanship/ application errors	On the walls where the dilatation is located, the plaster can be scraped off and the dilatation can be covered with curved insulation material, but plaster should not be applied on it and should be left open. Otherwise, the plaster will crack again.
5	 Moss formation, discoloration and shedding on the wall	When walls are not adequately protected from water and moisture and are constantly exposed to them, moss formation occurs in places where water leaks. Especially in areas that do not see the sun (north facades), moss formation is easier. The surface here is in the northwest direction and there is a waterproofing problem in the area above the wall.	▪ Workmanship/ application errors ▪ Inadequate supervision ▪ Usage errors	Water insulation can be applied to the source of water leaking into the wall. After the mossy layer on the wall is scraped off and the moisture dries, the wall can be sprayed with ready-made pesticides produced for mossy growth.
6	 Water leakage from the part where the water drains are located on the parking lot ceiling	Water can leak from the smallest crack in the structure. Therefore, spaces exposed to water should be well insulated against water. Especially in the parts of the structure where water drains are located, if the relationship between the water pipes and the ground is not resolved well, water leaks can occur as in the example.	▪ Workmanship/ application errors ▪ Inadequate supervision	By removing the pipes and finding the source of the leaking water, the junction point with the floor can be insulated against water.

Table 1 continued

7	 The presence of a protrusion that makes the living room wall useless	If the correct solutions are not made for the water drains of wet areas, it is necessary to close the water drains from the ceiling and wall of the hall as in the example. In this case, when the wet area on the upper floor is used, the sound of water is heard in the volume. In addition, there is a problem in furnishing.	▪ Design errors ▪ Workmanship/ application errors	Furnishings can be made in a way that will include/eliminate the protrusion on the wall. A shelf system can be designed. For sound, insulation can be applied, although it will increase the protrusion area.
8	 Scratches/abrasions on elevator doors	The doors may not have been placed in the elevator door shaft on a level. As a result, the doors rub against the shaft during opening and closing and wear occurs on the door surface. Another reason is that the elevator shaft may not have been placed on a level.	▪ Workmanship/ application errors ▪ Inadequate supervision	The problem can be solved by checking the elevator shaft and the balance of the doors. If the problem is with the elevator volume, the volume may need to be re-balanced.
9	 Mold formation on the wet area wall. Opening the door to the outside and the step	Mold fungus, which appears in different colors such as black, navy blue, green and spread over the entire surface, forms in secluded, cold, airless and damp areas where sweating occurs and accumulates. Ventilation and wall details must be resolved in accordance with the wet area.	▪ Design errors ▪ Material selection errors ▪ Workmanship/ application errors ▪ Inadequate supervision	Plasterboard walls can be removed and replaced with water-repellent green plasterboards. A mechanical system can also be installed to ventilate the space.

Table 1 continued

10	 The residence waste water drains are located in the open and the pipes are connected to each other at right angles.	The wastewater drainpipes in the basement are open to external effects. There is a possibility of hitting the pipes while parking the car. In addition, the pipes should be connected at a certain slope to prevent blockage in the pipes. There is a possibility of blockage and the pipes bursting.	▪ Workmanship/ application errors ▪ Inadequate supervision	The sections of the pipes that meet at right angles can be sloped. Then the area can be closed with a protection wall/iron barrier.

5. Conclusions

Structures shaped according to the needs of the users must provide certain comfort conditions. However, deteriorations may occur due to different reasons in the design of the structure, during the implementation phase and during the usage period. In the study, 10 of the deteriorations determined in the housing site selected for field research are presented under the titles of deterioration detection, causes of deterioration, error detection and solution suggestions for deteriorations.

When the obtained data is examined, many problems such as swelling/shedding/cracks/fungus/mold/moss/color change on the walls, dirt on the walls, plaster/paint flaking, water leaks, breakage/separation/wear in the structural elements are encountered in the detection of deterioration. As the detection of deterioration differs, the factors causing deterioration also to change. However, it can be said that the deterioration in the structure is mainly caused by physical factors such as water and humidity problems. It is thought that the fact that the structure is in the northwest direction influences this situation. Wet surfaces need to be ventilated and dried. However, due to its location in the northwest direction, there is little sun exposure in the structure. Therefore, wet areas cannot dry and this can cause problems.

When the fault detections of the deteriorations examined in the structure were made, it was seen that there were mainly workmanship/application errors and inadequate control. This was followed by design errors, material selection errors and usage errors. Table 2, which summarizes the fault detections according to deterioration numbers, can be accessed below.

Table 2. Summary of error detections according to the deterioration number.

ERROR DETECTION	DETERIORATION DETECTION NUMBER									
	1	2	3	4	5	6	7	8	9	10
Design Errors			✓	✓			✓		✓	
Material Selection Errors	✓			✓					✓	
Workmanship/application errors	✓	✓	✓	✓	✓	✓		✓	✓	✓
Inadequate supervision					✓	✓		✓	✓	✓
Usage Errors					✓					

The reason why almost all errors are encountered with workmanship/application errors and inadequate supervision is that the companies contracted to carry out the application process of the building do not do their jobs well enough. Even if the design of the structure is done correctly, poor application during the construction phase can cause many deteriorations in the following processes. Since the errors made during the construction phase were not inspected on site and at the right times, deteriorations could not be prevented. Another most encountered error in the examined areas was the design error. Errors were encountered at the points of the structure that would meet the needs and comfort of the users or in the areas expected to fulfill the purpose of use. Among these errors, design, workmanship/application and inadequate supervision errors are the most difficult errors to repair/repair/correct/renew. Finding the source of the error and the solution can be long and difficult. Usage errors, which can be solved relatively faster, are the least common errors.

When it is desired to minimize the deterioration in structures, it is important for the individuals involved in the implementation and usage processes to do their jobs meticulously, starting from the project/design phase of the structure. During the material selection phase, it is necessary to have a good command of the chemical and mechanical properties of the material and to make good, detailed solutions. It is also important to perform periodic maintenance and repairs during the usage phase. Correctly determining the causes of deterioration and fault detection in structures prevents the deterioration from growing and allows the solution processes to accelerate. Therefore, when deterioration is encountered, it is necessary to start detection work quickly.

Abstract. Recently developed construction technologies have made it possible to carry out processes more efficiently, quickly and sustainably. In this context, 3D concrete printing technology, automation, and robot technologies have emerged. This study aims to verify the reliability of the results obtained through experimental methods in producing different geometric forms in the 3D concrete printing process using multi-criteria decision-making (MCDM) methods. The study's main purpose is to examine the effectiveness of MCDM methods in verifying experimental data and to prevent waste of time and resources in experimental processes. The data obtained in the experiments were analysed using the selected MCDM methods, and it was determined that the circular geometry plan provided the optimum performance in terms of buildability, cost, and mass producibility parameters. MCDM analyses similarly showed that the circular geometry plan was superior regarding these parameters. The results revealed that the selected MCDM methods were broadly consistent with the experimental findings, and it was also determined that the methods were sensitive to different criterion weights and assumptions. This study demonstrates that MCDM methods can effectively support experimental results and serve as a valuable complementary tool in decision-making processes. The findings highlight the effectiveness of using experimental and theoretical approaches in decision-making processes.

Keywords: 3D concrete printing technology; automation; robot technologies; MCDM

1. Introduction

As one of the key technologies of Industry 4.0, additive manufacturing enables the production of products designed in a digital environment using the 3d printing (3DP) method. This technology, first developed in 1983, has become widely adopted in various sectors today, including automotive, aviation, and construction. In the construction industry, 3d printing (3DP) is used as an alternative to traditional molding methods, enabling the production of non-linear, complex architectural designs. This technology offers advantages such as reducing costs, shortening project time and ensuring sustainability by increasing automation and digitalisation in construction processes (Gebel et al., 2024; Takva et al., 2024).

In additive manufacturing processes, the selection of alternative building forms should be considered within the framework of criteria such as manufacturability, cost and sustainability. Multi-criteria decision-making (MCDM) methods can be an effective tool in such decision-making processes, as they save time and resources compared to traditional experimental approaches.

Multi-criteria decision-making (MCDM) methods typically involve processes such as determining alternatives, weighting criteria, and ranking options (Brugha, 2004). Majumder (2015) emphasises in his study that the correct result may not always be achieved in decision-making processes (Majumder, 2015). This study evaluated the similarities and differences between the results obtained using MCDM methods and the findings of a real-life experiment. The study's primary objective is to determine whether the results of an experiment can be accurately predicted using MCDM methods without the need for resources such as time, materials, and labour typically required for experiments.

2. Methodology

In this study, the authors' experiment for producing different forms using 3D concrete printing (3DCP) is tested using multi-criteria decision-making methods. Information is diverse, and designers' priorities differ in the field of design (Tan et al., 2021). In MCDM methods, the goal is to optimise the evaluation of experts and decision-making. At the first stage, the parameters to be evaluated will be explained. Then, the criterion weights will be calculated using the Fuzzy AHP method, demonstrating the relevant criteria's importance. At this stage, pairwise comparison matrices are created based on expert assessments. With this evaluation, weights are obtained. After these weights are received, the alternatives will be evaluated with the TOPSIS method, and the resulting ranking will be compared with the actual result. The flow chart for the explained algorithm is shown in Fig. 1.

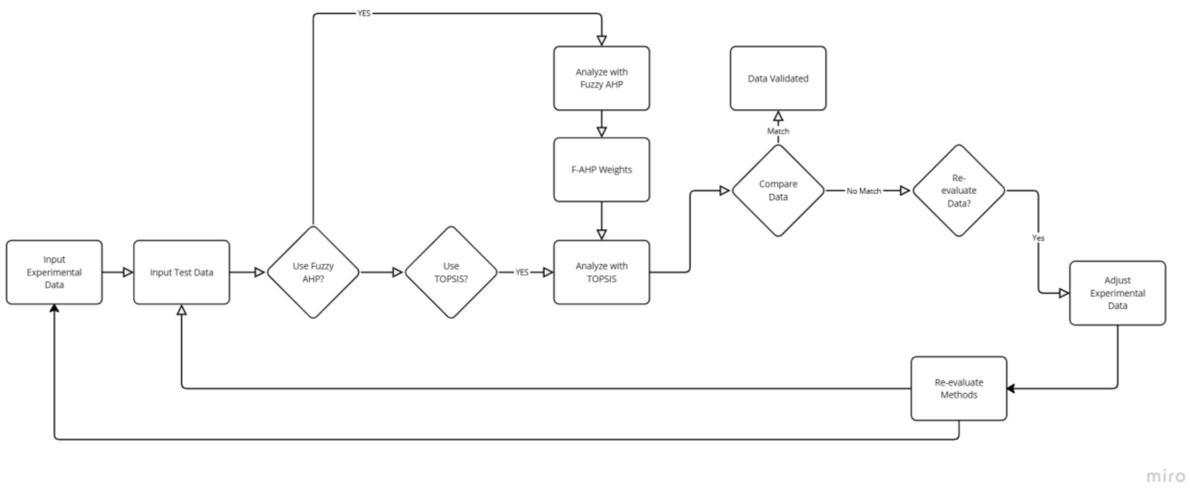

Fig. 1. Flowchart of the study

2.1. Fuzzy AHP

In the analytical hierarchy process, pairwise comparisons contain uncertainty because they are based on expert opinions; therefore, the Fuzzy AHP method is used in the literature to mitigate these situations. In this method, instead of evaluating with numbers (1-3-5-7-9) in AHP, experts are ensured to evaluate using linguistic expressions (Liu et al., 2020). The scale used in creating the fuzzy pairwise comparison matrices for the study is presented in Table 2.

Table 2. Linguistic variables (Huang et al., 2012)

Code	Linguistic Variables	L	M	U
1	Equally important	1	1	1
2	Intermediate value between 1 and 3	1	2	3
3	Slightly important	2	3	4
4	Intermediate value between 3 and 5	3	4	5
5	Important	4	5	6
6	Intermediate value between 5 and 7	5	6	7
7	Strongly important	6	7	8
8	Intermediate value between 7 and 9	7	8	9
9	Extremely Important	9	9	9

The fuzzy AHP method was applied through a series of steps that began with comparing pairs of criteria among experts. First, fuzzy decision matrices were created due to these comparisons and the fuzzy scale in Table 1 was used. Then, the fuzzy weights were normalised by calculating the consistency of the weights. Global fuzzy preference rankings were created for the alternatives, and the results were interpreted to guide the decision process. As a result, the rankings obtained by this method support the decision-making process. The findings obtained through the application of the method revealed the priority criteria for the 3D concrete printing process.

2.2. TOPSIS

The TOPSIS method is a straightforward and comprehensible technique that seeks to identify the alternative that is closest to the ideal solution and the farthest from the negative ideal solution in decision-making processes (Yoon & Hwang, 1995). The steps of the method are as follows: The creation of the decision matrix begins with normalising this matrix and obtaining the weighted decision matrix by taking into account the weights of the criteria. Then, the distances of each alternative from the ideal and negative ideal solutions are calculated. In the last stage, the relative proximity scores of the alternatives are determined, and the alternative with the highest score is selected as the best option. Due to its ease of application and the fact that its results are not subject to interpretation, the TOPSIS method is widely used in various fields (Fayaz et al., 2023; İlerisoy & Gökgöz, 2023, 2024; Lolli et al., 2022; Wang & Wang, 2014; Xiong et al., 2021).

3. Proposed Framework with Example

In this study, which compares the real-life application of 3DCP technology with the MCDM methods, the effectiveness of the MCDM methods in validating experimental data is measured. The TÜBİTAK project, with code 122M876, is used as experimental data. This experiment aims to identify errors and deficiencies by examining design parameters through models and to reveal the effects of these parameters by comparing them with one another. Building evaluation parameters based on research findings in the literature include comparative analyses of systematically modified design decisions in buildings with the same architectural plan and footprint. These analyses focused on specific structure evaluation criteria for geometric forms derived from 3DP. These are printing time, material usage, mass production, buildability, defect analysis, size consistency and cost criteria. As geometric forms, the square, chamfered square, rectangle, chamfered rectangle, circle, chamfered circle, hexagon, chamfered hexagon, octagon, chamfered octagon, and ellipse were evaluated, and these forms were considered alternatives in this study. The decision tree for this evaluation is given in Fig. 2.

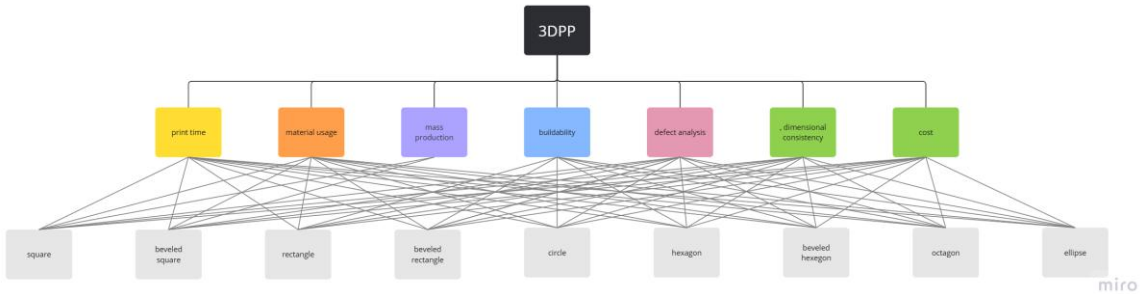

Fig. 2. Decision tree

This hierarchical evaluation was conducted by an expert team comprising five architects and five civil engineers who have specialised studies on the subject. The comparison matrix is presented in Table 1. Accordingly, the criterion weights in the criterion evaluations are given in Table 2.

Table 2. Criteria Weights

Criteria	Printing time	Material usage	Mass production	Buildability	Defect analysis	Dimension consistency	Cost
Weights	0.054	0.081	0.399	0.220	0.032	0.032	0.182

According to these evaluations, it was concluded that mass production was the most important parameter. The mass production parameter is crucial in determining the product's potential for mass production. The sum and analysis of the data obtained from other evaluation criteria help determine the systems suitable for mass production. In this process, the most appropriate mass production method and process should be determined by considering factors such as printing time, material usage, buildability, analysis of potential defects, measurement consistency, and cost. In this context, important factors such as production efficiency, quality standards, and cost-effectiveness are optimised, and successful results are obtained in mass production. The following criteria follow the mass production criterion, respectively: Buildability (0.220), Cost (0.182), Material Use (0.081), Printing Time (0.054), Defect Analysis (0.032), and Dimensional Consistency (0.032).

Buildability is the most critical parameter in evaluating printable mixtures. The extruded filament must maintain its shape without deformation, settle in harmony with the lower layers, gain sufficient stiffness and rapid strength, and form a strong bond between the layers (Ahmed, 2023).

The cost parameter, which ranks third after the buildability criterion, is a critical factor in determining the most economical geometry and is of great importance for applicability and mass production processes. The use of materials is a decisive factor in the printing phase, as the impact of different types and proportions of components on the final 3D printing (3DP) product is significant. Printing time stands out as a dynamic variable that is affected by other parameters and also affects them. Within the scope of defect analysis, the ability of different geometric forms to reach different layer heights is evaluated. On the other hand, dimensional consistency is an important criterion that examines the difference between input (design) and output (prototype printing) products.

In the evaluation using the TOPSIS method, the expert team evaluated the alternatives on a scale of 1 to 5. A ranking was created according to the criterion weights derived from the fuzzy AHP. Expert evaluation data are presented in Table 3, and normalised data are presented in Table 4.

Table 3. TOPSIS Expert Evaluation

Weights	0.054	0.081	0.399	0.220	0.032	0.032	0.182
Geometric Forms	Printing time	Material usage	Mass production	Buildability	Defect analysis	Dimension consistency	Cost
Square	3	3	3	3	2	3	3
Beveled Square	4	4	4	4	2	3	4
Rectangle	3	3	3	3	2	3	3
beveled rectangle	4	4	4	4	2	3	4
Circle	5	5	5	5	2	3	5
Hexagon	3	3	3	3	2	3	3
beveled hexagon	4	4	4	4	2	3	4
Octagon	3	3	3	3	2	3	3
Beveled Octagon	4	4	4	4	2	3	4
ellipse	5	5	5	4	2	3	5

Table 4. TOPSIS Normalization Data and Sequencing

	S+	S-	C	Rank
Square	0,082185378	0	0,00	7
Beveled Square	0,041092689	0,041092689	0,50	3
Rectangle	0,082185378	0	0,00	7
beveled rectangle	0,041092689	0,041092689	0,50	3
Circle	0	0,082185378	1,00	1
Hexagon	0,082185378	0	0,00	7
beveled hexagon	0,041092689	0,041092689	0,50	3
Octagon	0,082185378	0	0,00	7
Beveled Octagon	0,041092689	0,041092689	0,50	3
ellipse	0,018527342	0,075661411	0,80	2

As a result of these evaluations, considering all the criterion evaluations, it was seen that the best alternative was the circle form. This is followed by ellipse, chamfered octagon, chamfered hexagon, chamfered rectangle, chamfered square, square, rectangle, hexagon and octagon.

When the data obtained from the experiment are analysed, when we look at the printing time and material usage, collapse heights, maximum number of layers during printing and perimeter lengths between square, rectangle, circle and ellipse geometric forms; circle in terms of printing time, circle in terms of material usage, circle in terms of collapse height and circle in terms of number of layers showed the best performance. The results are shown in Fig. 3-4. This shows the accuracy of the study model.

4. Results and Discussion

This section presents the results obtained with the multi-criteria decision-making methods used in the study and compares them with the experimental results.

Upon examining the findings obtained from this study, it was determined that the mass production parameter was the most important criterion (Fig. 5). This parameter is a comprehensive factor that optimises elements such as production efficiency, quality standards, and cost-effectiveness, and determines the impact of many other criteria. In this context, academicians who expressed their opinions in line with the experiments carried out in the laboratory environment also emphasised that the mass production parameter is the most important criterion. Thus, the criterion evaluation obtained in the multi-criteria decision-making analysis overlapped with the important criteria determined in the experimental environment.

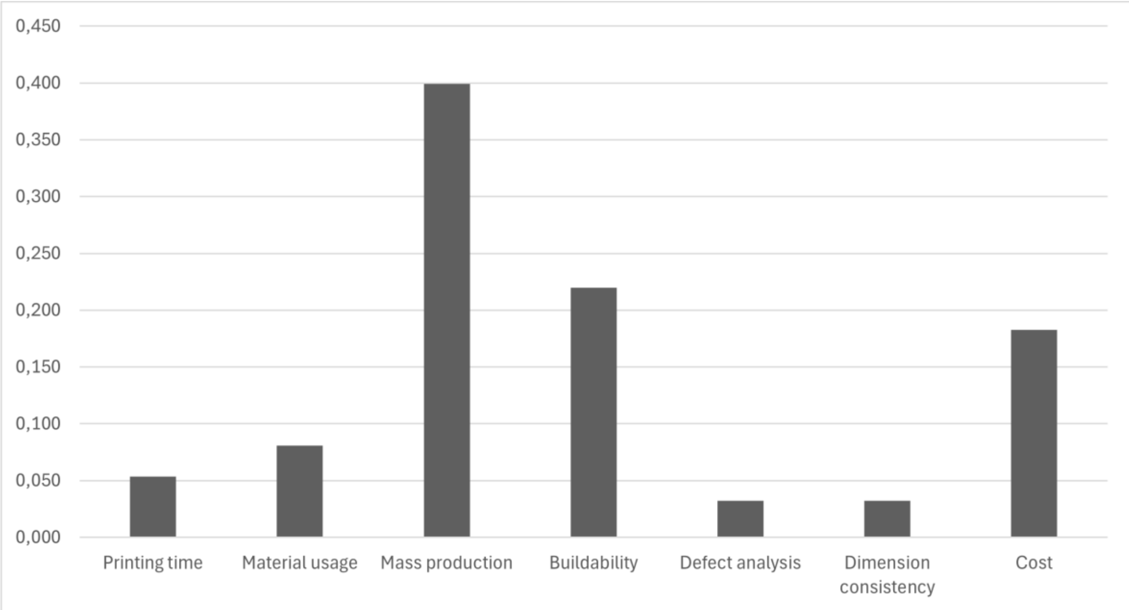

Fig. 5. AHP Results

The buildability parameter is crucial for successful printing. The filament needs to retain its shape, merge well with the layers and harden quickly. Otherwise, the print quality may decrease. In this parameter, a result was obtained that matched the experimental environment.

Printing processes on forms include printing time, material usage, mass production, buildability, defect analysis, and dimension consistency. The circle form got the best results in evaluating the cost criteria, and the presence of the circle form in the experiment shows that the model in this study works (Fig. 6).

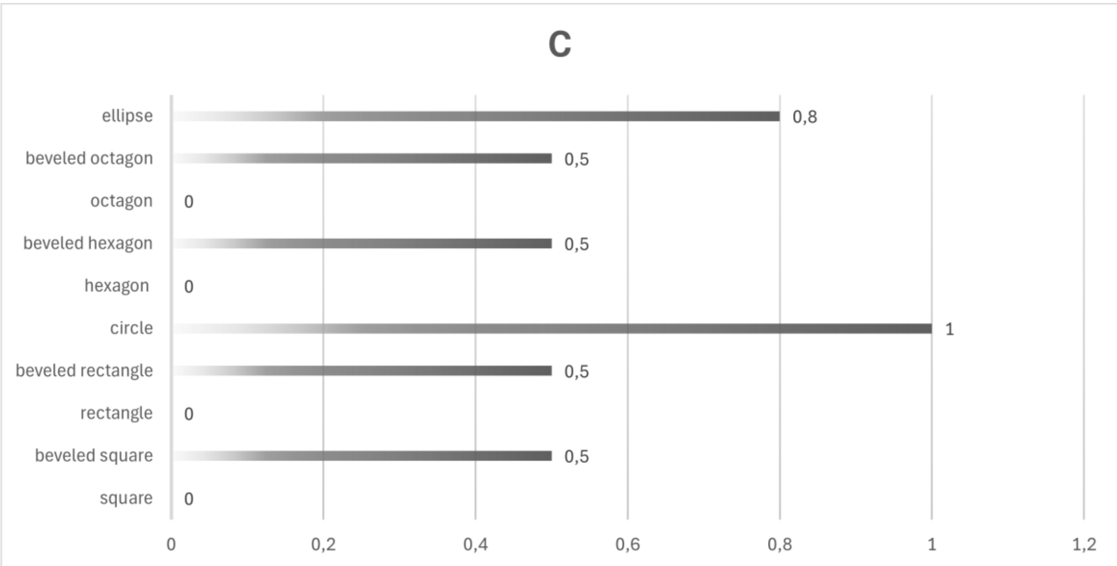

Fig. 6. TOPSIS Results

As a result of these evaluations, it was determined that the most suitable alternative was the apartment form, taking into account all relevant criteria. The circle is followed by an ellipse, a beveled octagon, a beveled hexagon, a beveled rectangle, a beveled square, a square, a rectangle, a hexagon and an octagon, respectively. The most effective criteria for the emergence of these results were mass production, buildability and cost. In the evaluations conducted in the experimental environment, it was found that the circle form exhibited the best performance, particularly when all criteria, including these parameters, were considered. This situation demonstrates that the results obtained using the Multi-Criteria Decision Making (MCDM) method are consistent with experimental studies.

4. Conclusion

This study showed that multi-criteria decision-making methods can evaluate alternative solutions without requiring the use of resources in experimental processes. The results obtained largely align with the experimental findings, indicating that MCDM methods can be a valuable tool in decision support processes. In future studies, the effectiveness of these methods in different decision settings and with more complex criteria may be examined in more detail.

The findings of this study reveal that the most important parameter in the three-dimensional concrete printing process is mass production. Mass production is a critical factor in determining the suitability of the prints for production processes and the efficient operability of the system. When the alternatives were evaluated by experts within the framework of all parameters, it was determined that the best-performing form was the circle. The circular form has demonstrated high performance in all parameters due to its soft lines along its circumference, which enable it to exhibit superior performance compared to other forms.

In this context, the study's findings can be considered an important step in developing alternative approaches to experimental methods in decision-making processes. Experimental studies entail the consumption of resources, such as time, materials, and labour, which can lead to both material and moral losses. Using Multi-Criteria Decision-Making (MCDM) methods, criteria can be weighted, and alternatives can be analysed systematically through expert evaluation questionnaires. Thus, comprehensive and efficient assessments can be carried out without wasting resources.

A brief overview of historical water supply structures in ancient Tabriz

Elham Kazemi*[1], Mohammad Taghi Sattari[2], Rahmat Mohammadzadeh[1]

[1] *University of Tabriz, Department of Civil Engineering, Tabriz, Iran.*
[2] *University of Tabriz, Department of Water Engineering, Tabriz, Iran.*

Abstract. Tabriz is a historical and ancient city located in the northwest of Iran with a dry and cold climate. This city has been one of the largest commercial, political, educational, and cultural centers of the South Caucasus and Eastern Anatolia along the Silk Road. From ancient times, the inhabitants of Tabriz and other cities in the Iranian plateau created large water reservoirs and underground channels known as qanats to cope with water scarcity. The water stored in qanats was transferred through clay pipes underground to the reservoirs located in neighborhoods and houses, where it was stored and used in structures called sardab. Until years ago, before the water supply of Tabriz was provided through piping, the aforementioned historical structures played a significant role in supplying water to this city and its prosperity. In this research, using a descriptive-analytical approach, maps and information related to historical structures were first collected through existing documents and books, and then the method of water supply and distribution in the city through these existing structures was examined. The results show that over time, due to lack of use, change of function, destruction, and burial of the paths of most qanats, water reservoirs, and sardabs, they have disappeared in the city of Tabriz. Field studies indicate that only a very limited number of these historical water supply structures still remain and are sometimes in use. In this research, the structure, architecture, and method of operation of a number of these remaining structures have been examined and analyzed.

Keywords: Historical structures; Qanat; Water reservoir; Sardab; Tabriz.

1. Introduction

Certainly, the early inhabitants of Tabriz, like other human communities, were engaged in efforts to access water. At times, they utilized the most basic resources, and gradually, with the expansion of the city and urbanization and the increasing need for water, they implemented suitable solutions according to the conditions of time and place to ensure access to water for all. Over time, the river water that has flowed through this city since ancient times, along with the water from the springs along the rivers or those found in various corners of the plain, was insufficient for the community of that day. On the other hand, it was difficult for those who had lived together and become accustomed to one another to detach from their community. Thus, the increase in population and the expansion of society necessitated planning for water supply, which manifested in various ways throughout history. It is evident that the historical ups and downs, wars, and the destruction resulting from them have obscured certain periods of history, leaving no trace of the methods of water supply and distribution during those times. It can be said that the first period of water supply in Tabriz dates back to the Ilkhanate period of the Mongols. Furthermore, every city throughout its history has had its own methods for water distribution, yet unfortunately, there is ambiguity and darkness surrounding the issues related to water. Tabriz is also among those cities that have made necessary efforts throughout history to supply and distribute water. For example, during the Qajar era and the reign of Fath Ali Shah Qajar, due to the familial ties with Azerbaijan, more attention was given to the city of Tabriz, and water supply issues were resolved with the drafting of a text known as the "Fooladnameh." The Fooladnameh mentions that during the reign of Fath Ali Shah Qajar, under the efforts and insight of Fath Ali Khan Beiglar Beigi, a meeting was held in the capital city of Tabriz with the village heads and elders of the city and locality, as well as the wise deliberation of the Sadaat, to adopt a method for regulating water distribution. This was necessary because due to the disturbances and damages that had occurred, anyone from the residents could access water without rules or laws, and those who were situated at the source were successful, while many others suffered from thirst and lack of water. It was decided that the water from the Mehran River would be distributed in an orderly manner among

*Corresponding author, E-mail: elhamkazemi@tabrizu.ac.ir

https://doi.org/10.31462/icearc2025_a_aen_916
golden light publishing

them. In the year 1950, the first water reservoir in Tabriz was put into operation. Prior to that, in addition to the water from the Mehran River, which supplied various areas of the city according to a plan, a significant number of qanats around Tabriz played an important role in providing drinking and agricultural water for the city. The digging of qanats became common to meet the water needs, and both individuals and legal entities engaged in the construction of qanats, a practice that continued until the late reign of the Qajar dynasty, and they were utilized. During the Qajar family era, when Tabriz was the crown prince's residence and the capital, the water supply and distribution methods in this city were at their peak of fame, and diggers were engaged in creating qanats in various parts of the city and its surroundings. During this period, about 70 qanats and springs with good water flow were active for supplying Tabriz (Hashemi, 2010).

The digging of the qanat was one side of the story, and the method of transferring water to the city of Tabriz was the other side. Since the city of Tabriz is situated in a plain surrounded by mountains, qanats were dug at the foothills, with the mother well on the slope of the mountain and the outlet of the qanat located near or sometimes in the center of neighborhoods. In neighborhoods where the outlet of the qanat was within the area, water taps were installed, and people would collect their needed water using buckets or other tools. However, in places where the outlet was far away, water bearers would transport water from the outlet to the people using carts, or the qanat water would be transferred through clay pipes from the outlet to the center of the neighborhood and sometimes to the yards of houses. After transferring the water, it was stored in cisterns for use when needed. The cisterns had openings to control the water level, but access to the inside of the cistern was practically impossible. Alongside the cisterns, there was an underground space known as the "sardabeh," which was used for retrieving the stored water and had many steps leading outside. Another structure known as the "icehouse" complemented the cisterns, using the low temperatures on the brink of freezing during winter nights in the desert to create ice. Another space that was fed by the qanat water was the "hozkhanah," which existed in most old houses. It was a summer room with a small pond in the middle, where the cool water helped to humidify and lower the air temperature on hot summer days. These complex yet practical structures and the way water is transferred from the mountains to the required locations through these structures have their own specific mechanisms. This article aims to showcase how these structures operate and how they supply water in the dry and semi-dry region of the city of Tabriz. Given that today Iran, including the city of Tabriz, is facing a serious water scarcity issue, familiarity with the structure of these structures and, if necessary, their revival may be a fundamental step in addressing this problem. However, the importance of paying more attention to these structures becomes evident when most of them are at risk of destruction due to the negligence of the relevant authorities.

2. Materials and methods

Tabriz is located in the eastern corner of a flat sedimentary plain with an area of approximately (55*30) square kilometers. This plain has a gentle slope towards the northeastern shore of Lake Urmia and is irrigated by several rivers, the most important of which is the Ajichay (Tolkhorud), which originates from the southwestern slopes of Mount Solan (Sabalan) and, after passing near Garajeh-Dagh, which is the northern boundary of Tabriz, enters the plain and flows northwest of the city. The Mehran River (current Midanchay), which flows through the center of the city, joins the Tolkhorud from the left. The elevation around various parts of Tabriz can be considered between 1350 and 1500 meters according to a Russian geographical map, and in the northeastern area of the city, Mount Ainli-Zinli (the shrine of Awn ibn Ali and Zayd ibn Ali) is visible, with an elevation of 1800 meters, acting as a ridge that connects the Qara-Dagh mountain range located to the north and northeast with the slopes of Mount Sahand, whose highest peaks are about 3547 meters (this mountain is located fifty kilometers south of the city). Since Qara-Dagh is a mountainous, unproductive, and sparsely populated region, and the large Mount Sahand occupies all the distance between Tabriz and Maragheh, Tabriz is the only suitable route for transportation between the east (route: Astara - Ardabil - Tabriz and Tehran - Qazvin - Miyaneh - Tabriz) and the west (route: Trabzon - Erzurum - Khoy - Tabriz). Finally, since the slopes of Mount Sahand create a very narrow passage along the eastern shore of Lake Urmia, the transportation route between the north (Transcaucasia, Qara-Dagh) and the south (Maragheh, Kurdistan) must pass through Tabriz. The weather in Tabriz is harsh in winter with abundant snowfall, and in summer, due to the proximity of Mount Sahand and the abundance of surrounding gardens, the weather becomes mild and temperate.

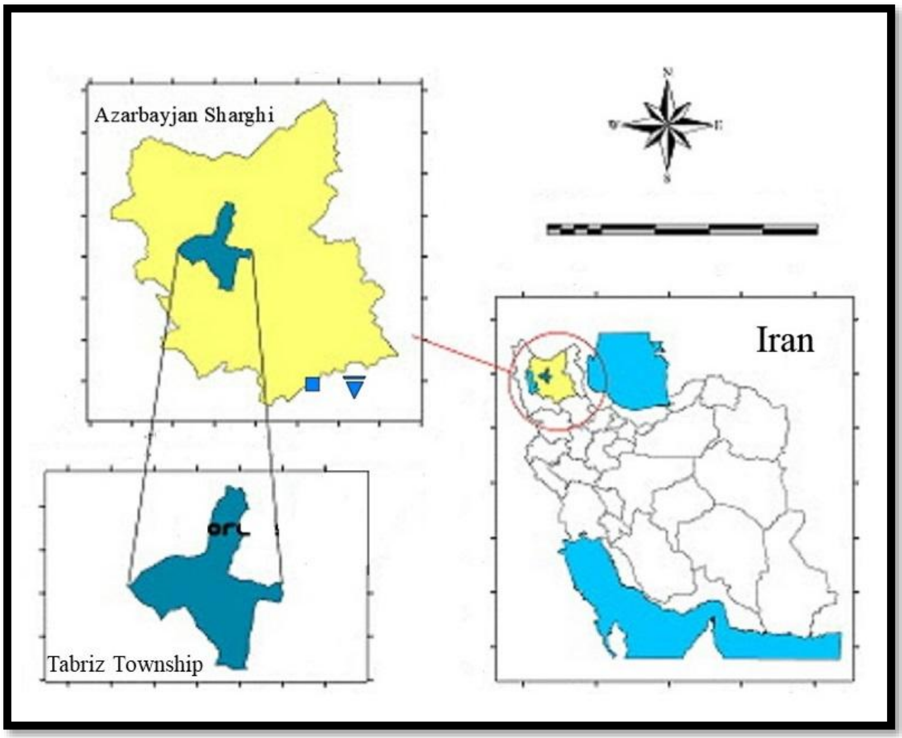

Fig. 1. Location of Tabriz city

In this research, with a descriptive-analytical approach, maps and information related to historical structures were first collected through existing documents and books, and then the way water supply and distribution in the city through existing structures was examined.

3. Results and discussion

3.1. Qanat

Iranians were pioneers in the construction of qanats, and after the Arabs took control of Iran, they brought Iranian qanat builders and specialists to North Africa to establish qanats. Ghirshman stated in his book "Iran" that the Iranian plateau has been irrigated manually since prehistoric times, and during the Achaemenid period, there were extensive underground networks known as qanats or kariz. The qanat was invented in Iran and gradually spread to other parts of the world, including the establishment of qanats in the Near East and the Middle East (in areas of present-day Eastern Turkey and Eastern Azerbaijan), in Africa, in South America near the Pacific Ocean, in Mexico, and in Europe in the region of Zelle in Germany, all of which originated from ancient Iran (Hashemi, 2010). (Fig. 2)

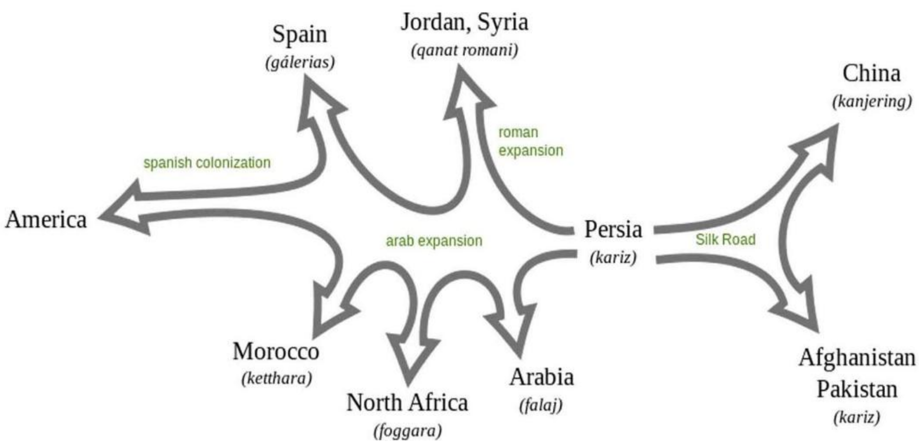

Fig. 2. The historical expansion of Qanats from Iran to other regions

In relation to the operation of qanats, after the qanat diggers (qanat workers) have confirmed the presence of water in the area and studied the specific conditions of the location, determining that the area is suitable for digging a qanat from every aspect, they begin the exploration operations. To ensure the presence of water, the qanat diggers undertake the drilling of exploratory wells in the water-bearing sections, and the number of these exploratory wells can reach up to three. With the use of buckets and simple tools, these skilled masters can estimate the water yield of the location. In the past, after this stage, the master worker would use surveying tools to determine the slope of the land and the distance from the exploratory wells to the qanat outlet, and then proceed to dig the mother well. The mother well is, in fact, the main source of nourishment for the qanat and is the part of the qanat that must produce and supply water throughout the year, making it particularly important. Mother wells are usually located in the water-bearing layers and are considered the deepest well among the series of vertical wells of the qanat. The method of digging mother wells is such that after drilling the exploratory wells and ensuring the presence of sufficient water resources and the existence of slope at the static level, they begin to dig the second exploratory well, which is the mother well. In fact, the mother well is the last well on the mountainside that leads to the underground channel and is considered the source of the qanat. The shafts are components of the qanat that are considered essential parts of it and apparently did not exist in the most primitive types of qanats. However, as the depth of horizontal wells continually increased to access more water, the issues of aeration and soil removal became more challenging, leading to the idea of creating shafts. The excavation of shafts in a qanat has four important and major uses. The first and most important benefit of these vertical wells is to provide air to individuals working deep underground. The second benefit of the shafts is related to when the qanat needs to be cleaned, which essentially serves to give the qanats a new life. The third benefit of the shafts is observed during the excavation of the water channel, where they play a crucial role in removing soil and rock resulting from the digging, saving time and energy. The last benefit of these wells is to guide the path of the qanat from above and control the direction of the channel. The depth of the shafts in a qanat starts from zero, which is the outlet and spring of the qanat, and reaches its maximum at the mother well located in the aquifer layers. The channel or conduit of the qanat is another component that is responsible for transporting water from the mother well to the spring of the qanat. This work also begins, like digging the shafts, from the spring and ends at the water sources. The method of operation is such that first, two adjacent shafts are excavated, and then the excavation of the channel is started from the downstream well and reaches the upstream well, progressing in this manner from the spring of the qanat to the dry areas. After ensuring the presence of water in the aquifer layers and drilling test boreholes, the first task is to determine the location of the spring, which is the point where the water emerges. The spring is usually located near a village or town so that the water can be easily used for people's needs, both for drinking water and agricultural purposes. The qanat, in fact, reaches the surface at the spring after traveling through its underground path, which is situated at various depths. To determine the location of the qanat spring, first, the depth of the mother well is measured, followed by the depth of the first test well, and then the slope of the ground surface and a slight slope that will be given to the underground channel are considered. Subsequently, the spring and the path of the underground channel are determined using a level and a compass. Another component of the qanat is the "haranj." The water from all qanats at all springs is not fully usable, meaning that sometimes there is a long distance from the qanat spring to where the water needs to be used. In this case, an open ditch or small channel is used to transfer water from the spring to the place of use. This open channel is called "haranj" or "haranj" (Sajadi, 1982). (Fig. 3) (Fig. 4)

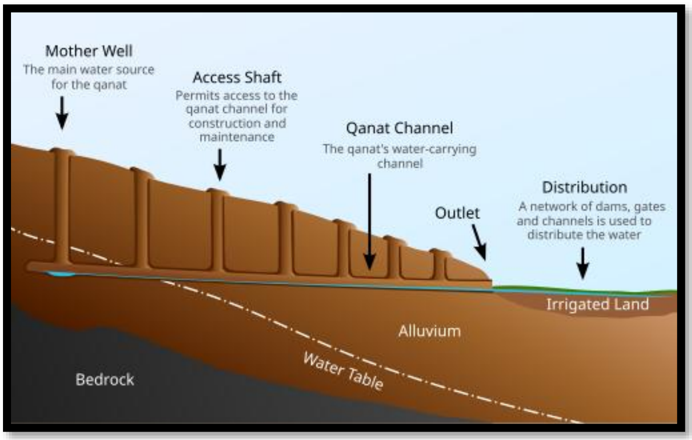

Fig. 3. Mechanism and components of a Qanat

Fig. 4. Hrang

The Qanats of Tabriz, which have existed since the Qajar era, have a similar structure. These Qanats include: Qanat Zobeideh, Qanat Hassan Padeshah, Qanat Shah Chalabi, Qanat Khwaja Ali Beik, Qanat Khwaja Qasim, Qanat Qurchi Bashi, Qanat Topchi Bashi, Qanat Hokmabad, Qanat Azizollah, Qanat Gazaran, Qanat Akbarabad, Qanat Mirza Ali, Qanat Marjan, Qanat Allahverdi Khan, Qanat Yengi Cheshmeh Shatervan, Qanat Cheshmeh Sheshgolan, Qanat Sanjaq, Qanat Haji Hassan Beik, Qanat Ahmad Pasha, Qanat Amir Nezam, Qanat Haji Jafar, Qanat Ilanlu, Qanat Montesh, Qanat Mirjalil, Qanat Sardar, Qanat Sharbaafan, Qanat Keshish, Qanat Koshk, Qanat Vazir, Qanat Ali Khatoon, Qanat Mir Qasim, Qanat Qazi, Qanat Imam Jom'e, Qanat Kucheh Bagh, Qanat Akhuni, Qanat Amir Aslan, Qanat Khan Mohammad Khan, Qanat Aqa Ali Akbar, Qanat Haji Mohsen, Qanat Tumas, Qanat Pahlavan, Qanat Heybat, Qanat Sultan Bozorg, Qanat Molla, Qanat Zaferanlu, Qanat Hoseyniyeh, Qanat Aqa Ali, Qanat Haji Mohammad Baqir, Qanat Haji Mirza Baqir, Qanat Kourjan, Qanat Vazirabad, Qanat Haji Abbas, Qanat Khatib, Qanat Molla Ali, Qanat Heydar Beig, Qanat Haji Mirza Hashim Agha, Qanat Fathabad, Qanat Shahzadeh, Qanat Haji Mirza Baqir, Qanat Nazem al-Tijar, Qanat Haji Saleh, Qanat Siraj, Qanat Baba Amin, Qanat Khatib, Qanat Mohammadiyeh, Qanat Qarasoo, Qanat Kreshkhuni, Qanat Haji Seyyed Hossein. The locations of some of the Qanats that are specified are drawn on the map of Dar al-Saltanah. (Fig. 5)

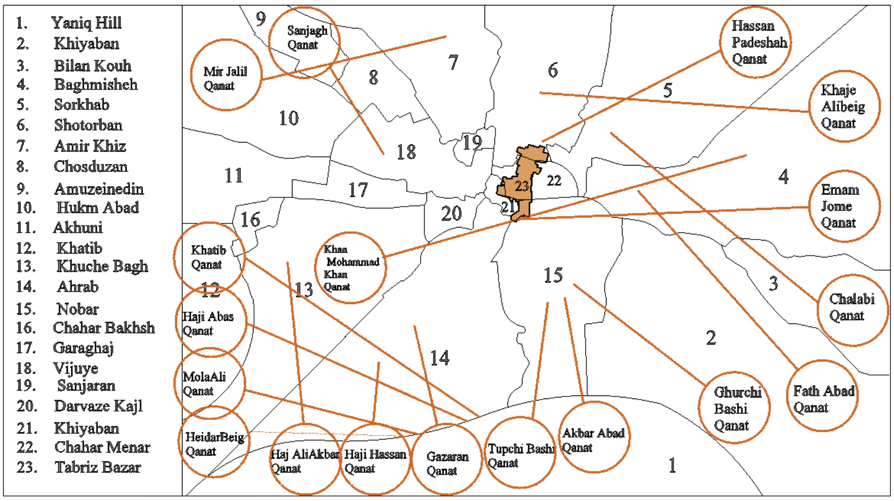

Fig. 5. Location of some Qanats on the map of Dar al-Saltaneh Tabriz

The use of qanats by people occurred in various ways, depending on the length of the qanat routes, the location of the water emergence or the spring of the qanats, and the residents along the route. Vegetable gardens, orchards, and similar places located downstream of the water spring of the qanats benefited from their water. Residents of neighborhoods situated along the qanat routes dug diagonally from the surface to the point where the water flowed underground to access drinking water, creating a staircase-like path that usually had a steep incline. They constructed the ceilings and walls of the tunnels with bricks so that people could easily access the water underground. The longer the distance from the source to the spring of the qanat, the greater the possibility of having multiple staircases (Hashemi, 2010). In addition, each qanat had a source in the center of the neighborhood, which had a water tap, and the residents of the neighborhood could use its water. (Fig. 6) (Fig. 7) (Fig. 8)

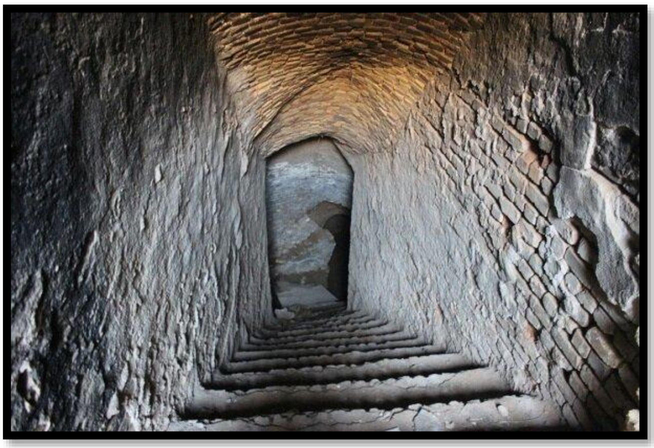

Fig.6. Outlet of Qanat in the center of the neighborhood Fig.7. A sample of the Forty-steps of a Qanat

Fig.8. The Outlet of the Qanat in the Gazaran neighborhood

The neighborhoods of the city of Tabriz each had a water master, whose duty was to channel the water from the streams and qanats using an "angaj" (a water distribution device, or in other words, a water distributor or divider) through the streets and yards to the homes. The angaj was a device made of a board with a thickness of five centimeters or more and of the required length and width. On this board, cutouts were made to meet the needs of each home and garden, and the water exiting from each cutout was directed to the specified home, yard, and garden (Hashemi, 2010). (Fig. 9)

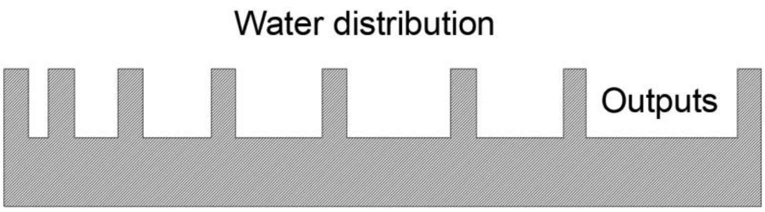

Fig.9. Angaj (Water distribution system)

The water distributors (Mirab) were involved in water distribution. Often, excess water was wasted. Water for drinking was distributed to citizens who had more financial means using buckets, which was usually done with a water skin or from a water source that was transported by carriage (Hashemi, 2010). (Fig. 10)

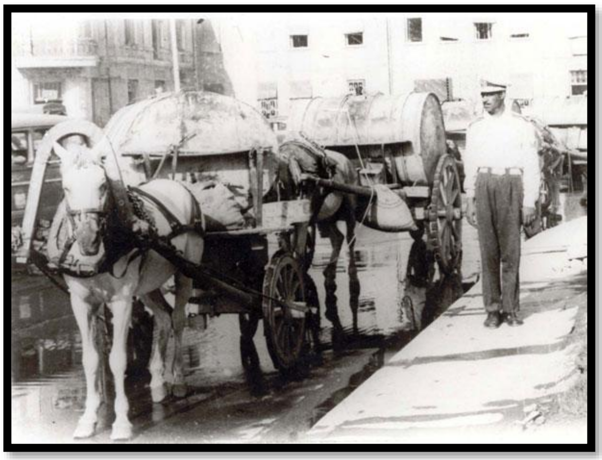

Fig.10. Mirab & Water transport Carriage in Tabriz city

3.2. Ab-Anbar (Water Storage)

A water reservoir has been a place for storing water. Due to the fact that the volume of water from qanats varies according to the seasons, and this volume is very high from Farvardin to Tir and experiences a decline starting in Mordad, by the end of the year, people have had to ensure a permanent water supply through reservoirs and ice houses. Two methods of passive cooling, aided by traditional architectural forms and local materials, have made it possible to store cold water and ice even in the hottest months of the year in the dry plains of central and eastern Iran. These cooling methods are carried out using energy resources available in the natural environment and are referred to as passive or self-sustaining methods. The architecture of water reservoirs in different regions has been so influenced by local architecture that they are recognized as part of the architectural identity of those areas. Specialists and experts in architecture, urban planning, history, and structures have categorized water reservoirs based on indicators such as functionality, efficiency, water intake capacity, the arrangement of stairways and other spaces, access to water, the shape of the tank and dome covering, construction methods, water supply methods and types, their specific locations in cities and neighborhoods, size, ventilation and cooling methods for water, as well as decorations, materials, into various styles and types. Water reservoirs are generally categorized into public, private (household), and a combination of public and private types. Public water reservoirs are typically large, impressive structures built by philanthropists, rulers, kings, and statesmen for the pleasure of God and the satisfaction of the people. The costs of construction, maintenance, water supply, repair, and restoration of these reservoirs were funded from public funds or endowment properties. Water reservoirs built in cities and villages on private properties for the benefit of the owners, their families, and members are called private reservoirs. These reservoirs or water tanks are mainly constructed in homes and sometimes in private gardens. Household reservoirs are generally made in three types: under courtyards, beneath buildings, or next to household wells. Courtyard reservoirs are built in cubic or rectangular shapes with flat or vaulted roofs, and access to them is possible through a bucket or pail. In these types of reservoirs, water is drawn through a hatch located in the roof or near the roof, or by using a hand pump connected to the tank. In reservoirs beneath buildings, access to water is achieved through a space called "pashir," which is level with the floor of the tank and is accessed using brass taps. The taps are placed slightly above the tank floor to prevent silt, mud, and other sediments from entering. In reservoirs near household wells, the water tanks are usually located above the building's foundation and close to deep wells. Thus, while providing drinking and household water, it has also contributed to the beautification of yards with ponds and fountains. The capacity of some of these cisterns was designed to supply the water needs of a household for three or four years. Some cisterns were used both publicly and privately. The water supply for the cisterns was sourced from rivers, rainwater, or manually. Rural, desert, and steppe cisterns were irrigated from river water, such that an inclined embankment was created in the riverbed to direct the water to a channel that connects to the cistern. Cisterns that were fed by rainwater fell into two categories: those that stored water collected from rooftops and those that collected rainwater from the ground surface. In the first type, the rooftops were constructed in such a way that rainwater would flow through a special downspout into the underground cistern. These cisterns have faucets and steps that are installed outside the tank. The second type of cisterns were desert cisterns built by humans in deserts but were filled with rainwater naturally (without human intervention). In manual cisterns, the structure of these cisterns is such that they do not fill with rainwater or river water (Dehgani, 2009), Rather, they are irrigated through human intervention, by transferring water from another location using well water, qanat, or spring. Sometimes, water must travel a distance of ten farsangs to reach the reservoir (Ayvaziyan, 1995). The method of accessing water has been through covered and open reservoirs. Covered reservoirs are dome-shaped or have a flat surface. These cisterns are very hygienic, and the water is ventilated and cooled by windcatchers, kheykhans, or openings in the ceiling. The main materials used in these cisterns are brick and mortar, but there are also types made of adobe and clay. A staircase is also located next to the reservoir leading to the pashir space. The use of water in these cisterns is not possible without access to the reservoir tap. Cisterns that have open reservoirs are also referred to as ponds or water cisterns. According to the definition by Master Bagban-zadeh: "A manual cistern means a cistern from which water is drawn by hand, either with the palm or with a bucket or container." These cisterns are built in two forms. In some of them, there is no water tap, and the staircase for drawing water is inside the reservoir, while in the other form of these cisterns, water is drawn using a rope, pulley, and bucket (water-lifter) (Dehgani, 2009). The appearance of water reservoirs is cylindrical, cubic, or hall-like. (Fig. 11)

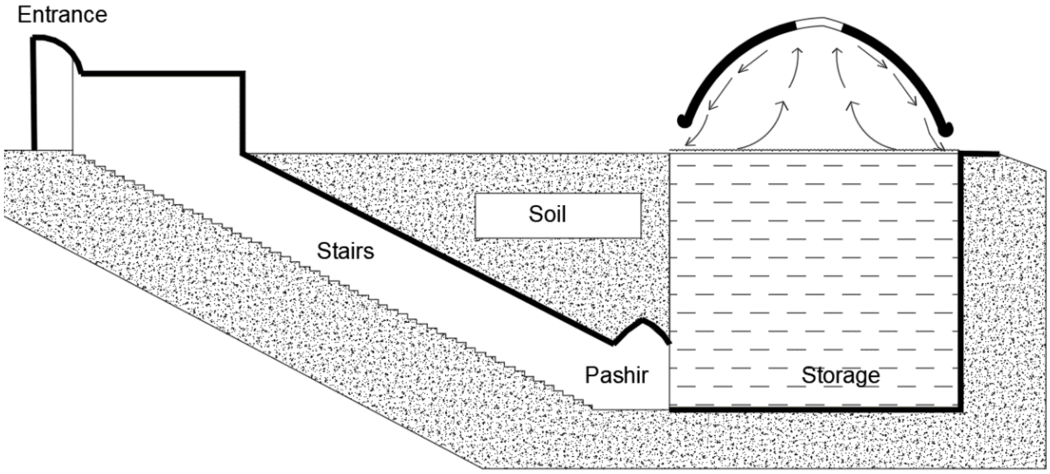

Fig.11. Ab-Anbar (Water Storage)

In the city of Tabriz, in some cases, the water from springs, qanats, or rivers was directed into water reservoirs to be used by the residents and inhabitants of different parts of the city. Additionally, there were private water reservoirs where individuals filled them based on their own resources from the water quota provided to them by the water overseers, using the water for drinking and other household purposes. The quotas were specified, and each neighborhood and family benefited from the amount of water measured by the angaj and separated from the main channels. Public water reservoirs were also filled with this water for public use. The water from some springs and qanats, which was very palatable, was distributed to people by water carriers using leather bags, or this type of water was sold in barrels on carts to wealthy families, with one rial paid for each bucket of water. The water that was stored stagnant in the reservoirs usually lost its quality, and often small red worms were found in the water reservoirs, prompting various methods to address the use of such water. People filled the reservoirs annually, and each year after complete emptying, the reservoirs were cleaned out, and necessary repairs were made to their walls and floors before being refilled with water. The situation in public water reservoirs was similar (Hashemi, 2010). For example, the cistern of the Selmasi House in Tabriz, which has now turned into a museum, is 8.4 meters long, 3.6 meters wide, and 4.8 meters high, and it was filled with water up to a height of about 3.8 meters, with a vent in the ceiling for ventilation. (Fig. 12)

Fig.12. Salmasi house's Ab-Anbar

3.3. Ice-House

Another phenomenon that has been used in people's lives as a complement to water reservoirs since the past is icehouses, which produced ice using passive cooling methods and taking advantage of the low temperatures at the threshold of freezing during the winter nights in the desert. The founders of this phenomenon, with their ingenuity and the use of simple architectural elements, created a collection of icehouses on the outskirts of villages and towns (Dehgani, 2009). In many warm regions of Iran, storage facilities such as ice houses were built to keep ice for the hot days of the year. Ice houses and water reservoirs are two superior skills of the Iranians (Jorgensen, 2012). These ice houses had a tall wall beside them, referred to as the "shade wall." In the shade of this wall, there were shallow water catchments where water was poured during cold weather to freeze into ice. The tall wall prevented the ice from melting during the day. To fill the catchments with water during the cold winter months, water was directed to the channels beside the catchments in the morning, and workers would sprinkle the water onto the catchment with shovels. Since the weather was cold, a thin layer of water would freeze. Then, water would be sprinkled on top again, making this layer thicker. This process was continued as needed. The ice was then broken into pieces and thrown into the ice house to prevent the pieces from sticking together. Finally, the entrance was sealed, and the ice was stored for the summer (Rafie Sereshki et al., 2004). The construction of icehouses is not particularly complex. The main components of an icehouse include the main shade wall, the secondary shade wall, ice production pools, the icehouse storage structure, a warehouse, an ice keeper's room, and an entrance; however, not all of these components exist in every icehouse, nor are they all the same (Papeli Yazdi & Labbaf Khaniki, 1999). In the city of Tabriz, like in other cities of Iran, several icehouses remain, one of which is the icehouse located on United Nations Street in Tabriz, which is at risk of destruction. (Fig. 13)

Fig.13. Sample of a Ice-House on United Nations street in Tabriz

3.4. Sardabeh

In the traditional architecture of the dry regions of Iran, spaces were constructed within the earth for specific and defined purposes, generally referred to as "underground." A Sardab is a type of underground space built in proximity to water. In some sar-dabs, traditional architects raised the height above ground level to bring light into the space, while in others, which were completely sunken and did not protrude above the courtyard, different methods were employed to bring light inside, such as using marble in the courtyard floor. Traditional craftsmen used bricks to pave the floor of the sar-dab. Initially, the bricks were laid dry, and then a mixture of clay and lime was poured into the joints, or a layer of clay and lime was applied over them. The ceiling of the Sardab was generally constructed using techniques such as barrel vaults, Roman arches, and elephantine arches. The materials used in the ceiling of the Sardab were mostly bricks, and if adobe was also used, the underlying layer was covered with bricks. The forces exerted from the ceiling are broken down into horizontal and vertical components and transferred to the ground by the walls. At first glance, the decorations of the Sardabs may seem very simple, but upon closer inspection, niches can be seen that are adorned with bricks and plaster, creating numerous visual beauties. The niches served as storage spaces for household items, and their height from the ground was determined based on the height of adults for placing or retrieving household items. Additionally, the niches played an important role in reducing the mass and weight of the walls, as well as saving materials and costs. The entrances to the Sardabs were often located in the corners of the courtyard, guiding people inside with spiral stairs. In fact, going underground is a way to achieve thermal balance in the environment. The conditions for a cellar located at a depth of less than six meters are different; the air temperature inside the cellar depends on the stable ground temperature at the average depth of the cellar and the outside air temperature. Throughout the different seasons of the year, the temperature of the cellar changes with the variations in outside air temperature. In the spring and summer, the temperature of the cellar is optimal and remains almost constant, with the influence of stable ground temperature on the cellar temperature being greater than the variations in outside temperature. In the fall and winter, the cellar temperature is more affected by outside temperature changes; during these seasons, the cellar temperature drops, and the influence of ground temperature decreases due to increased natural ventilation, while the influence of outside air temperature increases (R. Mazarron & Canas, 2009). (Fig. 14)

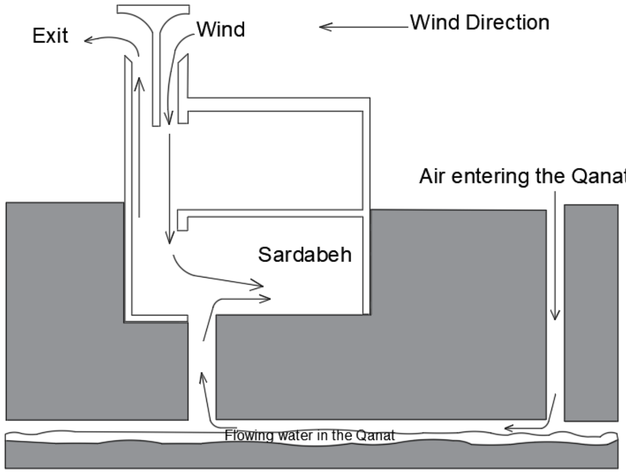

Fig.14. Sardabe (Kind of Basement)

3.5. Hozkhaneh

The poolhouse is a summer space and usually has an octagonal shape. In the middle of this space, a small pool is built, which typically has an octagonal shape, and the reason for its naming is due to the presence of this pool in the space. The presence of cool water in this area moistens and reduces the air temperature on hot summer days. The poolhouse is an enclosed space that receives light from the ceiling, and in some poolhouses, a tall windcatcher is constructed to bring cool air into the interior of the poolhouse. The operational system of the poolhouse works such that the spraying of water by the fountain cools the environment (Zangane, 2011). The water for the fountains is usually supplied by a qanat. The qanat water is transferred from the source through clay pipes to below the poolhouse and enters the pool through the fountains. (Fig. 15)

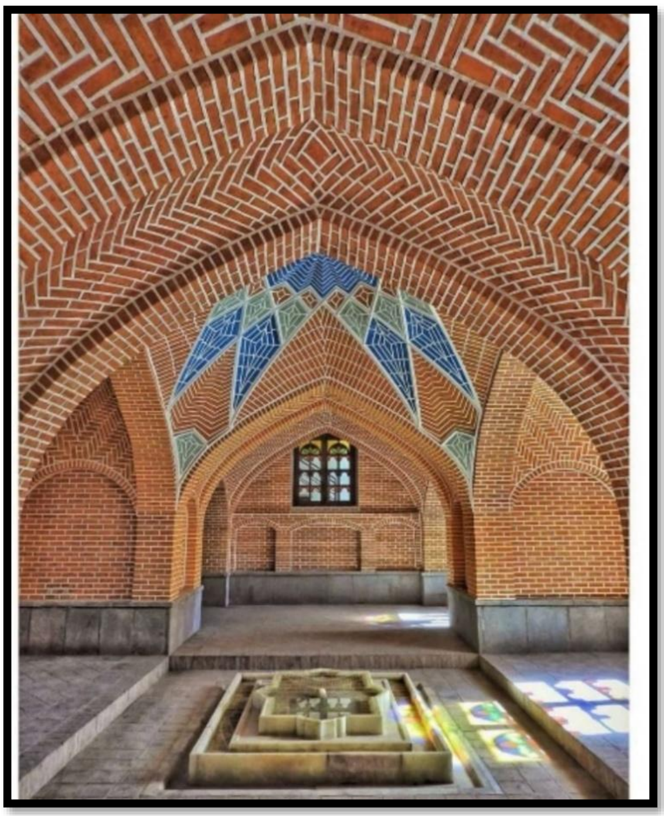

Fig.15. Sedqiani's pond in Tabriz

4. Conclusions

In ancient times, with the expansion of qanats, which were essentially the main source of water supply for other related structures, the needs of humans for water and associated issues were well addressed. In Iran, this method of water supply dates back three thousand years; however, it is still one of the significant water sources in the central and eastern cities. Yet, since Azerbaijan is the birthplace of qanats and the site of their emergence, out of the hundreds of qanats present, only a limited number are active and in use. In addition to qanats, other structures such as ice houses, water reservoirs, and cold storages in the city of Tabriz are also at risk of destruction. This article aims to take a small step in expressing the importance of these structures in supplying water to the city of Tabriz by examining how they function. According to Henri Goblot, qanats are underground tunnels for draining deep waters, with their endpoints revealed by openings. He states that a qanat is a method for obtaining or delivering water, a technique with mineral characteristics that makes the exploitation of groundwater possible through drained tunnels. Since the aquifers in the city of Tabriz still exist, this structure can be revived and used. Other structures examined in this article share the same conditions; for example, there are large water reservoirs and ice houses throughout the city that can be restored and made usable again with rehabilitation and major repairs.

Potential of using agricultural wastes as thermal insulation material: The case of wheat straw insulation on external walls

Mustafa Ehven*[1], Buket Metin[2]

[1] Abdullah Gul University, Graduate School of Engineering and Science, Department of Architecture,38080, Kayseri, Türkiye
[2] Abdullah Gul University, Faculty of Architecture, Department of Architecture, 38080, Kayseri, Türkiye

Abstract. Climate change has become a critical problem globally. In this context, it has become inevitable to enhance the environmental performance of buildings in the construction sector, which consumes the most energy and causes the most carbon emissions. Thermal insulation materials play a crucial role in reducing the energy requirement for heating and cooling of buildings by improving their thermal performance. Currently, inorganic materials constitute the majority of thermal insulation materials utilized in the construction sector. Despite these materials' excellent heat transmission properties, their manufacturing processes are highly energy-intensive, resulting in considerable carbon emissions. However, bio-based thermal insulation materials can replace conventional thermal insulation materials used in buildings due to their exceptional thermal performance and low carbon emissions.

In Türkiye, expanded polystyrene (EPS), extruded polystyrene (XPS), rockwool (RW), glasswool (GW), and polyurethane (PUR) are commonly used thermal insulation materials in buildings. This research aims to interpret whether using bio-based thermal insulation materials as an alternative to conventional thermal insulation materials will increase the energy efficiency of buildings in Türkiye, a country rich in biomass. Within the scope of this research, wheat straw (WS), which has the highest amount of agricultural waste in Türkiye, was selected for the case study. The effect of using wheat agricultural waste as a thermal insulation material on the buildings' external wall systems on the thermal performance was assessed through energy simulations using the OpenStudio and EnergyPlus building energy modeling tools. In line with the obtained data, the usability of agricultural wastes as thermal insulation material, alternatively to conventional insulation materials commonly used in Türkiye, was evaluated.

Keywords: Climate change; Energy efficiency; Agricultural waste; Innovative building materials; Bio-based thermal insulation materials

1. Introduction

The climate change problem has been one of the most significant environmental threats in recent years. Increasing global industrialization and excessive use of fossil fuels have led to rapid consumption of energy resources and increased global temperatures due to greenhouse gas emissions, triggering environmental problems (Chen et al., 2022). The building sector was responsible for 32% of global energy consumption and 34% of global carbon emissions in 2024 (United Nations Environment Programme & Global Alliance for Buildings and Construction, 2025). Likewise, in Türkiye, the building sector is the largest energy-consuming sector, accounting for 30% of total energy consumption in 2023 (Ministry of Energy and Natural Resources of Türkiye, 2024). To cope with the problem of increasing energy demand and rapid depletion of energy resources, reducing external dependency on energy, using alternative energy sources, and increasing energy efficiency have become inevitable necessities in the building sector.

50–60% of heat gain and loss in the building occurs through the building envelope; therefore, building envelope insulation is crucial for energy-efficient buildings (Kumar et al., 2020). Conventional insulation materials, currently used in building envelopes, contribute to reducing energy consumption in buildings due to their low thermal conductivity values. However, their manufacturing process requires high energy since they contain mineral and fossil-based materials. Therefore, in addition to the thermal performance of insulation materials, their life cycle should also be considered, and the use of environmentally friendly insulation materials produced using renewable resources should be considered (Ajabli et al., 2023). In this context, bio-based insulation materials stand

*Corresponding author, E-mail: mustafa.ehven@agu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_928

golden light publishing

out as clean and energy-efficient alternatives that reduce energy use and greenhouse gas emissions (Rabbat et al., 2022). In addition, bio-based insulation materials have significant potential to improve buildings' thermal performance and promote sustainability in the construction industry (Cosentino et al., 2023). Insulations based on agricultural waste can be an alternative to existing insulation materials in reducing environmental impacts, depending on the sustainability of their production processes (Palumbo et al., 2015). Moreover, insulation materials obtained from straw, a local agricultural waste product, have attracted significant attention as promising insulation materials in this field due to their high hygrothermal performance, low life cycle cost, and low carbon footprint features (Zhou et al., 2022).

In 2023, over 220.7 million hectares of wheat were grown worldwide, and 808.4 million tonnes of wheat were produced. Furthermore, Türkiye became the ninth-largest wheat-producing country in the world, with a wheat production of 22 million tonnes this year (Food and Agriculture Organization of the United Nations, 2024). In addition, Türkiye, which stands out with its cereal production, has agricultural lands that constitute 30.4% of its land, and the most abundant agricultural product is wheat in Türkiye. Therefore, a significant amount of wheat waste is generated yearly (Cakal & Celik, 2022). However, agricultural waste is not evaluated sufficiently in Türkiye, and wheat, which creates a significant amount of waste after harvest, is commonly used as animal feed (Unlu et al., 2023).

The primary purpose of this study is to evaluate the feasibility of using agricultural waste as insulation material in the building industry in Türkiye, which is rich in biomass. Within the scope of the study, the usability of wheat straw (WS) as an alternative to conventional insulation materials (EPS, XPS, RW, GW, and PUR) widely used in Türkiye was evaluated by comparing their thermal performances. In this context, the thermal performance of different insulation materials in various climatic conditions of Türkiye was examined in terms of their use in buildings' external walls.

2. Materials and Methods

The study consists of five main steps: definition of the sample building and different building external wall system insulation scenarios, selection of the cities, determination of the minimum insulation thickness to use according to different climatic conditions, performing energy modeling of the defined scenarios, and evaluating the results (Fig. 1).

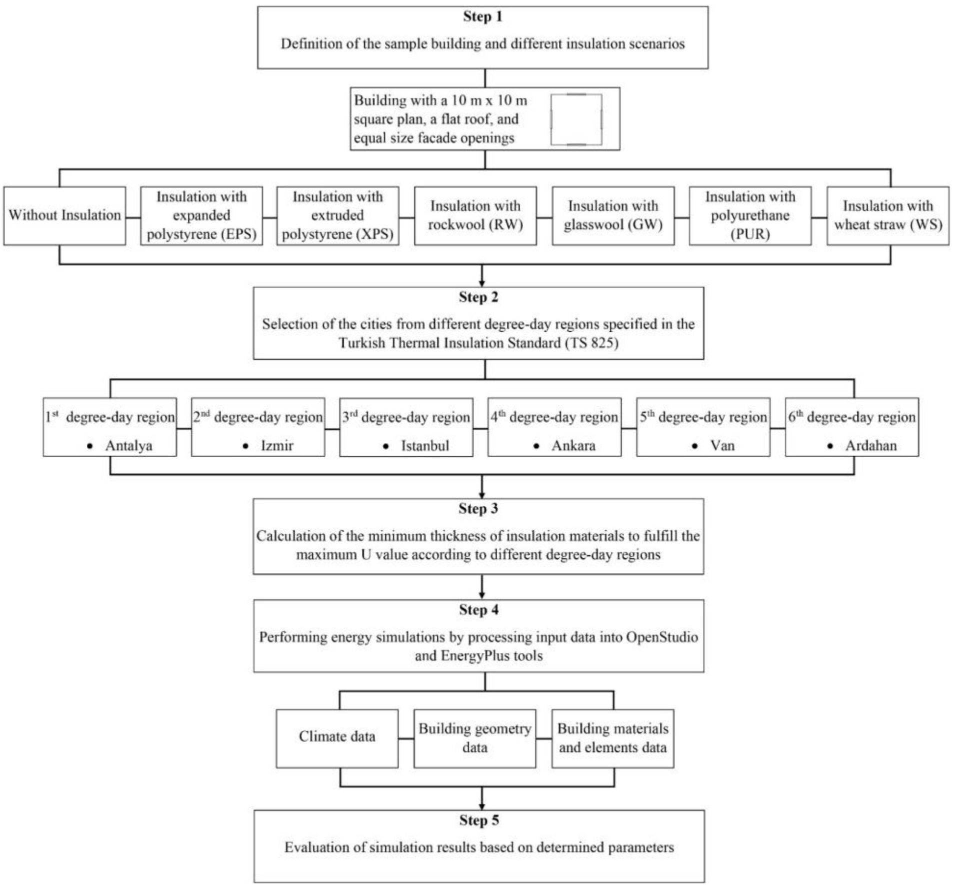

Fig. 1. The research design framework

This study applied the methodology to a typical building with a 10 m x 10 m square plan, a flat roof, and equal openings on all facades. In the study, the external wall system of the building envelope was included in the scope for the thermal performance evaluation of the insulation materials (Table 1). The thermal performance of the external walls was evaluated according to scenarios where there was no insulation, and different insulation materials were used. The thermal transmittance behavior of the external walls was evaluated by energy simulations considering different climatic conditions and facade orientations. The building geometry, layer structure of the building elements, physical properties of the building materials, and climate data inputs were processed using the OpenStudio building energy modeling software. The process of obtaining energy simulation results was carried out by using the OpenStudio and EnergyPlus tools simultaneously. As a result of the energy simulations, the thermal performances of the external wall components were analyzed based on the internal and external surface temperatures.

According to the TS 825 standard, Türkiye has six climatic zones (Fig. 2). The regions representing the climate zones are determined according to the average temperature degree and heating days and are called degree-day regions. The temperatures of the climate zones decrease from the first-degree-day zone to the sixth-degree-day zone (Turkish Standard Institution, 2024). The research was conducted by selecting one city from each climate zone. Antalya, Izmir, Istanbul, Ankara, Van, and Ardahan constitute the cities of the case study. While performing energy simulations, weather data belonging to these cities were used.

In the study's first phase, the minimum insulation thicknesses required by climatic zones for different insulation materials were calculated based on the TS 825 standard, which defines different climate conditions in Türkiye. The calculations aimed to present the combination of materials and minimum insulation thicknesses that fulfill the energy performance requirements according to different climatic zones. For this purpose, the heat transfer coefficients (U values, W/m^{2}K) of external wall systems were fixed to the maximum possible value foreseen by the TS 825 standard for each climatic zone (Table 2).

Table 1. External wall system design of the sample building

Building external wall system	Layers	Thickness (m)	Thermal conductivity (W/mK)	Density (kg/m^3)
	1-Cement-based interior plaster	0.02	1.0*	1800*

Ardahan	0.115	0.11	0.13	0.13	0.1	0.185

The insulation thickness calculations that will meet the U value requirement were found through the Eq.(1) established with the internal surface thermal resistance (R_i), the total resistance of other materials in the wall layer (R_w), the thermal resistance of the insulation material (x_{ins}/k_{ins}) and the external surface thermal resistance (Ucar & Balo, 2009). The thermal conductivity coefficients (k, W/mK) of EPS, XPS, RW, GW, and PUR insulation materials were obtained from the average values specified in the TS 825 standard. For WS, the average of the thermal conductivity coefficients (k, W/mK) obtained from the literature was taken (Table 1).

$$U = \frac{1}{R_i + Rw + \frac{x_{ins}}{k_{ins}} + R_o} \quad (1)$$

The calculations revealed the minimum insulation thicknesses that meet the maximum U value limits for cities selected from different climate zones (Table 3). The thickness data revealed that wheat straw (WS) insulation required more thickness in all regions to fulfill the U-value requirements due to its higher thermal conductivity coefficient than other insulation materials. While the thickness values of conventional insulation materials ranged from 0.045 m to 0.13 m from the first-degree-day region to the sixth-degree-day region, the thickness values of wheat straw (WS) insulation ranged from 0.08 m to 0.185 m.

In the study's second phase, the data obtained were processed using OpenStudio software to create an energy model for the sample building. When developing the energy model, external weather conditions specific to the selected cities were considered. During the energy modeling phase, the building properties were kept constant, while simulations were conducted by varying the insulation material properties and weather data for different insulation scenarios and cities.

In the final phase, the energy models created were transferred to EnergyPlus software to obtain simulation results. This approach allowed for a comprehensive evaluation of how insulation materials that fulfill the U-value requirement for different climatic zones impact the building's thermal performance. In line with the simulation results, evaluations were made on the data regarding the inside and outside surface temperatures of external walls.

3. Results and discussion

In this study, the heat transfer behavior of external wall components constructed with no insulation and different insulation materials was examined seasonally according to cities and facades. The inside and outside surface temperature values of the external wall components were used to evaluate the effectiveness and thermal performance of the insulation material. The difference between the external wall systems' inside and outside surface temperatures directly revealed the extent to which the insulation materials prevented heat transfer. Since the thicknesses of the insulation materials were determined to fulfill the same U-value requirement, the heat transfer behavior of the wall components was similar in the insulated scenarios, even if the material type changed. Therefore, identical inside and outside surface temperatures occurred in the wall systems formed with different insulation materials. However, the inside surface temperatures were generally higher in the insulated scenarios than the uninsulated ones. This situation revealed that the insulation materials effectively provided indoor comfort.

The first finding is the thermal transmittance behavior of the external walls of a building in Antalya, which were designed with no insulation and different insulation materials according to months and facades. As can be seen from Fig.3,

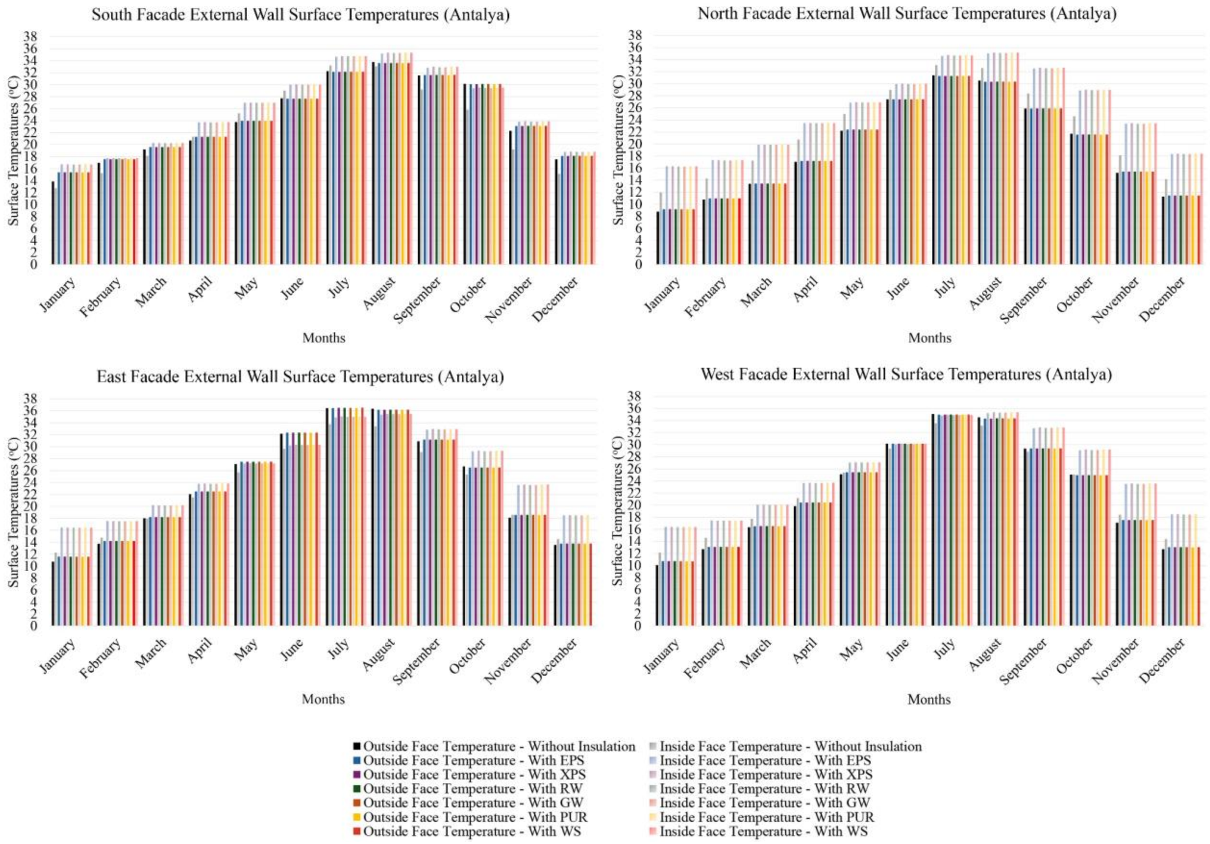

Fig. 3. Inside and outside surface temperatures of external wall systems of a building in Antalya according to facades and months.

- In the summer months, the average inside surface temperatures of uninsulated walls were observed to be 30.6 °C on the south facade, 29.3°C on the north facade, 34.6 °C on the east facade, and 33°C on the west facade. Despite the intense solar radiation and natural heating that showed its effect on all facades in Antalya in the summer months, the inside surface temperature did not tend to increase excessively. This result indicates that the insulation materials exhibited a positive performance since they limit the transfer of excessively hot air from the outside to the inside surfaces of the walls to a certain extent.
- In addition, in the south facade, which receives the most heat in the winter months, the outside surface temperatures reached 18°C. On the other facades, where the direct solar radiation is less seen, the highest outside surface temperature in winter was 14°C. On the other hand, the inside surface temperature of all facades in uninsulated walls dropped to 12°C, while it increased to 18°C in insulated walls. This result shows that even if the outside surface temperature is low on facades where the solar radiation effect is less visible, the insulation materials are not directly affected by the outdoor temperature decrease and show good effectiveness.
- Due to the sun's exposure effect on the facades, the outside surface temperature on the east, south, and west facades was higher than that of the north facade throughout the year. However, although the outside surface temperature decreased on the north facade, the inside surface temperatures on the insulated walls remained high. This result shows that the insulation materials prevent the cold air from passing from the outside to the inside and are effective.
- Wheat straw (WS) insulation, when used at a thickness of 0.08 m in the cities of the first-degree-day region, exhibits similar thermal transmittance behavior to conventional insulation materials in different months and on various building facades.

The second finding is the thermal transmittance behavior of the external walls of a building in Izmir, which were designed with no insulation and different insulation materials according to months and facades. As can be seen from Fig.4,

- In the summer months, the average inside surface temperatures of uninsulated walls were measured as 31.3°C on the south facade, 30.6°C on the north, 29.3°C on the east, and 31.3°C on the west facade. In the insulated cases, inside surface temperatures were fixed at approximately 33°C on all facades. This result shows that insulating materials effectively limit the temperature increase rather than reduce the interior temperature in absolute terms on facades heated by intense solar radiation in the summer.

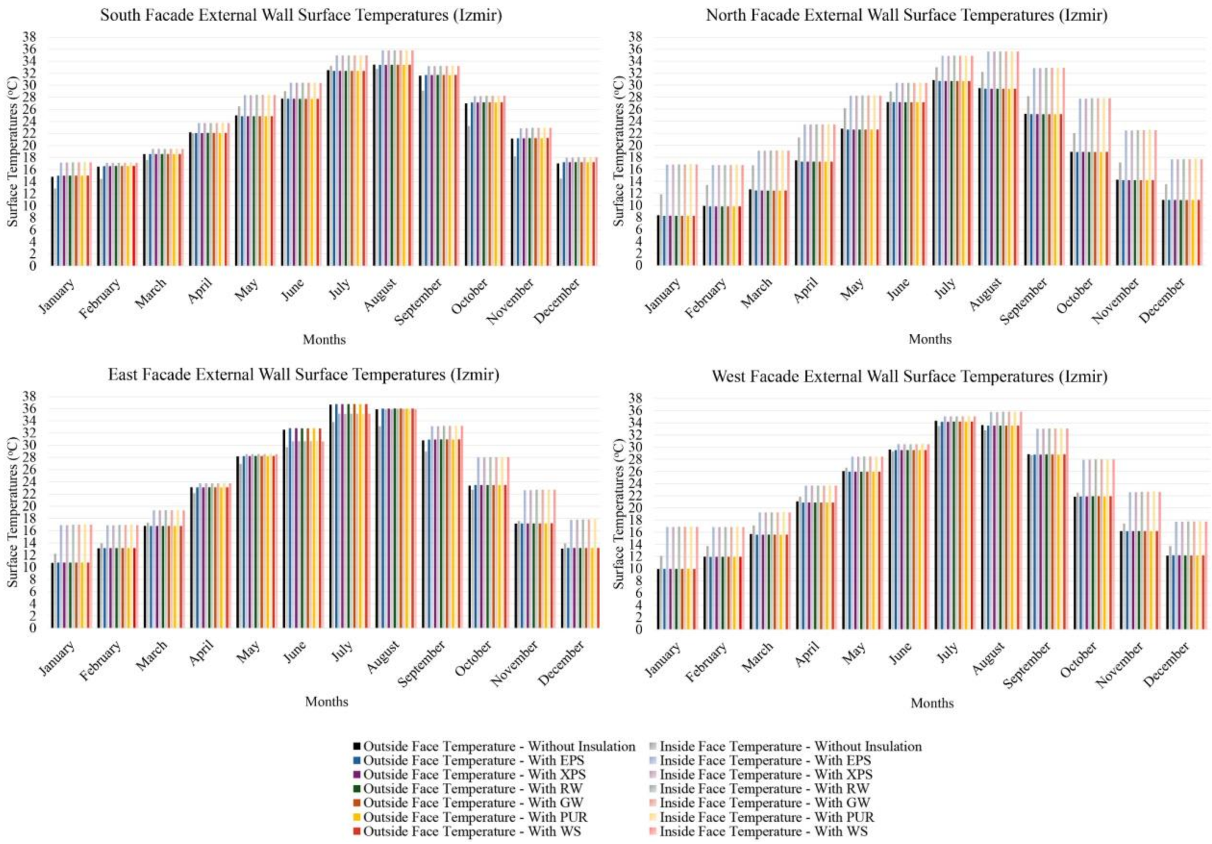

Fig. 4. Inside and outside surface temperatures of external wall systems of a building in Izmir according to facades and months.

- In winter months, uninsulated walls exhibited low interior surface temperatures on all facades. When the average temperature values were examined, inside surface temperatures of 13.3°C were recorded on the south facade, 12.3°C on the north facade, 12.6°C on the east facade, and 12.6°C on the west facade in uninsulated walls. In the insulated scenarios, inside surface temperatures increased significantly in all insulation material types in the winter months, reaching approximately 16–16.3°C. Especially on the north facade, where solar radiation is limited, the effect of insulation became apparent, and the inside surface temperature increased by approximately 4°C compared to the uninsulated situation.
- Wheat straw (WS) insulation, when used at a thickness of 0.095 m in the cities of the second-degree-day region, exhibits similar thermal transmittance behavior to conventional insulation materials in different months and on various building facades.

The third finding is the thermal transmittance behavior of the external walls of a building in Istanbul, which were designed with no insulation and different insulation materials according to months and facades. As can be seen from Fig.5,

- In the summer months, the average inside surface temperatures of uninsulated walls were observed to be 27.3°C on the south facade, 27.3°C on the north facade, 28.3°C on the east facade, and 28°C on the west facade. When insulated scenarios are examined, inside surface temperatures on all facades increased to approximately 30°C. This result shows that in the cooler summer conditions of Istanbul compared to previous case cities, insulation helps limit daily temperature changes by reducing thermal emissions rather than absolute temperatures. On the east and west facades, the effect of insulation materials against temperature increases caused by direct solar radiation in the morning and afternoon was partially limited; however, they prevented overheating in inside surface temperatures.
- In winter months, uninsulated walls showed lower inside surface temperatures. When the average temperature values were examined, inside surface temperatures were measured as 11.6°C on the south facade, 11°C on the north facade, 11°C on the east facade and 11°C on the west facade. In the scenarios where insulation was applied, all insulation materials showed similar performance, increasing inside surface temperatures to an average of 14.5°C in winter months. Insulation materials exhibited similar thermal transmittance behavior on the north facade, where solar radiation was limited, and on other facades where solar radiation was more dominant, and showed positive effectiveness in increasing inside surface temperatures.

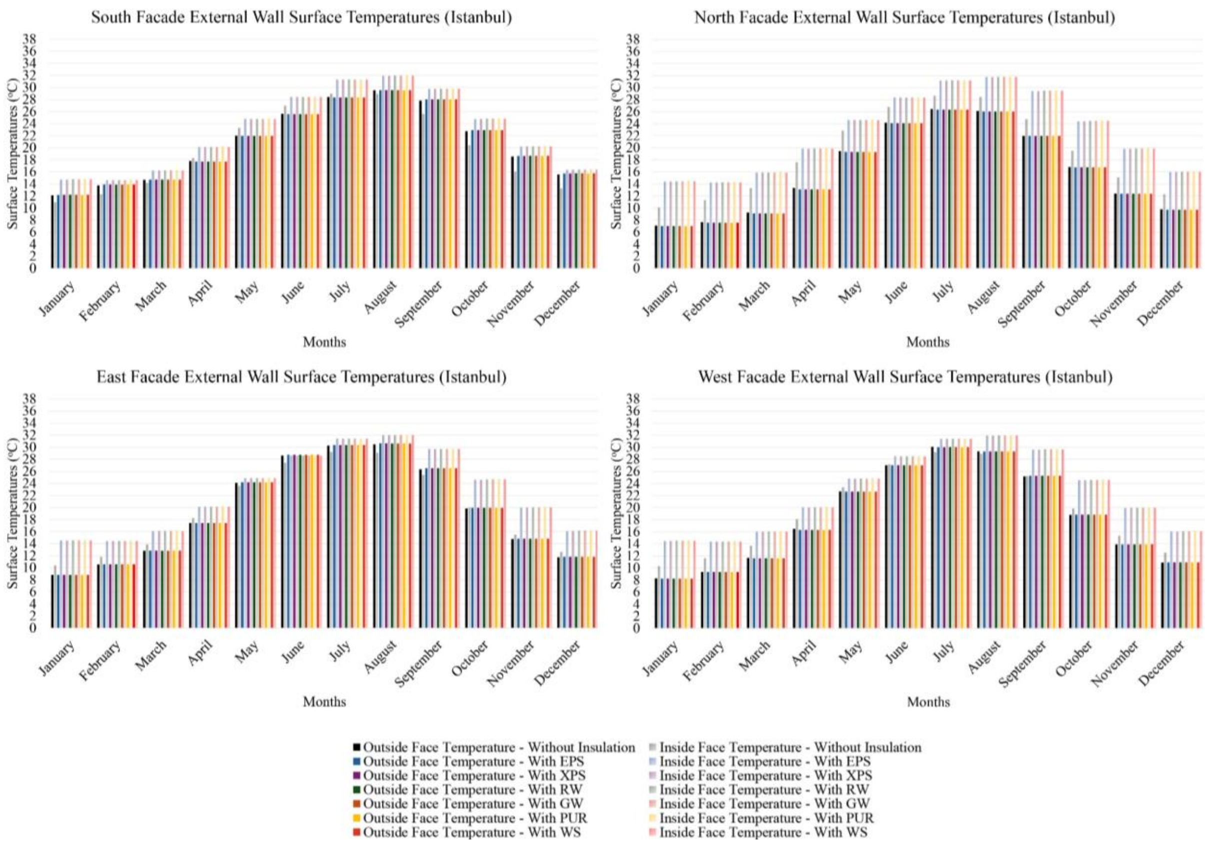

Fig. 5. Inside and outside surface temperatures of external wall systems of a building in Istanbul according to facades and months.

- Wheat straw (WS) insulation, when used at a thickness of 0.095 m in the cities of the third-degree-day region, exhibits similar thermal transmittance behavior to conventional insulation materials in different months and on various building facades.

The fourth finding is the thermal transmittance behavior of the external walls of a building in Ankara, which were designed with no insulation and different insulation materials according to months and facades. As can be seen from Fig.6,

- In the summer months, the average inside surface temperature of uninsulated walls was observed as 27°C on the south facade, 27°C on the north facade, 27.6°C on the east facade, and 27.3°C on the west facade. The average inside surface temperature in the insulated scenarios was 29.5°C on all facades. This result reveals that insulation materials tend to keep the inside surface temperature constant at a specific temperature by protecting it from overheating rather than reducing it in the summer months.
- In the winter months, especially on the north facade, where the sun's effect is low, the inside surface temperatures remained high even though the outside surface temperature of the walls was very low. The temperature difference between the insulated walls' outside and inside surfaces reached 9°C on the north facade. This situation reveals that the insulated walls prevent the low exterior surface temperature transfer to the interior surface and show good thermal performance.
- Furthermore, in winter, the average inside surface temperature of uninsulated walls was observed as 8°C on the south facade, 7°C on the north facade, and 7.3 °C on the east and west facades. In the insulated scenarios, the average inside surface temperature of the walls was observed as 12.3°C on the south facade, 11.3°C on the north facade, and 12°C on the east and west facades. This result shows that the insulation materials contributed an average of 4.5°C to the increase in the inside surface temperature on all facades. A similar thermal transmittance behavior was observed on the east and west facades in all insulation scenarios. Although natural solar radiation was effective on these facades in winter months, the insulation materials significantly increased the inside surface temperature.
- Wheat straw (WS) insulation, when used at a thickness of 0.115 m in the cities of the fourth-degree-day region, exhibits similar thermal transmittance behavior to conventional insulation materials in different months and on various building facades.

The fifth finding is the thermal transmittance behavior of the external walls of a building in Van, which were designed with no insulation and different insulation materials according to months and facades. As can be seen from Fig.7,

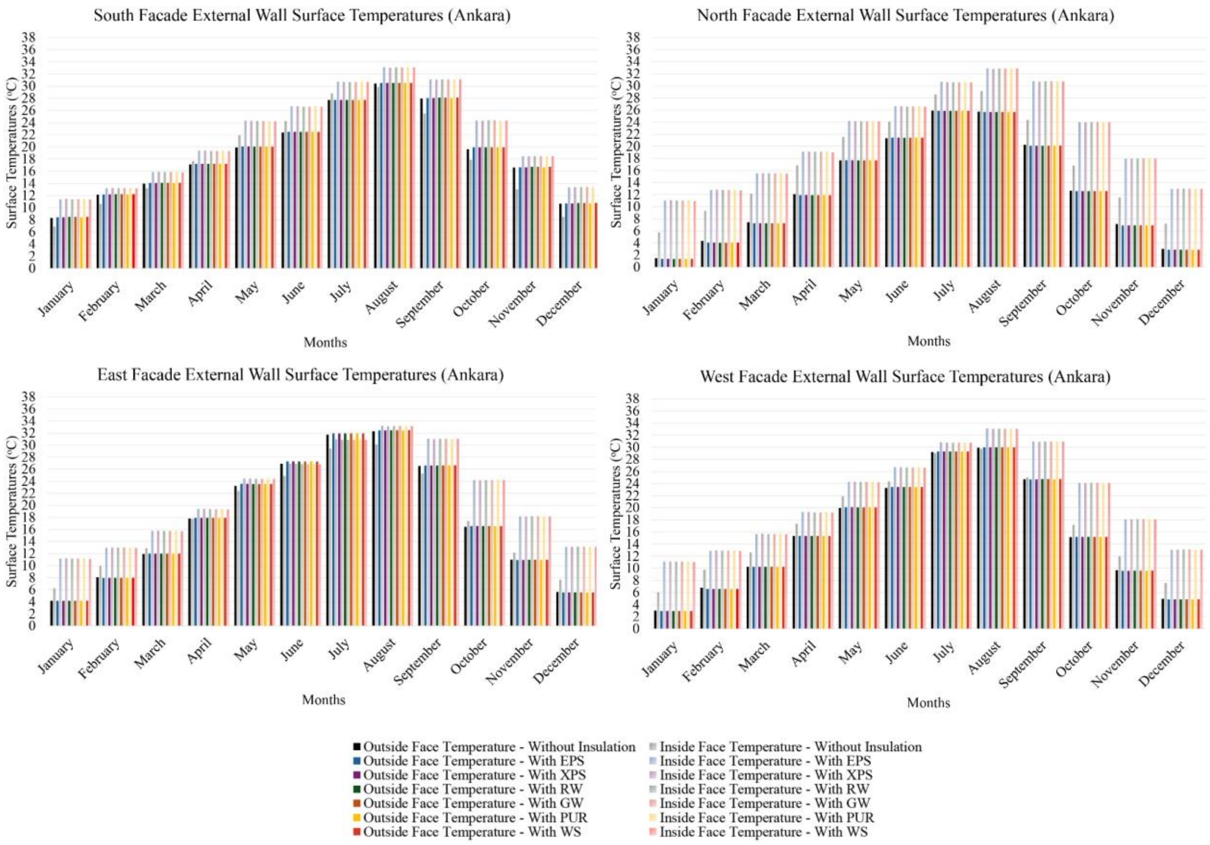

Fig. 6. Inside and outside surface temperatures of external wall systems of a building in Ankara according to facades and months.

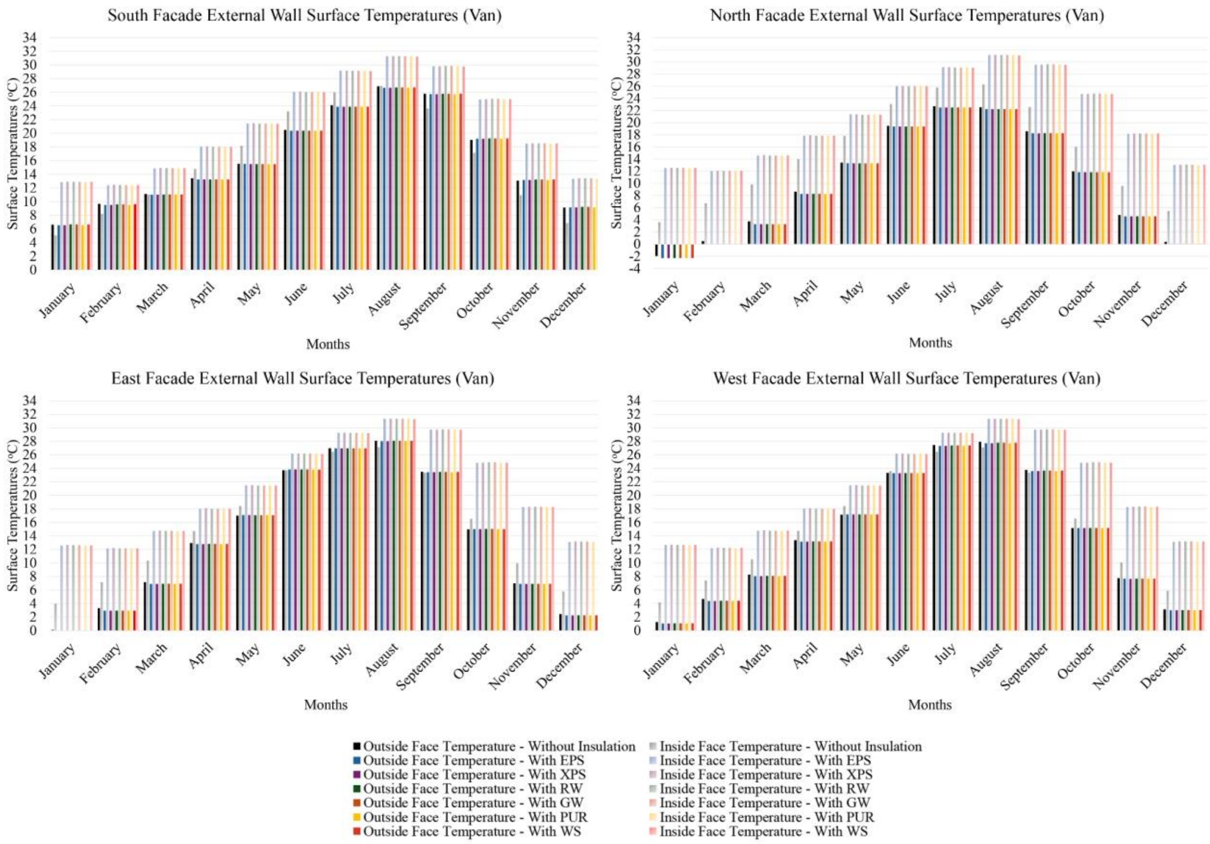

Fig. 7. Inside and outside surface temperatures of external wall systems of a building in Van according to facades and months.

- In the summer months, the average inside surface temperatures of uninsulated walls were measured as 25.3°C on the south, east, and west facades and 24.6°C on the north facades. In insulated cases, the inside surface temperatures were fixed at approximately 28.6°C on all facades. This situation shows that in insulated scenarios, insulation materials slightly increase the temperature on the inside surface but keep it constant after a certain degree.
- In winter months, a significant difference was observed between the outside surface temperatures and the inside surface temperatures of the insulated walls. This effect was most dominant on the north facade, where the sun's effect was the least. While the outside surface temperatures on the north facade dropped to an average of -0.6°C, the inside surface temperatures on all insulated walls remained constant at an average of 12.3°C. The 12°C difference between the outside and inside surfaces shows that the insulation effectively limits the cold air transfer from the outside environment and provides good thermal performance.
- Moreover, in winter, the average inside surface temperature of uninsulated walls was observed as 6.3°C on the south facade, 4.6°C on the north facade, and 5 °C on the east and 5.3 °C on the west facade. In the insulated scenarios, the average inside surface temperature of the walls was observed as 12.3°C on all facades. This result shows that the insulation materials contributed an average of 6-7°C to the increase in the inside surface temperature on all facades.
- Wheat straw (WS) insulation, when used at a thickness of 0.185 m in the cities of the fifth-degree-day region, exhibits similar thermal transmittance behavior to conventional insulation materials in different months and on various building facades.

The final finding is the thermal transmittance behavior of the external walls of a building in Ardahan, which were designed with no insulation and different insulation materials according to months and facades. As can be seen from Fig.8,

- In the summer months, the average inside surface temperatures of uninsulated walls were measured as 22.6 °C on the south, east, and west facades and 22 °C on the north facades. In insulated cases, the inside surface temperatures were fixed at approximately 25°C on all facades. This result shows that the insulation materials provide a slight temperature increase in the inside surface temperatures of all facades; however, they keep the inside surface constant at a specific temperature by protecting it from temperature fluctuations.

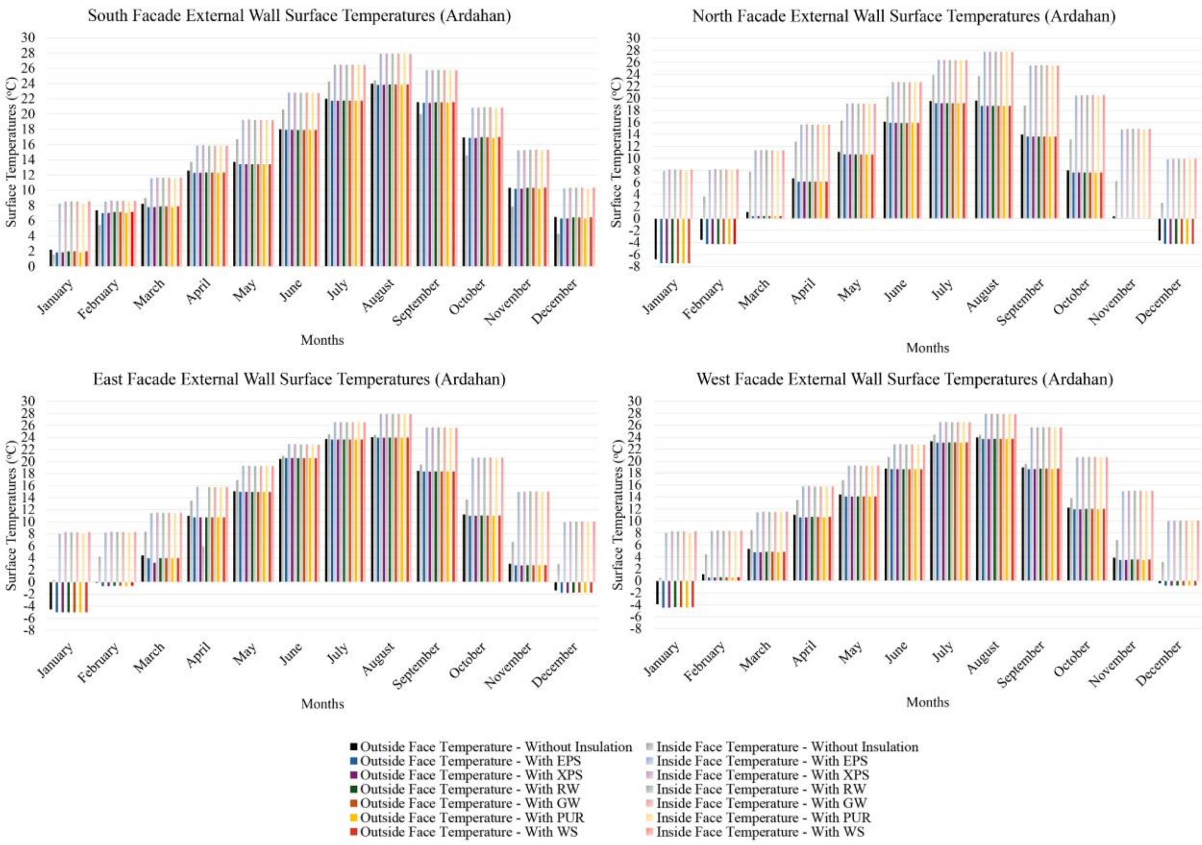

Fig. 8. Inside and outside surface temperatures of external wall systems of a building in Ardahan according to facades and months.

- In winter months, a significant difference was observed between the insulated walls' outside and inside surface temperatures, similar to Ankara and Van. While the outside surface temperatures on the north facade dropped to an average of -5 °C, the inside surface temperatures on all insulated walls remained constant at an average of 8°C. The 13°C difference between the outside and inside surfaces shows that the insulation effectively limits the cold air transfer from the outside environment and provides good thermal performance.
- Furthermore, in winter, the average inside surface temperature of uninsulated walls was observed as 3.3°C on the south facade, -4°C on the north facade, and -1.6°C on the east and -1°C on the west facade. In the insulated scenarios, the average inside surface temperature of the walls was observed as 8.6 °C on the south and west facades and 8°C on the north and east facades. This result shows that the insulation materials increased the inside surface temperature on all facades. For this reason, all insulation materials exhibited the same behavior in heat conductivity despite cold climatic conditions.
- Wheat straw (WS) insulation, when used at a thickness of 0.185 m in the cities of the sixth-degree-day region, exhibits similar thermal transmittance behavior to conventional insulation materials in different months and on various building facades.

4. Conclusions

In conclusion, the study revealed that agricultural waste has the potential to be used as an insulation material in a country like Türkiye, which is rich in agricultural waste. Expanded polystyrene (EPS), extruded polystyrene (XPS), rockwool (RW), glasswool (GW), polyurethane (PUR), and wheat straw (WS) insulation materials, whose thermal conductivity behavior was examined within the scope of the study, exhibited similar performance in all cities. The fact that the exterior wall components were designed to fulfill the maximum U-value requirement according to the TS 825 standard is an essential factor in this situation. According to the data obtained in the study, insulation applications in different climatic zones and on all facades significantly contributed to indoor comfort by increasing the interior surface temperatures in the winter months and limiting the temperature fluctuations in the summer months. The fact that wheat straw (WS) insulation material exhibited similar thermal performance to other insulation materials showed that wheat straw (WS) could be a good alternative to conventional insulation materials when used in appropriate thicknesses. As a result, since wheat straw (WS) is a natural material, it causes much less energy consumption and carbon emission in the production process, as opposed to conventional insulation materials, and this has emerged as the most crucial advantage of this material. However, wheat straw (WS) insulation material requires a greater thickness than other materials to exhibit good thermal performance, which can be considered a disadvantage since the material will increase the building load. Future studies, which consider the effect of various insulation thicknesses on thermal transmittance behavior and external wall surfaces' heat gain and loss energies, will help fully define the potential of using wheat straw (WS) insulation on buildings' external walls.

Parametric modelling and geometrical arrangement of ellipse-plan diagrid structural system

Esra Elçin*[1], Ahmet V. Orhon[1]

[1] *Dokuz Eylül University, Department of Architecture, 35390 İzmir, Türkiye*

Abstract. The diagrid structural system, developed for high-rise buildings, is widely used in such structures due to its structural efficiency and architectural potential. The structural system offers a unique application area in terms of angular arrangement and geometrical harmony of the elements in plans with nonlinear forms. This study aims to standardize the bearing elements of the diagrid carrier system with an ellipse-plan, which is nonlinear and exhibits variable curvature, into a homogeneous arrangement. The geometric arrangement of a 60-storey diagrid structure with a floor height of 4 meters was modelled using Grasshopper. The result was a non-extruded shape characterized by variable cross-sections. Additionally, geometric arrangements were easily modified using parametric tools during modelling. In addition to the model, the ellipse-plans were divided into equal lengths using the implemented code. These divisions were then used to determine the coordinates of the node points. The calculation of the coordinates of the node points was an important stage in the arrangement of the structural elements of the system. In the modelled study, different node angles and diagonal element lengths were obtained by varying the number of diagrid modulus plies and the number of node points. This study provides a potential approach for the geometric arrangement of ellipse-plan diagrid systems and the standardization of their structural elements.

Keywords: Diagrid structural system; High-rise buildings; Geometric arrangement; Parametric modelling; Ellipse-plan

1. Introduction

With increasing urbanisation and population density globally, tall buildings are becoming increasingly important. These buildings not only provided accommodation and workspaces, but also became an indicator of architectural expression and technological developments. For this reason, the design processes of tall buildings are becoming increasingly complex and require the integrated work of different disciplines. Especially in tall buildings, the structural arrangement of structural systems is critical in terms of architectural flexibility and ease of application. In this context, diagrid structural systems are an innovative and flexible structural arrangement method developed as an alternative to traditional column-beam systems (Jani & Patel, 2013).

Diagrid structural systems are geometrically based on the diagrid module, which is the basic building block of the triangular pattern stacked along the height of the building and covering one or more floors. The division of the building into diagrid modules is usefully used for preliminary design and analysis (Mele et al., 2019). Diagrid modules consist of inclined elements and horizontal rings. The inclined elements have a dual function, acting as support and inclined columns (Boake, 2016). In addition, as shown in Fig. 1, the inclined elements are called 'diagonal', while the horizontal rings are called 'ring beam' and are connected at the floor levels with the node.

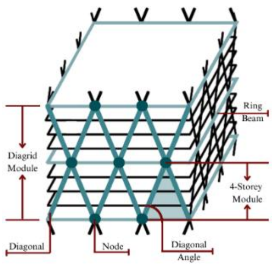

Fig. 1. Eight-storey diagrid structural system module, modified from K.S. Moon (Moon, 2016).

* Corresponding author, E-mail: esra.elcin@ogr.deu.edu.tr

https://doi.org/10.31462/icearc2025_a_aen_949

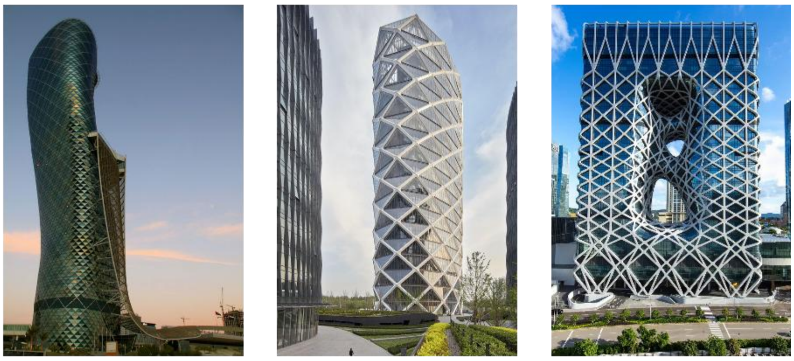
The structure is divided into a series of diagrid modules along its height. In practice, diagrid modules usually cover more than one storey; in Fig. 1, the node point occurs every four storeys. The location of nodes is widely used to identify diagrid modules (Asadi & Adeli, 2017). The positioning of diagrid modules and the placement of nodes directly impact the overall mechanical behaviour and stability of the structure. This modular structure offers structural efficiency, homogenisation of load distribution and optimised performance in material utilization (Rahimian, 2016). In addition, this structural system provides a flexible design approach that allows the creation of complex geometric forms.

Due to its advantages, the diagrid structural system has been the subject of scientific research for many years. Studies generally address structural optimisation, wind and seismic behaviour, digital design and fabrication methods, and integration of architectural expression (Moon, 2016; Mirniazmandan et al., 2018; Tomei et al., 2018; Brunda & Bhavanishankar, 2022; Naik & Modhera, 2023). In addition, research on the plan geometry and nodal angle of structures has enabled the development of various properties in these areas. However, studies in the literature have generally focused on structures with idealised simple geometries (such as square, circle and triangle plans) and research on complex geometries such as ellipses has been limited. The main reason for this situation is that plans with simple geometries provide an important convenience in structural analyses. This makes it possible to focus on a single geometrical parameter (e.g. height or diagonal angle) while balancing stiffness and mass distribution (Moon, 2016). The study of a complex geometry such as an ellipse may require several parameters to be varied simultaneously (eccentricity, radius of curvature, load distribution, etc.), which makes comparative research difficult.

Square/rectangular plans have been frequently used in research as it is possible to ensure that each floor plan is the same and studies with similar dimensions have been developed. Moon's (2008) study modelled with 36x36m plan sizes of 40, 50, 60, 70 and 80 storeys also proposed the optimum angle value for high-rise buildings. Furthermore, in subsequent studies, researchers adopted the 36×36 m plan type as the basic specification for modelling and analysis. In Moon (2016), 60, 80, and 100-storey diagrid building models were used, and the height of each storey was fixed at 3.9 m. The structural behaviour of different geometric configurations was investigated by showing a 36x36 m square plan and floor plans deviating from the original square form between ±1.5 m and ±4.5 m. As a result of diagrid modules covering eight floors, an optimal diagrid angle of approximately 69° was obtained. In the study conducted by Mirniazmandan et al. (2018), the effects of different plan geometries on a 180-meter-tall building with a diagrid structural system were investigated. In the study, the building plan geometry was considered an important parameter; the plans were formed in circular and polygonal (3, 4, 5, 6, 8, 10, 12-sided) forms. In the models, 10 diagrid modules were used. The diagrid angle (θ) was calculated depending on each module's height and base width; for example, an angle of approximately 63° was obtained for a 6-storey module. In the study, the effects of different diagrid angles such as 33.5°, 53°, 63°, 70° and 81° were investigated. Thus, the effect of different plan geometries on structural performance was evaluated through parametric models. This study by Tomei et al. (2018) used a 90-storey high-rise building model with a total height of 351 metres and plan dimensions of 53×53 m square. The height of each floor was taken as 3.9 m, and this model served as the basis for the evaluation of real-scale diagrid systems. Different plan geometries, diagrid angles and module placements were evaluated. Brunda & Bhavani Shankar (2022), in order to determine the optimum grid geometry of the diagrid structure, models with different numbers of stories and diagrid angles were created, and their performances were analysed. For the same area (1296 m²), square (36 m × 36 m), rectangular (54 m × 24 m) and circular (diameter ≈42.6 m) plan models were created. The modelled structures are 12, 24, 36, 48, 60 and 72 storeys, each with a height of 4 m. It was observed that the optimum diagrid angle was 60° for 12 and 24-storey models and 69° for 48, 60 and 72-storey models. Naik & Modhera (2023) studied a 36-storey high-rise building model with 36 m × 36 m plan dimensions and a height of 3.6 m on each floor. The model's building plan geometry is square, and the diagrid system is arranged as triangular modules repeated around the building. The angle of the diagrid elements along the whole structure was determined as 74.50° (the optimal range recommended in previous studies is generally accepted to be around 65°-75°).

In summary, the literature has largely focused on optimising the diagrid system in prismatic tall buildings with square, rectangular, or circular plans. Nowadays, the use of diagrid carriers is also seen in tall buildings with complex plans and forms, curved, twisted, or free-form high-rise buildings, and the gaps in the literature on this subject are beginning to be filled.

For structures that are not perfectly symmetrical, such as ellipses, and whose plan dimensions vary in one axis relative to the other, the design of diagrid structural systems poses unique challenges. The study on ellipse by Rosin & Pitteway (2001) examined the mathematical foundations of the ellipse and the modelling of the ellipse form by applying segmented arcs. In addition, while the study demonstrated the potential of the ellipse to be applied in structures, it also addressed the computational difficulties that may be encountered in construction applications of this geometry. These mathematical foundations show that ellipse-plan geometry can be integrated into building design. However, the geometrically irregular plan in the diagrid structural system can form façade diagonals with different angles and dimensions in each region. An example is the Capital Gate Tower in Abu Dhabi (Fig. 2a.), which is designed with an 18-degree inclined silhouette.



a)Capital Gate Tower in Abu Dhabi b)Poly International Plaza in Beijing c) Morpheus Hotel in Macau

Fig. 2. a, Capital Gate Tower; b, Poly International Plaza; c, Morpheus Hotel (URL-1, 2, 3).

The plan of the building varies from a curvilinear triangle to a curvilinear quadrilateral, and a diagrid structural system is used both externally and internally. Due to the curvature of this building form and the curvilinearity of its plan, more than 800 unique nodal connections had to be designed (Schofield, 2012). The fact that each node is geometrically different from the other causes profound complexity in terms of manufacturing and assembly. As seen in the analysed studies, rectangular, square plans with a fixed angle (regular) diagrid may be sufficient to produce only a limited number of types of nodes since the façade modules can be repeated. This example clearly shows that the concept of standardised elements becomes difficult in ellipse or free-form plans.

Similarly, the Poly International Plaza (Fig. 2b.) in Beijing has an ellipse-plan. The diagrid structural system is arranged in four-storey modules with a distance of approximately 18 m between each module. The total number of nodes in the structure is more than 200, and the angle of the node is 50°. The architects designed the diagonals much more oblique than usual (below about 40°) to give the building a lantern appearance (Chow et al., 2017).
In tall buildings with ellipse or similar free-form plans, homogenisation of element dimensions and nodes becomes complex and may adversely affect structural performance. In such free forms, classical methods are insufficient to efficiently and feasibly design the diagrid system. Accordingly, parametric modelling-based approaches have been increasingly used in recent years to overcome these challenges.

Advanced parametric design and analysis tools are key in optimising diagrid systems with complex geometries. Parametric design is an approach that dynamically updates the design form by comparing many interrelated models within specific parameters and rules. This allows a systematic examination of the effect of each parameter on other parameters and the main form (Ardekani & Alaghmandan, 2023). In addition to parametric modelling, special scripts and algorithms have been written for complex models to meet the model's needs. In some buildings with diagrid structural systems, models that optimise the positions and angles of diagrid elements have been developed with scripts. For example, in the design of Morpheus Hotel (Fig. 2c.), the Zaha Hadid Architects team created a parametric model of the building form and exoskeleton and wrote special 3D scripts to define the diagrid structural system (Piermarini et al., 2018). This work exemplifies how parametric modelling in the diagrid structural system rationalises the complex form and transforms it into constructionally manageable parts.

In this study, with a similar approach, the geometric arrangements of diagrid structural systems used in high-rise buildings are examined on ellipse-planned building forms in order to homogenise and standardise the elements. Using parametric modelling techniques aims to optimise the angular and dimensional compliance of the structural elements. This approach aims to develop potential solutions for the optimisation of the building system.

2. Methodology And Parametric Modeling

The building was modelled with the Grasshopper plugin on Rhinoceros, using the flexibility offered by digital design tools to plan and implement each stage in detail (Fig. 3.).

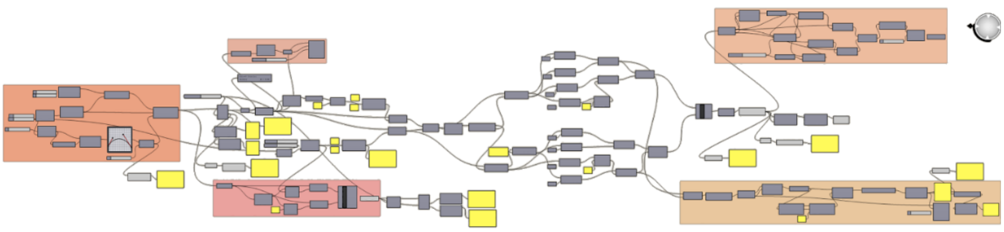


Fig. 3. Interface image of the study modelled with Grasshopper plugins.

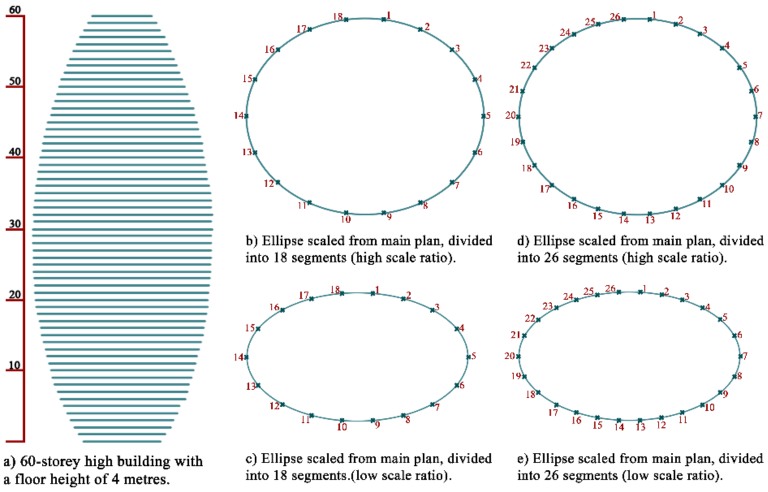

Fig. 4. a, modelled 60-storey high-rise building; b and c, ellipse divided into 18 equal parts; d and e, ellipse divided into 26 equal parts.

In this context, the parametric design method allows the design form to be dynamically updated by comparing a large number of interrelated models within certain parameters and rules. This allowed us to systematically examine the effect of each parameter on other parameters and the main form (Ardekani & Alaghmandan, 2023).

Thanks to this method, all parameters to be included in the model and the relationships between them were determined in detail. In the reviewed studies, parametric models generally adopted reasonable base dimensions, which are common in the existing literature, rather than extreme or unconventional dimensions. The dimensions utilized for square, rectangular, or circular plan forms were observed to be similar across these studies. Although there is currently no existing research specifically focusing on ellipse-plan forms, dimensions and parameters used in this study were derived by referring to analogous tall building designs documented in the literature. The modelling process started with the definition of the general geometry of the targeted tall structure. Considering the design criteria widely referenced in the literature, 40, 60 and 80-storey building studies and typical slender tower type projects were extensively analysed in this context. In the parametric modeling, the height and number of storeys of the structure were chosen to ensure that the structure remains within a certain slenderness range; for example, a 60-storey building with a storey height of 4 meters (Fig. 4a) was considered.In this context, the plan size for the 60-storey diagrid structural system was determined to give a ratio of approximately 1:6 with the building height (36 m base width and ~216-234 m height) (Moon, 2008, 2011, 2016).

The geometric properties of the ellipse-plan were determined, and 38x46 m values were used as dimensions. In addition, the geometric changes of the ellipse-plan at different scales could be analysed in line with the determined scale range (0.5-1.5) (Fig. 4b.,4c.,4d.,4e.), thus preserving the building's geometric integrity and aesthetic harmony.

After modelling the ellipse tall building, more specific methods were applied to calculate the locations of the points that will divide the ellipse into equal parts. In calculating the locations of the points, considering the changes in the dimensioning of the ellipse, the division of ellipse-plans into equal lengths is based on geometric calculations. For idealized simple geometries, the division can be done quickly by taking the center angles equal to the axes and other directions, but this method is insufficient for the ellipse (Rosin & Pitteway, 2001).For this reason, a special Python script was developed to divide each ellipse-plan into equal segments of equal length, which is implemented in Grasshopper (Fig. 5.).

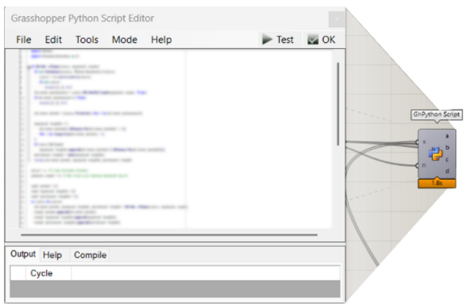

Fig. 5. Python script for the model implemented in Grasshopper

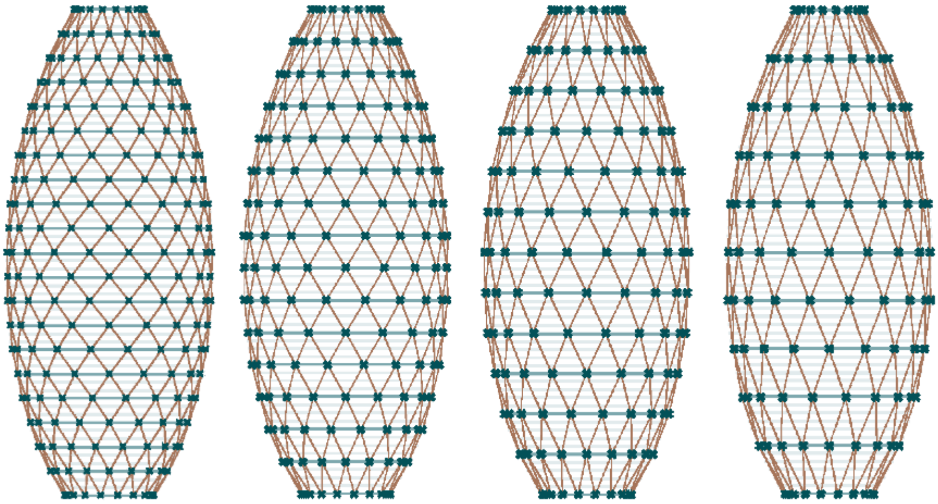

Fig. 6. a, module of 6-storeys; b, module of 8-storeys; c, module of 10-storeys; d, module of 12-storeys

The script developed in this study uses Rhino and RhinoScriptSyntax libraries and takes each ellipse curve in the model as input. First, the script takes essential inputs from the model, such as ellipse dimensions and the number of nodes, and calculates the splitting parameters according to the number of segments specified on the given curve (for example, n segments). While the code parametrically divides the ellipse-plan, it also allows the user to choose the number of nodes in different values such as 18, 20, 24, 26 or even 30 (Fig. 4b.,4c.,4d.,4e.). Equally spaced division points are obtained on the curve. The segment lengths are determined by calculating the distances between two consecutive points; if the curve is closed, the distance between the last and first points is added. As a result, the script calculates each ellipse's segment length, the ellipses' total circumference, and the coordinates of the points obtained. The coordinates of the points obtained as a result of this calculation are used as a reference in determining the coordinates of the nodes and optimising the structural element lengths.

The building height is first divided into triangular modules in modelling the diagrid structural system. In the model, the triangular modules are framed by the diagonal elements of the floor edge beams, and these triangulations come together to form a diamond-like structure (Moon et al., 2007). The ply numbers of the diamond-shaped diagrid modules cover 6,8,10, and 12 plies to divide 60 plies equally (Fig. 6.).

According to the number of diagrid module floors and the number of nodes in a floor, the values of the diagrid structural system elements and connections change. Geometric relationships can be established with these geometric parameters of the structural system. The total number of diagonals (T_{dia}) and the total number of nodes (T_{nod}) can be calculated using the number of storeys diagrid module (N_{module}), the number of nodes in a storey (N_{nod}), and the total number of storeys of the structure (N_{str}). In the equation for T_dia, the number of elements in two directions in each module and the nodes at the base level are considered. The equation is defined as follows:

$$T_{dia} = \frac{4N_{str}N_{nod}}{N_{module}} \tag{1}$$

The constant term 4 arises from doubling the floor ratio and the number of nodes. For example; when the total number of storeys of the structure (N_{str}) is 60, the number of nodes in a storey (N_{nod}) is 22, the number of storeys diagrid module (N_{module}) is 8, the total number of diagonals (T_{dia}) is 660. Similarly, the equation for the total number of nodes is defined as follows:

$$T_{nod} = N_{nod}\left(\frac{2N_{str}}{N_{module}} + 1\right) \tag{2}$$

In the equation, the term $2N_{str}/N_{module}$ represents the number of triangles along the structure's height; constant 1 is then added to account for the nodes in the topmost triangle. For example, when the total number of storeys of the structure (N_{str}) is 60, the number of nodes in a storey (N_{nod}) is 22, and the number of storeys diagrid module (N_{module}) is 8, the total number of nodes (T_{nod}) is 352. These formula-based calculations can be compared with the outputs of the parametric model. During both calculations and modelling, different variations were quickly generated and values were obtained as one of the advantages of parametric design. In this context, systematic variation of the parameters specified in the model (e.g. number of nodes, number of modules) allowed the lengths and angular properties of the elements in the structure to be examined through the geometric outputs obtained. This methodology is presented in detail to guarantee the study's reproducibility; the digital tools and algorithms used are explained in a way that contributes to the study's scientific validity.

3. Results and Discussion

3.1. Model Results

In the parametric modelling study, geometrical arrangements of the ellipse-plan diagrid structural system were made using the code developed. The data obtained with the developed Python script are presented in tabular form (Table 1). At the foundation of this study, the ellipse-plan's perimeter was divided into equal segments. In this way, the obtained nodes were utilized as a reference point for placing the primary structural elements of the diagrid system. Table 1 presents the numerical variations in the dimensions of the diagrid structural system, resulting from dividing the ellipse into equal segments, depending on the number of nodes and storeys per diagrid module.

The values in this table show the ranges of changes in element dimensions and angles as the number of nodes and storeys per diagrid module increases. For instance, increasing the number of nodes allows the ellipse-plan to be divided into more segments. In addition, changes in the number of diagrid module multiples effectively determine diagonal element lengths and angular arrangements.

The data in the table provides important information about specific parameters (e.g. minimum/maximum ellipse segment length, average diagonal length, node angles) of the ellipse-planned diagrid structural system. Firstly, the minimum and maximum ellipse segment lengths vary according to the number of nodes per floor, and the segment lengths decrease as the number of nodes increases. For example, when 20 nodes were used per floor, the minimum ellipse segment length was 3.019 metres, and the maximum segment length was 8.836 metres, whereas, with 24 nodes used per floor, the minimum ellipse segment length was 2.516 metres and the maximum segment length was 7.365 metres.

The number of storeys per diagrid module is a critical parameter affecting the overall consistency of the geometry. As the number of storeys of the diagrid module increases (6, 8, 10 or 12 modules), a decrease in the number of diagonals, an increase in the average diagonal length, a decrease in the number of nodes and an increase in the average node angle was observed. While this increases the length of the elements, it also allows the distribution of the nodes throughout the structure to settle in a specific order.

Table 1. Length and angular variations of diagrid elements based on the number of nodes and diagrid module layers

Number of Points Per Floor	Minimum Ellipse Segment Length	Maximum Ellipse Segment Length	Number of Storeys Per Diagrid Module	Number of Diagonals	Average Diagonal Length	Number of Nodes	Average Node Angle
18	3.354 m	9.816 m	6	720	15.062 m	378	53
			8	540	18.756 m	288	58
			10	432	22.628 m	234	62
			12	360	26.600 m	198	64
20	3.019 m	8.836 m	6	800	14.643 m	420	55
			8	600	18.420 m	320	60
			10	480	22.350 m	260	63
			12	400	26.365 m	220	65
22	2.745 m	8.033 m	6	880	14.324 m	462	57
			8	660	18.166 m	352	61
			10	528	22.142 m	286	64
			12	440	26.189 m	242	66
24	2.516 m	7.365 m	6	960	14.076 m	504	58
			8	720	17.971 m	384	63
			10	576	21.982 m	312	65
			12	480	26.055 m	264	67
26	2.323 m	6.798 m	6	1040	13.879 m	546	59
			8	780	17.816 m	416	64
			10	624	21.856 m	338	66
			12	520	25.959 m	286	68

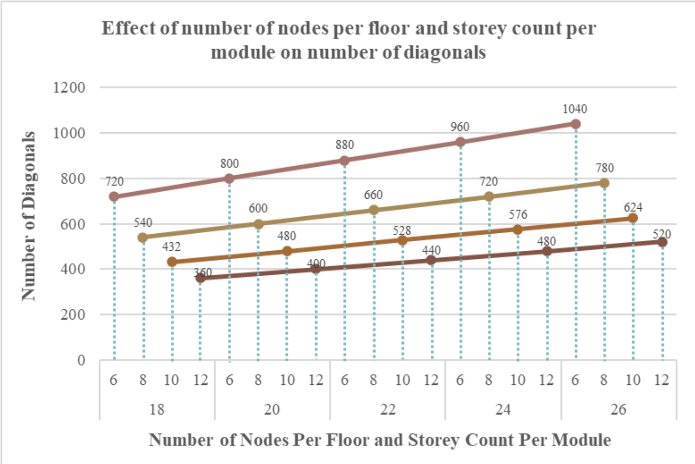

Fig. 6. Effect of number of nodes per floor and storey count per module on number of diagonals

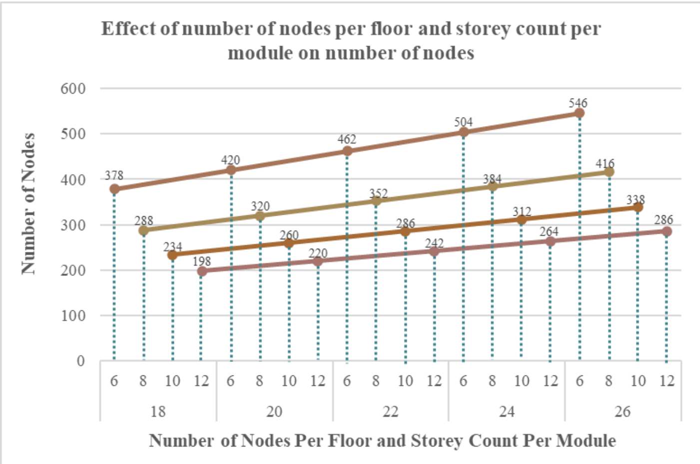

Fig. 7. Effect of number of nodes per floor and storey count per module on number of nodes

As seen in fig. 6., when the number of nodes 18, and the number of diagrid module multiples is increased from 6 to 12, the number of diagonals decreases from 720 to 360, and the diagonal length increases from 15.062 metres to 26.600 metres. This overlaps with the increase in the length of the diagonal elements when the horizontal and vertical support network of the diagrid structural system becomes more sparse.

The total number of nodes also varies according to the effect of these parameters. As the number of points used to divide the ellipse-plan perimeter into equal segments increases, the lengths of the diagonal elements shorten, and the angles between the nodes decrease. In addition, the increase or decrease in the number of nodes and the preference for more or less modulus coefficients affect the density of the carrier system to be formed along the façade. Using more nodes and less modulus coefficients (e.g., an 8-storey module) reduces the distance between the elements by creating a denser network structure in the outer frame of the building. Fig. 7. shows 420 nodes for a 6-storey module with 20 nodes, while this number increases to 546 for a 6-storey module with 26 nodes. This approach requires a balance between structural efficiency and ease of fabrication and assembly since increasing the number of nodes increases the number and complexity of joint details.

The average node angles vary between 53° and 64°, reflecting the general trend of the angle of the diagonal elements to the vertical, as seen from the data taken from the model. As the number of nodes and the number of diagrid module storeys increases, the node angle increases and the elements are placed with a steeper geometry along different storeys. Increasing the diagrid element angle in tall buildings is frequently discussed in the literature, especially in improving flexural stiffness (Moon, 2014). However, it should also be considered that angular increase may require different joint details during the manufacturing and assembly process.

In summary, the data in Table 1 show that the diagrid structural system with the ellipse-plan significantly affects the parametric variables (number of nodes and diagrid modulus multiples). These observations constitute an important data set for the geometric optimisation of the structural system or structural performance evaluation in the later stages of the study and provide quantitative data to guide design decisions.

3.2. Structural and Architectural Evaluation

Although important parameters such as structural material, bearing capacity or load distribution of the load-bearing system modelled in this study were not addressed, the study's results allow various inferences regarding structural efficiency. The model results show that parametric variations affecting the element dimensions and node angles provide important data to establish a consistent approach to geometrical arrangement. In this context, it is seen that the data obtained with different node numbers and diagrid modulus coefficients have significant effects on other elements of the structural system. If it is inferred from the data in the table, increasing the node density caused the diagonal elements to have a more homogeneous distribution. This homogeneity resulting from increased nodes may provide a more regular geometric structure throughout the structure and encourage equal distribution of loads on the elements. In addition, since the average length and node angles of the diagonal elements can play a determining role in the possible flexural stiffness and horizontal load transfer of the system, it will be possible to perform a more comprehensive performance analysis by including factors such as material properties and load combinations in future studies.

However, dividing the ellipse-plan into equal parts with the script developed in the study contributes to homogeneity by helping to standardise variations in the geometric arrangement of the diagrid system. Standardisation of element dimensions within certain limits offers significant advantages in adapting building elements to prefabricated production processes. Therefore, this study provides a valuable perspective for adapting a parametric design approach to prefabricated production processes.

When evaluating architectural harmony, the ellipse-plan form is evaluated using a parametric approach, which supports innovative applications in the design processes of modern architecture. The ellipse-plan provides a much more dynamic appearance than square or rectangular plans and allows diagonal lines to add functional and aesthetic value to the building.

4. Conclusions

Within the scope of this study, geometrical arrangements of the ellipse diagrid structural system have been investigated with a parametric modelling approach, and findings for the standardisation of the structural elements have been obtained. Ellipse-plans with different width scales are divided into equal segments using the developed code script, and diagonal element lengths, segment lengths of ellipses and angles of the node are calculated parametrically. The effects of the parametric changes made in the model on the element dimensions are numerically analysed. The results showed that changing the number of nodes resulted in differences in ellipse segment lengths, and changing the number of nodes and diagrid modulus coefficients resulted in differences in the lengths and angles of diagonal elements. In this context, the main output of the study is the demonstration that standard dimensioning can be approached under certain conditions with parametric control in ellipse-planned diagrid carrier systems. The ability to control the diagrid structural elements within a specific standard can make the load distribution, connection details and overall system behaviour more predictable. This, in turn, may lead to favourable project costs and implementation time results by enabling prefabricated applications during the production and construction phases.

The present study, modelling and parametric analyses provide an approach to the parametric regulation of the diagrid structural system in non-linear, variable curvature plans and non-standard geometries. The structural material of the structural system modelled in this study is not specified, and no bearing capacity or load distribution analyses are performed. In future studies, the structural strength of the ellipse diagrid structural system should be comprehensively evaluated by integrating the existing model with the material performance and dynamic load analyses. In addition, detailed simulation studies should be carried out to optimise the system by considering different load scenarios, environmental factors, and effects on long-term usage.

In conclusion, this study presents an approach to the geometrical arrangement and standardisation of the structural elements of the ellipse diagrid structural system while demonstrating the potential advantages of the system both structurally and architecturally. The obtained parametric data provides a solid basis for future detailed structural analyses and gives important clues for the optimisation of the system and its application potential. Future comprehensive studies will increase the applicability of this model and lead to sustainable and economical building solutions by integrating it with modern construction technologies.

Evaluating generative AI capabilities for architectural visualization

Duygu Savur*[1], Şeyda Emekci[1]

[1]Ankara Yıldırım Beyazıt University, Department of Architecture, Ankara, Türkiye

Abstract. Architecture is one profession that involves a lot of development and change, architects are involved in the planning of creative and provocative works. The process involves the deployment of the different means of visualization and or techniques. Within the past twenty years, the most utilized means of visualisations have included AutoCADs, Revit, SketchUp, Rhinos for 3D modelling and V-Ray; Lumion or Corona rendering. However, the last three years brought a revolution in the architectural visualisation, advancing AI. This paper's goal is to offer a brief assessment of the application of various generative AI technology in architecture. Moreover, it tries to use similar procedures to these tools when they are used in similar conditions. After that, the productivity of such tools is measured in the sense of their ability to create realistic and innovative architectural designs. This paper's results and discussion focus on the use of AI in the design aspect of architecture and outline the advantages of adopting AI-based generation in architectural models as well as the general challenges and opportunities of designing generative AI in architectures.

Keywords: Architectural rendering; Comparative analysis of AI tools; Generative AI

1. Introduction

Over the past few years, generative AI has become an essential component of architecture since it reduces the amount of human contribution in the process. When it comes to the content generation, generative AI has been successfully applied for such tasks as text-to-image synthesis, as well as the text-to-3D model creation, getting very close to or achieving state-of-the-art performance (S, 2023). AI image generators are reinventing an architectural landscape through greater design creativity and efficiency. With issues such as prompt proficiency and ethical considerations still unresolved, these tools are nonetheless capable of changing architectural design and education. Future advancements in artificial intelligence development will take integration of these tools into the architectural workflow one step further, allowing a rise in inventive and collaborative approaches (Beyan & Rossy, n.d.).

This sector is multifaceted and is broad in terms of topics, themes, and scope of work because architectural design is extensive (Eilouti, 2021). For each project, there is a need to have a style, and as we proceed to develop complicated designs, there is even more variety. The investigations conducted in the past have shown that architectural preliminary 3D form design is within this domain, in addition to areas such as detailed and optimization design. These are layout designs of buildings considering the nature of generative problem solving (C. Li et al., 2024). A bibliometric analysis of the recent articles containing the keywords identified in the present article showed a significant growth in the number of articles and papers discussing architectural design with the help of generative artificial intelligence. The number of research articles utilising generative AI technology at various stages of architectural design provides insight into the evolution of trends within each subfield. While the majority of research is concentrated on the field of architectural plan design, research in the field of concept design and architectural image production has increased exponentially over the past two years (Eilouti, 2021). This continued growth trend clearly demonstrates that generative AI in architectural design is expanding at an unprecedented rate. It also reflects the architectural design and computer science community's high level of interest and increasing investment in generative AI technologies. Table 2 presents the most commonly employed productive AI techniques. In contrast to the most prevalent diffusion models (such as Dall-E 2, Midjourney and Stable Diffusion) and their derivatives, artificial intelligence tools have been selected for this article (C. Li et al., 2024).These tools can be employed at various stages, from student to professional levels.

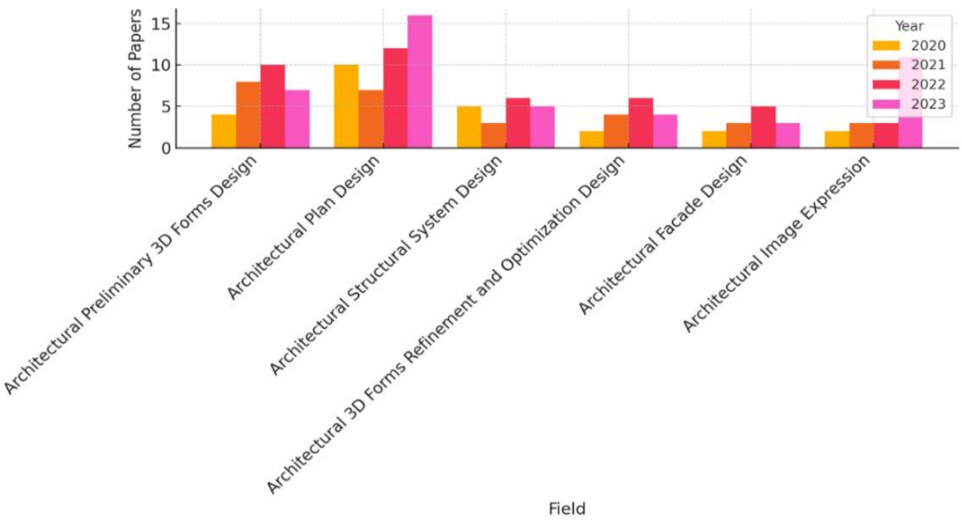

Fig. 1. The number of research papers using generative AI technology to various architectural design steps (Kapliński & Bonenberg, 2020)

In this regard, the latest studies in the literature were examined and the following results were obtained. (P. Li et al., 2024) test that comprehensive workflow on the architectural design which is sketch to real model. It decided that defining architectural style, material, type, and landscape is crucial for directing the AI tools. Also, the paper presents the creative, rapid, and effective design methods for AI from the early stages to the final model. (C. Li et al., 2024) this study examines how designers employ image AI to inform their 3D designs, as well as the limitations of this approach. The findings indicate that image AI can be a valuable resource for architectural designers. (C. Li et al., 2024) search for the using generative AI technologies during the architectural design phase. 3D generative and diffusion models present different creative tools and integrate architectural design. This paper highlights generative AI tool productions like 3D models and 2D images and videos. In conclusion, AI is adopted in the architecture sector, increasing its use and applications while forcing off conventional boundaries. This paper also suggested that while revealing potential of the AI, new research ways and application areas for architectural design. (Yıldırım & Demirarslan, 2020) discuss that evaluations have been made on where artificial intelligence is in the design process today and how useful it is to the interior designer. Conclusions; AI benefits the analysis and synthesis phase of the design.

2. Method

Nowadays, Generative AI tools are increasing and users meaning architects and architectıre students are trying lots of programs for developing designs (Zhang et al., 2023). This is important for them because the last stage is presenting someone and the opposite side should apprehend the project. The AI tools are easy for them however all of them don't give similar results under the same conditions. To determine this problem, the most popular five generative AI rendering (Prome AI, Versa, Visoid, Mnml AI, Lookx AI) programs are used and enter the same solid project photos and the same prompts. The project defines a rectangular building and hotel concept. The most popular architectural prompts are examined and this prompt text is created according to this.

2.1. PROMEAI

The PromeAI represents a major advancement in generative AI, providing a suite of tools to enhance creative workflows. Its sketch-to-render functionality transforms simple sketches into detailed renders, while the Erase & Replace feature allows seamless modifications of specific image elements. Embedded capacity for HD up scaling is useful in the platform as imparts a higher resolution before it is scaled up to high definition standards. Moreover, it may also be the case that users may have an image of what they would like to be produced and this in a way would assist in setting the measures as per what should be produced in as much as visual measures are concerned. Furthermore, the unique aspect of PromeAI is that users can turn the 'creativity knob', which means that they can influence how much interpretation the changes made by the AI. Due to these characteristics, PromeAI becomes a valuable and innovative approach when it comes to art and design performed in the digital space.

2.2. VERAS

VERAS system is offered by Evolabs and is targeted at those people who willing to achieve the dramatic look. In this regard, the system offers a number of set programs that may be used to this end. The templates can also be enhanced with prompts and accurate project match as to what is needed for the specific task and that is very vital especially where the design is geometrically constricted and a high precision is called for. The basic features of this software are the Geometry Slider since it set the geometry override of the scene, and the Render Selection if the user only wishes to fine touch to some area on the project. The "Build from the Same Seed" option can be resumed of reflecting the patterns of repeated thoughts as people are let to go back to the previous blends and further elaborate them. Also, one of the functionalities of the web application is to possess the image manipulation functionality that allows new images to be created from the others. All these aspects allow VERAS to act as a special and efficient tool of digital designing and affect the enhancement of professional performance.

2.3. VISOID

VISOID can be defined as specialized architectural rendering tool that employs artificial intelligence technology to fast deliver high quality 3D images. The fact that it is cloud-based also leads to a large number of various specialists being able to access it with no need for specialized hardware to render quickly. In this case, it is easy to use VISOID to visualise because the process is simplified by the fact that multiple and complicated works such as scene generation, lighting and collection of objects are all done by the AI tool. This cuts out the time needed for testing as the program increases design productivity which enables architects to work more on the style of their projects. It means that architects are provided a chance to engage in a kind of a game where one can influence moods, environments, colours or even switch between styles within a relatively short time span. However, with regards to the given project one has to provide very detailed prompts, rendering is very time consuming, the tool saves the work as well as suggests enhancements to the images which substantiates that this tool is very versatile and of fairly good quality.

2.4. MNMI.AI

MNML AI is revolutionizing architectural design as an AI-powered assistant that transforms ideas and sketches into impressive designs with just a few clicks. This platform enhances creativity and efficiency in the design process, catering not only to architects but to anyone seeking faster, more efficient design solutions. MNML AI's user-friendly interface enables designers to swiftly advance their projects, turning sketches into professional designs and pushing creative boundaries. Its features herald a new era in architecture and digital design, empowering users to expand project scope, emphasize originality, and overcome design challenges. MNML AI significantly streamlines the design process, making it more accessible and effective.

2.5 LOOK X AI

LookXAI is an advanced AI tool designed for early concept iterations in architecture. This highly customizable and trainable model allows architects to upload reference images or samples to generate initial design ideas. Key features include the Style Adapter and Word Template, which enhance the quality, depth, architectural precision, and style of renderings. The rescaling feature corrects imperfections and improves image quality, facilitating subtle optimization of projects. LookXAI supports faster and more effective design progress, enabling architects to realize their original projects more easily. Additionally, it offers video rendering capabilities. Available at a low cost, LookXAI provides substantial support in the early design stages, boosting architectural creativity and efficiency.

In order to write a prompt, it is essential to utilize a correct prompt method and an equation can be created for this purpose (Liu et al., 2023). If one considers the process as an order, it is only when the correct information is provided that the desired result can be achieved.

Building type+Architectural style+ Architect name+ Material+ Rendering style+ Imagination Landscape or surroundings + Light + Developer words

Prompt Text (Table 1); *"Hotel project, contemporary style, design by Zaha Hadid, white concrete building, organic facade form, sustainable material, Vray render, aerial perspective view, ambience lighting, greenery, super realistic, high detail, high resolution, night time render*

Negative prompts; *low quality, deformed, blurry "*

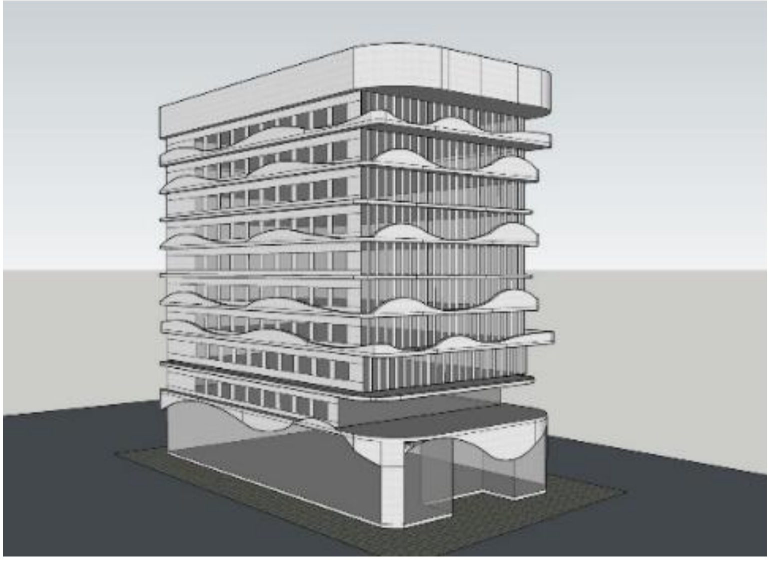

Fig. 2. Solid model of the building (Created by Author)

The image depicts a 3D architectural model of a multi-story building designed in SketchUp. The building has a modern, sleek appearance, with nine floors. The design incorporates undulating, wave-like patterns on the facade, giving it a distinctive and dynamic look. The ground floor features a glass entrance, which appears to be part of a commercial or public space. The structure follows principles of modern and sustainable architecture, emphasizing both aesthetic appeal and functionality. The building's overall form is rectangular, with each floor extending slightly outward, creating a sense of depth and movement in the design. It is situated in an urban environment, as suggested by the simple, gray context of the surrounding area in the model.

Table 1. Prompt List (Archi Lab, 2023)

MATERIAL	STYLE	FACADE	BUILDING	LANDSCAPE
Aluminum	Ancient Egyptian	Art Deco Facade	Architectural	Alpine Landscape
Framing	Ancient Greek	Bamboo Facade	Landmarks	Arid Desert
Asphalt	Art Deco	Brickwork	Cityscape Features	Landscape
Bamboo	Art Nouveau	Facades	Commercial Towers	Autumn Forest
Brick	Arts and Crafts	Cladding	Futuristic Towers	Bamboo Grove
Cement Board	Baroque	Corrugated Metal	Glass Facades	Beachfront
Concrete	Bauhaus	Curtain Wall	High-Density	Best Quality
Drywall	Beaux-Arts	Facade	Development	Cinematic Quality
Fiberglass	Brutalist	Decorative	High-Rise	Coastal Cliffs
Foam Board	Byzantine	Facades	Apartments	Corona Render
Glass	Chinese Traditional	Digital Printed	High-Rise	Countryside
Granite	Classical	Digital Screen	Construction	Meadow
Limestone	Constructivist	Facades	High-Rise Designs	Dense Jungle
Marble	Contemporary	Dynamic Facade	Iconic	Dry Savannah
Masonry	Critical Regionalism	Geometric	Skyscrapers	Frozen Tundra
Metal Roofing	Cubist Architecture	Facades	Megatall Buildings	Grassland Plains
Plaster	Deconstructivism	Glass Curtain	Modern Skyscrapers	High Detail
Plastic	Expressionist	Walls	Residential	High Resolution
Plywood	Architecture	Green Facade	Skyscrapers	High Resolution
Quartz	Futuristic	High-Tech	Sky-High Structures	Hyper Quality
Reinforced	Gothic	Facade	Skyscrapers	Japanese Zen
Concrete	High-Tech	Hybrid Facade	Steel And Concrete	Garden
Sandstone	Architecture	Industrial Facade	Towers	Lumion Render
Shingles	Industrial			Lush Rainforest
	Islamic			Mangrove Forest

Table 1. (continued) Prompt List (Archi Lab, 2023)

MATERIAL	STYLE	FACADE	BUILDING	LANDSCAPE
Tiles, Metal Roofing	Japanese	Interactive	Tall Buildings	Mountain Range
Steel	Traditional	Facade Metal	Tall Towers	Rocky Canyon
Steel Framing	Minimalist	Paneling	Towering Structures	Rolling Hills
Stone	Architecture	Minimalist	Urban Architecture	Serene Lake
Stucco	Modern	Facade	Urban Growth	Snow-Capped
Tiles	Neoclassical	Parametric	Urban Skyscrapers	Peaks
Timber	Neo-Futurism	Facades	Vertical Construction	Tropical Island
Timber Wood	Organic	Postmodern	Vertical Living	Visual Masterpiece
Wood	Architecture	Facade		Volcanic Landscape
	Ottoman	Reflective		Waterfall Scene
	Parametricism	Facade		Wetland Marsh
	Postmodern	Shuttered		Winter Wonderland
	Renaissance	Concrete		
	Rococo	Solar Facade		
	Romanesque	Terracotta		
	Scandinavian	Facades		
	Structural	Timber Clad		
	Expressionism	Translucent		
	Sustainable	Facade		
	Vernacular	Ventilated		
		Facades		

3. Results

Firstly, floor plans and architectural 3D mass models were created based on the sketches. Subsequently, the mass models were employed to ensure that the architectural renderings were rendered in equal conditions. This process enabled the production of architectural renderings during the concept phase. Table 2 illustrates the overall results produced. Architectural design elements were supported by textual descriptions.

Table 2. The generation of architectural designs from simple sketches has been further develope

AI	RENDER 1	RENDER 2	RENDER 3	EVALUATION
PROMEAI				Details and general perspective are medium level, new generations will be good according to these.
VERAS				General perspective is good level however details are not satisfactory

Table 2. (continued) The generation of architectural designs from simple sketches has been further develope

AI	RENDER 1	RENDER 2	RENDER 3	EVALUATION
MNML.AI				Added more details and generated many different versions.
LOOKxAI				Too much solid and nondetailed render, however, render quality is satisfactory

4. Discussion

The use of generative AI in architectural rendering has proven both promising and exceedingly complex to implement. The contrast at the stage of comparison between different AI tools— PromeAI, VERAS, VISOID, MNML AI and LookXAI indicates distinctive strengths and limitations for each platform. Some provide a large leap in detail and an iterative flow such as PromeAI & MNML AI, while others like VISOID or LookXAI show deficiencies for various reason on the quality of their outputs but with Fractalina producing better results later it could be due to early-stage development problems. Additionally, PromeAI has utilized its sketch-to-render utility and the capacity for HD upscaling to produce detailed images from basic sketches — an impressive display of AI improving creative workflows. On the other hand, VISOID's cloud complex system is better than nothing but easily gets stuck in repetitive and evolutionary paths that are not so realistic as desired: this demonstrates a clear boundary of how much detailed we can afford with prompts before its final output conveys zero realism; which goes to show up-to-date AI capabilities only get you yet this far.

Unique features such as the Geometry Slider and Render Selection tool allow for geometrically precise designs, making this a creative alternative to VERAS Font Family. But even then, it falls short on any level of detail anyway- which only indicates that while generative AI can replicate general viewpoints quite well without difficulty at all from a technical standpoint, reproducing finer details is still more difficult. MNML AI specializes in texture-aware editing fashion design creation, and LookXAI is able to augment simple line sketches with rich detail for high-resolution images. While these tools extend the creative frontier and accelerate design process, LookXAI-generated renders are on the more static side with not enough intricate detailing which showcase a wide scope for enhancements.

The results indicate that, even though generative AI tool technology provides as considerable aid in the early design stages and supports creativity to a greater extent than efficiency improvements yet remain shortcomings which need further research and development attention. This imaging is flawless, certainly very impressive for AI artists, but needs a lot of protein to fully enter the professional practice It must be topped with literature in architect-scale accuracy and detail. In the end, this adoption of generative AI in architecture is breaking traditional limits and allows architects to redefine how designs can be approached. Moving forward, no doubt these technologies will advance further and become vital tools for architectural visualization which create a large margin of room to bring out creativity and innovation in the field. Toward that end, research must be directed at streamlining and extending the capabilities of these tools throughout all stages in architectural design from conceptual development to detailed renderings.

Reconsidering online whiteboards as collaborative design interfaces in architectural education

Ömer Can Bakan*[1], Altuğ Kasalı[2]

[1] Yaşar University, Faculty of Architecture, Department of Architecture, 35100 İzmir, Türkiye
[2] İzmir Institute of Technology, Faculty of Architecture, Department of Architecture, 35430 İzmir, Türkiye

Abstract. Architectural education requires students to develop skills concerning collaboration, communication, and design representation. Novice architecture students often face challenges in teamwork within design studios, traditionally structured around physical interaction, feedback, and iteration. However, the shift toward distance learning, accelerated by the pandemic, has introduced new opportunities for novel pedagogies in design education. Online tools have increasingly supported creativity, problem-solving, and peer learning. Among these, online whiteboards, though not originally designed for architectural design processes, provide an effective medium for idea generation and communication.

This study examines the role of online whiteboards in fostering collaborative learning in architectural education and discusses how more efficient interfaces can be developed. While online collaborative tools have been rapidly integrated into design education, their effectiveness in addressing students' cognitive, perceptual, and sociological needs remains an area for further exploration. Retrospective studies highlight both the benefits and limitations of these platforms, emphasizing the need for more adaptable and profession-oriented tools.

Platforms such as Miro, Moodle, Microsoft Whiteboard, and Google Jamboard serve as research environments to analyze participants' cognitive processes and communication strategies. Among these, Miro is frequently cited as the most effective digital tool for co-design processes. This research investigates its use in collaborative design, aiming to identify specialized interface requirements for architectural education. While emphasizing the potential that the developing digital tools offer for design collaborations, this paper concludes by highlighting certain limitations involving cognitive engagement, software integration, and deficiencies in workflow and structured communication.

Keywords: Design education; Design collaboration; Online whiteboards; Co-design solutions

1. Introduction

The integration of technology and online platforms has significantly transformed collaborative design practices, enabling more efficient communication and coordination among team members. These digital tools foster innovation by facilitating real-time idea exchange, co-creation, and knowledge sharing. Additionally, online collaboration enhances the diversity and inclusivity of design teams by allowing participation from individuals who may be geographically distant or unable to engage in traditional, in-person settings. However, despite its advantages, online collaboration also presents notable limitations. The absence of face-to-face interaction can hinder the spontaneous and tacit exchanges that are fundamental to design ideation and problem-solving. As Margot Brereton's empirical research highlights, design experts derive substantial benefits from social interaction in physical design environments, where implicit agreements and shared understanding emerge naturally (Brereton et al., 1996). Building upon Schön's (1992) perspective, designers often operate with a tacit knowledge that is difficult to verbalize, making physical presence and direct engagement crucial for collaboration. While digital platforms attempt to bridge this gap, the extent to which they can replicate or compensate for these embodied interactions remains an open question that requires deeper investigation.

The COVID-19 pandemic accelerated the widespread adoption of online collaborative tools out of necessity, fundamentally reshaping traditional design workflows (WHO, 2022). Design practice, which has historically relied on physical proximity, sketching, and iterative dialogue, faced challenges in adapting to remote work settings, requiring novel strategies to reconstruct collaborative processes in virtual environments (Slingerland et al., 2022). In response, researchers have increasingly focused on integrating information and communication technologies (ICT) into design education and professional practice, aiming to develop more flexible, adaptive, and interactive

* Corresponding author, E-mail: omercan.bakan@yasar.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_058

systems (Saleh et al., 2022). This study builds upon these discussions by examining how online collaboration tools, particularly cloud-based platforms, mediate architectural design processes. Specifically, it investigates the role of online whiteboards as a central medium for structuring collaborative engagement and distributed cognition among design teams. By analyzing how these tools are instrumentalized in contemporary design education, this research seeks to contribute to the broader discourse on the evolving relationship between digital media and architectural pedagogy.

In the realm of design studies, the studies suggest that designers often face significant challenges that impact their progress and creativity (Erbil & Doğan, 2012; Fila et al., 2012; Hemdan et al., 2023). These struggles can be attributed to a lack of experience, inadequate social engagements, and maybe even insufficient use of design tools. In the situated environments of design, designers should also learn to work together by utilizing multiple media with colleagues and participants from other disciplines (Kan & Gero, 2009; Niedergeses, 2012; Ozbaki et al., 2016). The development of communication and design tools enables a notably more efficient collaborative design process between designers (Chamakiotis et al., 2013; Mahmoud Saleh et al., 2023). Recently, architectural design has been considered as a distributed cognitive system, which encompasses a multitude of representational media, virtual and analog design tools, communication channels, and more (Dorta et al., 2016; Thatcher & Brown, 2010). Therefore, providing an analysis that accounts for the distributed nature of design processes has the potential to develop a better understanding on contemporary practices in both educational and professional settings.

2. Background and Current State of Online Whiteboard Integration

One of the most extensively researched topics in the post-Covid era regarding online multimedia tools has been the role of online whiteboard platforms in supporting design activities. Recent studies in this area have frequently analyzed the usability and limitations of these tools by examining the social interactions of design stakeholders (Li et al., 2021). This process has generally been explored through detailed interviews conducted after collaborative design sessions with design students. There are also studies researching the technological modality strategies adopted by students. Sher and colleagues highlight that students actively manage their learning processes by integrating multiple platforms and devices, emphasizing the critical need to examine their strategies for technology adoption (Sher et al., 2019). The observations indicate the presence of diverse "behavioral patterns" in the utilization of various tools, ranging from handheld devices to PCs and desktops. The study highlights that these differing technological modality strategies have a direct impact on the overall effectiveness of students' learning processes.

As interdisciplinary online design and planning practices become integral to co-design processes, more in-depth investigations are needed to cover the internal dynamics of design teams and their evolving methodologies. Key aspects warranting further exploration include agile learning in virtual meetings, simultaneous creativity, reflexive digital design processes, and the mechanisms of visual discussion that facilitate collaborative ideation (Sclater et al., 2001). Scholars studying digital ecologies in collaborative design contexts have mapped the intersections of various online platforms, identifying innovative web-based tools that enhance co-design quality (Cerna & Müller, 2021).

Recent research on design cognition and collaborative practices increasingly associates creativity and adaptability with the use of online whiteboard tools, emphasizing their role in fostering dynamic and fluid exchanges between participants. These tools enable real-time sketching, idea structuring, and multimodal representation, allowing for a more interactive and flexible co-design environment. While various platforms are employed in architectural and design education, Miro Board has emerged as one of the most widely studied for its multi-user, cloud-based interface (Rojanarata, 2020; Cerna & Müller, 2021; Li et al., 2021). However, despite its growing adoption, there remains a critical gap in understanding how Miro Board and similar digital tools are recognized and utilized as creative collaboration mediums in collaborative design settings. Further research is needed to explore how these tools influence design decision-making, knowledge exchange, and the overall efficacy of virtual co-design in fostering innovative solutions.

The advancement of new technologies has significantly enhanced communication among designers, fostering more efficient and interconnected design processes. However, many digital design and collaboration platforms require a steep learning curve, as they necessitate familiarity with specific system functionalities before users can fully integrate them into their workflows (Sclater et al., 2001). Overcoming communication barriers in online design processes has become a critical focus of research, leading to the introduction and examination of various online collaborative tools (Koutsabasis et al., 2011; Peppler & Solomou, 2011). The effectiveness of collaborative design is shaped by several factors, including task interdependence—how closely team members must coordinate their work—and potency, which refers to the collective belief in the team's ability to achieve successful outcomes (Erbil, 2013, p. 9). Digital environments have increasingly become supportive tools in fostering collaboration among student design teams, allowing for more flexible and interactive design processes.

Given the rapid evolution of technology and shifting outcome expectations in design disciplines, it remains challenging to anticipate how the norms of co-design environments will continue to evolve. Computer-supported collaborative work environments are now fundamental components of contemporary design teams, and online whiteboard tools have emerged as a widely adopted medium within architectural design processes. These tools, which integrate multiple layers of social interaction into virtual design processes, warrant further investigation to assess their potential in fostering creativity, enhancing team agility, and promoting interdisciplinary collaboration in architectural education and practice.

Miro Online Whiteboard has recently emerged as a widely adopted platform in design and construction disciplines, with increasing applications in academic research and design education (Pikas et al., 2022). While numerous platforms, such as Moodle, Microsoft Whiteboard, OneNote, Google Jamboard, AWW, and Belkin Stage Pro, offer online collaborative whiteboard experiences, Miro has been frequently identified by architectural researchers as one of the most effective tools for enhancing co-design processes (Galabo et al., 2020; Cerna and Müller, 2021; Camiz, 2021; Pikas et al., 2022). Its multi-user functionality, real-time interaction capabilities, and diverse set of design-oriented features have contributed to its growing preference among design teams and educators.

Despite the widespread use of online whiteboards and cloud-based platforms in fostering collaborative learning environments, existing literature largely focuses on their general applications in education and interdisciplinary teamwork. There remains a significant gap in research addressing the specific ways in which student design teams utilize design-oriented and customized online whiteboards to support their creative workflows. Understanding how these tools can be tailored to architectural education, particularly in the context of iterative design processes, visual collaboration, and peer learning, is crucial.

3. Collaborative Design Infrastructures in Cloud-Based Platforms

This study aims to closely examine the interfaces of cloud-based collaborative platforms and assess their contributions to co-design processes, particularly within the context of architectural design studios. These platforms enable design teams to collaborate remotely and in real-time, supporting a decentralized and flexible workflow that is especially advantageous for student teams working outside traditional studio settings. By eliminating spatial constraints, cloud-based tools foster more inclusive and agile design interactions.

This paper prioritizes qualitative insights derived from the use of Miro Online Whiteboard, a platform that has gained increasing traction in collaborative architectural practices. While Miro serves as a focal point for analysis due to its widespread adoption and robust feature set, the study does not aim to promote this specific tool. Rather, it uses Miro as a case study to explore broader implications and emerging possibilities for digital co-design platforms. In the near future, it is likely that more advanced, discipline-specific tools will emerge, better tailored to the unique demands of architectural design and education.

Miro's interface allows participants to seamlessly share visual and textual information, integrating various forms of media such as images, videos, and documents. These capabilities support the iterative development of design ideas, which is especially crucial in competitive settings where time constraints and design clarity are vital. The platform also enables real-time commenting and annotation, fostering immediate peer interaction and responsive guidance from instructors. This type of input is essential for the continuous refinement of design proposals. Furthermore, the ability to create shared boards and collaborative workspaces enhances team dynamics by enabling concurrent engagement with evolving design content. These affordances position platforms like Miro as key infrastructural components in reshaping conventional design collaboration into more distributed, adaptive, and feedback-driven processes suitable for contemporary architectural education.

3.1 Limitations and Development Gaps in Online Whiteboards for Architectural Design Education

While platforms like Miro offer significant advantages in facilitating real-time, visually rich collaboration for design teams, several limitations and gaps persist, particularly when evaluated through the lens of architectural education. These issues highlight the need for more tailored, discipline-specific tools that respond to the complex and layered nature of architectural design learning.

3.1.1 Cognitive Overload and Interface Clutter

The open and real-time collaboration model provided by online whiteboards can unintentionally result in cognitive overload, especially for novice architecture students. When multiple team members simultaneously annotate, sketch, or comment on the same shared space, the interface often becomes visually saturated. This makes it difficult to filter, organize, or prioritize feedback effectively. Such visual and cognitive clutter can hinder the process of convergent thinking, which is essential for refining and consolidating design decisions after the initial idea generation phase.

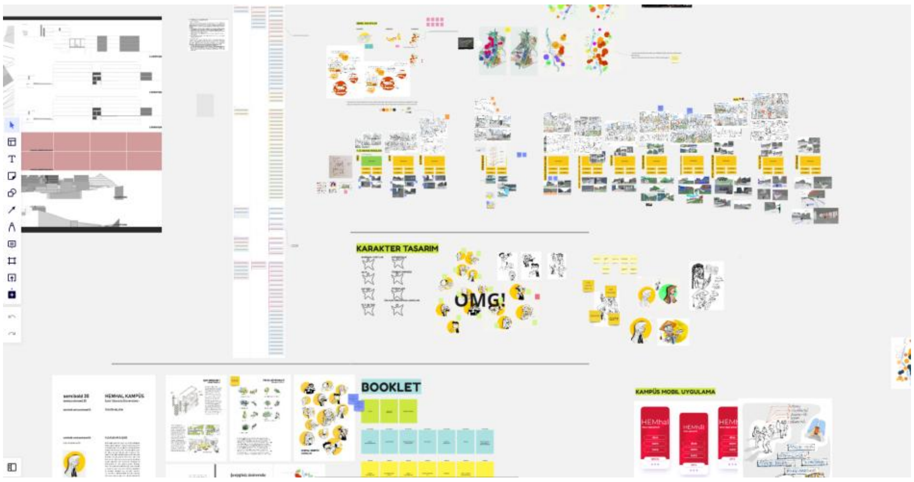

Fig. 1. General overview of a shared student design team whiteboard consisting of images and notations about: user definitions, representational decisions, storyboards, and urban diagrams (source: author)

3.1.2 Lack of Structured Feedback Channels

Although Miro and similar platforms allow commenting and note-taking, they lack more advanced feedback mechanisms such as threaded discussions, layered annotations, or feedback filters based on user roles. In architectural education, where continuous and structured instructor feedback is essential for refining design outputs, the absence of these features presents a major limitation. Tools that allow categorizing comments according to design phases, assigning feedback to specific participants, or distinguishing between peer and instructor inputs could significantly enhance the educational value of these platforms.

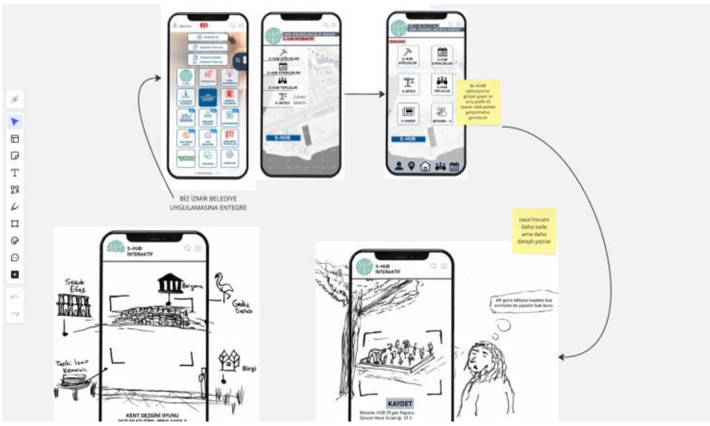

Fig. 2. Sticky notes and arrows as feedback affordances between instructor and architecture student (source: author)

3.1.3 Limited Integration with Architectural Software

Another significant limitation of current online whiteboard platforms is the inadequate integration with essential architectural design tools, such as AutoCAD, Revit, Rhino, and SketchUp. Presently, these platforms mainly support the upload of static exports, such as images or PDFs, which hinders the dynamic and iterative nature of architectural design processes. The absence of native support for editable and interactive file formats restricts the potential of online whiteboards to function as a seamless, integrated design environment. Ideally, these platforms should allow for the coexistence and simultaneous evolution of conceptual sketches, representational drawings, and technical models within a shared collaborative space.

To address this gap, future software development could focus on establishing deeper interoperability with industry-standard design tools, enabling real-time collaboration on 3D models and technical drawings. Such integration would allow design teams to modify and annotate each other's models, fostering a more fluid and interactive workflow. Additionally, introducing software-specific annotations, pop-up windows, and context-sensitive tools could enhance communication between team members, making it easier to exchange ideas and track design revisions. These enhancements could also play a key role in facilitating peer learning, as students would be able to work on and critique each other’s live models and sketches, simulating a more authentic collaborative design experience. By overcoming this barrier, online whiteboards could evolve into powerful, all-encompassing platforms that support both conceptual and technical design processes, bridging the gap between creative exploration and technical execution.

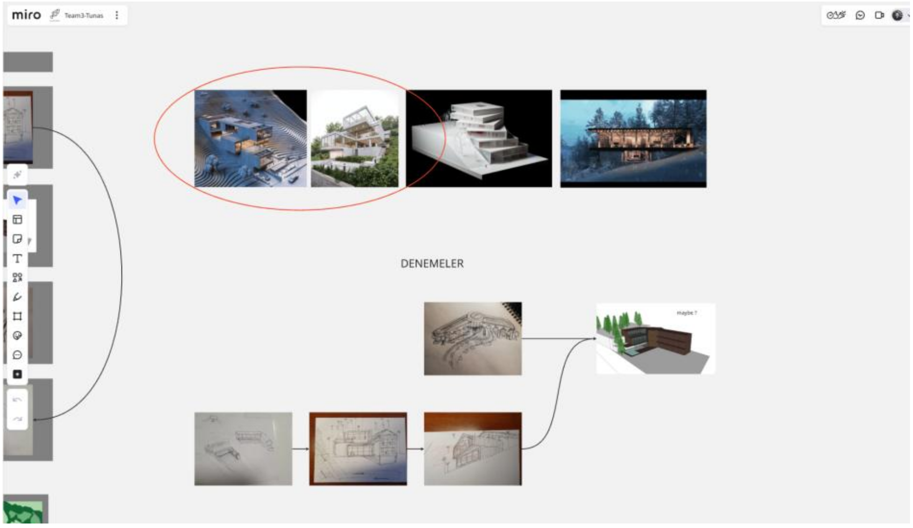

Fig. 3. Screenshots from software interfaces and sketches as the only solution for sharing ideas (source: author)

3.1.4 Insufficient Support for Time Management and Workflow Structuring

Collaborative design projects in educational settings require clear structuring of tasks and timelines. However, most online whiteboard tools lack features such as integrated schedules, task delegation, or phase-based workflows. Without these supports, student teams may struggle with pacing their work or managing group responsibilities. The inclusion of built-in studio calendars, task trackers, or workflow templates would greatly benefit architecture students working in collaborative settings. Although there are some templates for management and planning departments, there are no add-ons or guidelines to facilitate time and work management for students in architecture education.

3.1.5 Dependence on High-Speed Internet and Modern Devices

The effective use of online whiteboards assumes stable internet connectivity and access to up-to-date devices. Students with limited digital infrastructure may experience difficulties in loading complex boards or participating fully in collaborative sessions. Additionally, as boards become more content-heavy, performance issues may arise, particularly on lower-end hardware. These technical constraints create unequal learning conditions among team members and should be considered in future platform developments.

3.1.6 Absence of Architecture-Specific Templates and Tools

Currently, most online whiteboards offer general-purpose tools that are not specifically designed for architectural workflows. Architecture students, however, would greatly benefit from having access to discipline-specific features tailored to their design needs. These could include tools such as scaled grids for accurate drawings, customized drawing templates for plans, elevations, and sections, and mood board layouts to assist with conceptualization. Moreover, support for architectural notation standards, such as dimensioning conventions, section markers, and wall thicknesses, would ensure that students' digital drawings align with established practices in the field.

The addition of specific tools for architectural representation modes is crucial for enhancing the functionality and relevance of online whiteboards in design education. For instance, having human section figures available would allow students to rapidly discuss and communicate the scale of their section drawings, providing a quick and clear visual reference for size and proportion. Plan and site plan annotations could also be incorporated, including tools for marking north direction, adding directional arrows, and creating geographic references. These features would help students present their work in a manner consistent with professional architectural documentation.

In addition, user-friendly tools for texture creation and material representation are essential for conveying the aesthetic and tactile qualities of a design. Features that allow students to apply textures and visualize materials within their digital models would promote a deeper understanding of materiality and spatial experiences. Furthermore, tools for quickly creating architectural posters and presentation templates could be invaluable during jury or critique sessions, enabling students to efficiently prepare visual communication materials that highlight their design ideas while adhering to presentation standards.

Fig. 4. Screenshots from a student architectural design team utilising sketches and other techniques to represent their design ideas (source: author)

3.2 Implications for Future Development and Research

The limitations identified in current online whiteboard platforms underscore the necessity for more architecture-specific collaborative environments. From a software development perspective, these gaps highlight the demand for tailored interfaces that support both divergent and convergent design thinking, structured feedback systems, discipline-integrated workflows, and tools adapted to the representational needs of architectural practice. Developers could collaborate with design educators to prototype features such as layered annotation, CAD/BIM integration, time-managed studio workflows, and cognitive load-reducing visual filters.

From an academic research perspective, these shortcomings offer fertile ground for investigating how digital tools can better align with pedagogical goals in architectural education. Future studies might explore how novice design teams interpret and navigate overloaded interfaces, how structured feedback formats affect learning outcomes, or how cross-platform interoperability can support a more fluid digital design process. Ethnographic and user-experience-based research methods can be especially valuable in understanding how students adapt these platforms to meet their learning needs. Ultimately, addressing these challenges can contribute to the development of hybrid learning ecosystems that are not only more intuitive and inclusive but also more responsive to the evolving demands of architectural design education.

4. Conclusions

This study explored the use of online whiteboards in architectural design education, examining how these platforms support student collaboration and cognitive processes. Online whiteboards provide students with flexible spaces to externalize their ideas and collaborate in real-time, allowing for collective feedback and iterative design. While these platforms encourage collaborative creativity, their effectiveness depends on interface quality and support for students' cognitive engagement. However, some platforms fail to meet the specific demands of architectural education, with features that can overwhelm users or lack crucial design tools. Students often struggle with poorly designed feedback mechanisms and inadequate integration with specialized design software, limiting their ability to fully engage in architectural problem-solving.

The study also found that online whiteboards significantly influence teamwork and problem-solving strategies. They promote simultaneous ideation and creative collaboration, enabling students to break down complex tasks and refine design ideas together. However, the absence of architecture-specific features, such as scaled grids or proper notation tools, hinders students' ability to express and test design concepts effectively. This gap in functionality means that students often rely on general-purpose tools, which can restrict their problem-solving capabilities in the context of architectural design. Nonetheless, when used effectively, these platforms encourage adaptive teamwork strategies and can foster peer learning and real-time problem-solving.

Based on the findings, several key conclusions have emerged regarding the role of online whiteboards in architectural design education:

- **Cognitive Engagement and Feedback Mechanisms:** While online whiteboards can support students' cognitive processes, their effectiveness hinges on interface quality and the presence of structured feedback channels. Platforms should integrate visual filters, threaded discussions, and categorized feedback systems to streamline collaboration and mitigate confusion.

- **Integration with Design Software:** A significant limitation of current online whiteboard tools is their lack of integration with architectural design software like AutoCAD, Revit, and SketchUp. Future platforms should integrate real-time collaboration features with these tools, enabling seamless interaction with editable design models, rather than relying on static image uploads. This would promote a more cohesive design process, facilitating real-time problem-solving and collaboration among team members.
- **Discipline-Specific Features:** The study highlights the need for architecture-specific features that cater to the demands of architectural education, such as tools for architectural notation, section figures for scale discussions, and easily accessible templates for plans, sections, and elevations. These features would make online whiteboards more relevant to architectural education and improve the quality and speed of design iterations.
- **Support for Task Management and Workflow Structuring:** Collaborative design work requires clear task structuring and time management. Online whiteboards should incorporate task management features, such as calendars, workflows, and progress trackers, to enhance the organizational aspects of group projects. These features would help students better manage their collaborative processes, increasing both efficiency and effectiveness in the design workflow.
- **Enhanced Peer Learning Opportunities:** With the right tools, online whiteboards can significantly enhance peer learning by allowing students to annotate and critique each other's work in real time. Future platforms should offer advanced interaction features that enable collaborative modifications to shared design files and facilitate visualizing and communicating design changes.

In conclusion, online whiteboards hold substantial potential to transform architectural design education by fostering collaboration and problem-solving. However, their current limitations must be addressed. Future development should focus on creating more specialized tools to meet the unique needs of architecture students, enhancing platforms' ability to support iterative design processes, structured feedback, and real-time collaboration. By aligning these platforms with the demands of architectural practice and education, they can become more intuitive, embedded, and effective tools for both students and instructors in design studios.

Exploring the social affordances of physical setting in public open space of higher institution: Case of Ozyegin University Quad

Abdulrahim Darma Umar*[1], Nevset Gul Canakcioglu[1], Nese Ganic Saglam[1], Didem Boyacıoglu[1]

[1] *Ozyegin University, Department of Architecture, Faculty of Architecture and Design, Istanbul, Türkiye*

Abstract. Higher Institutions, such as universities are hubs for learning, but they should also be places where students can socialize, relax, and connect to foster essential skills, promote personal and professional growth, and enhance overall well-being. A university square is one of the open spaces meant to facilitate the above human needs with its spatial characteristics. Considering the importance of mental and social well-being, which is overlooked compared to physical safety during the design of public open spaces, this study investigates the functional diversity through social affordances offered by the physical setting of OzU Quad, a central public space at Ozyegin University. Affordance theory, which explores the relationship between an environment and its potential for user behavior, provides the framework for this research. The study combines in-depth one-on-one interviews with 17 students, and behavioral observations conducted at strategic times of the day. The interview participants represent a diverse range of genders, ages, nationalities, and durations of stay at the university. Data analysis reveals three categories of Quad users: frequent visitors, occasional visitors, and non-visitors. The findings demonstrate a clear connection between the physical design of the Quad and the social activities that take place. The open and spacious central area with diverse features (including fixed, semi-fixed and mobile elements) affords activities like relaxing, socializing, and observing people. Conversely, the completely paved area with limited seating primarily affords walking and smoking cigarettes. The research highlights the importance of considering user needs and preferences when designing public open spaces. Understanding the social affordances offered by the physical environment can help universities to create spaces that foster desired social interactions and enhance the overall campus experience.

Keywords: Affordance theory; Behaviour; Physical setting; Public open space; University square

1. Introduction

Social cohesion - the strength and quality of relationships and the sense of solidarity among members of a society-, well-being, and sustainability are essential interconnected concepts that shape the development of vibrant and equitable communities. In higher education institutions, public open spaces are more than just areas for physical movement or rest—they serve as critical sites for social interaction, creativity, and the development of a sense of community among students, faculty, and visitors. The design of these spaces plays a significant role in shaping how individuals engage with one another and their environment. Public spaces that are thoughtfully designed and that foster interaction are essential to the social fabric of campus life.

One framework that addresses the potential of these spaces is *placemaking*, a collaborative and inclusive approach that focuses on creating meaningful, engaging environments that reflect the values, culture, and needs of the people who use them. According to Madden (2021), placemaking goes beyond simply improving aesthetics or function—it seeks to transform public spaces into places that resonate with people on a deeper level, encouraging social connections, fostering a sense of identity, and supporting the ongoing evolution of the community. In the context of higher education, placemaking can help transform an ordinary campus courtyard or plaza into a vibrant, dynamic area that strengthens relationships and promotes collaboration (Kong & Zheng, 2023). Common challenges of public open spaces often include underutilization, limited participation, and inadequate consideration of users' well-being. In many cases, certain areas within public spaces, such as the University Square, remain underused due to various factors, with some community members, like students, not fully engaging with these spaces. This lack of participation can result from barriers related to accessibility, design, or the surrounding

* Corresponding author, E-mail: abdulrahim.darma@ozu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_070

environment, leading to spaces that do not serve the diverse needs of the population (Project for public spaces, 2009). Additionally, the mental health (Myers, Mabey, & Burleson, 2024) and well-being of users (Zhang, 2024), especially in spaces frequented by students, are commonly overlooked in the design and planning process. These challenges highlight the need to address the factors behind underuse, promote inclusivity, and consider the mental and emotional benefits of public open spaces to foster a more vibrant, accessible, and supportive environment for all users. In this sense, Gibson's affordance theory (1979; 2014) serves as an important perspective for the situation. The concept of affordances, according to Norman (1999), was introduced by ecological psychologist James J. Gibson in the 1970s. It helps us understand the relationship between an environment and an organism's capabilities for action.

Despite existing literature on public space design, there is a gap in understanding how affordances can influence student well-being and sustainability in these spaces. This paper adds to the expanding body of interdisciplinary research focused on measuring affordances as a means to enhance placemaking and support the Sustainable Development Goals within public urban spaces. By offering a qualitative evaluation of young people's behaviour and experiences in various contexts, our discussion emphasizes how affordances in public green spaces can illuminate the complex connections between student's well-being, environmental usage and sustainability, particularly in educational settings.

2. Literature review

2.1. Social Cohesion, Placemaking, and Public Space Design

Social cohesion is frequently seen as being jeopardized by the growing cultural and economic disparities in modern societies, along with the intensifying pace of urban life. As the primary setting for social interactions among strangers, public space plays a significant role in either promoting or hindering social cohesion. The first effort to compile scholarly knowledge at the intersection of public space design and social cohesion was Aelbrecht and Stevens (2018), offering a global perspective on research and urban design practices in both the Global North and South. It brings together contributions from leading and emerging scholars and practitioners from both regions to explain what precisely 'social cohesion' means, how it is experienced in public spaces, and what impact the design of urban areas can have on fostering or hindering it. Public space plays a vital role in our social lives by contributing to people's attachment to their cities, neighbourhoods and local communities, creates opportunities for social interaction, social mixing, inclusion and community building, and supports people's well-being and individual and group identities (Amin, 2008). However, despite efforts by social scientists to identify them, clear answers on achieving social cohesion remain elusive (Aelbrecht & Stevens, 2018). Aelbrecht and Stevens (2018) further identify five important themes which include the emerging typologies of public spaces, symbolism and sense of belonging, design elements that encourage social interaction, processes of engagement and placemaking, and reflections from urban design practice. These themes offer a diverse perspective on how public space design influences social cohesion.

Regarding what makes a great place, Kathy's (2021) *Principles for Creating Great Community Places* further stress the importance of community involvement, thoughtful design, and continuous improvements to create vibrant public spaces. The first principle underscores the value of engaging the community as experts to ensure that the space reflects their needs and values. Rather than focusing solely on design, the objective should be to create a functional "place" that encourages interaction and connection. Collaboration with partners, observing how people use the space, and implementing minor, affordable improvements are critical to success. A clear, community-driven vision helps shape the space's purpose and identity, while the ability to adapt over time is essential as needs change. Ultimately, these principles highlight that creating exceptional public spaces is a continuous process that requires creativity, attention, and a commitment to evolving alongside the community's needs.

One of the challenges regarding social cohesion is the division between sociological and urban design research, with some studies focusing solely on the sociological aspects of social life while others focus on the physical attributes of public spaces (Aelbrecht & Stevens, 2018). Another issue is the lack of knowledge exchange between urban design theory and practice, as well as the limited integration of scientific knowledge into environmental design disciplines. A need to look at the issue holistically is paramount.

2.2. Well-Being and Mental Health in Public Open Spaces

Well-being and mental health of the users in public open spaces are of utmost importance. There is a growing body of literature showing how the design of physical open spaces influences the health outcomes of the user (Myers, et al. 2024; Nissen, *et al.* 2020) and productivity of students (Darma, Arshadi, Cumurcu & Mizrak, 2023). Traditionally, design disciplines have not been focused on public health, but there is a growing recognition of the role designers play in promoting or hindering health. An example includes the assertion of the "United States Surgeon General at the 2014 Design + Health Summit" that architects should be viewed as "public health workers." (Myers, et al. 2024). The World Health Organization (2020) defines health as a comprehensive state of three dimensions; physical, mental, and social well-being. It emphasizes that the right to enjoy the highest standard of health is a fundamental human right, irrespective of race, religion, political belief, or any economic or social status. The simplified definitions of the three dimensions were tabulated by Myers, et al. (2024) as shown in Table 1.

Table 1. Definitions and examples of measures of health dimensions (Myers, et al., 2024)

Health dimensions	**Definition**	**Existing measures and metrics**
Physical	Bodily health and abilities	Mortality, disease, self-reported general health.
Mental	Emotional, psychological, and cognitive	Depression, positive and negative affect, attentional function, cognitive decline, dementia.
Social	Relationships and interactions within society	Perceived social cohesion, reciprocity, loneliness, social networks.

Table 2 below summarizes key findings from recent literature on mental health and design elements of public open spaces such as parks, squares and other green spaces and their contribution to psychological restoration, social interaction, and overall quality of life.

Table 2. Key Findings from recent literature on Public Space Design and Health (Source: Authors).

Design Element	**Key Findings**	**Citation**
Green Spaces	Exposure to green spaces reduces stress and alleviates anxiety and boosts productivity.	(Bressane et al., 2024; Darma et al., 2023; Shahmiri et al., 2024)
Natural Elements (Water features etc)	Higher degrees of naturalness in green spaces correlate with lower mental distress.	(Bressane et al., 2024)
Sensory Design	Multi-sensory experiences in green spaces enhance psychological restoration.	(Qu & Ma, 2024)
Accessibility & Inclusivity	Inclusive design that caters to diverse populations enhances well-being.	(Addas & Maghrabi, 2021; Ziersch et al., 2023)
Physical Activity & Social Interaction	Public spaces that promote physical activity and social interaction improve mental health.	(Addas & Maghrabi, 2021; Livingston, 2024)

Myers, et al. (2024) also explore a variety of design approaches aimed at improving holistic health outcomes by prioritizing the involvement of multiple stakeholders in the design process. Approaches like design for well-being and people-centered design focus on enhancing physical, social, and emotional well-being, emphasizing inclusivity and equity. Methods such as human-centered design (HCD) and participatory design involve end-users in the design process to ensure their needs and values are considered, which can enhance well-being. However, these approaches have limitations, including criticisms of their focus on privileged groups and the potential harm of poorly executed participatory methods. There's a need for a deeper theoretical understanding of how specific design choices impact health outcomes, particularly for vulnerable populations, to ensure that design practices lead to improved health and well-being.

2.3. Affordance Theory and Public Space Interaction

Scholars in man-environment studies have made significant efforts to establish a relationship between human behavior and the environment by examining how physical, social, and cultural surroundings influence human actions and well-being (Barker, 1968; Norman, 1999; Rapoport, 1977). They have explored various interdisciplinary fields like psychology, sociology, geography, anthropology and environmental science to understand how people perceive, interact with, and are affected by their environments. This includes topics like environmental stress, urban design, place attachment, and how natural or built environments can impact emotions, productivity, and social behavior. One promising concept among such efforts, especially for exploring experiences of individuals, is Gibson's affordance theory (Myers, et al., 2024). The literature indicates that applying Affordance Theory to environmental design has the potential to enhance the functionality and experiential quality of spaces for human users (Li, 2013). In 1979, psychologist James Jerome Gibson developed the theory of affordance to explain how individuals respond to the physical characteristics of their environment. He defined affordances as what the environment offers to individuals, regardless of their needs or perceptions. Fig. 1 shows the basic and original concept of affordance adopted from Li (2013). Affordances are invariant, always present, but may be perceived differently depending on the observer's needs and capabilities. For instance, a flight of stairs affords ascending to the next floor, but an infant who cannot climb stairs would not perceive this affordance. Gibson also introduced the concept of "niche," which he describes as how a species lives, not only where it lives, suggesting that a niche consists of a set of affordances (Heras-Escribano & Pinedo-García, 2018). He noted that humans modify the environment to create more positive affordances and fewer negative ones. In public space design, affordances include paths that enable pedestrian movement and separate traffic, or parks that provide space for physical activity and social gatherings. Some affordances are positive, like a park's recreational benefits, while others can be negative, such as a park that separates socioeconomically distinct neighborhoods (Li, 2013).

Affordance theory has been expanded through various classifications proposed by different researchers. Reflexive, reactive, and reflective affordances were introduced by Kannengiesser and Gero (2012). Reflexive affordances require minimal internal processing; reactive affordances result from a deliberate search process; and reflective affordances are exploratory in nature. These categories build upon hidden and false affordances, earlier proposed by Gaver (1991). Real and perceived affordances, as described by Yilmaz, Mumcu, and Cigdem (2017), distinguish between the designer's intended functionality (real) and the user's interpretation of possible actions (perceived). Passive and active affordances, introduced by Ozbil, Ozgur, Mujesir, and Kenan (2018), are defined based on the level of user interaction—passive being static possibilities and active requiring user engagement. Finally, improvised and serendipitous affordances, identified by Stevens, Dalay, and Dovey (2023), refer respectively to those that emerge through user adaptation and those that arise unexpectedly by chance. Ciavola and Gershenson (2012) explains how affordance theory aligns with function-based design. However, despite these advances, affordances are rarely mentioned in product design processes. Some criticisms suggest that affordances are too abstract and ambiguous for practical implementation (Myers, et al., 2024). Davis (2020) outlined mechanisms and conditions of affordances (Fig. 2), providing insights into how designers can influence desired affordances.

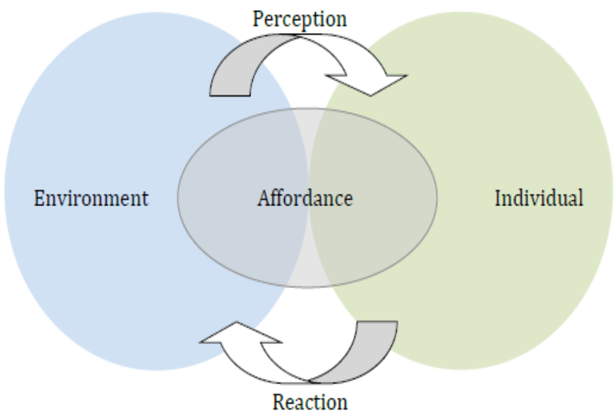

Fig. 1. The original concept of affordance (Source: Li, 2013).

Fig. 2. Davis (2020)'s mechanisms and conditions of affordances.

Scholars have also proposed Affordance-Based Design, which shifts focus from functions to affordances, most of them examining the relationship between physical activity and objectively assessing built environment, and improving the space's condition (Smith et al., 2017). Despite its potential, affordance theory remains underutilized in renovation design practices.

According to Nissen et al. (2020), early research on youth and urban affordances focused on the functional aspects of the environment, examining the opportunities and restrictions local places offer to young people. While this approach remains prominent in some urban design research, Nissen et al. (2020) acknowledge that later work by Clark & Uzzell (2002) and Kyttä (2002) introduced a more socially, emotionally, and culturally informed concept of affordances. From this perspective, the environment's physical aspects are seen as foundational to experiences, best understood through local knowledge, social behaviors, and norms. Affordances are understood as the meaningful relationships that arise between an individual's perceptual and action capabilities and the features of the surrounding environment. This approach challenges the subject-object dichotomy, recognizing affordances between the individual and the environment. For instance, Clark & Uzzell (2002) assessed local environments based on what they afford residents, such as opportunities for activity, enjoyment, safety, or social interaction. Examining affordances offers a deeper understanding of the relationship between youth and their urban surroundings, moving beyond simple descriptions to explore why certain preferences exist (Li, 2013).

Kaaronen proposes that integrating affordance theory into sustainable development raises critical planning questions, such as: *Which affordances are encouraged, restricted, or neglected, and how do these decisions shape everyday behavior?* Additionally, other scholars emphasize that social inequality significantly influences young people's access to urban affordances (Nissen et al. 2020). This theory focuses on spatial relationships and flow, demonstrating that public spaces can be analyzed beyond physical elements. Several key factors related to environmental affordances have been identified in the literature. Several previous studies, according to Abu Elkhair, Sarhan and Bayoumi (2023) have identified five key social qualities that influence the use of outdoor spaces: (1) the effectiveness and diversity of social activities, (2) the diversity of users, (3) the design and enclosure of surrounding buildings, (4) the accessibility of pedestrian movement lanes, and (5) the density of vegetation, including tree planting and shading elements. The social and cultural context of the environment plays a role in shaping affordances. Shared norms, activities, and meanings associated with a space can enable or constrain certain behaviors and interactions (Rietveld, Haan, & Denys, 2013). On the other hand, people's characteristics, experiences, and intentions can also influence how they perceive and respond to the affordances in their environment. Factors like age, personality, and familiarity with a space have been found to mediate affordance perceptions (Bagais, n.d.). Studies have found that elements like density of plantings, enclosure, availability of seating, and presence of community gardens can all impact the social and recreational affordances perceived by users (Almadina & Marcillia, 2024; Hadavi, Kaplan, & Hunter, 2015; Şen et al. 2020). Other important factors, including sensory dimensions like water features, universal design, safety, and ease of navigation have all been shown to influence affordances, especially for children and those with disabilities (Bagais, n.d.; Guo, Shi & Chen, 2023). Ozbil et al (2018) quantitatively investigated factors affecting occupation patterns in the open spaces of Ozyegin University in Istanbul. The study concentrated more on the population of the users -not the affordances- and considers the whole university setting. However, this study aims to focus on the affordances, behavior richness, and usage pattern specifically of the OzU Quad, as it has distinct characteristics from the other outdoor areas in the university.

3. Methodology

Affordances theory has its roots in e*cological psychology* - which focuses on the interactions between people and their environments - (Norman, 1999). It has also been seen in the literature that affordances are not limited to the environment or objects alone. Morgenthaler et al. (2022) explain that affordance theory acknowledges the agency of the physical environment from a transactional perspective, where the person and the environment are equally important in shaping human behaviour. This suggests that the best way to deal with affordances is to look at both the person and their environment. Looking at the person means to look at their behaviour in the environment. On the other hand, looking at the qualities of the environment may include both tangible and intangible qualities. This study used observation (both behavioural and environmental), along with interviews to explore the social affordances that contribute to the social well-being of students in public open spaces in higher institutions, and to sought explanation as to why the problems of concentration of behaviour, underusage, over-usage, social cohesion and inclusivity of the environment occur despite the designers' efforts to address them during the design phase. For this purpose, Özyeğin University was selected as the study area, and ethical approval was granted by the university's committee on research ethics.

3.1. Study Area

The study area is Ozyegin University Central Square (OzU Quad) which is the heart of the Çekmekoy Campus, located in Nişantepe, Cekmekoy on the Asian side of Istanbul in Turkey (Fig. 3). Özyeğin University (OzU), established in 2007, was initially situated in its Altunizade Launch Campus, and moved to its Çekmeköy Campus in 2011 (Ozbil et al, 2018). The campus main entrance gate is located along Orman Street, which can be accessed through Saray Street that is connected to Şile Highway at the two ends (Ekşioğlu Mah. and Nişantepe Orman Park traffic circle).

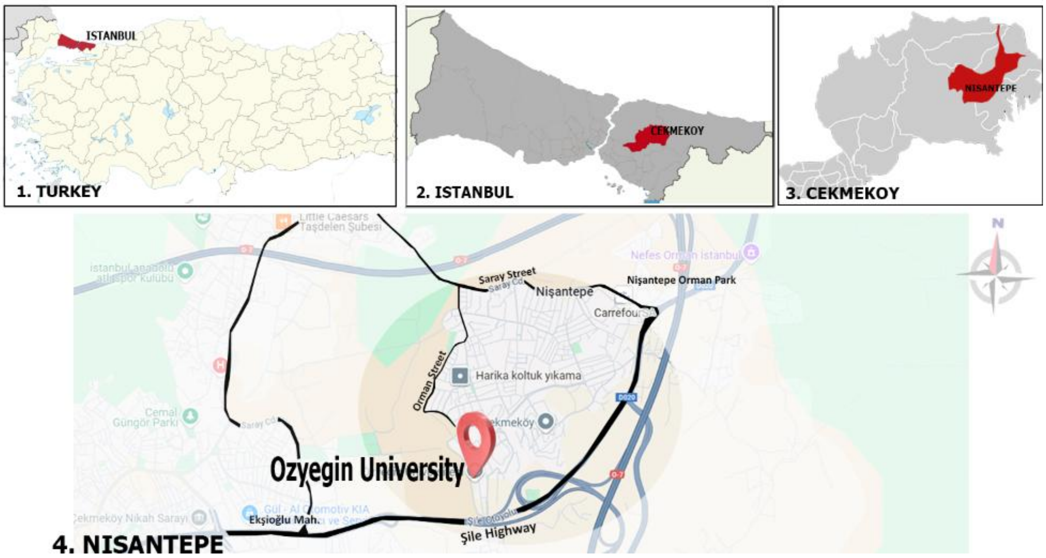

Fig. 3. Maps showing the Location of the University (Source: Authors).

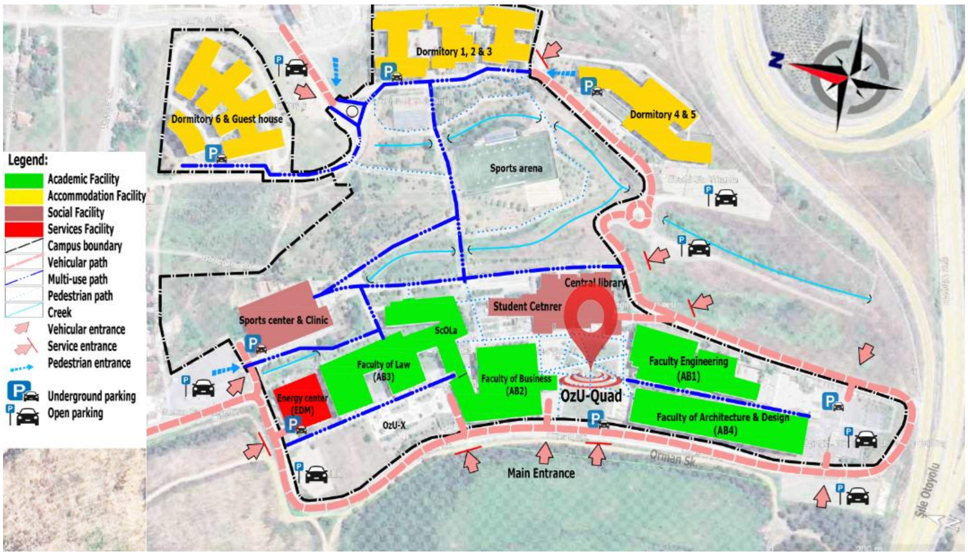

Fig. 4. Land use map of Ozyegin University Campus (Source: Authors).

The campus spans a total area of 283,264.9 square meters, with 132,946.1 square meters (about 47%) dedicated to open spaces. It consists of various facilities designed to support academic and social interactions, such as modern classrooms, laboratories, a sports center, and communal areas essential for fostering social engagement and collaborative learning among students. The university offers 25 undergraduate programs, 36 graduate programs, and 10 doctoral programs, with a student body comprising 6,261 undergraduates, 570 graduate students, and 194 postgraduate candidates with 529 full-time faculty members (Ozyegin University, 2024). Fig. 4 below shows the land use within the boundaries of the campus.

The OzU campus's main identifiable features are its modern buildings on a sloping terrain (Ozbil et al., 2018). The setting is surrounded by a wire fence and is enclosed by 11 vehicular gates (including service gates), with the main gate located on the west along Orman Street and other gates strategically located all around the boundary, each connected to the 14 parking spaces -both open and underground parking spaces. There are 3 pedestrian entrances - at the main gate, near the sports center and at the hostel area. The land use configuration is mainly divided into 3 along the east-west axis -Accommodation on the East, sports at the center, and Academic on the West- all connected using a multi-use pathway. The OzU quad is in the heart of the academic area, surrounded by the students' center, central library, faculty of engineering (AB1), faculty of architecture (AB4), and faculty of business (AB2).

OzU Quad serves as an outdoor meeting point for students and faculty alike because it is the intersection of all faculties where students meet and enjoy outdoors, share a cup of coffee with friends, study, or relax between classes. At the same time, host concerts and other vibrant activities of students' clubs. This area is highly integrated with the other parts of the campus (Şen et al., 2020; Ozbil et al., 2018). As shown in Fig. 5, it can be accessible by pedestrians, including physically challenged, from both the surrounding buildings and the connected pathways from other parts of the campus.

The total area of the Quad is measured to be approximately 8,355m^2, comprising the areas. For the sake of analysis, the Quad area was divided into six portions as shown in Fig. 6 below: Student center entrance (Q1), Faculty of Engineering entrance (Q2), Central area (Q3), Faculty of Business bank (Q4),Lower quad (Q5) and the Faculty of Architecture entrance (Q6).

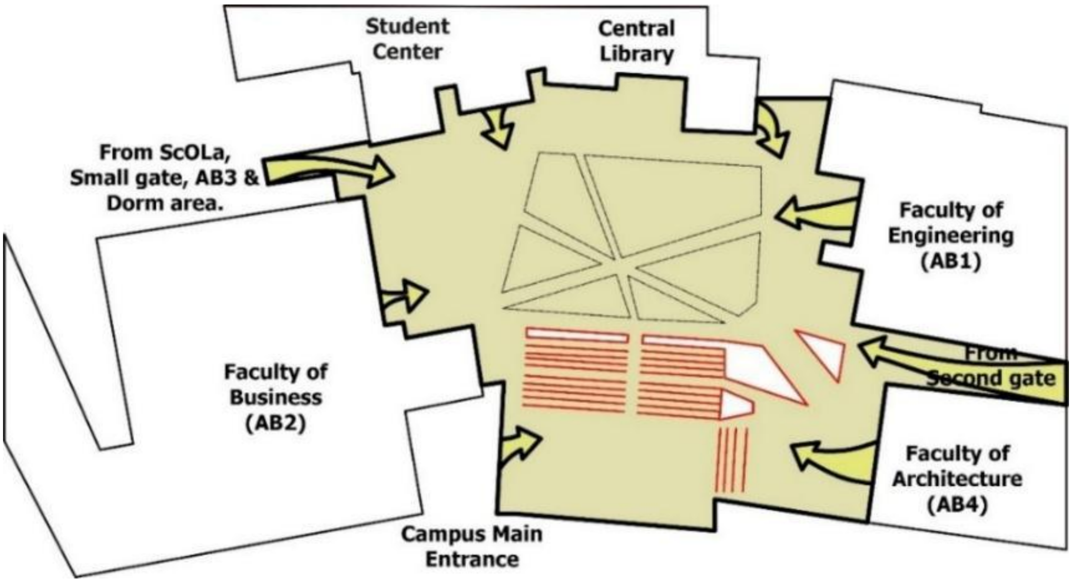

Fig. 5. The OzU Quad Accessibility (Source: Authors).

3.2. Behavioural Observation

In this study, behavioral observation—a systematic observation method and an effective tool for recording both stationary and dynamic human activities, as well as social interactions in outdoor spaces (Abu Elkhair et al, 2023)—was employed. The data was presented through tables and people-centered maps, which use cartographic techniques to capture patterns of social tasks and outdoor space use. The exercise was designed for a period of five workdays. The observations took place on Tuesday, April 16th, 2024; Wednesday, April 17th, 2024; Thursday, April 25th, 2024; Friday, April 26th, 2024; and Monday, May 6th, 2024 (intentionally excluding the weekends), this is to enable the observations to cover both students living on and off campus. The study is mainly interest in observing as much as possible variety of behaviours and activities, therefore observations were scheduled three times a day: mornings (9:00-10:00), lunches (12:00-13:00), and evenings (16:00-17:00), totalling 15 observation sessions -these are peak usage period of the spaces as it coincide with morning breaks, launch breaks and lecture closing periods respectively- although not primarily concern with population. Another important issue is the ability to observe and record in all 6 parts of the quad within a very short period. Since the study deals with both active and passive behaviours, there is a need to cover all portions within a short period of time, because the change in behaviour or even position may occur, which can cause double counting and distorted mapping. However, video recording and picture taking were employed to reduce such challenges, which were handled ethically by keeping safe and ensuring that none of such recording is disclosed to the public. The observations recorded all behaviours including; individual -such as using mobile phone- and group -such as club events-, regardless of all other categorization; Real affordances and Perceived affordances (Yilmaz et al., 2017), passive and active (Ozbil et al., 2018), Improvised and Serendipitous (Stevens et al., 2023), however, *dominant* (those that occur many times), and *present* -those that occurred few times- (Bechtel, 1989) were later sorted out for analysis. As shown in Fig. 7, the following affordances were observed as individual behaviours in each of the six portions of the quad; *walking/standing* were put together as one behaviour; *sitting* on a bench, lawn or any other object/surface; *Sunbathing*, those laying down under the sun on any surface or object; *eating* any kind of food; *drinking coffee*, for those holding any drink container; *observing people and activities* meant for those looking at one places in a thinking posture; *Listening to music* is for those wearing earpiece/headphones; *smoking*, holding any type of cigarettes; *Taking pictures*, holding/posing with a camera or mobile phone; *Using mobile phone* for those on phone call, or looking at computer, phone or tablet screen; *reading* for those holding/looking at any type of paper. There are also instances when more than one behaviour was observed in the same place and time, the situation termed "niche" by Gibson (Li, 2013). Some group activities recorded include meeting with friends, sports/gaming, club activities, music/dance performances, International/cultural events, and campus activities, such as homecoming not located on the map but separated in a table presented in the results section.

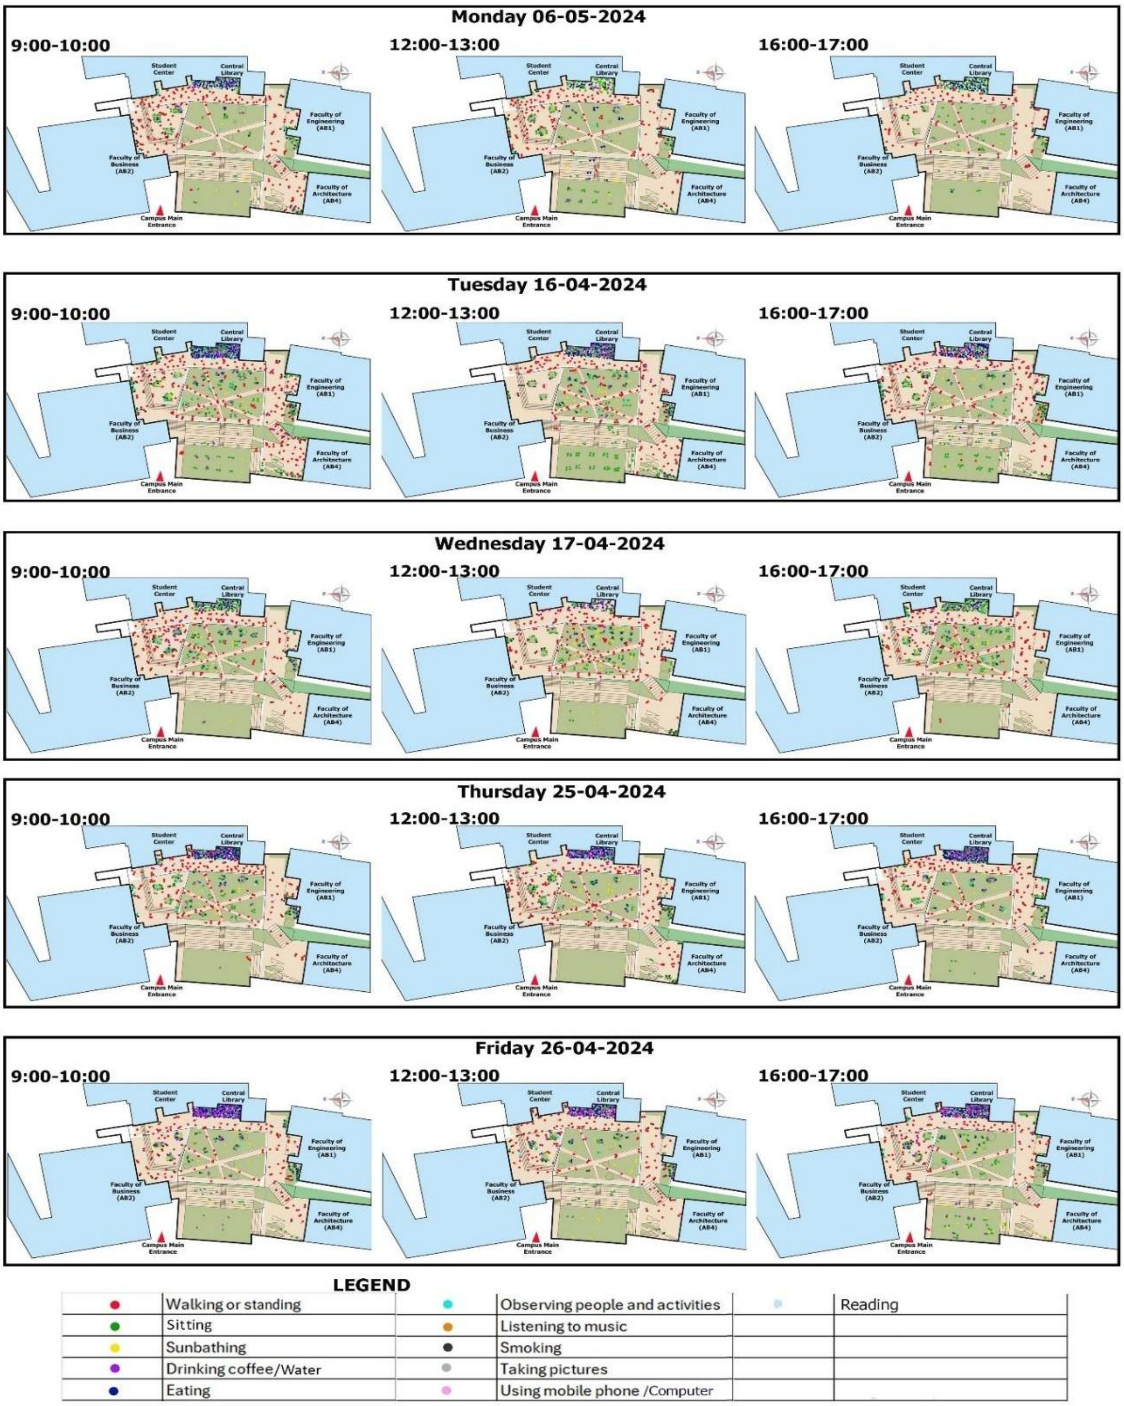

Fig. 7. Behavioural mapping of observed behaviours (source: Authors).

3.3. Survey/Interview

The study was limited to only the students of the Ozyegin University because they make the highest population of users in the space (Ozbil et al., 2018), and no age or gender restriction whatsoever. An interview was conducted to 17 students randomly selected from various departments and nationalities both physical (7 participants) and online (10 participants), the choice for online or physical is attached to the interest of the participants. As the online participant avail their contacts for online participation for reasons only known to them. This interview was made up of 12 guiding open-ended questions regarding students' satisfaction and mental well-being of the quad, the participants were asked to take part in one-on-one chat sessions lasting about 20 to 35 minutes. Based on their consent, they were asked to share their experiences and perceptions of the OzU Quad regarding the spatial configuration, physical elements, design and activities in the spaces (excerpt of the data is presented in the data presentation section). The data was analysed using thematic analysis to identify common ideas.

4. Results

4.1. Behavioural observation result

The overall observed activities across six Quad portions (Q1 to Q6) revealed varied patterns of space use. Walking or standing was the most frequent activity overall, particularly in Q1 (473) and Q3 (307). Eating and drinking coffee were also prominent, especially in Q1, with 475 instances of eating and 350 of drinking coffee. Sitting was highly observed in Q3 (194) and Q5 (133), indicating preferred zones for rest. Sunbathing was most common in Q3 (106) and Q5 (46), suggesting these quarters provided favorable conditions for relaxation. Smoking had notable peaks in Q2 (131) and Q4 (154), while the use of mobile phones or computers was fairly distributed, with the highest count in Q5 (59). Observing people and activities, though less frequent, was observed most in Q4 (50). Less common activities included taking pictures, listening to music, and reading, with the latter being the least observed across all quarters. This has been graphically illustrated in Fig. 8 below.

Table 4. Cumulative observed behaviours for each portion Q1 to Q6 (Source: Authors).

Behaviours/Spaces	Q1	Q2	Q3	Q4	Q5	Q6
Walking or standing	473	198	307	276	6	118
Sitting	107	25	194	113	133	25
Sunbathing	8	4	106	16	46	4
Drinking coffee	350	36	95	54	15	11
Eating	475	19	88	19	4	0
Observing people and activities	54	22	38	50	2	1
Listening to music	7	8	29	6	1	0
Smoking	89	131	53	154	1	52
Taking pictures	12	15	15	10	3	4
Using mobile phone/computer	99	35	49	45	59	10
Reading	11	5	6	4	2	0

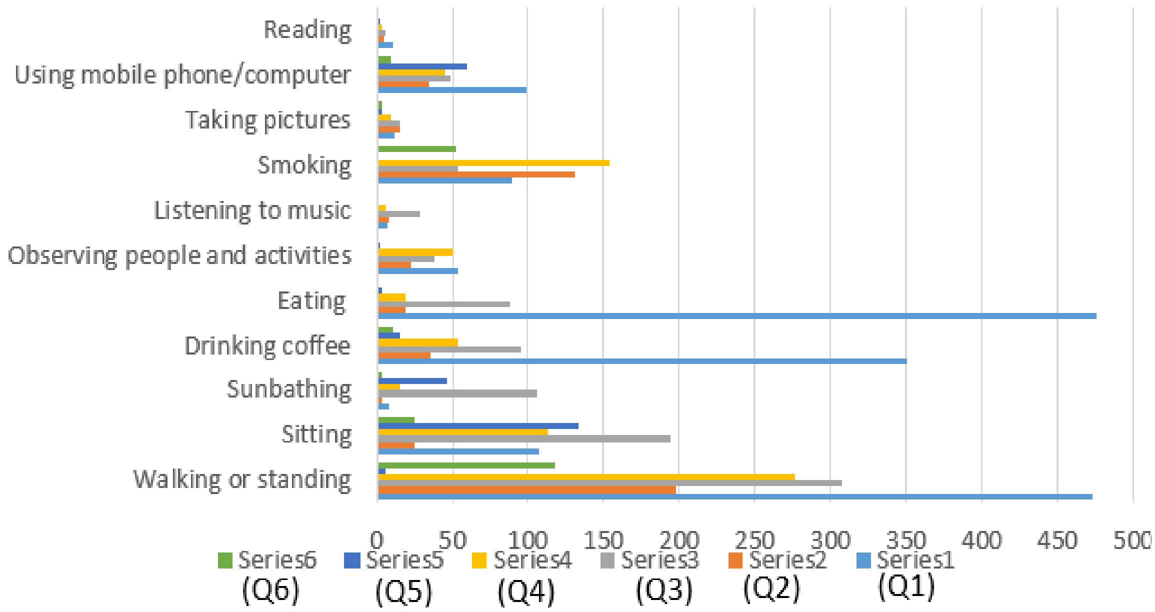

Fig. 8. Behavioral counts and the spaces (Source: Authors).

From another perspective, an analysis of behavioral variety across the six quarters reveals distinct differences in how each space is used. Portion 1 (Q1) demonstrated the highest diversity and volume of activities, with high counts in walking or standing (473), eating (475), drinking coffee (350), and mobile phone/computer use (99), indicating it as a highly active and multifunctional space. Portion 3 (Q3) also showed a wide range of behaviors, particularly in sitting (194), sunbathing (106), and moderate levels in most other activities, suggesting it supports both relaxation and light social engagement. Portion 4 (Q4) exhibited a balanced mix of behaviors with noticeable counts in smoking (154), observing people (50), and sitting (113), reflecting a socially interactive environment. In contrast, Quarter 2 (Q2) had fewer types of high-frequency activities, dominated by walking or standing (198) and smoking (131), suggesting a more transitional or utilitarian use. Portion 5 (Q5) showed specialization in more passive behaviors such as sitting (133), sunbathing (46), and mobile phone use (59), indicating it may offer comfort or amenities conducive to longer stays. Portion 6 (Q6) exhibited the lowest activity levels and behavioral variety, with only modest counts across most categories, suggesting it may be underutilized or less inviting for diverse public use.

4.2. Evaluation of the sub-areas.

Student Center Entrance (Q1) **-**Fig. 9**-** is an area totalling 1,139 m² (7:1 floor to wall ratio), which connects to the Student Center, Café Nero, Central Library, Scola/hostels, and Quad portions Q2–Q4. With an axial, clearly defined 6.7 m-wide paved pathway – finished with ebony granite stone- with flowerpots, making a 2% vegetation cover separating pedestrian space from Café Nero. The 33% shaded area of the portion has 55 outdoor dining chairs, 11 wooden garden chairs and 3 backless metal benches with quite several ashtrays. This area acts as a transitory threshold between social, academic, and commercial spaces. The strong axial pathway ensures efficient pedestrian movement, while minimal vegetation and furniture indicate a focus on circulation over lingering. Despite limited greenery, decent shading (33%) offers some environmental comfort. This has been demonstrated by the highest diversity and volume of activities recorded, with high counts in walking or standing.

The Faculty of Engineering Entrance (Q2) in Fig. 10 occupies an area of 997m² and serves as a primary access point to the Engineering building (AB1), the Central Library, and adjacent zones including Q1, Q3, and Q6. It features a wide, flat 10-meter paved surface made of natural and cobblestone materials, with shrubs adding subtle greenery (8:1 floor-to-wall ratio). However, the space lacks defined walkways, resulting in a broad open layout that allows flexible circulation but may reduce clarity in pedestrian movement. With a moderate vegetation cover of 16.7% and shading at 32%, the environment offers a fair level of comfort, although the presence of only three furniture units limits opportunities for rest and interaction. According to the observed data, this portion had fewer high-frequency activities, dominated by walking or standing and smoking, suggesting a more transitional or utilitarian use.

Fig. 9. Views of the Student Center entrance (Q1) (Source: Authors).

Fig. 10. Views of the Faculty of Engineering Entrance (Q2) (Source: Authors).

Fig. 11. Views of the Central Area of the Quad (Q3)(Source: Authors).

Fig. 12. Views of the Faculty of Business bank (Q4) (Source: Authors).

The Central Area (Q3), Fig. 11, spans 2,020m² and stands out as the most interconnected zone on campus, linking all other major spaces from Q1 through Q6. Its circulation is defined by a network of linear walkways ranging from 1.8 to 3 meters wide, converging at the center to create a strong sense of orientation and movement. The area is open (with floor-to-wall ratio of 47:1) and notably lush, with a high vegetation cover of 60%, which enhances its visual appeal and environmental quality. However, despite its greenery, shading is minimal at just 3%, leaving the space largely exposed to sunlight, particularly during hot seasons. Q3 is well-furnished with 17 seating units of movable picnic benches and fixed wooden platforms, encouraging various social behaviors. The presence of natural stone walkways, grass, and wood contributes to a warm and inviting atmosphere. Observations indicate diverse activities taking place here, including sitting, sunbathing, and moderate social engagement, positioning Q3 as both a dynamic movement hub and a relaxing green oasis.

The Faculty of Business Bank (Q4), an area that covers 1,134m² and is defined by a relatively high degree of enclosure, with a floor-to-wall ratio of 6:1. It connects directly to the Faculty of Business (AB2) and neighboring zones Q1, Q3, and Q5, making it a moderately accessible space within the campus layout. The entire area is paved and features five shallow steps (0.1 meters each) on three sides, contributing to a sense of layered movement but potentially posing challenges for universal accessibility (Fig. 12). Vegetation and shading are limited at just 4.3%, which may affect user comfort during hotter parts of the day. Despite this, Q4 is densely furnished with 20 fixed and movable seating units (metal and wooden backless benches), making it one of the more populated zones in terms of furniture. The material usage—natural stone, wood, and patches of grass—adds texture and warmth to the space. Observational data indicate a socially active environment, with high instances of sitting, people-watching, and smoking, suggesting that Q4 functions effectively as a social pause point, particularly suited for short-term stays and casual interactions.

The Lower Quad (Q5) spans a generous area of 2,335 square meters and serves as a key transitional and recreational space, connecting the campus main entrance with zones Q3 and Q6. Its circulation design is defined by stepped walkways, with 1.7-meter-wide paths seamlessly integrated into the stepped spectator seating, creating opportunities for both movement and passive engagement. The space boasts a high vegetation cover of 54.4%, contributing to its visual appeal and sense of calm (Fig. 13). However, it lacks any form of shading (0%), which can significantly impact user comfort, especially during hot or sunny weather. With 10 picnic furniture units distributed across the lawned space and a material consisting of natural stone and wood, Q5 presents a warm and earthy atmosphere. Observations revealed limited behaviours mainly in the passive category, such as sitting, sunbathing, and frequent mobile phone use, suggesting that this area supports relaxed, informal occupancy. Its layout and use patterns indicate that Q5 functions as a multifunctional open space, ideal for resting and potentially hosting casual or impromptu gatherings.

Fig. 13. Views of Lower Quad (Q5) (Source: Authors).

Fig. 14. Views of the Faculty of Architecture entrance (Q6) (Source: Authors).

The Faculty of Architecture Entrance (Q6) covers 1,196 square meters and provides access to the Architecture building (AB2) while connecting to Q2, Q3, and Q5 zones. Its circulation is anchored by an 8-meter-wide stepped walkway leading to Q2, with the remainder of the space fully paved, creating a formal and direct entry experience. The space integrates 14% vegetation cover alongside high shading at 52%, making it one of the more comfortable zones in terms of environmental protection. Material usage—granite, steel, glass, and grass—reflects a contemporary design language (Fig. 14). Despite these qualities, the area contains only three fixed granite seating units, limiting opportunities for rest or social interaction. Observational data recorded the lowest activity levels and minimal behavioral variety, suggesting that Q6, while aesthetically refined and functionally direct, may be underutilized and lacks features that encourage lingering or diverse public engagement.

4.3. Demographic data

The biographic data of the participants shows a good representation of gender, age, cultural background and level of experience and stay at Ozyegin University. Regarding gender, as seen in Fig. 6 above, 52.9% of the participants are female, which is nearly half of the sample size, and the remaining 47.1% are male. In terms of age, the data in Fig. 15 shows that even though there is representation of each age range, most of the respondents (41.2%) are between the ages of 21 and 25, followed by 35.3% which are between 26-30 years, then 31-35 years and those below 20 years each category has 11.8%.

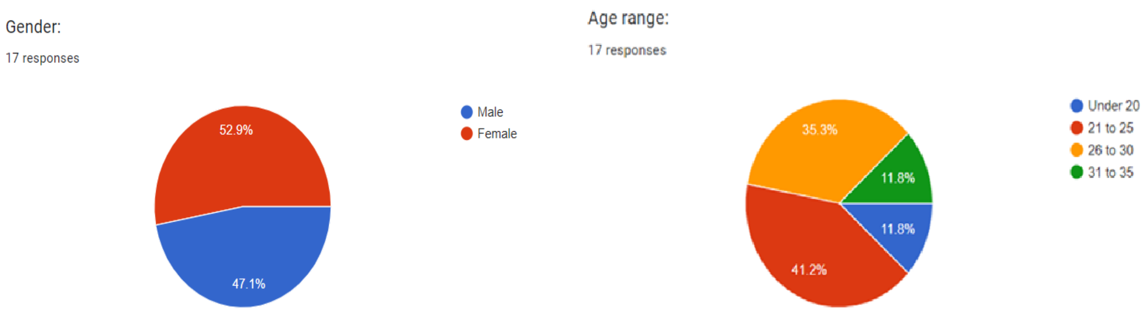

Fig. 15. Demographic data of the interview participants (Gender and age) (Source: Authors).

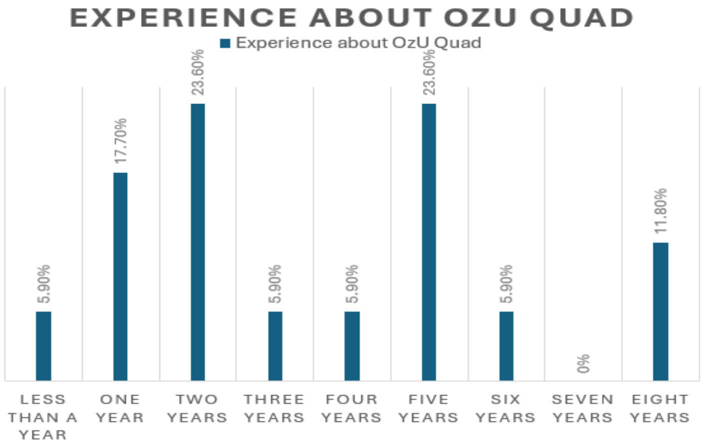

Fig. 16. Experience or duration of stay in Ozyegin University (Source: Authors).

Fig. 16 above is a bar chart about the experience or duration of stay in the University by the participants, those with 2 years and 5 years have 23.6% each, then those with 1 year have 17.7%, followed the 11.8% for 8 years, while 3 years, 4 years, 6 years and those with less than a year have 5.9% each. The participants were also a mix of varied cultural backgrounds available on the campus, consisting of Turkish, Nigerians, Ghanaians, Iranians, Iraqis, Bangladeshi, Jordanians, Mauritians, and others.

The data further reveals three categories of participants: Frequent visitors, Occasional or Rare Visitors, and Non-Visitors. Perception of all is important as it will contribute to answering the research question. According to Bagais (n.d.), people's personal characteristics, experiences, and intentions can have influence on how they perceive and respond to the affordances in their environment. He identifies sub-factors like age, personality, and familiarity with space mediators of affordance perceptions. According to the data, several participants visit the Quad frequently, favoring specific spots for various reasons. For example, some respondents prefer quieter sections, like the area near the Faculty of Architecture and Design or the lower Quad, which is described as more peaceful and less crowded. The area near the Student Center or around Café Nero is popular because it's a central meeting place that allows easy socializing. Some respondents mention the banks near the business building or grassy areas, noting their spaciousness and a more relaxed atmosphere. For occasional users, these respondents tend to pass through the Quad without spending much time there or only visit occasionally. They tend to seek less crowded spots when they visit, preferring quieter corners or shaded areas. A few participants mentioned they like to visit the lower Quad when it's less busy, allowing them to have a coffee or relax without much disturbance. For the non-visitors, a few participants indicated that they don't visit the Quad at all or rarely do so, without providing specific reasons. Some mentioned they feel comfortable anywhere on campus, suggesting that the Quad isn't particularly significant to their campus experience. The majority of the frequent users seem to appreciate and decode the affordances given by the spaces regarding accessibility, sociability, comfort and activities.

5. Discussion

Two recent studies (Şen et al., 2020; Ozbil et al., 2018) related to OzU are both more quantitative in nature because they integrate space syntax analysis with behaviors, which prevents them from being able to look in depth at the variety of behaviors in this area, which makes Ozbil et al. narrow down the behaviors to only two categories (passive and active). Şen et al (2020) focused on the population of users and not mainly on behaviors. Therefore, using affordance theory in this study revealed the presence of variety of affordances and niches (Li, 2013) including the real affordances & perceived affordances (Yilmaz et al., 2017), passive and active (Ozbil et al., 2018), improvised & serendipitous (Stevens et al., 2023), dominant and present (Bechtel, 1989), reflexive, reactive, reflective (Kannengessier & Gero, 2012), hidden and false affordances (Gaver, 1991, as cited in Li, 2013) resulting in different behaviors depending on the location and characteristics of both users and the environment. The characteristics of the environment including aesthetic value (Guo, et al., 2023), space organization (Abu Elkhair et al. 2023; Ozbil et al., 2018) as we have seen, proximity, location and accessibility played a role in making areas such as the front of student centers (Q1) and the central area (Q3) very active and containing the most behaviors due to their proximity to both social, academic and commercial areas. Design elements also contribute significantly to the health, well-being and affordances of urban open public spaces, as Ozbil et al (2018) and Bressane et al (2024) have shown, we have seen how design elements such as integrated walkways, and the number and types of seating or other objects encourage or discourage certain affordances. Natural elements such as grass and water features have also been shown to be beneficial when it comes to environmental affordances as Bressane et al (2024) has shown, similarly during the interviews some of the occasional visitors and non-visitors pointed to absence of natural elements such as water features as being among the things that make them less concerned about using spaces. While frequent users pointed to greenery as one of the objects that attracts them to the place. On the other hand, survey results also showed the relationship between individual/group characteristics (Bangis, nd.) and affordances. Rietveld et al (2013) reported that shared norms, activities, and meanings associated with a space can enable or constrain certain behaviors and interactions. However, some of the non-users could not give a reason for that, a number of them also indicated that many other places on campus could provide them with what the Quad would provide, and some occasional visitors related their usage pattern to the number of people, climatic conditions, or their mental state. Some of the frequent users acknowledged that using the OzU quad when they were under stress helped them in relieving stress, this aligns to the findings of (Bressane et al, 2024; Darma et al, 2023 & Shahmiri et al, 2024) on exposure to green spaces and reduction of stress and alleviation of anxiety and boost productivity. Generally, this indicates challenges of social inclusivity due to the existence of occasional users and non-users among students. Additionally, there are indications of under-utilization and concentration of behaviours, which were also reported as 'overcrowded' by Ozbil et al (2018). It is evident in an imbalance of behaviors and affordances that some parts of the Quad possess, for instance, the difference between the behaviors and affordances observed in front of the student center (Q1) or central quad (Q3) and the lower quad (Q5) or front of the architecture faculty (Q6).

The primary objective of this study is to explore the affordances that OzU quads have on students in schools by looking at their behavior in this environment and the qualities of this environment, which together will allow us to understand the affordances that are encouraging and those that are discouraging. Additionally, this will allow us to identify issues of social inclusion, concentration of behaviors, and underutilization. To foster more inclusive and dynamic public urban spaces, a multifaceted approach is essential. Promoting social inclusion begins with designing for diversity by incorporating flexible seating, shade, interactive and more natural elements that accommodate various user needs across age, culture, and ability. To disperse concentrated behaviors, amenities such as seating and shading should be evenly distributed, and spatial designs should offer a mix of quiet zones, social hubs, and transitional paths. Lastly, under-utilization spaces can be revitalized by enhancing comfort through improved shading, greenery, and ergonomic furniture, activating them with occasional events or art installations, and improving signage to guide users towards these areas, making them feel more inviting and purposeful. Participatory design and occupancy evaluation are also useful things as Ozbil et al (2018) suggest.

This study was conducted within a limited period (5 days of observations) within a specific season of the year -the fall of 2024. Expanding this period to cover the whole year might reveal more seasonal or occasional usage affordances. It is also recommended that conducting studies of this nature relating to affordances should be on a regular basis in outdoor spaces so that they can help to understand the use of the space and identify problems that occur as a result of usage and behavioural change to improve its social capability and efficiency.

6. Conclusion

Affordance theory is a very useful tool for understanding human behavior and how they interact with their environment. This study explored social affordances that encourage behavior in Ozyegin University central square (OzU Quad) to improve its social quality, which is very important for students' social and mental well-being. The findings of this study were based on behavioral observation and mapping, which allows evaluation of social affordances that cause these behaviors. In-depth interviews were also conducted with some of the students to hear their experiences and the influence of the environment on their social well-being. The results concluded that spatial organization, especially the proximity and location of facilities, plays a significant role in creating the environment's affordances. The same applies to objects in the environment, for instance, areas with fewer seats that afford movements and discourage social behaviors such as relaxing and other passive activities. Furthermore, the results showed three basic categories of students which include frequent visitors, occasional visitors, and non-visitors, this is associated with reasons related to overcrowdedness, and the lack of certain natural features such as water bodies, etc. This shows a need to promote social inclusivity and address challenges of concentration of behaviors and under-utilization by providing flexibility in the design and arrangements of objects, and improving signage, shedding, etc. Participatory design is also essential as it will allow users to organize the environment based on their needs. Finally, there is a need for further research, especially considering that this study was conducted within a limited time, thus a need for the future research to cover the entire year, as there may be affordances and additional information due to climatic conditions and some annual social gatherings usage that were not captured during this observation. Additionally, research of this kind that deals with affordances is valuable and should be conducted regularly to better understand the relationship between behavior and the environment in light of how the world is changing, providing opportunities for improving the efficiency of the environment at all times.

A rock carving structure of Eymir Khan

Dilan Kakdas Ates[*1], Gülin Payaslı Oguz[1]

[1] *Dicle University, Department of Architecture, Diyarbakir, Turkiye*

Abstract. With the development of trade relations along the Silk Road and other trade routes, caravanserais and khans gained significance. These architectural characteristics were shaped by their periods' social, economic, commercial, and religious contexts. Since pack animals required rest approximately every 30-40 km, lodging facilities were built at these intervals. Caravanserais and khans provided accommodations, baths, stables, and services such as shoemakers, tailors, and dyers for travelers' needs. However, technological advances and the transition to motor vehicles replaced caravans, significantly shortening travel times and shifting trade into urban areas. Consequently, rural lodging facilities lost their purpose and became abandoned.
This study examines Eymir Khan, approximately 40 km from Gercüş in Batman Province, Southeast Anatolia. Constructed uniquely by carving into rocky terrain on a hillside, its exact construction date is unknown. The khan consists of two units: the central section is built from rubble stone adjoining the rock face, and another unit is considered buried underground. The building's condition was documented through site visits, detailed photographs, surveys, and architectural drawings. Its architectural features and preservation issues were identified, and recommendations for future conservation efforts were provided.

Keywords: Rock carving; Khan; Conservation; Construction system; Architectural heritage

1.Introduction

Rock-cut structures are unique in architectural history as physical and cultural expressions of humanity's relationship with nature. These structures emerged through the human manipulation of natural rock masses, designed to serve various purposes such as shelter, worship, defense, and trade. Unlike other construction techniques, rock-cut architecture is characterized by a subtractive approach, wherein rock formations are sculpted by excavation. Thus, it represents rare architectural examples created by removing rather than adding building materials (Pekin, 2014).

Rock-cut architecture has been widely utilized, particularly in regions with easily workable geological structures, such as volcanic tuff. The formation of these structures varies depending on local geological features, climatic conditions, and cultural dynamics (Dincer et al., 2020). This indicates that these structures' architectural forms and functional purposes are significantly influenced by their local context.

The Anatolian geography historically hosted significant trade routes, fostering the development of lodging structures like inns and caravanserais along these routes. These structures were more than temporary accommodation spaces; they became centers of trade, cultural exchange, and social interaction (Kılıçözlü, 1985). Particularly during the Anatolian Seljuk period, numerous caravanserais were built due to the flourishing trade, arranged systematically along important trade routes. Typically, these caravanserais featured a single entrance leading to a central courtyard surrounded by rooms accommodating people and animals (Burlot, 1995). Especially from the 11th century onwards, under Anatolian Seljuk rule, caravanserais evolved into key centers for commerce and social and cultural life (Köprülü, 1942). As cities expanded and trade shifted towards urban centers, inner-city versions of these structures emerged, known as "khan."

Three rock-cut, closed-plan khan structures were identified in a study conducted in the Southeastern Anatolia Region. These include the Eymir Khan in Batman Province, the Konak Khan in Diyarbakir Province, and the Merkez Khan in Mardin Province. When these khans are compared, the Merkez Khan is located in the Savur district of Mardin. Its construction date is unknown. According to information in the Savur Management Plan, it is thought to have been built in the 16th century, although no definite information has been found (SYP, 2016–2021). The structure in Gazi Neighborhood of Savur was constructed using rubble stone masonry. Except for the entrance façade, the remaining façades are attached to adjacent buildings and do not face the street.

[*] Corresponding author, E-mail: dilankakdas91@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_089

The structure is accessed through a semi-circular arched entrance gate with a non-original iron door. A column supporting the ceiling is located in the unit facing the entrance. This space is covered with a groin vault. The structure's central unit is divided into three naves by nine columns and was constructed using a rock-cut technique. A sealed doorway in this section is believed to have provided access to an adjacent room.

An additional structure was later attached to the original building, and entry to this section is through an iwan leading into rooms. The iwan is also covered with a groin vault. The structure shows significant similarities in plan and construction technique with the Eymir Khan, located approximately 25 km away in Batman.

Another example of a rock-cut khan is the Konak Khan located in Konak village of the Egil district in Diyarbakir. Much of the structure has collapsed in the present day. The construction date is unknown, and the building does not contain an inscription. It is currently used as a stable. The interior can be accessed through an opening on the north-facing entrance façade. The Diyarbakir Cultural and Natural Heritage Preservation Board (DKVKBK) registered the building in 2020. To the west of the entrance is a 2x3 unit, and to the east is a 5x3 unit. On the entrance façade's southern line, another space measuring 3x2 meters. The khan consists of a total of three units, which include rock-carved animal feeding troughs. The spaces are divided by rock-cut columns, and the passages between units feature low arches. Openings in the ceiling, believed to have been created for ventilation and lighting, are also present. This study aims to explore Eymir Khan as an example of rock-cut architecture developed within this historical context, examining its architectural, historical, and functional dimensions. By analyzing its construction technique, materials, and layout, this research will assess Eymir Khan's contributions to rock-cut caravanserai architecture in Anatolia. In this context, Eymir Khan will be thoroughly analyzed in terms of both its architectural characteristics and cultural and historical significance (Kakdas Ates, 2024).

2. Field Study

2.1. Location of Eymir Khan

Eymir Khan is located in the Southeastern Anatolia Region, within the boundaries of Eymir Village, affiliated with the district of Gercüş in Batman Province. Eymir Village is situated approximately 40 kilometers northeast of the Gercüş district center. Official records identify the khan structure as parcel 5, block 109. This information, sourced from the Batman Cultural Inventory published in 2017, classifies the structure as belonging to the Medieval period. One notable aspect of the building is the absence of any inscriptions, complicating the determination of its exact construction date. However, analyses based on architectural characteristics and construction techniques allow for some inferences regarding its historical period.

Eymir Khan distinctly differs from other regional inns in its construction technique. The rock-cut method in its formation enables the structure to blend harmoniously with its natural surroundings, providing an alternative example to local building traditions. Consequently, Eymir Khan surpasses its functional role as accommodation, standing out as a unique architectural exemplar (Fig 1).

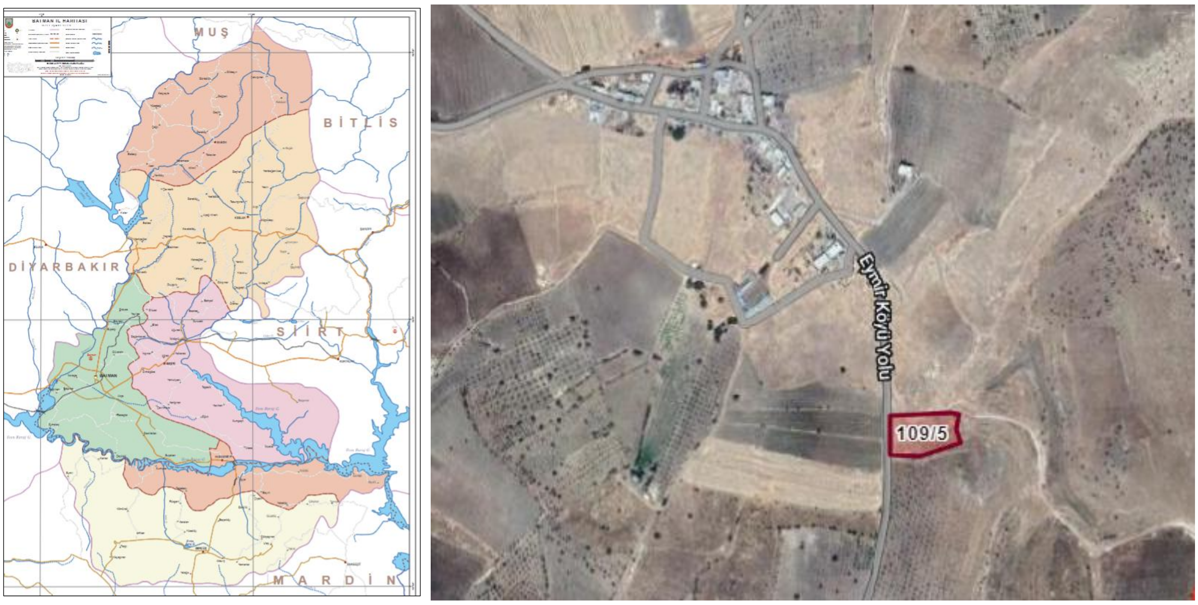

Fig. 1. Batman District Map (HGM, 2025), Location of Eymir Khan (TKGM)

2.2 Architectural Features

Eymir Khan features a simple yet functional layout consisting of two main units. The first unit served as a stable, while the second was designed for accommodating travelers. The section carved into the rocky ground is associated with its function as a stable, a hypothesis supported by on-site examinations. Particularly, the carved feeding troughs found within the space clearly indicate that this area was used for housing animals (Fig 2).

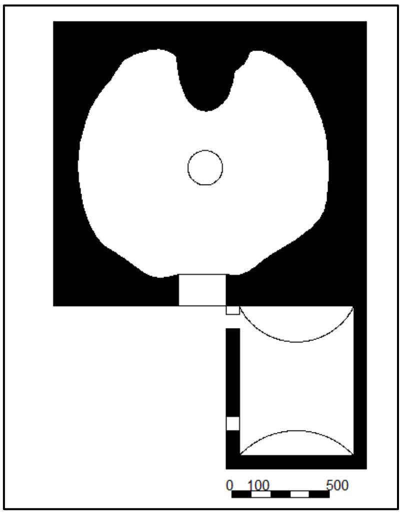

Fig.2. Plan Drawing of Eymir Khan (Author's archive)

Fig. 3. Photograph of Eymir Khan Entrance Door and Traveler Accommodation Unit (Author's archive)

The second unit, identified as the traveler accommodation area, was constructed using a different building technique. This section was built using rubble stone masonry rather than being directly carved into the rock (Fig 3). It features an entrance door and a small window, which provides lighting and ventilation. This window opening not only allows natural light to enter the space but also supports air circulation within the interior (Fig 4).

Fig. 4. Interior Photographs of Eymir Khan (Author's archive)

The coexistence of these two construction techniques indicates that Eymir Khan possesses a hybrid architectural character. While the rock-cut stable section was created by utilizing the natural features of the local geography, the rubble stone accommodation unit may have been added later or represent a different construction preference. This aspect is significant as it provides insights into the possible phases and transformations the structure underwent during its period of use (Fig 5).

Fig. 5. Photograph of Eymir Khan Entrance Facade and Top View (Author's archive)

3. Conclusion

Eymir Khan is an important example of how rock-cut architecture was applied in civil architecture, holding a unique place within Anatolia's historical and cultural heritage. Located in Eymir Village, affiliated with the district of Gercüş, the structure stands out for its integration with the natural environment and its combination of different construction techniques. The rock-cut section is stable, and the rubble stone masonry accommodation unit indicates that the building was designed with functional unity. Although the exact construction date remains unknown due to the absence of an inscription, based on its architectural features and building techniques, it belongs to the Medieval period. Eymir Khan can be regarded not only as a place of accommodation but also as an element that sheds light on its era's economic, social, and cultural structure. The study of the building reveals that it differs from other inns and caravanserais in the region and showcases an architectural approach tailored to local conditions. In this context, Eymir Khan provides important clues about the reflections of the rock-cut building tradition in civil architecture in Anatolia.

The preservation, documentation, and support of the structure through more comprehensive archaeological and architectural research are of great importance for both architectural history and the sustainability of cultural heritage. Future comprehensive studies will contribute to deeper analyses of the region's historic building stock and architectural diversity through examples such as Eymir Khan.

Analysis of design parameters in office buildings in terms of sustainability concept: The case of Ankara province

Salih Demirkaya*[1], Harun Tanrıvermiş[2]

[1] Ankara University, Faculty of Applied Sciences, Department of Real Estate Development and Management, Ankara Türkiye.
[2] Ankara University, Faculty of Applied Sciences, Department of Real Estate Development and Management, Ankara Türkiye.

Abstract. Office buildingss are among the pioneering architectural structures in terms of technological integration with significant energy consumption during both construction and operational phases. In addition to their structural features, the relatively high number of users and visitors causes energy consumption and therefore management costs to reach high levels in offices. Designing for lower energy use, integrating on-site energy generation systems, avoiding energy leaks and losses, and creating techniques for reusing otherwise wasted energy are all crucial tactics for achieving sustainability goals. System maintenance, structural improvements, and ongoing office space utilization are also essential for prolonging building lifespans and advancing sustainability goals. This study investigates the strategic operational decisions influencing office building management, how these decisions are reflected in design, and how spatial construction impacts energy conservation and operational costs. The research methodology includes a literature review on the economic dimensions of office sustainability, analysis of case studies, and field evaluations. Findings derived from interviews with office developers and designers in Ankara are compared with insights from the literature to assess alignment with sustainability criteria and identify design strategies that can reduce operational costs.Furthermore, the study proposes energy-saving solutions for office buildings. In the context of facility management of offices, attention was drawn to the spatial use decisions and the effects of the saving installations and systems used in them on energy costs. In this way, it is possible to increase awareness in sustainability studies by explaining the relationship between management cost and design. According to the results of the research, it has been revealed that significant energy savings are achieved with the rational use of design decisions taken in terms of energy use, this reduces the cost of management, and in this respect, sustainability can be achieved in terms of the use of office buildings, and also in terms of energy conservation, this situation serves sustainability due to its environmental effects. The research concludes with spatial solution proposals that enhance sustainability in office projects and outlines the advantages of sustainable design principles for both developers and designers.

Keywords: Office buildings; design parameters; management costs; energy use; sustainability

1. Introduction

The tendency to consolidate workspaces in public and private institutions necessitates the gathering of office workers from different walks of life and increasing accessibility. Offices are generally used in public areas with the increasing population mobility and urbanization effect. Office buildings, which are generally located in the city center; When evaluated in terms of aspects such as the line of work carried out, its capacity, the number of users and visitors, there are structures with high frequency of use (Demirkaya 2024). In particular, the high number of users triggers the energy consumption arising from the activities carried out, which also affects the operating cost and directly affects the return or profitability of the investment (Tanrıvermis & Tanrıvermis 2021).

Due to the fact that office buildings are large-scale investments, the measures that can be taken in terms of initial investment cost and usage opportunities have a significant impact on investment profitability. Strategic decisions and applications taken into account during the design phase are important in terms of the structural features of the building such as selected materials, installed systems, space organization, and the way the spaces are used. When this situation is evaluated, there is a need to determine the strategic design parameters that should be taken into account in investment decisions. In this study; By using the results of the resource research together with the in-depth interviews and cash results with investors, project developers and designers, the disadvantages

* Corresponding author, E-mail: Salih.Demirkaya@ankara.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_100

of existing office buildings were examined and it was possible to determine the issues that should be taken into account in new office projects to be built in the coming years. The results of the study are expected to be a guide for real estate developers, designers and investors.

2. Materials and methods

In the study, future design criteria and current usage characteristics for office buildings both in general and in Ankara were evaluated. In the study, data were collected by conducting in-depth interviews with office developers/investors and office designers. In this context, 10 people were reached as investors and 30 people as designers. It is considered that investors and designers, as important decision-makers in terms of design criteria and spatial expectations, play an important role in shaping the buildings, and that the building can provide significant energy conservation during the operation or usage period with the decisions to be taken in terms of sustainability and energy conservation.

Within the scope of the research conducted for offices with professional facility management located within the borders of Ankara province and offices managed at the independent department level and with traditional usage styles, opinions and data on both groups were reached. Care was taken to collect data for office buildings with different use, design and management features, and the findings were mutually examined. Since the office typologies that office users can prefer are predominantly in these two groups and each typology has its own usage characteristics and potentials, it is aimed to reach the data for the groups determined in the study. By evaluating the obtained data with a focus on facility management and sustainability, it is aimed to reach the basic design parameters for new projects and office investments that can be developed and designed in the coming years.

3. Literature

3.1 Research on building materials, population, and construction processes

Life cycle processes of a product; raw material acquisition, production of equipment, production of the product, packaging and distribution of the product, application of the product to the structure, use, maintenance and repair of the product, repetition of use, recycling or destruction of the product with the completion of its useful life (Tuna & Taygun 2011). Similarly, facility and building management starts with the birth of the project idea and covers many processes such as planning, feasibility studies, construction and construction process, use phase, demolition phase. The characteristics of each of these stages differ, but when their effects on each other are evaluated, they should be considered as a whole.

The production and use phases of building systems are defined by Gültekin (2006) as the extraction phase of the raw material, the production phase, the construction phase, the use phase, the demolition phase and the post-demolition phase (Fig. 1). In the use and production stages of the buildings, it is necessary to provide the needed energy, materials and resources. In these processes, which include highly dynamic and complex processes, all stages must be designed in a holistic manner in order to ensure the use of the buildings in a sustainable manner and a well-thought-out facility management strategy must be implemented in order to provide the necessary services to the users without interruption.

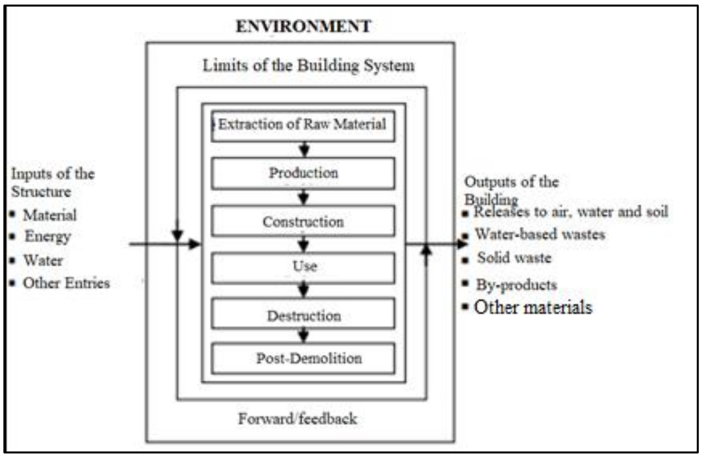

Fig. 1. Building system diagram (Gültekin, 2006)

Although the factors of facility management vary considerably, one of the most important issues is the construction of the systems, the organization of the space and the selection of the building materials that make up the space. At this stage, all factors and usage scenarios that may be encountered regarding the structures should be discussed in detail. On the other hand, the compatibility of the systems with each other, the level of exposure to external stimuli and the similar conditions of the technical benefits they provide have an impact on the economic life of the buildings.

The variety of uses and usage possibilities of building materials have been directly related to the proximity to raw materials for the traditional building production period. Issues such as the supply of raw materials, their use as building materials, transportation and processing have led to the emergence of construction styles according to the region and have been effective in the choice of use of materials. Building production has changed over the years, the way the materials used are brought together has changed due to aesthetic concerns in some cases, functional needs and technology used in some cases, and an improvement has been tried to be achieved in the production of building materials. With the development of technology, factors such as the diversification of the tools used in construction and the production of intermediate structural elements extended to the production of new building materials with the Industrial Period. It has been possible to transfer building materials and structures produced in a prefabricated style, and in addition to intercity and international transportation opportunities, construction technologies have evolved to robotic production technologies under current conditions (Fig. 2).

Fig. 2. The main properties of materials (Çorbacı, 2015)

With the increasing technology in structural production, it is clear that the energy requirement used in production is at a low level with less processing costs and there is a need for structural production with materials that can be found in the conditions of the production geography. On the other hand, it is noteworthy that the degradation and maintenance needs of the materials in its geography are at a lower level than other structural systems and the cost of use is low. It is noteworthy that materials that move away from naturalness with chemical and mechanical processing have negative effects on human health if they are used as building materials.

Air conditioning, which is provided by active and passive solar systems, which is one of the environmentally compatible building design criteria, is suitable for human health due to its naturalness, as well as reducing harmful effects on the environment. It is also understood by traditional architectural examples that solutions provided by natural methods are healthier. If the materials used in a building are produced or sufficient in the region where the building is located, they are healthier in functioning and creating internal climates as natural building materials determined by the climate of that region (Bozdoğan, 2003). In the past, 30-40% organic materials such as wood, straw and reed and 60-70% inorganic materials such as adobe, stone, tile and lime were used in buildings, but today 90-100% artificial materials are used and healthy spaces cannot be created in terms of environment and people (Akman, 1999).

It is noteworthy that the world population has increased more than 4 times in the last century, and under current conditions, the world population is 8 billion people (Anonymous, 2025). The fact that this increase was only 2 times in the previous century reveals the importance of the issue. The increase in the need for the built environment also reveals the need for an increase in the artificial environment with the technological developments. It should be noted that with the increase in the world population, there is a need to increase the presence of the built environment such as housing, workplaces, and social centers (Fig. 3).

It is noteworthy that in the face of the increasing population, the production rate has increased in order to meet basic needs such as food, accommodation and creating a living space. It should also be noted that the concept of sustainable emerged in this way. Meeting the housing and structural needs of the growing population is also seen as a necessity, as well as the consumption of natural resources is intense.

With the increase in the population, it is expected that there will be an increase in the number of built spaces used and the total usage area. This increase is realized both at the level of the built area per capita and with the diversification of collective living spaces that emerge with the increasing population. It is an issue that attracts attention in urban living spaces where the need for indoor space that people need increases with increasing technology. For example, although the areas where the need for sports is met in rural areas are places such as open fields, fields or roads that are not frequently used by vehicles, there is a use of areas where structural production is needed, such as landscaping and indoor sports centers, in urban living conditions. When evaluated in terms of residences, relatively small-scale buildings are produced in rural areas, while there are more intensive uses in urban living areas, as well as the presence of many gathering places such as bus terminals, cinema and theater halls, museums, recreation areas, work centers, offices, factories, logistics and storage units and public transportation centers as the meeting point of the masses, is similarly effective in increasing the amount of buildings. It should be noted that this situation is related to the use of technology and the increase in the needs arising in urban development.

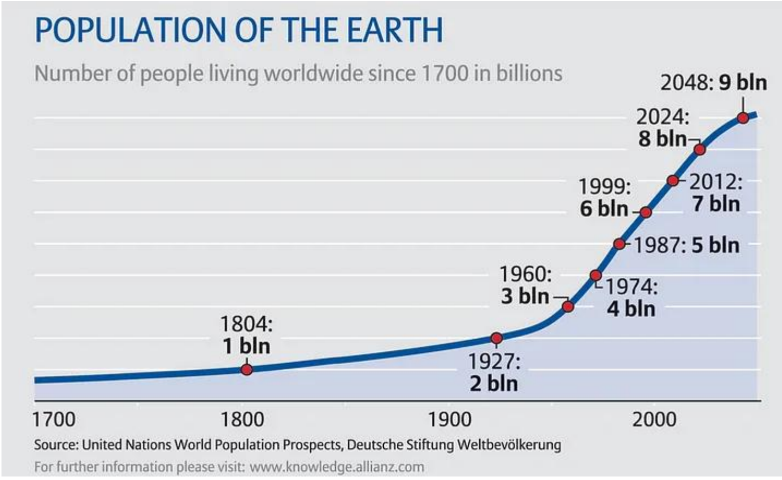

Fig. 3. The growth trend of the world's population (Anonymous, 2025)

With the increase in population presence and the diversification of usage needs in building production, there is a significant differentiation in the building materials needed for the use of space. The consumption of cement as a building material brought to the building sector by the Industrial Age has been compared with the population growth, and the increase in the amount of consumption, which has almost doubled in the last ten years, is almost equal to the increase in the period of about seventy years until ten years ago. This situation is an important proof that there is a lot of weakness in ensuring sustainability in building production. So much so that it is known that as a structural binder that cannot be easily reused, the damage caused by cement to the environment during the production phase is at a very high level.

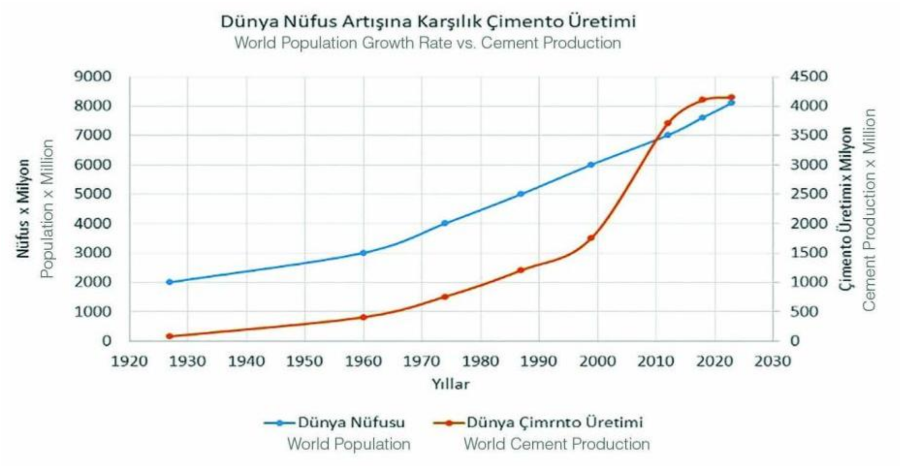

Fig. 4. The relationship between world population and cement production (Anonymous, 2024)

Heat island effect; It is the increase in the temperature in the city center by 2-3 °C during the day compared to the rural area by means of the solar heat stored on the roof and walls of the building. Increasing temperature is the cause of global warming (Oren 2010). Heat islands that emerge as a result of urban construction have an effect on the climate structure and regionally increasing temperature generally has negative effects on comfort conditions. This situation necessitates the control of the ambient temperature, and therefore energy consumption varies according to geographical regions and seasonal effects for this control.

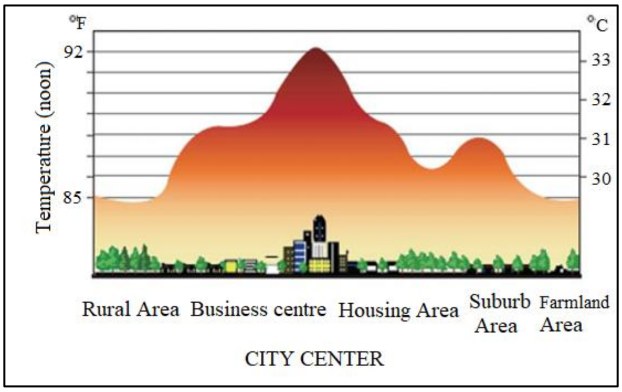

Fig. 5. Temperature changes in different regions with the heat island effect (Ören, 2010)

1.2. Examining energy use in offices
In the study conducted by Yalılı Kılıç & Yahşi (2019), the amount of energy consumption between classical office use and green office use was compared. In the comparison made regarding the use of electricity, natural gas and water, it was evaluated that the use of green offices was relatively less. This is considered as clear evidence of the contribution to the operating cost.

Table 1. Comparison of the use of electricity, heating and cooling systems of classical and green offices (Yalılı Kılıç & Yahşi 2019)

Product	Usage Amount - Classic Office	Usage Amount - Green Office	Savings Made (%)
Electricity	17,071.51 kWh/yıl	6,566.16 kWh/yıl	61.54
Natural gas	6,574 m^3/yıl	1,622.4 m^3/yıl	75.32
Water	833.28 m^3/yıl	275.52 m^3/yıl	66.94

In the examination of energy consumption for office buildings, energy consumption rates arising from heating, cooling, lighting, use of pumps, fans and machine use were examined. According to the results of the study, it was evaluated that the highest energy consumption was realized for lighting with 38%, heating with 24% and cooling with 19%.

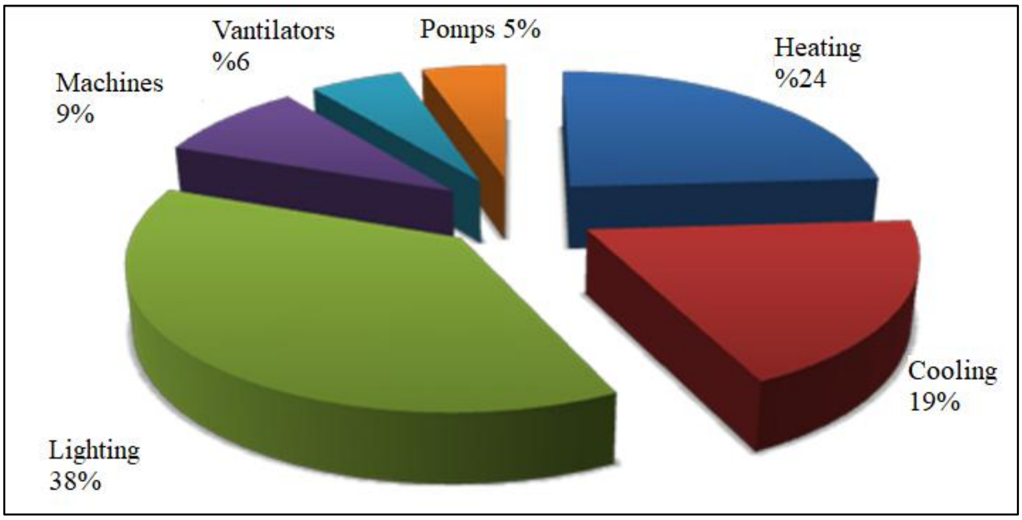

Fig. 6: Shares of energy consumption groups in total energy consumption (Ören, 2010)

In the study conducted by Ören (2010), the effect of daylight consumption on energy consumption was examined and the change in the amount of energy consumed for heating, cooling and lighting actions was simulated through the same structure. According to the results obtained, the total energy use rate of heating decreased by 27.5% for lighting and decreased by 12.5% for cooling processes, while the share of heating in total consumption increased by 12.8% (Figure 7).

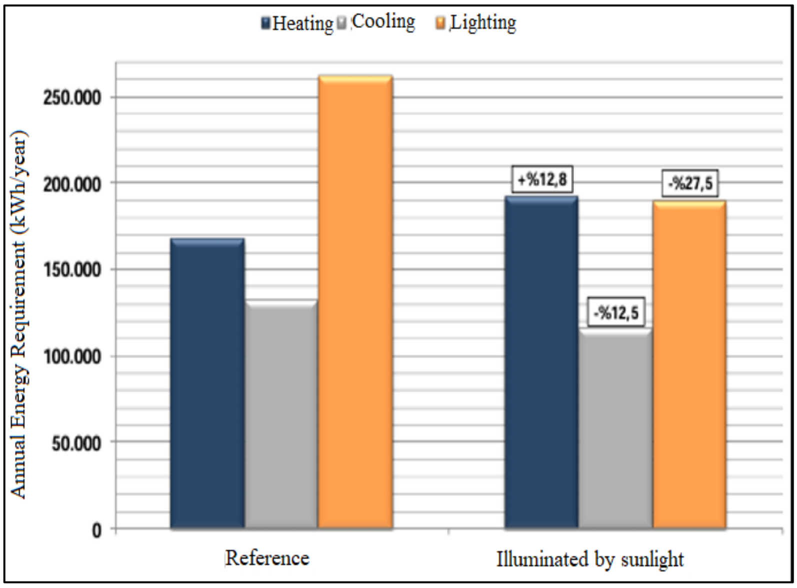

Fig. 7. Impact of daylight lighting on energy needs for reference building (Ören, 2010)

The amount of energy use needed for offices differs according to the units, the time spent in the units and the frequency, duration and form of use of the spaces. The spatial setup strategy is provided correctly and the needs-oriented design of the systems in the spaces have an impact on the amount of energy consumption. The amount of savings achieved through rational analysis is also reflected in the operating cost, which has an impact on the level of profitability for investments. In the study conducted by Erkin (2012), according to the simulation results of energy performance and saving calculations, the results of energy saving and lighting control and lighting energy performance and saving calculations for the office building with a total usage area of 12,170 m^2 were revealed. Accordingly, while 53.6% savings can be achieved with the energy saving model, 68.4% energy savings are achieved with lighting control (Table 2).

Table 2. Analysis of use according to energy control alternatives (Erkin, 2012)

Indicators	Current Status	Energy Saving	Lighting Control
Parasitic Power (W)	0	0	5.153
Parasitic Energy (kWh)	0	0	45.138
Lighting Installed Power (W)	240.959	107.180	107.180
Lighting Installed Power (W)	505.407	225.891	113.889
Total Electrical Energy (kWh/year)	505.407	225.891	159.026
AESG (kWh/m^2.year)	41,5	18,6	13,1
Energy Saving (kWh/year)	-	271.069	345.536
Energy Saving Rate (%)	-	53,6	68,4
AETG (kWh/m^2 year)	-	22,3	28,4
Investment Cost [TL]	-	205.860	358.530
Payback Period (years)	-	2,9	3,9
AETEG	-	1,32	0,96

The level of energy use in buildings varies depending on many variables such as the functions of the buildings, the intensity of use, the type of structural system and filling material, the location of the buildings and the selected mechanical and electrical installations. According to the data of the American Department of Energy (Anonymous, 2009), it is noteworthy that energy use differs at the level of installations used within the buildings as well as the building function.

Table 3. Total energy use distribution according to the functions of buildings (Anonymous, 2009)

Type of Consumption	Housing (%)	Office (%)	School (%)	Hospital (%)
Heating	43.1	35.3	47.4	37.5
Cooling	10.2	9.6	9.6	7.5
Lighting	5.9	24.9	13.8	17.6
Hot water	20.4	2.2	7.0	16.1
Other equipment	9.4	9.4	4.6	2.5

It is considered that the possibility of lighting is an important cause of energy consumption for office buildings. In particular, the right and desired light is needed for working environments, and in order to work in a concentrated manner, it is necessary to provide homogeneous lighting and therefore lighting control must be carried out. In the study conducted by Onaygil et al. (2005), energy consumption for lighting purposes and the share of lighting in total consumption were analyzed for office buildings with different sizes and usage possibilities. It was understood that the total energy consumption share and the amount and share of energy consumption for lighting purposes varied according to the characteristics of each building, and the share of energy used for lighting in the total for the buildings examined was in the range of 10.0-27.1% (Table 4).

Table 4. Energy use data of different buildings used as offices (Onaygil et al. 2005)

Building number	Construction area (m^2)	Lighting Power (W)	Annual lighting consumption (kWh/year)	Share of lighting (%)
Office-1	9.924	121.858	275.529	21,2
Office-2	12.997	145.523	341.425	23,9
Office-3	10.200	122.100	997.764	16,7
Office-4	18.000	260.239	654.409	21,0
Office-5	17.022	181.483	605.420	10,0
Office-6	35.295	255.525	710.518	13,1
Office-7	25.000	244.071	779.592	27,1

According to the results of the research, it has been evaluated that the comfort conditions of the users are suitable if the appropriate air temperature in the office environment is 21-22 0C and the humidity is in the range of 40-65%. In addition, if human movements, mechanical movements and structural elements such as doors and windows are open, it is inevitable to have air mobility in the working environment. For this reason, it should be noted that the speed of air movement, especially within the scope of ventilation of the environment, can be effective in distracting the attention of the employees. It should be noted that the optimal level of air movement for office workers may be appropriate if it is 0.10-0.15 m/s (Karaoğlu 2014). In order to provide the office comfort conditions within the specified scope, it will be necessary to operate the automation systems according to the comfort condition range, and therefore to use energy continuously in cases where the environmental variables are intense. However, if a sustainability-oriented design is made in the context of smart building and smart environment design criteria, it will be possible to provide comfort conditions with passive methods. In this respect, it is necessary to consider not only the building used, but also the climatic conditions, the building environment and the characteristics of the building biology.

It is known that the amount of energy used varies according to the working units. It is necessary to carry out special studies for each structure in order to construct energy management for offices. The plan system and spatial organizations of the buildings vary, and the analysis of each building in terms of energy performance should be provided, the energy performances of the spaces should be taken into account while designing the design and material selections should be provided accordingly. In the study conducted by Erkin (2012), space groups in office buildings; It is classified as working volumes that require attention, detailed work, visual comfort conditions are at the forefront, volumes that are not included in the working volumes, which are mostly for circulation, waiting or resting purposes or that require rough work, volumes where hygiene conditions are at the forefront, and technical volumes. It is important to analyze the factors affecting the design in terms of energy use in terms of energy use as well as the size, purpose and duration, frequency of use, capacity, materials used, exposure to external factors, building envelope properties in terms of working units, technical units, auxiliary spaces.

2. Results and discussion

In the study, data were collected in terms of facility management by referring to the opinions, suggestions and recommendations of the groups interviewed in depth. Data were collected from experts in their fields due to the experience of the developer and designer groups in the sector, their professional knowledge and their decision-making in practice. In this context, meetings were held with a group of 10 developers and a group of 30 designers, and the interviews were held for traditional offices and modern offices.

In the study, the expectations for office investments and offices in Ankara were questioned and the characteristics of the office buildings to be produced in Ankara in the future were revealed. It is possible to adapt the study according to different project characteristics and it is aimed to be a guide for decision makers. In addition, in the light of the current expectations for the office market, the importance levels of sustainability-related issues have been revealed. This situation has been mutually examined and discussed in terms of developers and designers.

2.1 Findings for developers

Office developers have a significant impact on designs, often due to the decisions they make, their role as the final decision-maker, and their entrepreneurial role that requires them to be active in project development, production, and marketing. Especially since they are experts who construct the financial structure of their investments, their views on design are important.

They were asked whether there was a need for production from new office buildings in Ankara and the majority of the participants evaluated that there was a need for the production of new office buildings in the province. 90% of the participants expressed a positive opinion to the question asked. This situation was considered as an indication that work could be done on new office buildings in Ankara.

Table 5. Production need for new office buildings in Ankara

Answers	Professional Office Building		Individual Office		Total	
	Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Yes	7	87.5	2	100	9	90
No	1	12.5	-	-	1	10.0
Total	8	100	2	100	10	100

The participants were asked about their opinions on the features that the offices that could be produced in Ankara should have, and in this way, the design parameters for the new offices that would be required in the province were also examined. According to the results obtained, the most important services needed are that they have technical infrastructure, parking and valet services, social facilities, security elements and can be divided for flexible spatial use of offices when necessary. In addition to expressing the opinion of 90% of the participants on technical infrastructure services, the expectation of 60% of the participants for office investments with parking and valet services and social facilities should be taken into account for new designs.

Table 6. Production needs and features of new office buildings in Ankara

Properties	Professional Office Building		Individual Office		Total	
	Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Social facilities	5	62.5	1	50.0	6	60.0
Technical infrastructure	7	87.5	2	100.0	9	90.0
Meets efficiency criteria	3	37.5	-	-	3	30.0
Divisible	4	50.0	1	50.0	5	50.0
Security	4	50.0	1	50.0	5	50.0
Hybrid tenant structure	2	25.0	-	-	2	20.0
Sole proprietorship	1	12.5	-	-	1	10.0
Professional management structure	3	37.5	-	-	3	30.0
Parking and valet services	4	50.0	2	100.0	6	60.0
Healthcare	1	12.5	-	-	1	10.0
Restaurant/cafe	3	37.5	-	-	3	30.0
Meet-and-greet services	2	25.0	-	-	2	20.0
Accomodation service	-	-	-	-	-	-
Green building	1	12.5	-	-	1	10.0
Alternative/flexible use	1	12.5	-	-	1	10.0
Possibility of sports and entertainment areas	1	12.5	-	-	1	10.0

When the participants were asked about the green building characteristics of the office spaces and their willingness to work in the green building, all of the participants expressed their opinion about the willingness to work in the green building. The main reason for this situation is that the developers have knowledge about green building practices and green buildings provide significant advantages in terms of operating costs.

Table 7. Willingness to make the office spaces currently working green buildings

Answers	Professional Office Building		Individual Office		Total	
	Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Yes	8	100.0	2	100.0	10	100.0
No	-	-	-	-	-	-
Total	8	100.0	2	100.0	10	100.0

The fact that the features and investment strategies for the design of the offices have an impact on the total energy use plays an important role in determining the design criteria and expectations. Investment decisions are effective for developers in terms of project profitability, sales and marketing opportunities. In cases where the right strategies are designed and the spatial features are compatible with the purpose of use, the investment success increases and this leads to the use of sustainable buildings. Operating costs are effective in making the right decisions for use, and this situation reveals the importance of integrating traditional design criteria into the project. It should be taken into account that factors such as usage capacity, functionality, space and material harmony in office buildings are the parameters that significantly guide the design. On the other hand, the fact that the decisions taken during the design phase are effective for the activities to be carried out during the use of the buildings requires detailed research on the decisions taken during the design process.

When the developers were asked about the priority issues for office investments, they were asked about their opinions on sustainable building design, energy efficiency, cost reduction and economy, functional buildings and compatibility of the space program. The most important feature that the developers consider important is that the structure is functional and economical in terms of cost and use. However, it has been evaluated that there is awareness of sustainable building design, energy efficiency and work-space harmony.

Table 8. Issues to be prioritized in the design of office buildings

Properties	Severity	Professional Office Building		Individual Office		Total	
		Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Sustainable building design	Strongly disagree	-	-	-	-	-	-
	Disagree	-	-	-	-	-	-
	Neutral	3	37.5	2	100.0	5	50.0
	Agree	4	0.0	-	-	4	40.0
	Strongly agree	1	0.0	-	-	1	10.0
Energy efficiency	Strongly disagree	-	-	-	-	-	-
	Disagree	1	12.5	1	50.0	2	20.0
	Neutral	2	25.0	1	50.0	3	30.0
	Agree	3	37.5	-	-	3	30.0
	Strongly agree	2	25.0	-	-	2	20.0
Cost/Economy	Strongly disagree	-	-	-	-	-	-
	Disagree	-	-	1	50.0	1	10.0
	Neutral	1	12.5	1	50.0	2	20.0
	Agree	2	25.0	-	-	2	20.0
	Strongly agree	5	62.5	-	-	5	50.0
Function	Strongly disagree	-	-	-	-	-	-
	Disagree	-	-	-	-	-	-
	Neutral	1	12.5	2	100.0	3	30.0
	Agree	1	12.5	-	-	1	10.0
	Strongly agree	6	75.0	-	-	6	60.0
Work and venue program	Strongly disagree	-	-	-	-	-	-
	Disagree	1	12.5	-	-	1	10.0
	Neutral	2	25.0	2	100.0	4	40.0
	Agree	4	50.0	-	-	4	40.0
	Strongly agree	1	12.5	-	-	1	10.0

2.2 Findings for designers

Designers are important decision-makers in matters such as shaping offices, ensuring their spatial organization, choosing building materials, and designing building systems. Generally, they come to the fore as experts and professionals who are primarily effective in making decisions regarding the level of influence of structures in many ways through teamwork. For this reason, in the in-depth interviews with the designers, their evaluations of office design were questioned and the results were revealed.

When the designers were asked about the production needs of new office buildings in Ankara, it was determined that the participants generally stated that there was no need for a new office building. However, considering the proportion of designers (40%) who stated that there was a need for production for new office buildings, it was evaluated that the features and expectations for new office buildings should be questioned.

Table 9. Production need for new office buildings in Ankara

Answers	Professional Office Building		Individual Office		Total	
	Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Yes	7	50.0	5	31.3	12	40.0
No	7	50.0	11	68.8	18	60.0
Total	14	100.0	16	100.0	30	100.0

When office designers were asked about the production characteristics of the new office buildings that should be produced in Ankara, it was evaluated that the most important features were the need for offices with technical infrastructure (93.3%), social facilities (63.3%), the ability to divide spaces when necessary (43.3%) and parking and valet services (43.3%). It has been determined that the specified features are generally related to the services that provide convenience in terms of the functionality and usage possibilities of the buildings.

Table 10. Production needs and features of new office buildings in Ankara

Properties	Professional Office Building		Individual Office		Total	
	Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Social facilities	8	57.1	11	68.8	19	63.3
Technical infrastructure	14	100.0	14	87.5	28	93.3
Meets efficiency criteria	7	50.0	8	50.0	15	50.0
Divisible	5	35.7	8	50.0	13	43.3
Security	4	28.6	5	31.3	9	30.0
Hybrid tenant structure	5	35.7	3	18.8	8	26.7
Sole proprietorship	4	28.6	1	6.3	5	16.7
Professional management structure	2	14.3	2	12.5	4	13.3
Parking and valet services	5	35.7	8	50.0	13	43.3
Healthcare	3	21.4	4	25.0	7	23.3
Restaurant/cafe	7	50.0	3	18.8	10	33.3
Meet-and-greet services	5	35.7	4	25.0	9	30.0
Accomodation service	-	-	1	6.3	1	3.3
Green building	2	14.3	6	37.5	8	26.7
Alternative/flexible use	3	21.4	4	25.0	7	23.3
Possibility of sports and entertainment areas	4	28.6	5	31.3	9	30.0

When the designers were asked about their opinions on the green building of the office spaces they are currently working on, it was noted that the answers of the participants were positive (90.0%). This situation is considered as an indicator of the sensitivity and willingness to use energy in buildings and sustainable building design. As emphasized by Tanrıvermis (2019) and Tanrıvermis and Tanrıvermis (2021), although the investment costs of green offices are relatively higher than traditional buildings, the return on investments is relatively shorter because the operating expenses are lower than traditional buildings.

The opinions of the designers are important in terms of shaping the buildings, constructing the organization of the space, establishing the relationship between the features brought by the size and capacities of the spaces with the structural elements. In particular, designers' analysis strategies and predictions for spatial needs are effective on the creation and functionality of scenarios in the use of buildings. The construction of spatial features has an impact on the activities to be carried out within the building, and this situation also affects strategic decisions in terms of the management of the buildings. There is a close relationship between management activities and spatial use characteristics. This relationship affects the use of office spaces and therefore the cost of use.

Table 11. Willingness to make the office spaces currently working green buildings

Answers	Professional Office Building		Individual Office		Total	
	Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Yes	13	92.9	14	87.5	27	90.0
No	1	7.1	2	12.5	3	10.0
Total	14	100.0	16	100.0	30	100.0

It was understood that the most important issues were that the most important issues were functionality (100%), work and space program (96.7%) and economical (100%) in terms of construction and usage cost (100%) when the designers were given priority when designing for offices. Although sustainable building design and energy efficiency are secondary priority issues for designers, it should be stated that significant levels of opinion are expressed in this direction (Table 12).

Table 12. Priority issues in the design of office buildings

Properties	Importance Level	Professional Office Building		Individual Office		Total	
		Number (n)	Rate (%)	Number (n)	Rate (%)	Number (n)	Rate (%)
Sustainable building design	Strongly disagree	-	-	1	6.3	1	3.3
	Disagree	2	14.3	-	-	2	6.7
	Neutral	3	21.4	1	6.3	4	13.3
	Agree	6	42.9	7	43.8	13	43.3
	Strongly agree	3	21.4	7	43.8	10	33.3
Energy efficiency	Strongly disagree	-	-	-	-	-	-
	Disagree	1	7.1	-	-	1	3.3
	Neutral	5	35.7	4	25.0	9	30.0
	Agree	5	35.7	7	43.8	12	40.0
	Strongly agree	3	21.4	5	31.3	8	26.7

	Agree	5	35.7	9	56.3	14	46.7
	Strongly agree	8	57.1	7	43.8	15	50.0

2.3 Comparison of findings and discussion

Office buildings are known as the type of building that should be emphasized for urban development due to their impact on their environment, their location in the city and their important investment tools. Due to the technologies they contain, they are also buildings that play a leading role in the building sector, and their spatial setups are generally developed according to certain assumptions. In this respect, structural concepts emerge, some structures are designed and built with a focus on comfort, some with a focus on prestige, technology, energy use or saving.

In the study, in order to evaluate the current situation of the offices and to evaluate the expectations for the offices that are designed in the future, interviews were held with office developers and office designers who are experts in office design and who are decision-makers, and it was tried to determine the features that the offices to be produced in the future should have.

Developers and designers were questioned about the need for office investments in Ankara, the features that offices should have, and the issues prioritized in office design. Issues that can provide sustainable use for office design are examined. It should be emphasized that developers and designers for office designs note similar features. The most important features that should carry their new offices are the functionality, which is the common view for both groups, and the advantages of the buildings in terms of cost and economic aspects. In addition, it was noteworthy that both groups responded positively to the green building characteristics of the existing offices.

When asked about their evaluations of office investment in Ankara, it was noteworthy that developers and designers responded at different levels. While developers state that new office investments are needed, the limited level (40%) of the designers' participation in this view should be perceived as an indication that comprehensive feasibility studies should be carried out for new investments. On the other hand, when asked about the features that office investments should have, it was determined that both the designer and the developer group needed offices that provide technical infrastructure, social facilities, parking and valet services, and whose spaces can be divided or expanded if needed.

In the research conducted on the scale of Ankara province, the current office investment needs and the features that the offices should have were evaluated, and the basic features that should be carried for new investments were determined. However, it is necessary to conduct detailed research on these features and to conduct comprehensive feasibility studies for marketing opportunities, usage possibilities and investment effects.

3. Conclusion and evaluation

Offices are seen as important real estate assets considering their features such as usage intensity, capacity, duration of use, number of employees and visitors. Considering their usage patterns and locations, they generally direct other real estate investments as projects located in the city center and creating attraction areas. The technology and construction techniques used in offices are often pioneering for other projects. Considering the usage densities and capacities, it is known that significant energy use occurs in offices. In addition, construction features that require advanced technology in terms of construction techniques generally require intensive energy use during the construction phase.

It is noteworthy that investment decisions are made during the project development, design and construction stages in the offices, taking into account the initial investment costs. However, when the total building life is taken into account, it becomes clear that the activities carried out during the use phase and the structural systems used are much more important than energy use and sustainability. Therefore, it is now a necessity to take into account the possibilities of use while making investment decisions and spatial arrangements for offices, and to focus on the sustainability goals of the design parameters and the environmental, social and governance analyses of the investments.

In the study, office design parameters were examined in terms of office developers and designers as two important stakeholders that are effective in ensuring spatial organization for office investments and deciding on design elements. In this context, research was conducted on the offices in Ankara, an in-depth interview was conducted with a developer group of ten people and a designer group of thirty people, and the data obtained were examined in terms of office use and project development and design parameters serving sustainability. Project development and design parameters that should be taken into account for future office investments in Ankara have been revealed. In particular, the relationship between office worker satisfaction and business success and preferability will play a key role in new investment projects.

Although the data obtained as a result of the study reveal the current situation and expectations regarding the scope and period of the relevant study, it should be considered as a reflection of the expected characteristics for office investments in general. For the office investments to be made, it is recommended to conduct detailed research on feasibility and investability and to provide demand analysis. According to the developers and designers, it has been noted that they have expressed their opinion that the functional structures for the new offices to be produced in Ankara should be economical in terms of initial production and usage cost. In fact, it has been evaluated that this situation is directly related to the correct design of the buildings in terms of design and the limitation of energy use within the scope of the activities carried out. Therefore, it should be expected that energy conservation-oriented designs will be realized in the investments to be made.In the study carried out, it is understood that there is a need to produce new office buildings in Ankara for the near term, and the features that office investments should have been determined as providing technical infrastructure, social facilities, parking and valet services, and being able to divide or expand the spaces if needed. It has been evaluated that successful office projects can be produced if these features are taken into account in the studies to be carried out. However, in order for office projects to be successful investments, it is a necessity to develop the right management strategies with a focus on facility management and to implement design setups in which the cost of use is minimized with rational methods. Under these conditions, it is foreseen that sustainability strategies will be integrated into buildings, the economic life of new buildings will be extended with the right maintenance and usage methods, and the preferability of investments that prioritize energy-water-waste management and user comfort and the rental money will be higher.

Abstract. Given its significant implications for project management practices, resource allocation, and overall project success, project complexity has emerged as a critical area of inquiry. This study presents a bibliometric analysis of research on project complexity within the construction industry. Utilizing the Web of Science Core Collection database (WoS), a systematic search strategy was adopted to construct a comprehensive dataset, targeting peer-reviewed articles, reviews, and proceedings published within a defined time frame. The search string was designed to capture three dimensions: the concept of complexity in projects, strategies for coping with complexity (e.g., defining, managing, and assessing), and a focus on the construction industry. 615 publications were analyzed, leveraging the R-based tool Bibliometrix for bibliometric analysis. The analysis employed several bibliometric indicators, including publication output, citation analysis, co-authorship analysis, keyword co-occurrence analysis, and thematic clustering. The findings reveal the evolution of research on project complexity, highlighting key thematic areas, emerging trends, and gaps in the literature. Significant insights are drawn regarding the interplay between project complexity and management strategies within the construction domain. By mapping the intellectual structure and knowledge evolution, this study contributes to a comprehensive understanding of the field, offering a foundation for future research. The findings aim to inform researchers and practitioners by presenting a detailed overview of the current research landscape.

Keywords: Project complexity; Construction Industry; Bibliometric Analysis; Project Management

1. Introduction

Project complexity has become a critical challenge in the construction industry due to technological advancements, globalization, and rising stakeholder demands (Luo et al., 2017). As projects increase in scale, managing this complexity is vital for effective resource allocation, risk management, and successful outcomes (Williams, 1999). However, the research on project complexity in construction is vast and fragmented, requiring a clear synthesis of the field.

This study uses bibliometric analysis of 615 publications from WoS (between the years 1996 and 2024) to map the field's intellectual structure and thematic evolution. Our goals are to identify key contributors, thematic clusters, and emerging trends, providing insights for researchers and practitioners to advance this important area.

The remaining sections are as follows: Section 2 details the methodology, encompassing the data source, search strategy, and bibliometric indicators employed. Section 3 presents the results, including descriptive statistics, productivity, citation analyses, network analyses, and thematic mappings. Section 4 discusses the implications of these findings for research and practice, spotlighting key trends and future directions. Finally, Section 5 summarizes the study's contributions and recommendations for advancing the field.

2. Methodology

The methodology adopted in this study was designed to ensure a systematic and reproducible approach to data collection, processing, and analysis. The data collection begins with selecting a robust and credible data source, then constructing a well-defined search string and applying precise filters and refinements to narrow the scope of the dataset. Data extraction was conducted with attention to detail, ensuring all relevant bibliometric information was retained for analysis. The study employed an advanced bibliometric software package to process and

* Corresponding author, E-mail: seckinkoralay@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_161

analyze the data, leveraging bibliometric indicators and visualization techniques to uncover patterns, trends, and key insights. This section outlines each step, providing transparency and rigor to the methodological framework.

Data Source: WoS is utilized for the analysis due to its extensive coverage of high-impact, peer-reviewed journals and robust indexing standards (Feng et al., 2024; Issrani et al., 2024). WoS is a trusted resource for analyzing scholarly trends and networks, ensuring the dataset's reliability and relevance.

Search String: It was crafted focusing on three key dimensions: (1) project complexity in the context of systems thinking, (2) how to address this complexity (e.g., defining, measuring, managing), and (3) the construction industry. Core terms were combined with Boolean operators (AND, OR) and wildcards (e.g., "complex*" for variations). The final search string—("project complex*" OR "complex projec*" OR "complexity of projec*" OR "complexity in projec*" OR "system complex*") AND (manag* OR defin* OR measur* OR assess* OR evaluat* OR quantif*) AND ((construction OR building) AND (indust* OR sector* OR project*))—captures the research scope effectively, ensuring inclusivity across relevant studies.

Filters and Refinements: To ensure the dataset's relevance, a series of filters and refinements were applied to create a comprehensive yet targeted dataset aligned with research objectives. The search was restricted to "topic, abstract, and keywords" fields. Only English-language "articles, proceedings, and reviews" were included, ensuring a focus on credible, peer-reviewed sources. Timespan was limited to publications since 1996, when project complexity emerged as a key research topic (Baccarini, 1996; Gidado, 1996). The dataset was further refined through "Research Areas" and "WoS Categories", targeting construction and management-related fields.

Data Extraction: On 30 December 2024, 615 publications, including full records and cited references, were exported as a BibTeX file. The BibTeX format provides a structured and standardized organization of bibliographic data, making it highly compatible with bibliometric tools and allowing seamless data processing. Exporting the "full record and cited references" enables a comprehensive bibliometric analysis for the research.

Analysis Tool: Bibliometrix, an R-based package, is selected over other tools like VOSviewer or CiteSpace for its robust capabilities in data processing, analysis, and visualization (Aria & Cuccurullo, 2017). It provides a broader range of analyses, is open-source, and also integrates seamlessly with other R packages such as ggplot2 for advanced visualizations, dplyr for data manipulation, and tm for text mining. Additionally, embedding it within a code-driven markdown framework (Fig. 1) enables a traceable, replicable, and adaptable process.

Bibliometric Indicators: To gain a comprehensive understanding of the dataset, a range of bibliometric indicators and visualization techniques were employed (Donthu et al., 2021; Öztürk et al., 2024):

- **Descriptive Analysis (General Overview):** It provides an overview of the research field by summarizing key dataset characteristics, such as the number of documents, document types, and timespan. It also analyzes temporal trends in publication using a line graph to identify milestones and developments.
- **Performance Analysis (Productivity and Citation Analysis):** It evaluates the productivity and citation impact of authors, institutions, and countries. It visualizes the geographical distribution of publications, identifies prolific and highly cited authors, and assesses the most influential journals.
- **Network Analysis (Science Mapping):** It reveals collaboration patterns by co-authorship, research schools by co-citation or bibliographic coupling, and major research areas by keyword co-occurrences. Networks represent relationships between entities, where the size of each node indicates its importance or connectivity within the network, and the edges show interactions.
- **Thematic Analysis (Research Theme Analysis):** It investigates the evolution of research themes by examining temporal trends in keyword usage to trace topic development and identify emerging and declining themes. It offers a structured view of the field's thematic landscape.

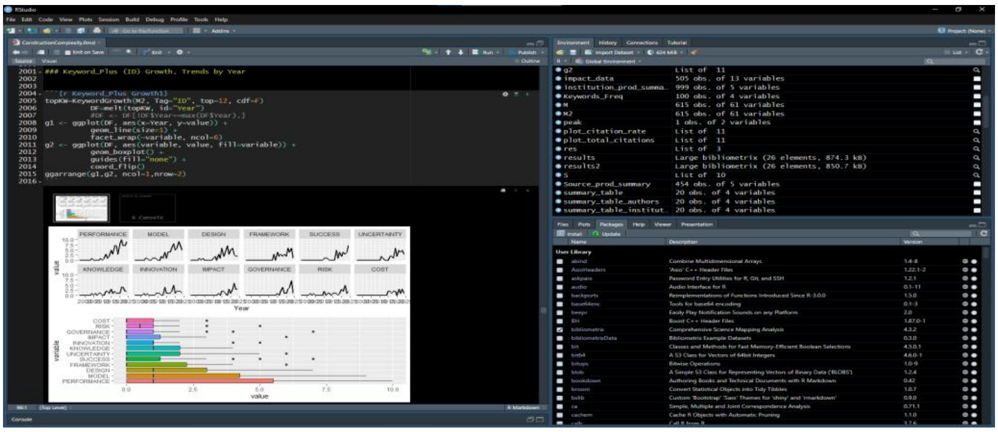

Fig. 1. R Markdown Environment Utilized During the Bibliometric Analysis

3. Results

As described in Table 1, the dataset encompasses 615 publications (between the years 1996 and 2024) on construction project complexity, offering a robust foundation for bibliometric analysis. The distribution of document types suggests that journal articles (417) are the primary medium for disseminating research in this field. At the same time, proceedings papers (162) indicate active participation in conferences, and reviews (28) provide a consolidated understanding of the field, adding depth to the analysis. The documents are sourced from 278 distinct outlets (journals, conferences), highlighting the interdisciplinary nature of the research. Spanning nearly three decades, it balances foundational and recent works (average publication age: 8.63 years), capturing evolving trends. Citation metrics (23.22 average citations per document) indicate strong scholarly impact, while 23,165 referenced works enable deep network analyses. The dataset's diversity, temporal breadth, and high citation activity highlight a thriving, interdisciplinary field with rich historical and emerging insights, ideal for mapping knowledge structures and trends.

The "Annual Scientific Production" graph (Fig. 2) illustrates the growth of research output. The research field evolved from a nascent phase with low, steady output (1996–2005) due to limited adoption of complexity theory and methodologies, followed by a sharp rise in publications during a mid-growth phase (2006–2015), and accelerated output in recent years (2016–2024). Research output has grown steadily at an annual rate of 12.42%, with a notable acceleration starting around 2006 and a peak around 2020, followed by some fluctuations in recent years. This upward trend highlights the topic's increasing academic interest and relevance over time, reflecting a maturing research domain with significant scholarly contributions.

Table 1. Key Dataset Metrics and Interpretations for Project Complexity Research

Metric	Value	Interpretation
Number of Documents	615	Represents a substantial dataset for analysis, indicating significant scholarly attention to the topic.
Document Types	Articles: 417; Proceedings Papers: 162; Reviews: 28; Article + Proceedings Paper: 8	Highlights the dominance of journal articles, active conference engagement, and contributions of review papers to synthesize knowledge.
Timespan	1996–2024	Reflects nearly three decades of research, allowing for an analysis of historical evolution and emerging trends.
Number of Sources	278	Indicates diverse publication outlets, demonstrating interdisciplinary interest in the field.
Average Years from Publication	8.63	Suggests a balance of older foundational works and recent research, enabling retrospective and contemporary analysis.
Average Citations per Document	23.22	Highlights a reasonable level of impact, with documents being widely cited and acknowledged in the research community.
Number of References	23,165	Indicates extensive cross-referencing, providing opportunities for network analyses to identify influential works.

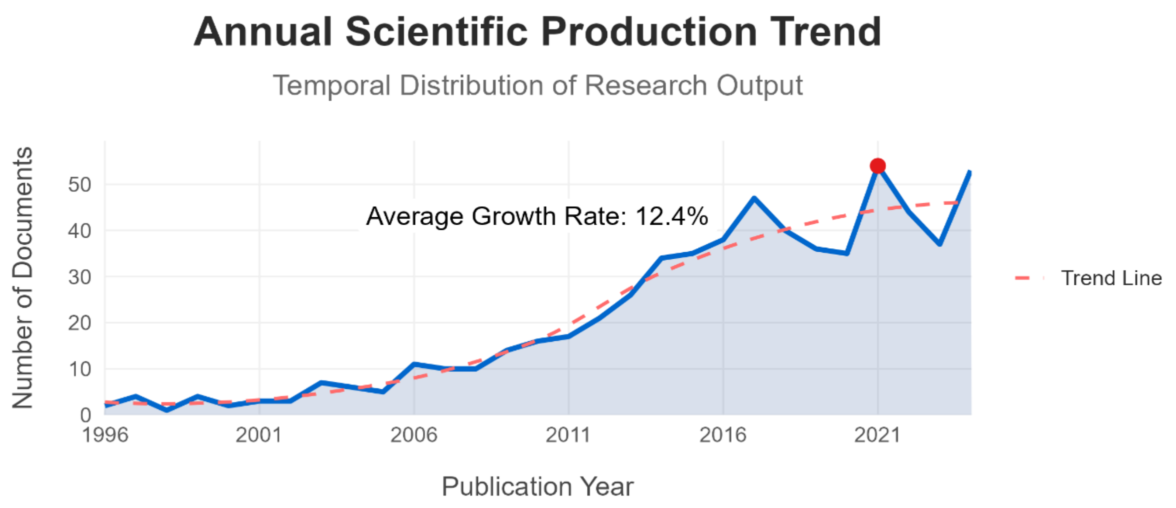

Fig. 2. Annual Scientific Production Trend of Publications Over Time

3.1. Global Research Productivity, Impact, and Collaboration Patterns

As shown in Fig. 3, the United States leads global scientific output, producing 115 publications (18.85% of total output), predominantly single-country papers, reflecting a strong independent research focus. China follows with 102 publications and a higher multi-country publication (MCP) ratio of 0.31, indicating significant international collaboration. Malaysia stands out with an MCP ratio of 0.50, and Australia (0.38) also emphasizes cross-border partnerships. Conversely, Brazil and the Netherlands prioritize independent research, with low MCP ratios.

Regarding impact, the USA (2,571 total citations) and China (2,209) top the citation charts due to their volume. Canada (42.75) and the Netherlands (30.08) excel in average citations per publication, suggesting higher research quality. Smaller producers like Singapore and Sweden also achieve notable citation averages.

At the institutional level, Tongji University (China) leads in productivity (14.09 fractional output) with 330.23 total fractional citations. Hong Kong Polytechnic University (China), despite lower output (6.62), achieves the highest average citations (61.21) and 405.03 total citations. Delft University of Technology (Netherlands) balances moderate output (8.57) with consistently high citations (33.06 average), whereas Arizona State University (USA) is ranked third in fractional productivity (8.00), yet with lower average citations (3.63).

The collaboration network (Fig. 4) identifies China (degree centrality 0.737), the UK (0.684), the USA (0.632), and Australia (0.579) as central hubs. Three clusters emerge, revealing regional collaboration patterns: a European (e.g., UK, France), an Asia-Pacific (e.g., Australia, Malaysia), and a USA-China-led cluster.

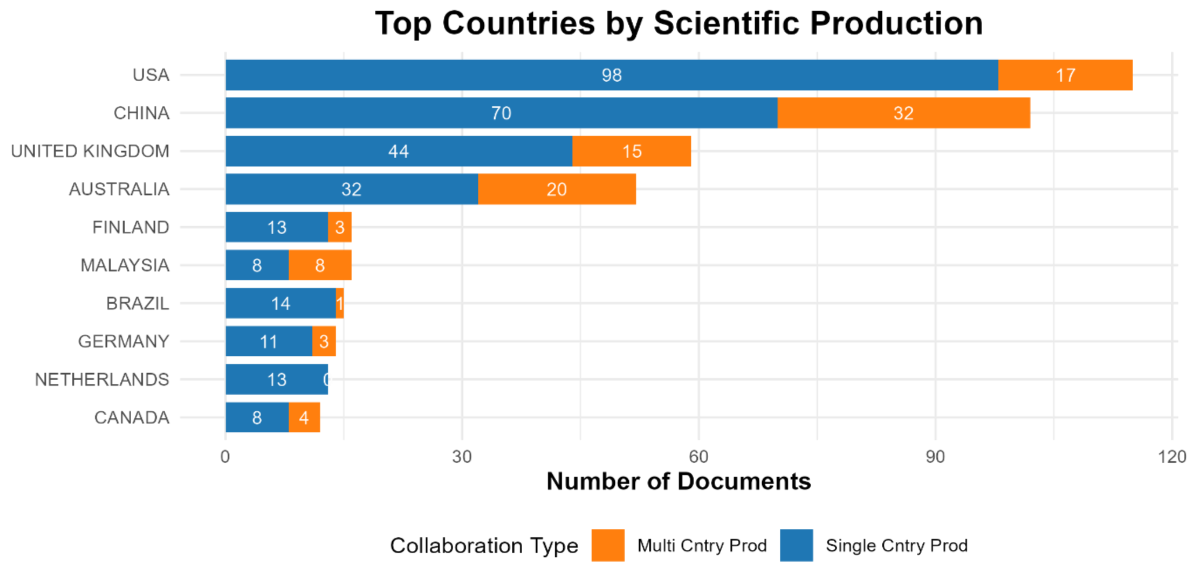

Fig. 3. Top Countries by Scientific Production in Project Complexity Research

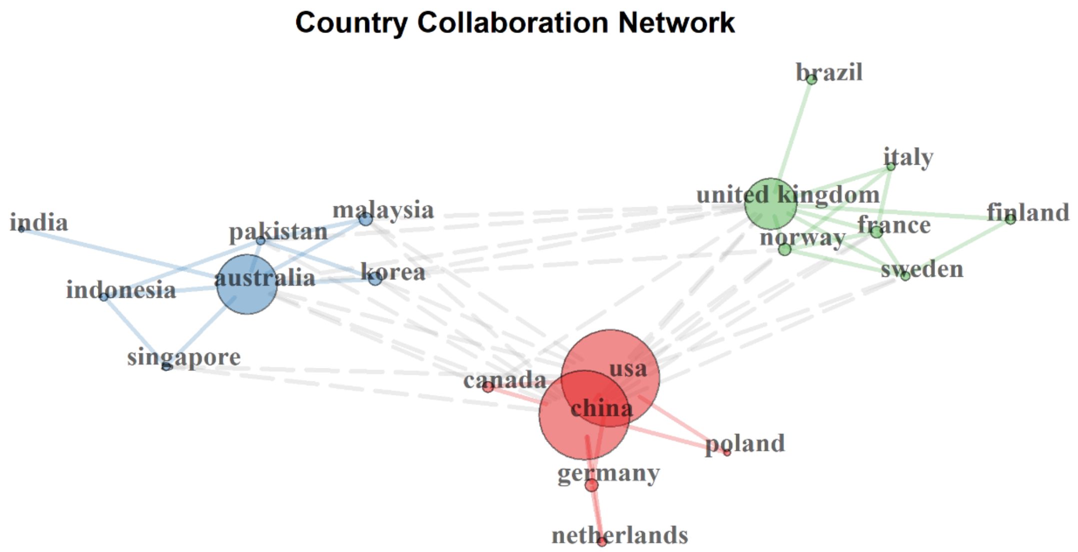

Fig. 4. Country Collaboration Network Visualizing International Research Partnerships

3.2. Leading Authors: Productivity, Impact, and Intellectual Connections

This section analyzes key researchers based on their publication output, citation impact, and intellectual connections. Fig. 5 depicts the publication timelines of the top 20 authors, with each horizontal line spanning from the earliest to the latest year of publication. Circle sizes indicate the contribution in a given year, while the color scale represents total citations per year, with darker hues signifying higher citation intensity.

Zhang L. and Kermanshachi S. top the list as the most prolific authors, each with 12 publications. Zhang L. has a significantly higher citation impact, receiving 821 total citations (averaging 68.42 citations per paper), while Kermanshachi S. has 252 citations. Other notable contributors include Luo L. (7 publications) and Skitmore M. (6 publications). Despite fewer publications, Davies A., Le Y., and Chan Apc. achieve a high average of citations. Davies A. leads with 92 citations per paper. Publication timelines reveal that authors like Zhang L. maintain consistent output and high citations over time. In contrast, others, such as Davies A. and Le Y., produce fewer but highly impactful works, reflected in larger or darker markers for specific years.

The author coupling network (Fig. 6), based on shared references, identifies thematic clusters among 40 researchers with a moderate connection density (0.237) and high clustering (0.496). Central Fig.s like Luo L. (degree centrality 0.949), Kermanshachi S. (0.744), and Zheng J. (0.615) bridge these clusters, facilitating knowledge exchange across the field.

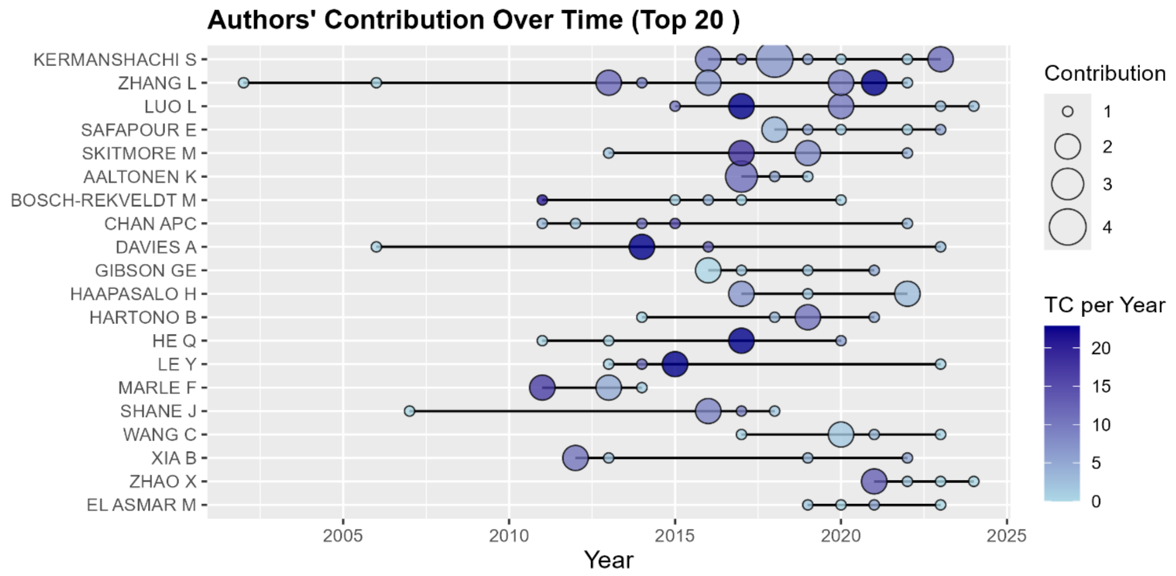

Fig. 5. Top 20 Authors' Contribution Over Time with Publication and Citation Trends

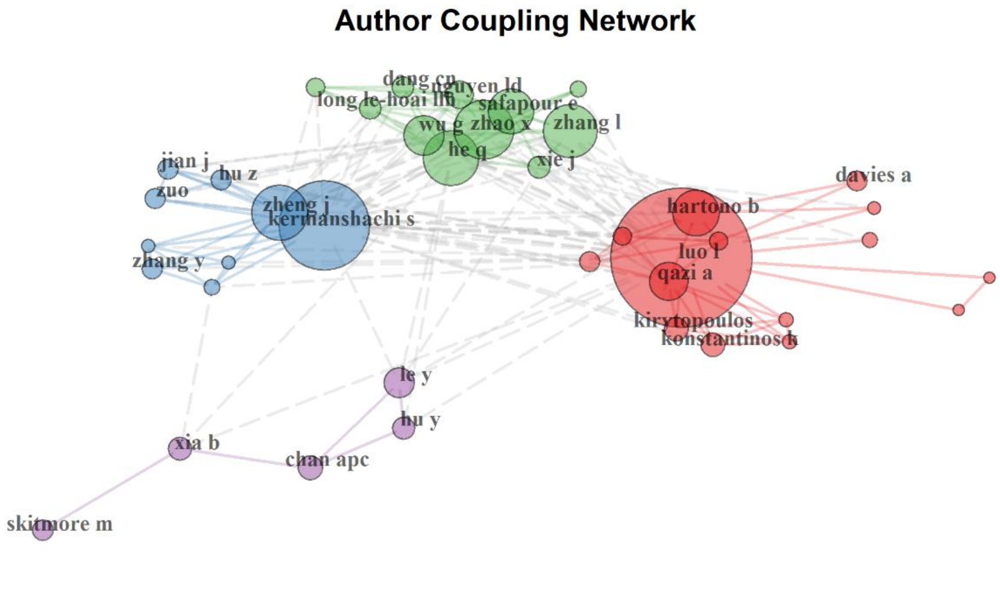

Fig. 6. Author Coupling Network Illustrating Thematic Commonalities Among Researchers

3.3. Key References and Publications

As for the references for a historical perspective, Table 2 highlights that the International Journal of Project Management emerges as the leading journal with 2,705 frequencies, far ahead of the Journal of Construction Engineering and Management (895) and Journal of Management in Engineering (763), reflecting its pivotal role in shaping project management scholarship. Among authors, Williams T. tops the list with 170 citations, followed by Flyvbjerg B. (140) and Love P. (126), underscoring their significant contributions.

Reference Publication Year Spectroscopy (RPYS) in Fig. 7 reveals the field's historical foundations by presenting the accumulation of references over time (Marx et al., 2014). There is a sparse amount of references before the 1970s, a gradual increase in the 1980s, and a sharp rise from the 1990s onward, indicating an expanding body of literature. A slight decline near 2020 suggests a typical citation lag for recent works. The years with unusually high or low citation rates point to landmark publications or shifts in research focus.

Fig. 8 (Reference Co-Citation Network) illuminates which specific works served as pivotal references, illustrating how frequently cited works form clusters based on how often they are referenced together. Three main clusters emerge, visible in color-coded groupings.

- **Cluster 1 (Red)** (12 documents, total referencing = 578, average referencing = 48.17) hosts the most influential references overall, as evidenced by Baccarini (1996)—the highest-degree node (0.2136) with 115 citations—and other key works by Williams (1999), Bosch-Rekveldt (2011), and Vidal (2011). These publications often define or refine conceptual underpinnings in project complexity, scope, and definition, thus anchoring the broader literature.
- **Cluster 2 (Blue)** (13 documents, total referencing = 412, average referencing = 31.69) consists of more recent studies, such as He (2015), Bakhshi (2016), Qazi (2016), and Luo (2017), which collectively focus on conceptualizing and measuring project complexity, while also examining emerging trends and implications in this domain. Although the average citation count here is lower than in Cluster 1, several nodes (e.g., Luo 2017) display relatively high individual citation Fig.s and centralities, underscoring their growing importance.
- **Cluster 3 (Green)** (5 documents, total referencing = 121, average referencing = 24.20) is smaller but includes influential works by Flyvbjerg (2014) and Davies (2014), often linked to mega-project governance, cost overrun debates, and the strategic management of large-scale projects. Despite fewer member references, the cluster maintains a moderate average centrality (0.0718), suggesting a cohesive sub-field interacting with the other two clusters.

Table 2. Top 10 Most Referenced Sources and Authors in the Dataset

Source	Frequency	Author	Frequency
Int J Proj Manag	2705	Williams T.	170

Int J Manag Proj Bus	283	Boschrekveldt M.	87
J Clean Prod	188	Luo L.	80

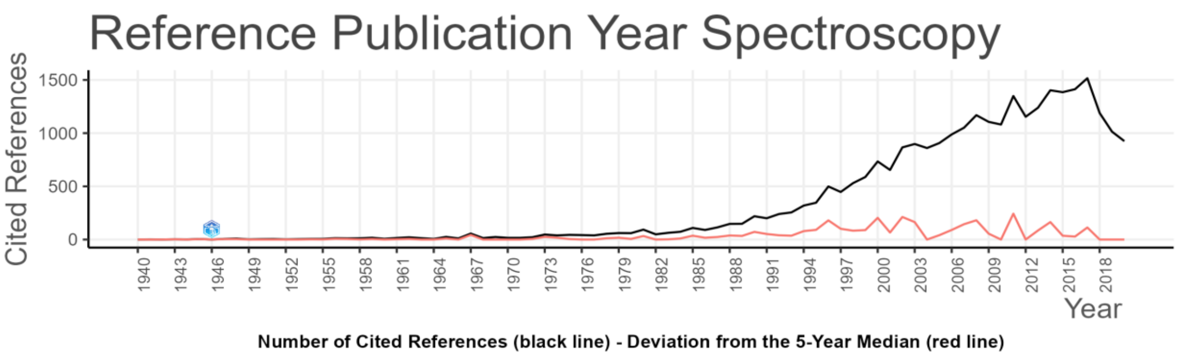

Fig. 7. Reference Publication Year Spectroscopy Showing Historical Citation Patterns

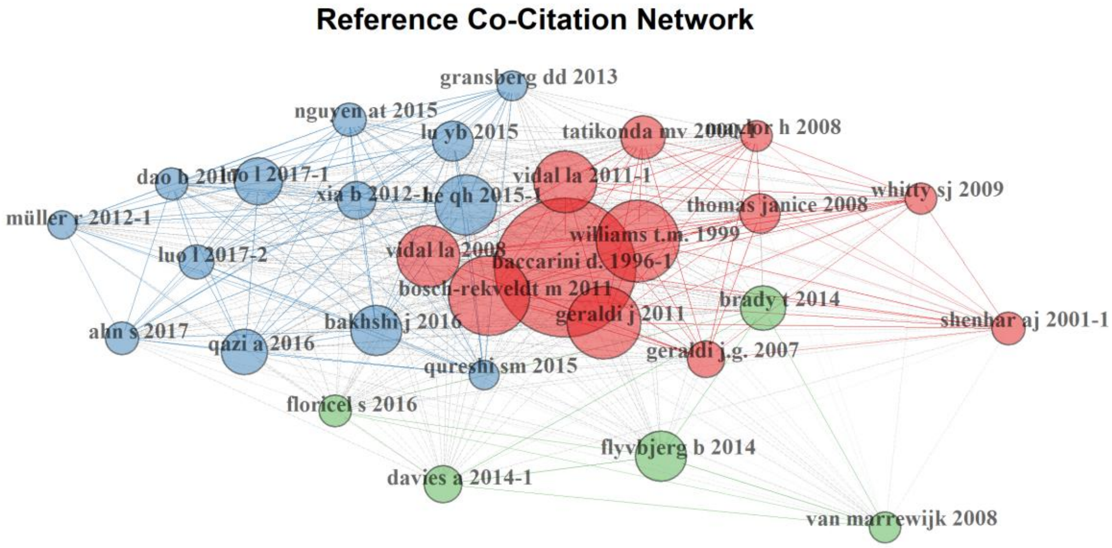

Fig. 8. Reference Co-Citation Network Depicting Clusters of Influential Works

For publications within the dataset, the Reference Coupling Network (Fig. 9) identifies three tightly coupled clusters. The network illustrates a multifaceted research landscape integrating measurement, theory, and practice.

- **Cluster 1 (Red) - Measuring Project Complexity:** (14 papers, total citations = 1,105, avg = 78.93) This cluster quantifies complexity and its impact, emphasizing early diagnosis for better decision-making. For instance, Qazi (2016) and Luo (2017) propose quantitative tools for mapping complex environments and clarifying risk pathways, while Zhao (2021) and Mirza (2017) explore the direct link between complexity factors and performance shortfalls.
- **Cluster 2 (Green) – Investigating Complexity–Success Relationships: (**11 papers, total citations = 305, avg = 27.73) This cluster features systematic reviews or advanced conceptual frameworks (bibliometric methods, DEMATEL, fuzzy logic, or qualitative comparative analysis) that examine the dimensional structure of complexity and its link to success (Ghaleb, 2022; Kim, 2021; Zheng, 2023; Ma, 2020). It is a nexus for synthesizing knowledge and understanding the multidimensional nature of complexity.
- **Cluster 3 (Blue) - Managing Complexity in Megaprojects: (**15 papers, total citations = 594, avg = 39.6) This cluster emphasizes managerial strategies for megaprojects. It highlights adaptive approaches, leadership, and theories to address project challenges (Maylor, 2017; Davies, 2016; Eriksson, 2017; Daniel, 2019; Hartono, 2019–2). These papers often build on complexity theory, stressing collaborative approaches, dynamic capabilities, and stakeholder alignment to improve project outcomes.

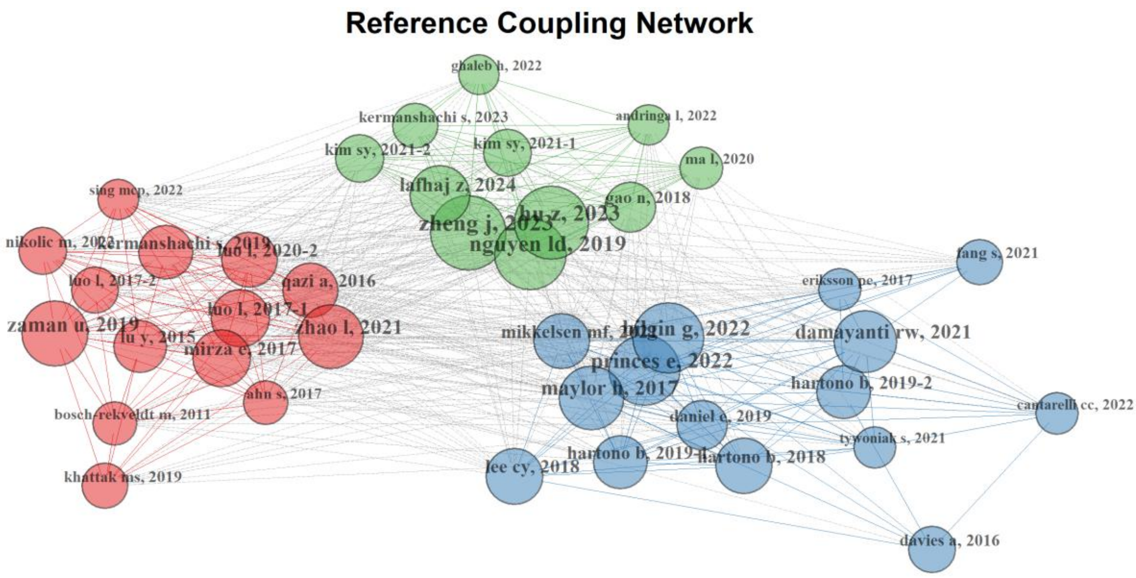

Fig. 9. Reference Coupling Network Revealing Thematic Linkages Among Studies

Fig. 10 analyzes the publication's impact through a scatter plot. The vertical axis shows total citations (scholarly influence over time), while the horizontal log-scaled axis tracks citations per year (recent impact). Bubble sizes reflect local citations (community relevance). The visualization aids in identifying key publications, mapping trends, and understanding the scholarly landscape. Several distinct patterns emerge from this visualization:

- **High global, low local impact:** Pan (2021), Singh (2011), Muller (2010), and Edmondson (2009) in the upper-right quadrant have high total citations but minimal local citations. These works have achieved significant global recognition, likely due to their broad applicability or foundational contributions across disciplines; however, they are not central to the current community focus.
- **Balanced global-local influence:** Bosch-Rekveldt (2011), Luo (2017), Qazi (2016), Vidal (2011), Brady (2014), and Davies (2014) strike a balance between significant total citations and high local citation counts. These works likely serve as intellectual pillars shaping the field's core frameworks.
- **Moderate dual impact:** Carvalho (2017), Sommer (2004), and Pitsis (2003) show mid-range citations globally and locally. These works likely contribute valuable insights yet lack the transformative impact of more foundational references. They play a supporting role, enriching the field.
- **Emerging works:** Positioned in the bottom-right quadrant, publications like Ghaleb (2022), Zhu (2022), and Afzal (2021) exhibit high citations per year but low total counts. These recent papers have a potential for increased impact as more scholars incorporate these findings into their research,

Table 3 ranks papers using a Composite Normalized Citation Score (CNCS) crafted by authors. It averages normalized total citations, citations per year, and local citations (each scaled 0–1). This balanced metric identifies top-performing works across all dimensions (total citation count, yearly citation rate, and local relevance), offering a concise guide to influential publications.

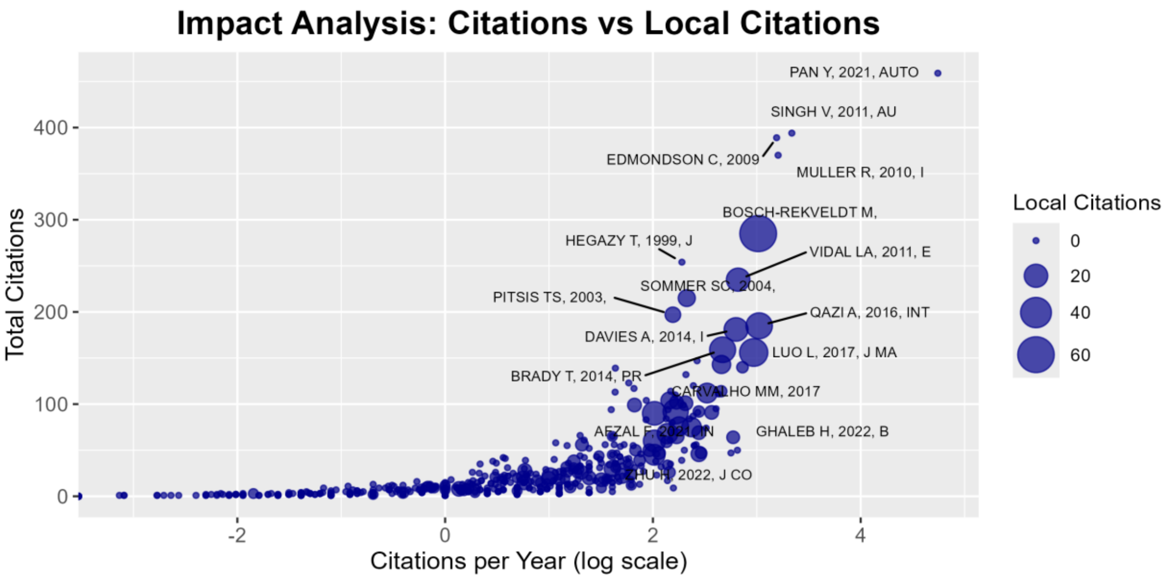

Fig. 10. Impact Analysis: Total Citations vs. Local Citations of Publications

Table 3. Top 10 Documents Ranked by Composite Normalized Citation Score

Publication (First Author, Year, Journal)	CNCS	TC	TCpY	LCS
Pan Y, 2021, Autom Constr	0.67	459	114.75	0
Bosch-Rekveldt M, 2011, Int J Proj Manag	0.60	285	20.36	61
Singh V, 2011, Autom Constr	0.37	394	28.14	0

Davies A, 2014, Int J Proj Manag	0.29	181	16.45	21
Sommer Sc, 2004, Manage Sci	0.23	215	10.24	8

CNCS: Composite Normalized Citation Score; TC: Total Citation; TCpY: Total Citation per Year; LCS: Local Citation Score

3.4. Most Relevant Keywords

Table 4 lists the Top 10 frequent Author Keywords (DE) and Keywords-Plus (ID). DE reflects author-emphasized themes, while ID (algorithmically generated by WoS) captures latent patterns from citation contexts. It is critical to note that terms such as "complex, complexity, system, project, management, construction, and industry" were excluded to avoid redundancy from the original search string. Their omission ensures an analytical focus on supplementary themes rather than overrepresented terms inherent to the research domain.

The top DE keywords are "risk" (47) and "performance" (39), highlighting concerns in megaprojects (14) and infrastructure (13). Top ID keywords are "performance" (75) and "model" (67), emphasizing methodological trends like "design" (49) and "framework" (36). Overlaps—"performance, success, uncertainty, innovation, knowledge"—show shared priorities, revealing a field focused on contextual challenges (DE) and methodological approaches (ID).

Fig. 11 "Author Keywords (DE) Co-occurrence Network" provides a thematic structure within the domain. This analysis identifies "risk" and "performance" as central hubs (highest centrality), connecting the sub-themes. Their prominence implies that risk assessment and performance evaluation are pivotal concerns, likely framing the broader discourse in megaproject or infrastructure research. Four distinct theme clusters emerge:

- **Risk Management and Planning** (risk, uncertainty, planning, scheduling, control, theory, building): Focuses on mitigating uncertainties in project execution.
- **Performance and Collaboration** (performance, collaboration, infrastructure, BIM, design, safety, cost): Emphasizes optimization via collaboration and technology.
- **Innovation and Knowledge Management** (innovation, success, communication, knowledge, information, case study): Highlights innovation and knowledge-sharing for success.
- **Analytical Approaches and Optimization** (analysis, megaprojects, dynamics, optimization, decision making, simulation): Centers on analytical methods for megaprojects.

Table 4. Top 10 Author Keywords (DE) and Keywords-Plus (ID) by Frequency

Author Keywords (DE)	Freq (DE)	Keywords-Plus (ID)	Freq (ID)
Risk	47	Performance	75
Performance	39	Model	67
Success	17	Design	49
Uncertainty	17	Framework	36
Innovation	14	Success	33
Megaprojects	14	Uncertainty	33
Infrastructure	13	Knowledge	30
Analysis	12	Innovation	27
Collaboration	12	Impact	25
Knowledge	12	Governance	24

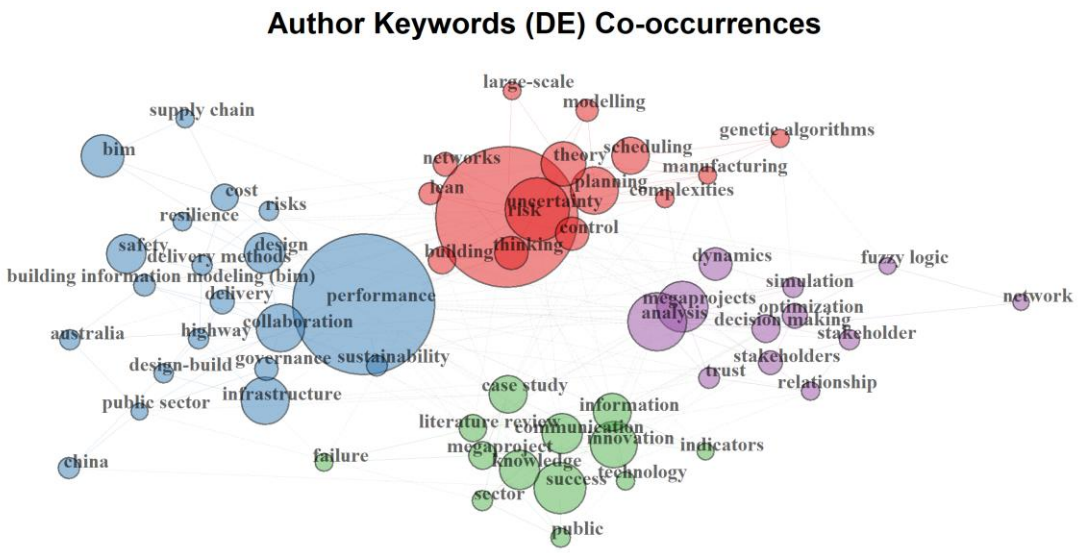

Fig. 11. Author Keywords (DE) Co-occurrence Network Highlighting Thematic Clusters

3.5. Thematic Evolution

The plot (Fig. 12) tracks top DE keywords' temporal distribution and frequency from 2008 to 2023. Horizontal lines show the publication year range (from quartile 1 to quartile 3), with dots marking the median year and sized by frequency. Three phases emerge: **(1) 2008–2014;** early focus on "modelling" and "China", with narrow spreads (6–8 years) and low frequencies (≤10), signaling foundational regional/methodological studies, **(2) 2015–2018;** peak activity with "risk" (frequency 47), "performance" (39), "uncertainty," and "infrastructure," reflecting prioritization of risk management and performance metrics, **(3) 2019–2023;** shift toward "success, megaprojects, stakeholder, supply chain, and sustainability", with moderate frequencies (6–17), highlighting emerging social/environmental priorities. In terms of temporal spread, sustained themes (risk, performance) show broad temporal spans (9–10 years), while recent terms (sustainability, supply chain) have shorter spreads (2–4 years), indicating concentrated modern interests.

The thematic map (Fig. 13), which is based on the work of Cobo et al. (2011), categorizes research themes into four quadrants by development density (maturity) and centrality (influence). This approach offers a comprehensive snapshot of the current research landscape, highlighting well-established topics, foundational areas with growth potential, emerging or fading trends, and specialized niches. Below, each quadrant is explained with its characteristics and associated themes:

- **Motor-Themes (Upper-Right: High density/centrality):** Mature, influential themes include project complexity management, multi-criteria multi-insight, verbal decision analysis, Delphi method, and transport. These topics serve as foundational pillars guiding both research and practice.
- **Basic Themes (Lower-Right: High centrality, low density):** Broadly relevant but underdeveloped themes like large-scale complex projects, procurement, risk management (e.g., risk process, risk factors), and tools (BIM, blockchain, digital twin) offer growth potential.
- **Emerging/Declining Themes (Lower-Left: Low density/centrality):** Themes such as social network analysis, coordination, systematic literature review, and Australia may be emerging (e.g., social network analysis) or fading.
- **Niche Themes (Upper-Left: High density, low centrality):** Well-developed, narrow themes like agile project management, construction disputes, infrastructure projects, and transaction cost economics provide specialized insights with limited broad impact.

4. Discussion

This bibliometric analysis of 615 publications from 1996 to 2024 examines project complexity in construction. It reveals a significant rise in research output (12.42% annual growth), especially since 2006. This increase likely reflects modern project demands driven by technological advancements, globalization, and complex stakeholder interactions.

Geographically, the U.S. (115 publications) and China (102) dominate, representing >35% of output. The U.S. favors single-country studies (MCP ratio: 0.15), while China prioritizes international collaborations (MCP: 0.31). Institutionally, Tongji University leads in output (14.09 fractional count), but Hong Kong Polytechnic University achieves a higher citation impact (61.21 vs. 23.43). Author coupling networks highlight Zhang L. (12 papers, 821 citations) as more influential than Kermanshachi S. (12 papers, 252 citations), with Luo L. (degree centrality: 0.949) bridging interdisciplinary clusters.

Citation patterns highlight the International Journal of Project Management (2,705 references) and authors like Williams T. (170 citations) and Flyvbjerg B. (140 citations) as field cornerstones since the 1990s, which is also recognized from the RPYS plot as a timeline. The reference co-citation network reveals thematic clusters: one centered on defining and measuring complexity (e.g., Baccarini, 1996), another on conceptualizing and assessing it (e.g., Luo, 2017), and a third on managing large-scale projects (e.g., Flyvbjerg, 2014). These clusters indicate a maturing field that spans theoretical grounding and practical application.

The keyword analysis provides further insight into thematic priorities. "Risk" and "performance" emerge as central themes across both Author Keywords (DE) and Keywords-Plus (ID), with frequencies of 47 and 39 for DE and 75 and 33 for ID, respectively. Their prominence indicates the field’s focus on mitigating risks and optimizing project outcomes. The temporal evolution of keywords—from early emphases on "modelling" and

"China" (2008–2014) to "risk" and "performance" in the mid-2010s, and recently "success", "megaprojects", and "sustainability" (2019–2023)—illustrates a progression from foundational or regional explorations to applied and contemporary concerns. This shift suggests that researchers are increasingly addressing broader societal challenges, such as sustainability, within the context of complex construction projects.

Despite these insights, the study acknowledges certain limitations. The exclusive use of the WoS database may omit relevant works from other sources, potentially skewing the representation of the field. The focus on English-language publications could introduce a linguistic bias. The dominance of the U.S. and China-based papers could result in a geographical bias. While bibliometric analysis excels at mapping the research landscape, it offers limited qualitative depth into the content of individual studies, necessitating complementary approaches for a fuller understanding. Deepening the interpretation of thematic shifts and maps would also add more insight (e.g., what are the factors for shifts? Industry crises, technological advancements, or influential publications).

5. Conclusions

This study synthesizes three decades of construction project complexity research, highlighting sustained growth (12.42% annual increase) and global leadership by the U.S. and China, with divergent collaboration strategies. Key contributors include Tongji University (volume) and Hong Kong Polytechnic University (impact), while authors like Zhang L. and journals like IJPM provide intellectual anchors. Seminal works by authors like Williams T. and Flyvbjerg B. further equip scholars to navigate the field's intellectual core. Thematic clusters emphasize risk management and performance, with emerging interests in sustainability and megaprojects signaling future directions.

In summary, this analysis maps the field's evolution, offering a roadmap to address growing complexity in global construction contexts and contributing a foundational understanding that can guide future scholarly and practical endeavors. The centrality of risk and performance highlights their critical role in managing complex construction projects. At the same time, the rise of sustainability and stakeholder-related themes suggests a need to integrate broader societal considerations into project management strategies.

Future research could explore these emerging areas in greater depth to advance the field, perhaps through qualitative studies or content analyses that complement the quantitative scope of bibliometrics. Other databases (e.g., Scopus) or non-English sources could be integrated to broaden the perspective.

Abstract. In architecture, often described as the art of creating space and constructing place, the concepts of space and place hold a central and indispensable role. Spaces are designed and built to facilitate human life and accommodate various activities. Humans, occupying a pivotal position within architecture, shape their lives within these constructed environments. Thus, space and human existence are deeply intertwined in a mutually reinforcing relationship. Considering space and place—terms with multidimensional structures and varied meanings across disciplines—solely in terms of their physical characteristics within architecture is both reductive and incomplete. Such an approach risks objectifying space and neglecting the role of the subject. To maintain the integrity of the human-space relationship, it is essential to understand these two concepts in all their dimensions. This requires examining the relationship between space and place to explore how they derive meaning in contrast to one another. Accordingly, this study conducts a comparative analysis of these concepts, tracing their definitions, transformations, and evolutions throughout history from various disciplinary perspectives.

Keywords: Place; Space; Architecture

---

1. Introduction

What is architecture? Renowned architect Louis Kahn defined architecture as "the ponderous creation of spaces." Similarly, Richard Meier stated, "Architecture is vital and enduring because it contains us; it describes space, space we move through, exit in and use." Greek architect and urban planner Stefanos Polyzoides, known as the father of New Urbanism, answered this question by saying, "Architecture is about building a place in the universe, not about mimicking a depleted, decrepit reality."

In The Dictionary of Architecture, Turkish architect and author Doğan Hasol describes architecture as follows: "The art of designing and constructing spaces to facilitate human life and sustain activities such as sheltering, resting, working, and entertaining by harmonizing functional needs with economic and technical possibilities through aesthetic creativity; in another definition, the art and science of designing and constructing buildings and the physical environment; structure and space design; briefly, the transformation of building action into art... Architecture is the activity of designing spaces and structures that organize the physical environment of settlements, ranging from shelters to urban dimensions" (Hasol, 2017, p.324).

It is evident that the various answers to the question "What is architecture?" generally converge on a common point: space and place. In architecture, whose fundamental action is known to be the creation of space and the construction of place, the concepts of space and place have always played leading roles. However, the reason for their prominence lies in their intrinsic connection to humans. Through spaces and places, people express their ways of living, even their very existence, and the resulting architecture profoundly impacts human beings. When we juxtapose Le Corbusier's statement, "Architecture is the starting point for anyone who wants to take humanity towards a better future," with Sir Winston Churchill's remark, "We shape our buildings; thereafter, they shape us," and Doğan Hasol's assertion, "Good people cannot be raised in bad spaces," it becomes clear that these thinkers emphasize architecture's role in shaping individuals, societies, and even the future of humanity. Therefore, to achieve good architecture, it is crucial to define and understand the concepts of space and place from various perspectives.

2. Materials and Methods

This study adopts a qualitative and theoretical research methodology, rooted in comparative philosophy and conceptual analysis. The research is primarily literature-based, involving the critical examination and synthesis of

* Corresponding author, E-mail: faezehasadzadeh.arch@gmail.com

https://doi.org/10.31462/icearc2025_a_arc_212

texts from philosophy, architecture, and social theory to trace the historical development and evolving meanings of the concepts of space and place.

The primary method involves an interpretative reading of canonical and contemporary works, including original philosophical texts by Plato, Aristotle, Descartes, Heidegger, Husserl, and Merleau-Ponty, as well as their subsequent interpretations by theorists such as Norberg-Schulz, Pallasmaa, Lefebvre, and Augé. These thinkers were selected due to their foundational roles in shaping spatial and place-related discourse across disciplines.

Academic sources such as peer-reviewed journal articles, doctoral dissertations, and books were systematically reviewed to construct a comprehensive theoretical framework. Special attention was given to etymological, historical, and phenomenological dimensions of the concepts, with a cross-disciplinary lens integrating philosophy, architecture, and urban theory.

The study does not involve empirical fieldwork but relies on the analytical comparison of texts, exploring how definitions, interpretations, and functions of space and place have transformed across time and schools of thought. This comparative approach aims to deepen our understanding of these concepts and their implications for architectural theory and practice.

To clarify the theoretical trajectory of this study, the following schema in Fig. 1, illustrates the main stages of the research and the key philosophical frameworks explored in each phase:

3. The Meanings of Space and Place

To embark on the journey of understanding and defining the concepts of space and place, it is logical to begin by exploring their linguistic meanings. When comparing the meanings of the terms "space" and "place," the distinction is more evident in some languages, while in others, it is more ambiguous, making differentiation difficult. For instance, in Turkish, the difference in meaning between these two terms is not explicit, and they are often used interchangeably, especially in everyday language. According to the Turkish Language Association, "mekân" (space) broadly refers to a place, a location, a home, a dwelling, or even outer space, whereas "yer" (place) is defined as the space or area occupied or that can be occupied by something or someone; a location, a surface walked on; a region, area, or place of residence; a state, position, or situation; a country; a workplace for earning a living; importance or significance; a mark; land suitable for construction; arable land; a location where an event occurs or will occur; and even the Earth itself.

In English, however, the terms "space" and "place" are recognized as distinct concepts despite overlapping semantic fields, making the distinction easier to identify. According to the Cambridge Dictionary, "space" is defined as an empty area, available vacant space, the continuous expanse in all directions around everything, outer space, or the physical distance between two people. In contrast, "place" refers to a specific area, city, or building, a suitable location, a house, a situation or state, a position in relation to others, or a role within an organization, system, or competition.

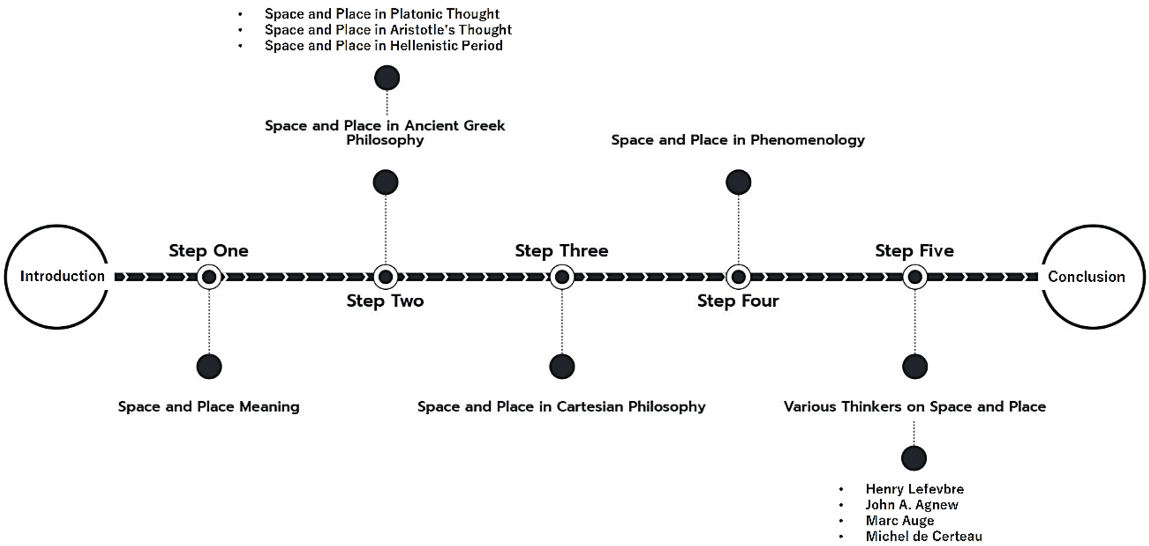

Fig. 1. Schematic diagram of the research process (visualized by the authors)

In Turkish, although "yer" and "mekân" may have different usages in some contexts, they appear to be synonymous in many others. As previously mentioned, in the field of architecture, these two concepts hold significant importance. Doğan Hasol's Encyclopedic Dictionary of Architecture defines "mekân" as "a space that separates humans to some extent from their physical environment and allows them to carry out their activities within it" and "yer" as "the surface of the earth, ground, land, or plot" (Hasol, 2017).

From this, we can conclude that to make a clear distinction between these two interconnected and multidimensional concepts and to understand how they derive meaning in relation to one another, it is necessary to delve into notable philosophical discussions throughout history. Such philosophical and conceptual inquiries are essential for a deeper comprehension. In line with this aim, the following section briefly introduces dominant philosophical approaches, particularly those from Western sources.

4. Space and Place in Ancient Greek Philosophy

4.1. Space and Place in Platonic Thought

The Ancient Greek philosopher Plato, one of the most influential figures in the history of philosophy, in his book *Timaeus* defines *khôra* as an indeterminate, receptacle-like medium that serves as the foundational "space" or "matrix" for the physical world. It is not a specific place but rather the condition of possibility for the existence of specific places (topoi). In contrast, *topos* refers to concrete, localized places within the physical world, where perceptible and affectable bodies occupy specific positions and interact within a defined geometry or locus (Plato, 360 BCE/2000; Casey, 1997).

When examining the epistemological origins of terms related to space, two key concepts emerge: *khora* and *topos*. The term *topos*, which shares the same root with words such as topography, topology, toponymy, utopia, and topic, is associated with location and is more closely linked to the notion of place. On the other hand, *khora*, which derives from the same root as technical terms like choreography, chronology, and chlorometry, inherently contains a temporal dimension. As a specific place, *khora* corresponds to the matrix of forms (Adıgüzel Özbek, 2016).

4.2. Space and Place in Aristotle's Thought

In *Physics*, Aristotle discusses *topos* (place) in a qualitative sense rather than *khora* and defines it simply as the portion of space occupied by a body (Nalbantoğlu, 2008). Aristotle rejects the idea of an empty place or an abstract concept of space in which nothing exists. Instead, he argues that place is always dependent on the relationship between bodies. Aristotle defines place (*topos*) as the boundary of the containing body that is in contact with the contained body. In other words, place is the innermost motionless boundary of what surrounds an object (Aristotle, 350 BCE/2000).

In Aristotelian philosophy, space is the natural location occupied by something in its movement, where its outer surface is in contact with the outer surface of another thing. In this sense, the place of an object encompasses and embraces it rather than being a space that enters into it or that the object itself occupies (Nalbantoğlu, 2008).

Aristotle's analogy—"To be in a place is very much like being in a vessel; place is something far beyond matter or form"—essentially describes the limitation of the body through the container's limiting function (Casey, 1997). The container represents the boundary or shape of a place, while the body serves as the shell of human existence (Tuncer Gürkaş, 2010). Referring to place as a kind of "container," Aristotle argues that the power of place lies in its ability to hold objects together. Objects without a place experience a form of loss, resulting in a kind of existential absence (Deviren, 2001). Thus, it is possible to conceive of space as a vast, all-encompassing physical form, while place consists of specific locations within this space, carrying meanings beyond being merely a form (Tuncer Gürkaş & Barkul, 2012).

Albert Einstein, who was significantly influenced by Aristotle's ideas, attempts to explain the difference between place and space through the example of a cherry crate. In this analogy, space can be thought of as the entity that holds the cherries within it—in this case, space is the crate itself. If we remove the cherries from this conceptualization, what remains is "space as a container." On the other hand, if space is conceived merely as an expansive area, an extension, or the part occupied by the cherries within the crate, then if we remove the crate from this thought experiment, what remains is "space as that which is contained" (Malpas, 2012).

4.3. Space and Place in the Hellenistic Period

The dominant philosophical perspective of the Hellenistic period, represented by the 'atomists,' asserted that nothing exists apart from atoms and the void. In relation to space, they introduced the concept of 'infinite space.' The atomist model posits a twofold infinity: the infinity of space itself and the infinity of the atoms that fill this space.

One of the most prominent thinkers of the period, Epicurus, countered the notion of infinite space by proposing three fundamental functions of general space: void, place, and room (*khôra*). Void refers to truly empty space, an unoccupied expanse. Place denotes occupied space and relates to the position of an object perceived within space. Room, translated from Plato's concept of khôra, signifies the medium within which movement occurs (Deviren, 2001).

5. Space and Place in Cartesian Philosophy

Newton's Mathematical Principles of Natural Philosophy, published at the end of the 17th century, marked a critical turning point in the distinction between space and place. Drawing from the disciplines of physics, mathematics, and geometry, Newton reduced the concept of place to position and advocated for the theory of absolute space (Deviren, 2001). According to Newton, "space is an absolute expanse independent of its contents and should not be confused with the objects within it" (Usta, 2020).

During the early modern period, two significant terms were introduced into discussions on space: extension and motion. Extension (or spatial expanse) was mathematized by Descartes. As explicitly stated in Principles of Philosophy, Descartes assimilated the reality of place into the abstraction of space. Place was reduced to mere position, while space emerged as a purely abstract concept (Deviren, 2001). In an era dominated by the natural sciences, physics, mathematics, and geometry, place came to be understood as position, while the theory of absolute space—rooted in Euclidean geometry—was defended, shaping a Cartesian understanding of space.

6. Space and Place in Phenomenology

Abraham Moles (1920–1992), one of the pioneers in the conceptualization of space, categorized the human relationship with space into two philosophical perspectives; "physical-mathematical space" which is based on Cartesian philosophy and "phenomenological space" (Seçer, 2016). In the physical-mathematical perspective, space is conceived as a homogeneous, three-dimensional void, independent of human experience and meaning. This view perceives space as an empty framework in which the human subject exists separately, acting as an impartial observer detached from the world. However, this fragmentation of the human-space relationship suggests a disconnection between individuals and their spatial environments. While mathematical models may provide an ideal framework for studying space, they prove insufficient when addressing the complexities of social existence. In contrast, the phenomenological understanding of space emphasizes lived experience, focusing on inhabited space or spatial experience. This perspective foregrounds the human body as the starting point, proposing a human-centered, directly perceived, and experience-driven conceptualization of space.

Along with phenomenological studies on place, the concept of pure and absolute space has undergone a significant transformation, gaining new meaning through the notion of movement. This phenomenon of movement also forms the core of the phenomenological approach developed by Edmund Husserl, the founder of phenomenology (Deviren, 2001). Husserl, who emphasized 'the necessity of bracketing preconceptions to achieve true understanding,' argued that understanding space requires experiencing it, and experiencing it necessitates movement within it. Experience, therefore, occurs through movement. Accordingly, he focused on the concept of place as dependent on kinesthetic perception, stating that "place is realized through kinesthesis, and in this reality, the character of place is optimally experienced" (Husserl, 1962). This perspective reveals that place is not merely a location but rather a complex whole. Consequently, in addition to the concept of movement, the notion of experience has also been integrated, making it an active component of place (Deviren, 2001).

According to Heidegger (1927) the state of being-in-a-place, or In-der-Welt-sein (being-there), is fundamental to human existence. It denotes the inseparable relationship between individuals and the world around them. For Heidegger, human beings are not detached from their environment; rather, their being is realized through their interaction with the places they inhabit. The world and human existence are co-constituted, and it is through lived experience that humans come to understand and engage with the world.

Heidegger contends that human beings are 'thrown' into a specific situation or place, a concept that underscores the contingency and unpredictability of human existence. Individuals cannot predetermine their existential circumstances, such as their socio-economic status, cultural background, physical abilities, or intellectual capacities. Rather, they find themselves 'thrown' into a particular world that shapes their experience. Heidegger rejects the Cartesian notion of space and argues that, just as humans and the world are inseparable, so too are humans and the spaces they inhabit. He critiques the idea of an abstract, absolute space, asserting that 'Space by itself is nothing; there is no such thing as absolute space (Heidegger, 1927; Bolak Hisarlıgil, 2007). For Heidegger, space is a site of interaction and experience, and to experience space is to be-in-the-world.

Heidegger distinguished between space and place by stating, "Space consists of linear orientations and measurable, calculable dimensions." In contrast, the concept of place reflects a mode of understanding space through practical knowledge that brings the sense of belonging into consciousness—transcending mere spatiality to grasp its reality. Through this distinction, Heidegger also clarified the difference between "building" and "dwelling". According to him, not every structure constitutes a dwelling, nor does every space necessarily provide a sense of place. Building refers to a more physical condition, akin to space, whereas dwelling, like place, occurs in the realm of thought. For instance, a truck driver may "dwell" on the roads, as they become his home, yet the road itself is not a lived, inhabitable space. Thus, space is a "form," whereas place is a "mode of being" (Tuncer Gürkaş, 2010).

The Norwegian theorist Christian Norberg-Schulz extended Heidegger's ideas into the field of architecture, introducing a new concept: *Genius Loci*—the Spirit of Place. Originally a Roman concept, *Genius Loci* in ancient Roman belief referred to the unique essence and protective spirit inherent in every entity (Koçyiğit, 2007). Schulz argued that places possess a distinct spirit independent of the observer and the meanings people attribute to them. He maintained that each place has an identity, a unique character, and specific qualities that architecture must reveal; otherwise, architecture becomes a meaningless endeavor (Norberg-Schulz, 1968).

According to Schulz, architecture must first immerse users in the conditions and influences of the natural environment. Then, through wholeness and form, it should envelop users freely and without constraint. Finally, the architectural product must respond to the conditions of its surroundings. He emphasized that these elements are essential for creating meaningful places for human beings. Schulz's primary focus in architecture was not only the function of buildings but also the forces that shape them and the meanings they convey (Seçer, 2016).

Building upon Heidegger's philosophy, Schulz highlighted the direct relationship between human existence and architecture. He focused on the meaningful connections between humans and their environment, as well as between architecture and place. He asserted that architecture, as a human-made environment, should be shaped according to the characteristics of its location and should reveal the spirit of that place. Thus, spaces should not be designed as detached, empty volumes in space, independent of their surroundings. In this regard, Schulz also critiqued modern architecture, emphasizing the necessity of revealing the spirit of place and its distinctive features (Norberg-Schulz, 1968; Seçer, 2016).

In his exploration of how a space transforms into a *place*, Schulz argued that the organic connection between space and place originates from *Genius Loci*. He introduced the concept of *lived experience* (*Erlebnis*), which he defined as a behavioral and cognitive schema that shapes human orientation and existence. He distinguished three types of spatial experience: (1) *pragmatic space*, defined by action; (2) *perceptual space*, which generates immediate orientation; and (3) *existential space*, which forms an environmental image (Eyce, 2011).

In the phenomenological studies of the French philosopher Maurice Merleau-Ponty, perception is fundamentally embodied, with a strong emphasis on the concept of embodiment. His philosophy positions the human body as the central subject of the experiential world (Merleau-Ponty, 2005; Sezgin, 2015). While Heidegger conceptualized existence as "being-in-the-world," in Ponty's thought, this notion transforms into "becoming and embodying within the world". This perspective suggests that every encounter with the world involves a process of rediscovery, as if learning anew (Eyce, 2011).

According to Ponty, the individual is both a thinking body and a social being who engages in spatial experiences within daily life. Opposing the Cartesian view that considers space as a geometric extension and reduces individuals to mere users of space, Ponty argues that space cannot be separated from the body and that each person is inherently part of and intertwined with their spatial environment. Subject, object, and world co-constitute one another in a simultaneous and reciprocal interaction. In other words, reality is understood through bodily perception and comes into existence through momentary experience (Merleau-Ponty, 2005; Seçer, 2016). We inhabit space through our bodies, and our connection with the external world is always mediated by the body. Since we are bound to our bodies and cannot detach from them, we are equally dependent on space. Given this interdependent relationship, Merleau-Ponty's assertion that "space is existential, and existence is spatial" holds significant weight. Space enables existence; it is the womb that gives rise to being and provides its foundation. The existence of space is animated by bodily movement and the dual relationship between subject and object. Existence is inherently spatial because there is no being without place. Even in the absence of human life and bodily interactions, spaces persist in their material reality. A bombed-out city in wartime, an abandoned village emptied due to terrorism, an obsolete industrial structure, a deserted house, or a closed shopping mall affected by economic crises—all remain as spatial entities. Although they depend on bodily movement to be fully lived and experienced, their physical existence is independent of human presence. However, the inverse is not true: there is no existence of the body without place (Tuncer Gürkaş & Barkul, 2012).

Ponty's approach presents an integrated relationship between the body, space, and movement, where each concept is explained through the others. In this dynamic interaction, the body acts as the interface that moves and perceives; movement constitutes the act of transition initiated by the body; and space serves as the substrate for movement. Put differently, the body generates movement, movement enables spatial experience, and space, through its physical presence and the movement it accommodates, provides perceptual and experiential data to the body. These data correspond to sensory information that the body receives (Sezgin, 2015). Spatial experience, therefore, is an extension of the perceived world, characterized by a mutually constitutive relationship between the perceiving body and the perceived space (Topal, 2013).

Like Merleau-Ponty, Pallasmaa emphasizes the importance of the cooperation of the senses in perceiving the external world and critiques the privileging of vision over other senses. According to him, architecture is not merely a visual discipline but rather an interplay of multiple sensory experiences that interact and merge with one another (Sezgin, 2015). In his book *The Eyes of the Skin* (2011), Pallasmaa distinguishes between two types of spaces: the optic space, perceived through vision, and the haptic space, experienced through touch. The optic space is shaped by the dominance of vision in modern architecture, where perspective and the privileging of the eye place sight at the center of human perception. In contrast, the haptic space is what truly leads to understanding, activating the world of the senses and fostering an interaction between humans and their environment. According to Pallasmaa, in contemporary society, technology has further reinforced the prioritization of sight and hearing while suppressing the other senses, leading to a lack of bodily experience in architectural spaces. He argues that truly human-centered spaces can only be created by engaging the body as a whole, encompassing all the senses. Criticizing modern design for being predominantly visual, he asserts that it alienates the body—along with its sensory memories and dreams—rendering contemporary architecture devoid of existential and spatial experience (Pallasmaa, 2011). He also differentiates between two modes of vision: focused vision, which is fixated on a single point and aligns with the intellect's notion of the "ideal," and peripheral vision, which encompasses the preconscious field of perception beyond the focused area. It is peripheral vision that envelops the subject in space and enables spatial perception to emerge.

Pallasmaa argues that the reason contemporary cities often feel alienating compared to natural and historical environments, which possess strong sensory qualities, is their lack of engagement with peripheral vision. This perspective concretizes Merleau-Ponty's phenomenological approach to embodied experience within the field of architecture. Our bodies engage with the world through touch, establishing a connection and becoming integrated with it. The essence of space can only be grasped through lived experience; it cannot be predetermined or designed to yield absolute and definitive outcomes (Seçer, 2016).

7. Various Thinkers on Space and Place

7.1. Henry Lefebvre (1901–1991)

A Neo-Marxist existential philosopher, Henry Lefebvre was a sociologist of urban and rural life and a theorist of social space who made significant conceptual contributions to the study of space (Hubbard & Kitchin, 2018). In his most well-known and widely read book, *The Production of Space* (1974), he examines social space as the national and planetary expression of modes of production. Lefebvre's comprehensive and multifaceted spatial theory has provided a crucial foundation for subsequent discussions and studies on space. The concepts of 'spatial periodization' and 'spatial triad' have become two primary elements forming the structural basis of his theory of the production of space.

7.1.1. Spatial Periodization

As an implication of Lefebvre's assertion that "space is a social product," spatial periodization aligns with the periodization of modes of production, a common approach in Marxist theory. According to Lefebvre, each mode of production possesses its own corresponding space, and throughout history, transitions from one mode of production to another have resulted in the creation of new spaces. Based on this idea, Lefebvre discusses absolute space, sacred space, historical space, abstract space, contradictory space, and differential space, thus outlining a brief history of space.

a) Absolute Space: The origins of absolute space, as described by Lefebvre, are rooted in agriculture, encompassing spaces where peasants or nomadic herders worked (Lefebvre, 2014). Primitive communities engaged in hunting or agriculture formed their own social spaces within these environments, which remained in harmony with nature. Due to the strong connection between these spaces and nature, as well as the constraints on human dominance over space, it was not entirely possible to sever these spaces from their natural ties and transform them into built environments (Lefebvre, 2014; Ghulyan, 2017).

b) Sacred Space: Sacred space emerged as absolute space gradually became occupied by political and religious authorities. Parts of nature were sanctified and appropriated by magical and religious power, becoming instruments of political control. Sacred space, although stripped of its natural state, continued to be perceived as part of nature and was both religious and political in nature. These spaces can be considered the initial distinction between the social and natural worlds and the beginning of the differentiation between the center and periphery in social space (Lefebvre, 2014; Ghulyan, 2017).

c) Historical Space: The fragmentation of sacred or absolute space by the so-called 'barbarians' who invaded Rome led to the first major agricultural reform in Europe during the feudal era. The settlement of these groups altered the nature of private property, giving rise to a new spatial production that marked a distinction between public and private domains. Consequently, spaces for accumulation emerged, and cities began to be organized as marketplaces. From the 12th to the 19th century, spaces of accumulation coexisted with spaces of war (Ghulyan, 2017).

d) Abstract Space: With the transition from feudalism to capitalism, nation-states and abstract spaces emerged, shifting the primary agent from the city to the state. Consequently, urbanized space was replaced by state-controlled space. The philosophical foundation of abstract space lies in Cartesian philosophy, which emphasizes the logical and mechanistic analysis of nature and space. Due to its Cartesian influence, abstract space is the realm of white paper, drafting boards, plans, sections, elevations, models, and projections (Lefebvre, 2014; Ghulyan, 2017). This type of space is not inherently abstract but is experienced as abstraction, defined through the perception of an abstract subject.

e) Contradictory Space: Contradictory space is essentially an extension of abstract space, sharing its characteristics. However, due to the latest developments in capitalism, the contradictions inherent in abstract space have deepened further. Thus, abstract space, both quantitatively and qualitatively, now manifests as contradictory space, revealing a more acute and visible series of contradictions than in the past (Lefebvre, 2014; Ghulyan, 2017).

7.1.2. Spatial Triad

Lefebvre analyzed historical spatializations through three axes that maintain a dynamic equilibrium and are dialectically interconnected. He proposed that space is experienced through three fundamental aspects: perceived, conceived, and lived space. In conceptualizing these dimensions, he introduced the triad of spatial practice, representations of space, and representational spaces.

a) Spatial Practice (Perceived Space): According to Lefebvre, a society's spatial practice produces its own space. Spatial practice primarily concerns space as a material reality. It encompasses buildings, structures, workplaces, private and leisure spaces, as well as the networks and routes that connect them. Consequently, it can be empirically observed. Due to its physical nature, it allows for the direct experience of space. In short, perceived space consists of physical spaces that house all daily practices and activities and can be experienced through perception by social actors (Lefebvre, 2014; Ghulyan, 2017).

b) Representations of Space (Conceived Space): This dimension of space is mentally constructed, designed, and related to metaphysics and ideology, often referred to as 'the space of the philosopher.' Conceived space is conceptualized as representations of space, stemming from individuals constructing mental representations of reality and their experiences with space (Fataar & Rinquest, 2019). These spaces are deliberately designed by experts to accommodate specific organizational outcomes (Lefebvre, 2014; Berti et al., 2018; Pawlicka-Deger, 2020).

c) Representational Spaces (Lived Space): The third aspect of Lefebvre's spatial triad comprises spaces occupied by inhabitants and users, which can be altered by ordinary people. These are spaces where spatial arrangements are adapted, modified, or transformed and where bottom-up changes can occur, even if inconsistently. Lived space, known as social space, signifies the lived experience of space—one that is produced and transformed over time through use and is imbued with symbols and meanings (Lefebvre, 2014; Fataar & Rinquest, 2019; Pawlicka-Deger, 2020).

To summarize, within the framework of the spatial triad, there are;

1. A physically produced and utilized form,
2. A mental representation,
3. A simultaneously material and mental lived dimension.

As visualized in Fig. 2, through the dialectical interplay of these elements, space is produced and modified over time (Berti et al., 2018). To simplify these concepts, in everyday social life, perceived space (*le perçu*) consists of ordinary activities and possibilities, yet it is often overlooked within the professionally and theoretically defined conceived spaces (*le conçu*) of cartographers, urban planners, and land speculators. Simultaneously, individuals exist within 'lived space,' which is sustained and accessed through art and literature and shaped by imagination. This type of space has the power to redefine and transcend the balance between perceived and conceived space (Hubbard & Kitchin, 2018).

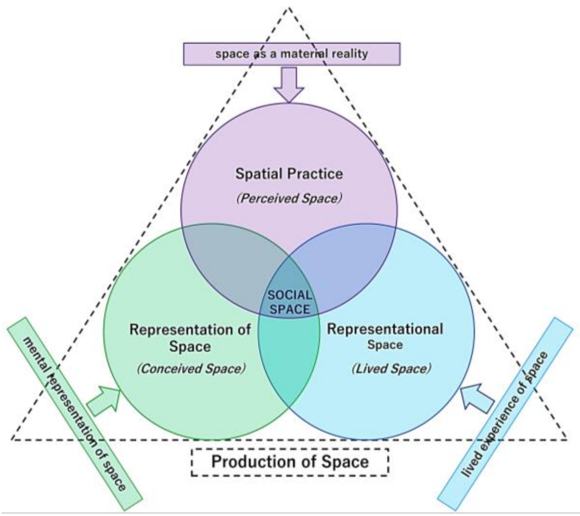

Fig. 2. Henry Lefebvre's triad of space production. (visualized by the authors)

7.2. John A. Agnew (1949 - …)

Like Lefebvre, who provides a rich theoretical framework for understanding how society conceptualizes, produces, and perceives space, political geographer John A. Agnew has defined three fundamental aspects of place:

1) *Place as a location or a site in space:* A settlement or a place where an action (or object) is located and is connected to other locations in space through interaction, movement, and diffusion. According to this definition, all places are distinguished based on their location, and all objects are defined through spatial relationships.

2) *Place as a series of locales or settings:* A place consisting of material environments for social relations, such as a series of neighborhoods, event venues, or contexts where everyday life activities take place. These spaces, which may include workplaces, homes, shopping malls, churches, etc., have a tangible form and encompass both social interactions and concrete behaviors.

3) *Place as a sense of place:* Identification with a place in terms of a unique community, landscape, or moral order. This dimension involves the emotional attachment necessary for settlement and the sense of belonging to a place, which is particularly significant. Here, place is not simplified as a mere material environment but is instead understood as having the power to shape social relationships through complex mechanisms of inclusion and exclusion (Pawlicka-Deger, 2020).

7.3. Marc Augé (1935 – 2023)

French anthropologist Marc Augé introduced the concepts of Anthropological Place, Non-place, and Super modernity in his most famous book, Non-Places: Introduction to an Anthropology of Super modernity, published in English in 1995. In this work, he systematically elaborates on the dimensions of space, place, and non-place, providing a conceptual framework for the anthropological study of spaces, practices, and cultures in contemporary Western society. Augé defines place as localized, occupied, organic, and historical—a space meaningful to visitors where identities can be produced. According to Augé, for an area to become a place, it must be mentally constructed through repeated encounters and complex face-to-face relationships. In essence, place is defined within the axes of identity, relationships, and historicity (Seçer, 2016; Hubbard & Kitchin, 2018).

Augé in this book uses the idea of supermodernity to describe today's world characterized by the three figures of excess; overabundance of events, spatial overabundance, and the individualization of references. Within such a world, there is a widespread transformation of the characteristics of space, time, and place, giving rise to non-places (Augé, 1995). Non-places are empirically measurable spaces that reflect individual experiences and perceptions of places. They lack the qualities of place such as meaning and belonging, having entirely lost their significance. Examples include metro stations, highways, airports, shopping malls, hotels, and holiday resorts—spaces that create their own realities and are generated by circulation, consumption, and communication, categorizing them as non-places. In these spaces, where social interactions are minimal, individual identities are invalidated, and every person is considered part of the crowd. Relationships in these places are defined by alienation, abandonment, and loneliness, and users inhabit these spaces temporarily (Berber, 2011; Hubbard & Kitchin, 2018; Usta, 2020).

Augé's work on non-places, which frequently attracts attention, differs significantly from other studies on the subject conducted by researchers like Edward Relph, who critiques placelessness in the Western world, or Melvin Webber, who examines the role of non-place in the emergence of flexible societies in urban areas. According to Augé, non-places can be comforting for many users due to the familiarity they evoke, yet for some individuals, the experience of these places can evoke a sense of indifference (Hubbard & Kitchin, 2018). Augé expresses that non-places never exist in a pure state, stating, "places continually remake themselves within themselves, their relations being refashioned and sustained within them... places and non-places are like opposite poles, the former never entirely erased and the latter never fully completed" (Auge, 1995; Hubbard & Kitchin, 2018).

7.4. Michel de Certeau (1925–1986)

Michel de Certeau explored everyday practices within the relationship between space and place, focusing on the distinction between the two concepts. In his seminal essay *Walking in the City*, featured in *The Practice of Everyday Life*, he begins by describing the pleasure of viewing Manhattan from the 110th floor of the World Trade Center—observing the whole and reading its order. He then transitions to a critique of urban theory, questioning the subject's position, urban planners' perspectives, the comprehensive control of space, and the claims of social theory, ultimately highlighting the difference between space and place (Hubbard & Kitchin, 2018).

From this example, de Certeau identifies two contrasting perspectives through which a subject might engage with space: one is the panoptic gaze that examines the city from above, while the other consists of the moving bodies observing urban structures from below. The former overlooks the transience of daily life, while the latter remains tied to it (Gelinas-Lemaire, 2018). In other words, de Certeau discusses the city in terms of two opposing figures: the 'walker,' who perceives the city from street level, and the 'voyeur,' who admires the city's overarching structure from above. He uses this dichotomy to explain space and place differences. (Gazzard, 2011).

According to de Certeau, the walker kinetically experiences the city through actions that defy the prescribed behaviors anticipated by cartographers and urban planners. In this sense, space is a practiced place. It consists of familiar "here and there" locations created by historically and culturally embedded practices (Tuncer Gürkaş, 2010). Thus, the city transforms into space through the actions of an individual walking along the geometrically defined streets of a plan (Hubbard & Kitchin, 2018). This perspective reverses the conventional geographic notion that associates space with abstraction and place with lived and experienced forms.

In de Certeau's terminology, space is characterized by mobility and dynamism, while place is described as static and fixed. He defines place as a position on maps and plans, whereas space is a meaningful position shaped by actions. Spaces are the lively streets traversed by people, while places are the buildings and other components of the built environment that define those streets (Tuncer Gürkaş, 2010). For de Certeau, space is produced through actions and defined by experiences, whereas place is a blank template upon which actions occur (Tuncer Gürkaş, 2010; Adıgüzel Özbek, 2016; Usta, 2020).

De Certeau likens the relationship between space and place to that of grammar and speech in language: although every language has a defined grammatical system, there are countless ways to construct meaningful sentences. Thus, if place is the word, space is the speech. Memories, stories, and narratives can transform a place into a space (Adıgüzel Özbek, 2016). De Certeau compares this to a walker's infinite ways of engaging with the street, stating, "A walker does not walk on walls, but the ways they use the street are limitless" (Tuncer Gürkaş, 2010).

8. Conclusion

Throughout history, the concepts of place and space have evolved across different philosophical and architectural traditions, shaping our understanding of how humans interact with their built environments. From Plato's and Aristotle's foundational distinctions to Lefebvre's socio-spatial theories and Merleau-Ponty's phenomenological insights, it is evident that space is not merely an empty container but a lived, experienced, and constructed reality.

In architectural discourse, this realization underscores the necessity of designing spaces that do not solely prioritize physical form but also consider the sensory, emotional, and social dimensions of human experience. The critique of modernist approaches, as articulated by thinkers like Pallasmaa, further emphasizes the importance of embodiment and multi-sensory engagement in creating meaningful places.

Ultimately, this study highlights that the relationship between place, space, and human experience remains central to architectural theory and practice. Recognizing the interplay between perception, movement, and memory within spatial environments challenges architects and theorists to move beyond rigid physical definitions and embrace a more dynamic, human-centered approach to space-making. Future research could explore how contemporary architectural practices integrate these philosophical perspectives to foster more inclusive, engaging, and identity-rich spaces.

Understanding architectural memory of Milli Reasürans building through cinematographic montage

İsmail Gökkaya[1*], Funda Uz[1]

[1] İstanbul Technical University, Department of Architecture, 34367 İstanbul, Türkiye

Abstract. This study investigates how cinematic montage can be utilized to reinterpret architectural memory, focusing on the Milli Reasürans building in Istanbul.Traditional architectural historiography tends to prioritize technical representations such as plans, sections, and elevations, often neglecting the experiential and temporal layers embedded in buildings. By incorporating cinematic imagery and montage, this research proposes an alternative approach that brings together fragmented memory traces—including archival documents, photographs, oral histories, and personal narratives—to construct a multi-layered spatial reading. The methodology is structured around three phases: collecting memory traces, analyzing representational memory, and reconstructing these fragments through cinematic montage. Informed by Henri Bergson's theories on duration and Gilles Deleuze's concept of the movement-image, alongside architectural and memory studies by Paul Ricoeur, Douwe Draaisma, and Marc Augé, this research examines how cinematic montage can reconfigure architectural narratives. The study engages a broader spectrum of montage strategies to explore the intersection of memory, space, and representation.The Milli Reasürans building is re-imagined as a living archive where the past is constantly reconstructed through the lens of the present, by layering images, textual records and experiential narratives, and by superimposing different fragments of time and memory. This approach not only challenges linear, chronological understandings of architectural history but also highlights how montage techniques can offer richer, multi-layered interpretations of space and memory. In conclusion, the study demonstrates that buildings, through cinematographic montage, have temporal and spatial narratives that extend beyond their physical boundaries, offering new possibilities for representing and understanding the role of architecture in urban memory.

Keywords: Milli Reasürans; cinematic imagery; memory; montage; architectural historiography.

1. Introduction

Architectural historiography often addresses structures through conventional representation tools such as plans, sections and facade drawings. These representations may be functional for documenting the physical characteristics of the structure; however, they carry the risk of ignoring the temporal layers of the space, its experiential traces and the connections it establishes with the user. In this context, the existence of structures within the city includes not only physical but also social, emotional and memoryl layers. In this study, a new approach to architectural historiography is proposed through the concepts of cinematographic image and montage. Cinematographic montage disrupts the sequence of fragmented images formed over time and allows them to be re-interpreted. In this context, it is possible to reconstruct the memory of a structure through interrupted narratives, experiences and representations.

The study takes the Milli Reasürans building, built in the mid-1980s, as a case study. The architectural characteristics of the building, its relationship with the city, the competition process and subsequent uses show that it is not only a physical object; it is also a living carrier of memory. Reading this structure through cinematographic montage aims to reveal temporal ruptures and traces of memory. Thus, a non-linear, layered and experiential architectural history writing is proposed. In this paper, the memory of Milli Reasürans will be examined with a three-stage analysis framework: Memory, Memory of Representation and Representation of Memory. Each title will discuss how we can transform the historical and spatial memory of the structure through cinematographic imagery and montage.

2. Conceptual Framework: Cinematographic Image and Montage

The cinematographic image is not limited to the visual aesthetics or composition of cinema frames within a film. This concept gains depth especially with Gilles Deleuze's "movement-image" and "time-image" theories. According to Deleuze, cinema does not only present momentary sections of movement; it conveys movement itself through images (Deleuze, 1983). In this way, images turn into narratives that carry the continuity and variability of space. Time-image can show the past, present and future simultaneously within the memory of a structure, especially by breaking the cause-effect relationship. At this point, the cinematographic image comes into play as a powerful tool to make the temporality of architectural representations visible.

Cinematographic montage determines the way these images are brought together. The understanding of montage theorized by Sergei Eisenstein has the capacity to produce new meanings through collisions arising from the juxtaposition of different images. Eisenstein's sub-genres such as "intellectual montage", "rhythmic montage", "tonal montage" and "metaphorical montage" can be read not only in cinema but also in architecture. When the plans of a building spread over time, user stories, archive documents and current images are brought together with these montage techniques, new meanings about the memory of the structure can emerge (Eisenstein, 2014).

The method used in this paper enables the production of cinematographic images by rethinking the different forms of montage in the context of architecture. While intellectual montage establishes the intellectual relationship of documents from different periods, rhythmic montage analyzes the temporal flow of circulation in the building. Tonal montage emphasizes the emotional effect of space through the relations of material, light and void. Speculative montage produces alternative memories of the structure with non-archival but fictional images.

Thanks to this theoretical framework, it becomes possible to address architectural representation not only visually or physically, but also with its temporal, intellectual and emotional layers. The Milli Reasürans building is at the center of the study as an architectural memory object that is both documented and reconstructed in line with this approach.

3. Historical Layers of the Building: Competition, Construction and Usage Process

Milli Reasürans T.A.Ş. General Directorate Building and Complex which was opened for use in 1995, is a structure with a strong public aspect. Its architects are Sevinç Hadi and Şandor Hadi Located at the intersection of Teşvikiye and Maçka Streets, the building is positioned between two important historical structures: Maçka Palas and Ralli Apartment. It also establishes a strong relationship with Abdi İpekçi Street. The rows of exhibitions and shops on the ground floor of the building serve as a passage connecting two different streets of the city. The 45-meter bridge facing Maçka Street, which is the iconic facade of the building, leaves a strong mark on urban memory; it both creates a response to Maçka Palas and gives the building a monumental appearance with the space left in the form of an iwan.

In 1984, Milli Reasürans T.A.Ş. organized a national architectural project competition by invitation for the new headquarters building (Dündaralp, 2011). The competition title envisaged not only meeting the need for offices but also producing a modern and permanent structure that reflected the prestige of the institution. 15 offices were invited and 9 of them submitted their projects. Sevinç Hadi and Şandor Hadi's project was selected as the winner in the competition, and only an honorable mention was given because the other projects did not offer a viable alternative. The jury reports emphasize that the Hadi couple's proposal fully complied with the specifications and was highly applicable.

The project area contains important reference points in terms of both architectural and urban context. Structures such as Maçka Palas and Ralli Apartment were decisive in the formation of design decisions; especially the iwan solution spatially expressed the relationship established with these structures. The iwan not only provides urban continuity and permeability, but also strengthens the monumentality of the structure. As Sevinç Hadi emphasizes in her own narratives, this decision is both a solution to mass fears and the product of an approach sensitive to the historical environment.

The history of the structure should be considered by dividing it into three main periods: the competition and design process (1984–1985), the construction process (1988–1992) and the usage period (Dündaralp, 2011). The evaluation criteria of the jury during the competition process included criteria such as land and environmental conditions, harmony with historical structures, elevation differences, placement of program components with symbolic value and technical feasibility. The presence of the structure in Maçka should be evaluated as a reflection of the transformation in Turkish architecture in the 1980s. This period is the years when architecture was considered not only as a physical production but also as a tool of image, identity and representation.

The passage program added to the design reinforced the structure's place in the collective memory. Programs such as restaurants, bookstores, exhibitions, cinemas and bars strengthened the structure's relationship with public life and made it not only an institutional center but also an urban meeting place. Despite its relocation to Levent, the Milli Reasürans Passage continues to be in public use today. This continuity is an important layer that preserves the memory of the structure.

The structure is built on a 34,000 m² development right and is divided into three main sections: the general directorate, auxiliary facilities and general service sections. Design decisions were shaped by both the technological possibilities of the period and the relations established with the urban texture (TRT 2, 2024). The parking system, which goes down to four floors underground, draws attention in terms of construction technology and also makes an indirect contribution to the foundations of the surrounding historical structures with the anchor system. The cinematographic images and montage representations to be produced regarding the structure will be fed by these historical layers and the urban context. The next section will discuss how this historical background can be reconstructed through images.

3. Reconstructing Milli Reasürans with Cinematographic Montage

The Milli Reasürans building, beyond being just a physical structure, requires a cinematographic reading with its spatial structure that offers transitions between different levels, passages where interior and exterior spaces are intertwined, and its dynamic relationship with public spaces. In traditional architectural historiography, structures described through plans, sections, and facades may be insufficient to reflect such multi-layered spatial experiences. Therefore, a cinematographic image approach is necessary to make sense of Milli Reasürans' traces in memory, its spatial changes, and its interaction with its users. The building's passage (that includes stores and restaurants), exhibition areas, inner courtyard, and its relationship with public spaces at different scales cannot be read from a specific perspective; they can only be made visible with cinematographic techniques that intertwine multiple perspectives. Unlike plans and sections, the cinematographic image offers a new perspective to architectural historiography by addressing the structure through changes in movement, time, and perception. In this context, Milli Reasürans is not only evaluated as a static structure, but as a living organism that includes different user experiences and layers of memory.

Cinematographic montage has a methodological basis based on how different types of montage (intellectual montage, tonal montage, rhythmic montage, speculative montage) can be transferred to architectural representation, based on the theoretical framework developed by Eisenstein. This approach enables not only the reproduction of physical space, but also the reinterpretation of the relationship established with the past of the structure and the traces it leaves in the urban and user memory. In this context, montage is not only a method of establishing a narrative, but also a tool that multiplies temporality, emphasizes the transition between spaces, and produces new meanings by bringing together representations from different periods. In the case of the Milli Reasürans structure, this montage method allows the superimposition of the phases the structure has gone through, different user practices, and urban context to be read.

Within the scope of this study, the Milli Reasürans building was studied through 3 cinematographic montages.

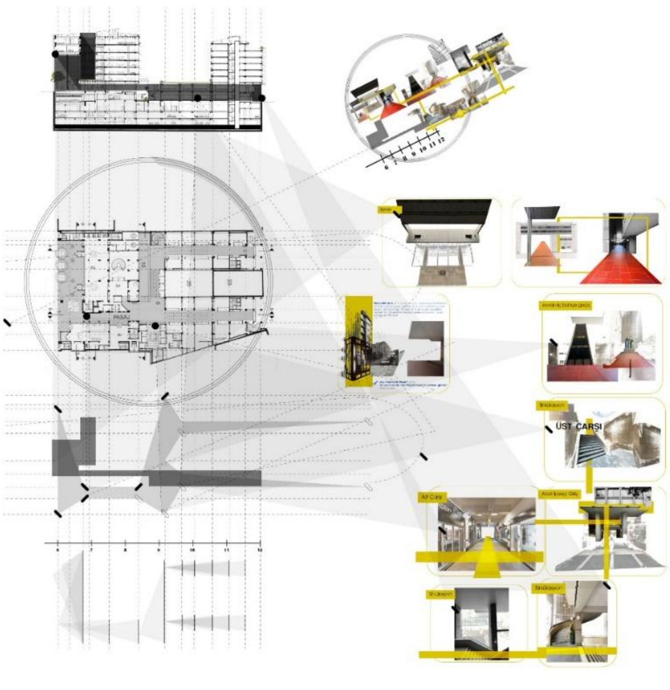

Fig. 2. Rhythmic Montage

In the first image study, the passage starting from the iwan of the building towards Teşvikiye and reaching Abdi İpekçi Street was traced through sections and plans. In this study, which is based on the experience of space and the imagery of perception, a multi-layered and duration-based canvas was created by presenting a path through the user's perception of space. Focusing on the relationship of the building with the public space, the movement/space inventory of the building was made both as a whole and as a fragment, within the boundaries of the private/public distinction. The representation of temporal experiences such as circulation, transition between levels, light and shadow in the interior spaces of the building was created with rhythmic montage.

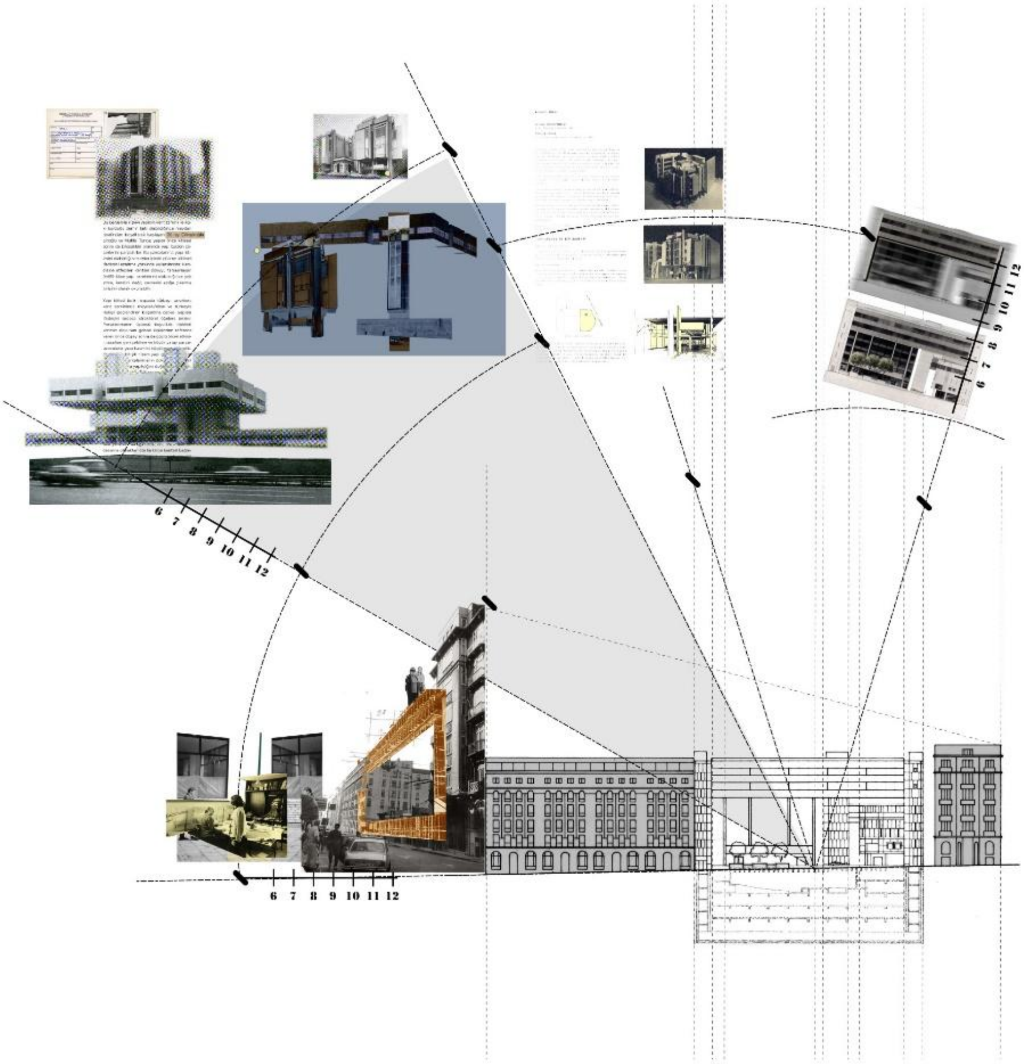

Fig. 3. Intellectual Montage

The second image study is based on the question "What is the building a plural of?" and explores the relationship of the structure with Maçka Palas and Ralli Apartment, as well as how these neighboring buildings influenced the architectural decisions made for Milli Reasürans, especially in terms of its facade design. Furthermore, the image juxtaposes Milli Reasürans with other buildings from different spatial and temporal contexts that, at first glance, seem unrelated. This connection is established through a metaphorical/intellectual montage. The image also illustrates how Sevinç Hadi and Şandor Hadi, who won second place in the Istanbul Reklam Sitesi architectural competition, later transferred the spatial strategies of the winning project by Günay Çilingiroğlu into the design of Milli Reasürans. In particular, the decision to position the executive offices on the upper level in the competition project is echoed in Milli Reasürans, where both the form and the functional organization reflect a similar hierarchy (Mimarlık Dergisi, 1969).

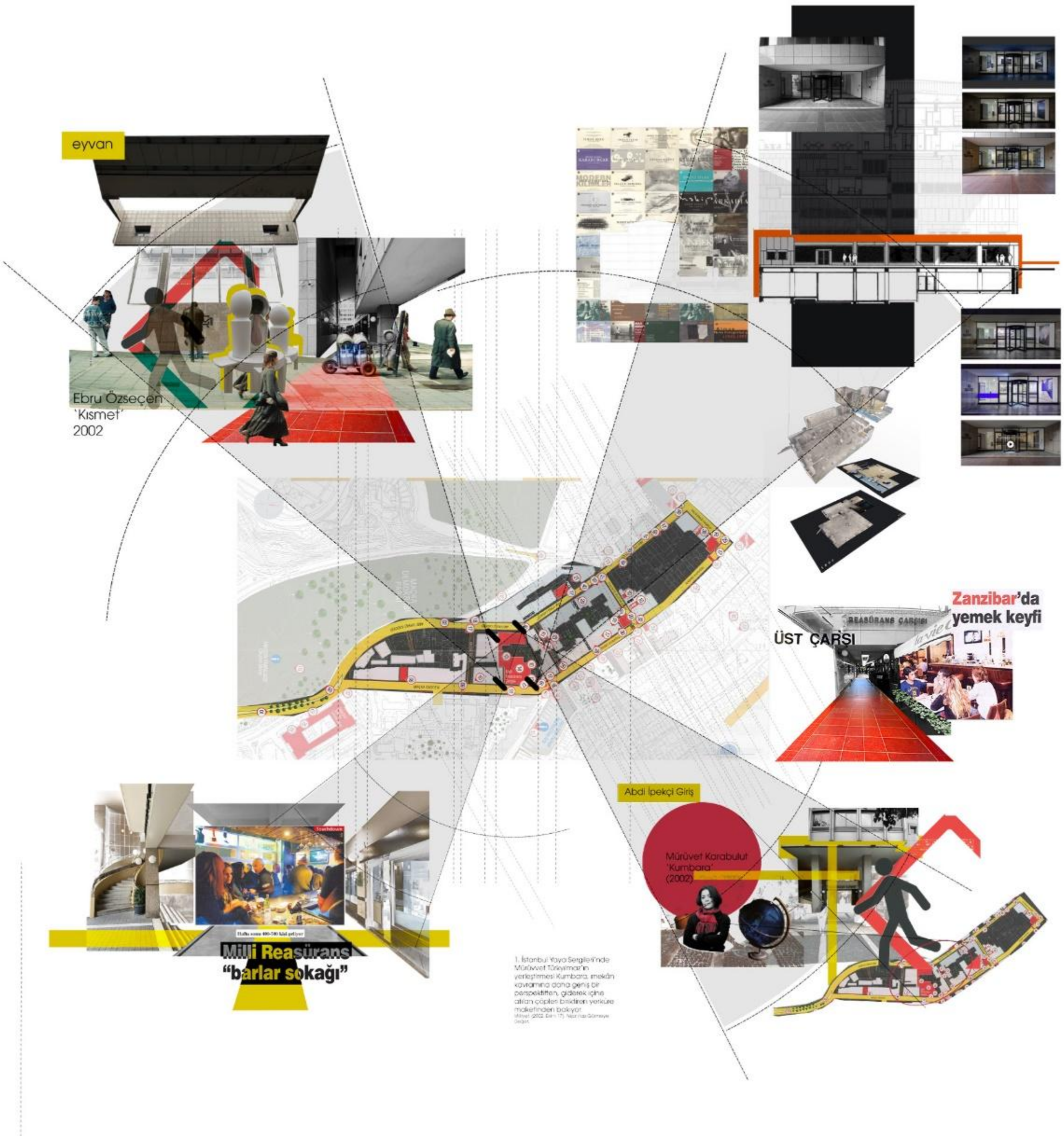

Fig. 4. Overtonal Montage

As the third image, an overtonal montage was used to create a multi-layered narrative by superimposing different levels of meaning through the combination of rhythmic, tonal, and intellectual montage techniques. This approach aimed to simultaneously represent the spatial, historical, and emotional layers of the Milli Reasürans building, revealing aspects of the structure that have been forgotten or overlooked in conventional architectural historiography. Within this framework, the memory of the ongoing exhibition tradition since 1995 is visualized, along with an imagined extension of the works displayed in the 2002 1st Istanbul Pedestrian Exhibition, which took place in Nişantaşı, into the Milli Reasürans context (İstanbul Yaya Sergileri, 2002). Additionally, former restaurants that once operated in the building, reflected in newspapers and magazines but now closed, are reimagined as part of the building's evolving and layered memory (Milliyet, 2002).

4. Conclusions

This study investigated the potential of cinematographic montage as a methodological tool for interpreting the architectural memory of the Milli Reasürans building. The aim was to go beyond conventional representational frameworks and to develop a more layered, experiential, and temporally nuanced understanding of architecture. Through archival research, spatial analysis, and visual montage practices, the study provided a non-linear reading of the building that foregrounds memory, perception, and temporality.

- The use of cinematic montage enabled a rethinking of architectural historiography by highlighting the temporal ruptures and spatial transformations of the building over time.

- Rhythmic, intellectual, and overtonal montage strategies provided multiple layers of representation, allowing the reconstruction of both physical and emotional aspects of the building's memory.
- The case study of Milli Reasürans demonstrated that architectural memory is not static but continuously shaped by the structure's engagement with its users, the city, and its historical context.
- The montage-based visual representations revealed overlooked narratives, such as the evolution of public uses within the building and its symbolic connection to adjacent urban elements like Maçka Palas and Ralli Apartment.
- Ultimately, this approach contributes to architectural theory by expanding the possibilities of how buildings are read, remembered, and represented, suggesting that cinematographic montage can serve both analytical and creative functions in contemporary architectural historiography.

Abstract. Van Pier has been an important maritime transportation point since the pre-Republican period. For many years, it has been the most important transportation point to reach Van city center. Since 1971, the trains coming from Tatvan Pier, the opposite shore of the lake, have started to be transported to Van Pier by ferry. The trains coming from the west of the Anatolia, disembark their passengers at the Tatvan Station. The trains cross Lake Van without passengers, and they are transferred from Van Pier to the railway only as freight trains. The transportation continues by rail and reaches Van Station. They take their passengers again at Van Station and continue their Asian voyage through Iran. This is a significant railway route opening to abroad from Anatolia to Central Asia. This railway route is significant as the modernised continuation of the historical Silk Road route. Moreover, Tatvan Pier and Van Pier is one of the unique examples in terms of providing land connection of railway vehicles over the lake. This study aims to examine the development of this railway and maritime transportation with its vehicles and structures, with the focus on Van Pier and Tatvan Pier. The research study is based on the review of relevant literature and analysis of old archival data from the architects' perspectives and field observations. This study might shed light on architectural history and transportation structures.

Keywords: Van Pier; Tatvan Pier; Transportation structres; Railway; Sea route

1. Introduction

Railway transportation and sea transportation are interdisciplinary research subjects in which lots of disciplines, such as mechanical engineering, civil engineering, architecture, urban planning, etc., are interested with. Turkey has a significant railway routes between Europe and Asia. These railway routes are interrupted in two marine points: Bosphorus in İstanbul and Lake Van in Van. The intersection of railway transportation and sea transportation is a significant subject needed to be documented and analysed in the architects' point of view. This study focuses on Lake Van and aims to examine the development of this railway and maritime transportation with its vehicles and structures. This study might shed light on architectural history and transportation structures.

2. Materials ans methods

The research study is based on the review of relevant literature and analysis of old archival data from the architects' perspectives and site observations. The reviewed literature is mostly related to the history of railway transportation, marine transportation, Van Lake, Tatvan and Van. Tatvan Train Station, Tatvan Pier, Van Pier and Van Train Station were analysed on site.

3. History of train ferry and sea transportation in Lake Van

The signifact international railway route of Turkey starts from Edirne Train Sataion and ends with Van Train Station. It connects Europe to Asia as parallel to the historical silk road, which was economical bridge between continentals. However, on this route, there are two significant marine points, in which rail system has no land connections. The trains started to pass he Bosphorous in İstanbul by sea vehicles in 1926. It is said that the early sea vessels used for this were like simple rafts. The first modern train ferry started to be used in Istanbul in 1958. Similarly, the trains started to be pass Lake Van with train ferries after 1971 (
Fig. 1,

Fig. *2* and Fig. 3).

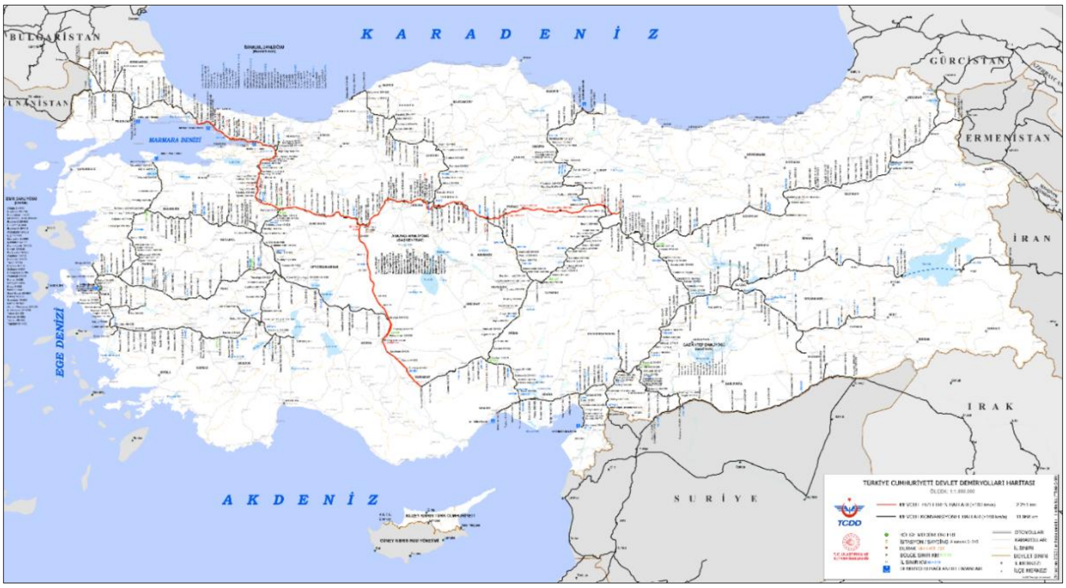

Fig. 1. Railway map of Turkey (TCDD, 2025)

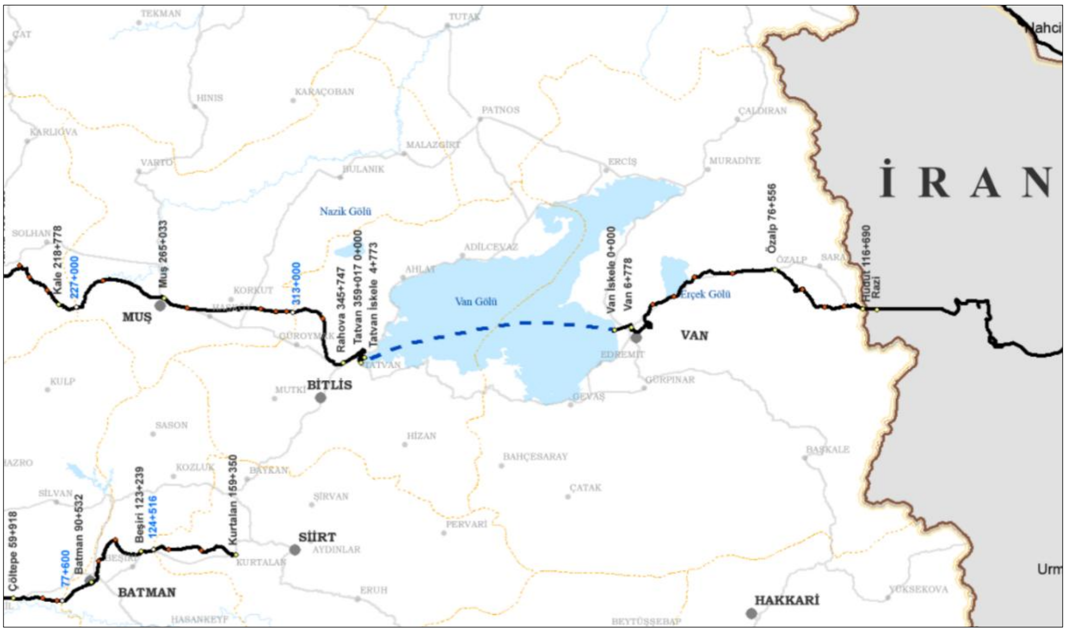

Fig. 2 Railway map of Turkey, a close view of Lake Van and surroundings (TCDD, 2025a)

Fig. 3 GoogleEarth map of Lake Van. Van Pier and Tatvan Pier are marked by the authors.

In the 1800s, transportation services in Bosphorus were supported by simple boats of *Tersane-i Amire*. In 1954, *Şirket-i Hayriye*, the first domestic company to transport passengers, was established. Hüseyin Haki Efendi was the innovative manager of the company and spent his years on thinking how to facilitate the transportation of vehicles in the Bosphorus. Finally, he asked Mehmet Usta, the architect of the company, to develop the idea. As a result of one-year work together, they designed the "*Suhulet*" and constructed it in UK Shipyard. "*Suhulet*" started to be used in Istanbul in 1871. It was also considered as the first car ferry in the world (Raily News, 2015).

"*Suhulet*" was 45.7 meters long and had 450 weighing gross ton. It served for the transportation of vehicles in the Bosphorus. After 1926, the trains also started to pass the Bosphorous. The first modern train ferry, called "*Demiryolu I*", started to be used in Istanbul in 1958. In 1966, the second train ferry, "*Demiryolu II*" was constructed. On those days, the constuction of railway route to Van was not comleted yet. The first train came to Tatvan Train Station in 1965. Van Train Station started to be activated in 1971 (Ayaz & Özyıldıran, 2023). The first trains passed the Lake Van via train ferry called "*Orhan Atliman*" in 1971. Hence, non-stop railway transportation from Europe to Asia started in Van in 1971. Table 1 illustrates all the train ferries constructed between the years of 1958 and 2007. There were seven train ferries, the three of them, called *Demiryolu I, II* and *III* were for Bosphorous, and other four were for Lake Van. The train ferry services from Sirkeci to Haydarpaşa were stopped in 2013, after the construction Marmaray, the tunnel under sea (Kukul, 2020). In current time, only two train ferries were servicing in Lake Van. They are called "*Sultan Alpaslan*" and "*İdris-i Bitlisi*" (table 2) (Ertek, 2025). Two of them can serve better than the total of the old ones. They are considered as the biggest ferries in Turkey (T.C. Tatvan Kaymakamlığı, 2025).

Table 1. Train Ferries constructed from 1958 to 2007 (Kent ve Demiryolu, 2007)

Name	Weight	Lenght	Shipyard	Year
Demiryolu I*	1422 gross ton	72,45 m	Haliç Shipyard	1958
Demiryolu II*	1233 gross ton	72,45 m	Haliç Shipyard	1966
Orhan Atliman	1918 gross ton	81,85 m	Haliç Shipyard	1971
Rafet Ünal	1918 gross ton	81,85 m	Haliç Shipyard	1972
Tatvan	1766 gross ton	81,84 m	Haliç Shipyard	1975
Van	1777 gross ton	81,84 m	Haliç Shipyard	1976
Demiryolu III*	1232 gross ton	72,45 m	Haliç Shipyard	1978

*Demiryolu I, II and III were constructed for İstanbul, and the other four ferries were constructed for Lake Van.

Table 2. Train Ferries constructed from 2015 to 2025 (TCDD Van Gölü Feribot Müdürlüğü, 2025)

Name	Weight	Lenght	Shipyard	Year
Sultan Alpaslan	6921 gross ton	135,66 m	İstanbul&Tatvan	2015
İdris-i Bitlisi	6921 gross ton	135,66 m	İstanbul&Tatvan	2018

4. Tatvan pier

Tatvan Pier has a significant role in sea transportation since the Ottoman period. Since the Lake Van is surrounded by high mountains, such as Artos in the south, Nemrut in the west, Süphan in the north, it is not possible to maintain the railway all the way around the lake. Hence, the main transportation way to Van city center had been over the Lake until 1960s. During the Ottoman eastern campaigns, the army passed by ships departing from Tatvan. When soldiers were sent to Korea in 1950s, they were transported by ships departing from Tatvan (Demirtaş & Subaşı, 2015).

During the Russian occupation of 1915-1918, a shipyard was built by the Russians in Ernis, in the north side of Lake Van. In 1926, this shipyard was transformed into the "*Van Gölü Seyr-ü Sefain İdaresi*". In 1936, it moved from Ernis to Tatvan and named "*Van Gölü İşletmesi*". In Tatvan, besides the pier, a shipyard, lodgings and a hotel were built. "*Van Gölü İşletmesi*" has a significant role in the economic and cultural development of Tatvan.

After "Van Train Station" and the railways route to İran were constructed in 1971, the railway transportation is also preferred to be continued over the lake by the train ferries. It is the most safe and economic way in the surrounding of Lake Van. However, the trains continue only with cargos, since the loads are heavy and the Lake transportation is very slow. All the passengers left the train in Tatvan Train Station. If the passangers want to continue their journey to Iran, they have to pass the Lake Van via highway and get on the train at the Van Railway Station. Fig. 4 illustrates current view of Tatvan city center together with Tatvan Railway Station and Tatvan Pier. Fig. 5 illustrates Tatvan Pier in more close view and

Fig. *6* illustrates the train ferries. Over time, there have been demolitions, transformations and additions to the old buildings of the facility.

Fig. 4 GoogleEarth map of Tatvan. Tatvan Train Station and Tatvan Pier are marked by the authors.

Fig. 5 GoogleEarth map of Tatvan Pier. Structures are labelled by the authors.

Fig. 6 Tatvan Pier and the train ferries (TRT, 2023).

5. Van Pier

One of the two significant piers of Lake Van is Van Pier. It is very close to the Van Citadel, which was traced back to the Urartu Civilisation from the ancient times. In current time, the pier is the starting point of "*İskele Caddesi* (Pier Street)" which was the longest lineer street in Turkey and it is said that it is the second longest street in the World. Hence the position of the pier is very strategic in the urban plan of Van.

"Van Ferit Melen Airport" was constructed in 1943. However, airway transportation was very expensive until the foundation of Anadoljet in 2008. The construction of the regular highway, surrounding the Lake Van, to the city center lasted until the 1960s. Until 1960s, the main transportation of the city center was sea transportation over the lake.

In 1971, Van Train Station was opened and train transportation started from Van to İran as an opening to Asia (

Fig. *7*). At the same time, train ferry services started from Tatvan Pier to Van Pier (

Fig. *8*). Thus, an uninterrupted train service from Europe to Asia was provided. Similar to Tatvan, trains came from Van Pier to Van Train Station without passengers, only with cargos. All the passenger get on the train at the train station. The passengers coming from the east also get off the train in Van Train Station. If they want to contionue to the west via railway, first they have to go through highway and get on the train in Tatvan Train Station. These problem can be solved in the future when the train ferries can be faster and more developed.

Fig. 7 GoogleEarth map of Van city center. VanTrain Station and Van Pier are marked by the authors.

Fig. 8 GoogleEarth map of Van Pier. Structures are labelled by the authors.

7. Results and discussion

The findings of this study reveal the unique character of the Van-Tatvan railway-sea intersection in the context of transportation history of Turkey. Unlike other parts of the railway network, the Lake Van crossing offers a distinctive model that combines railway, maritime and architectural components. The two piers - Tatvan and Van - were constructed not only as transport nodes but also as complex facilities integrating administrative, residential, and industrial elements. Archival data, literature reviews, and on-site observations demonstrate that the Van Lake crossing has played a significant role in maintaining uninterrupted railway connections between Europe and Asia since 1971. Although the ferries currently carry only freight wagons due to time and cost limitations, the infrastructure continues to serve as a strategic asset. Moreover, the train ferries "Sultan Alparslan" and "İdris-i Bitlisi" represent modern improvements in Turkey's maritime freight capacity. However, the full potential of the pier infrastructure is yet to be explored, especially in terms of passenger transportation and urban integration.

8. Conclusion

This study examined the architectural and infrastructural significance of Tatvan and Van Piers, focusing on their historical development and current function within the railway-sea-rail transportation corridor. The study underlines the need to document and preserve such hybrid transportation structures as part of Turkey's architectural and engineering heritage. The case of Van Lake presents a rare example of inland maritime railway connectivity, which could inspire similar integrated systems in other topographically challenging regions. Improving ferry speed and capacity, as well as reintroducing passenger services, could enhance the continuity and efficiency of East-West.

From theory to practice: Bridging cognitive and psychomotor domains in descriptive geometry

Fernando B. Bruno*[1], Fábio G. Teixeira[2], Régio P. Silva[2], Tânia L. K. Silva[2]

[1] *Federal University of Rio Grande do Sul, Department of Design and Graphic Expression, Porto Alegre, Brazil*
[2] *Federal University of Rio Grande do Sul, Graduate Programme in Design, Porto Alegre, Brazil*

Abstract. The development of Descriptive Geometry (DG) by Gaspard Monge facilitated the separation between design and construction processes by enabling the precise transposition of conceptual designs into tangible forms. As a result, DG remains a core subject in courses like Engineering and Architecture, fostering logical and spatial reasoning alongside drafting skills. Historically, DG education combined theoretical and practical activities; however, it gradually evolved into a more abstract and axiomatic discipline, often neglecting psychomotor skill development. Research highlights that DG curricula frequently emphasise cognitive objectives, assuming students already possess the requisite psychomotor skills for handling drawing instruments. The taxonomy proposed by Simpson categorises psychomotor objectives into stages such as perception, preparation, guided response, mechanism, complex response, and adaptation/creation. These stages underscore the importance of practical engagement in DG learning. Integrated Thematic Instruction (ITI) and Design-Based Learning (DBL) approaches have proven effective in enhancing student engagement and learning outcomes. ITI prioritises thematic relevance, varied activities, and authentic assessment, while DBL promotes hands-on, collaborative problem-solving tied to professional practice. HyperCAL^{3D}, a 3D modelling software designed to support the DG teaching-learning process, complements these methodologies by providing tools for creating and visualising DG activities. This platform supports practical learning through geometric designs, reinforcing psychomotor and cognitive skills. Since its systematic implementation at the Federal University of Rio Grande do Sul (UFRGS) has facilitated the integration of theory and practice in DG activities, offering students meaningful learning experiences.

Keywords: Descriptive Geometry; Design-Based Learning; Integrated Thematic Instruction; Spatial Reasoning; HyperCAL^{3D}.

1. Introduction

The development of Descriptive Geometry (DG) by Gaspard Monge can be regarded as one of the factors responsible for the separation between design and construction/manufacturing processes, as it precisely and rigorously enabled the accurate translation of the designer's envisioned object into a tangible form (Perez-Gomes & Pelletier, 2000 apud Gani, 2016). Consequently, undergraduate programmes that place design at their core, such as Industrial Design, Engineering, and Architecture, include DG in their curricula, as its study enhances the development of logical and spatial reasoning and establishes the foundations for technical drawing representation (Teixeira et al., 2015).

The teaching of DG, as conceived by Monge, envisaged that students would learn the general methods within the first two months of the course, dedicating the remainder of the year to the practical application of knowledge through construction activities such as stone and wood cutting, determination of projected shadows, and the elaboration of perspectives, among others (Monge apud Gani, 2016). Over time, however, as DG evolved into an autonomous discipline, it detached itself from the activities to which it was originally linked, and its teaching transformed into an "abstract instruction" (Gani, 2016, p. 2), based on axiomatic methods (Silva, 2005; Teixeira et al., 2015) and more focused on rules and conventions than on autonomous reasoning (Montenegro, 2005)

Despite this distancing, DG remains a theoretical and practical discipline and, as such, its teaching/learning process should be conducted not solely through cognitive domain objectives — knowledge, comprehension, application, analysis, synthesis, and evaluation (Bloom et al., 1974) — as typically occurs in lecture-based classes, but also through the psychomotor domain. Approaches that fail to consider the development of psychomotor skills often allocate little or no time to the practical component, which is fundamental in any graphic expression discipline.

* Corresponding author, E-mail: fernando.bruno@ufrgs.br

https://doi.org/10.31462/icearc2025_a_arc_279

An analysis of DG teaching plans applied in the Engineering programmes at the Federal University of Rio Grande do Sul (UFRGS) highlights that the objectives set are predominantly cognitive, assuming that students already possess the psychomotor skills required to handle drawing instruments (Silva, 2005).

According to Krathwohl et al. (1964, apud Simpson, 1966, p.17), psychomotor objectives are those that "emphasise muscular or motor skills, manipulation of materials and objects, or activities that require neuromuscular coordination." Several authors have organised these objectives into taxonomies, hierarchically structured in a similar way to Bloom et al., (1974) regarding the cognitive and affective domains: Krathwohl et al. (1964 apud Simpson, 1966), Simpson (1966), Dave (1970), Harrow (1972), Ferris & Aziz (2005), Hill et al., (2018). Among the various taxonomies, that proposed by Simpson (1966) proved the most suitable for the present work.

The categories of Simpson's psychomotor domain taxonomy are:

- **Perception** – recognition of elements through the senses and the organisation of sensory stimuli in the interpretation of situations for undertaking motor actions;
- **Set** – preparatory adjustments, states of readiness, for carrying out an action;
- **Guided response** – development of basic skills that constitute more complex skills, often involving imitation and trial-and-error processes;
- **Mechanism** – naturalisation and standardisation of sets of skills through increased confidence and performance;
- **Complex overt response** – execution of complex motor actions following the mastery and standardisation of simple actions, characterised by efficiency and fluidity;
- **Adaptation/origination** – ability to adapt actions to different contexts or varying requirements.

These psychomotor objectives not only underpin the practice of technical drawing, but are also crucial in developing practical skills for handling tools and executing precise geometric operations—skills essential for training future professionals in the fields of Engineering, Architecture, and Industrial Design.

Although DG encompasses a dense theoretical component requiring high levels of abstraction, it demands learning experiences that simultaneously develop or refine hand-instrumented drawing skills while striving to achieve cognitive objectives. In order to attain learning objectives across different domains simultaneously, Beatty (2009) suggests Theme-Based Instruction, or Integrated Thematic Instruction (ITI), an approach to facilitate learning by involving various domains in support of a unified theme.

In ITI, key values include: the relevance of learning to students' lives, the relationships among domains, real-world application, appeal and effectiveness (rather than efficiency), activities linked to a unified theme, varied resources and activities, flexibility, and, on the part of the lecturers, a willingness to relinquish some elements of direct control (Beatty, 2009).

In tandem with these methodological principles and to reduce the level of abstraction, previous studies conducted at UFRGS have shown that the integration of DBL with DG not only increased student engagement but also led to a significant improvement in the understanding of descriptive geometry concepts, as evidenced by higher performance in both practical and theoretical assessments (Teixeira et al., 2006), yielding positive results in terms of student engagement and learning (Teixeira et al., 2010, 2015; Bruno et al., 2019).

Design-Based Learning (DBL) is an educational strategy grounded in the active participation of students in design processes, fostering meaningful learning and the collaborative construction of knowledge. DBL is based on the principles of constructivism (Piaget, 2013), constructionism (Papert, 2020), and experiential learning theory (Kolb, 2014), and is implemented through practical projects developed via the integration of multiple disciplines and the creation of innovative solutions.

In the context of DG, DBL emerges as a relevant approach and an opportunity to address the challenges posed by the predominantly abstract nature of the discipline. Spatial representation, orthographic views, auxiliary views, and descriptive operations can be worked on in a practical, more concrete, visual, and interactive context.

Thus, activities may include geometric designs involving three-dimensional objects related to real-world forms, where students create physical or digital artefacts that meet specific geometric and dimensional requirements and constraints. Another focus may involve solving applied spatial problems related to form and position, such as the development of mechanical or architectural components. Furthermore, the use of tools such as interactive graphic software, allowing the exploration of concepts such as projection, auxiliary views, sections, and intersections, assists in the understanding of DG concepts within the practical context of design activities. Other possible applications include the creation of visual materials and simulations to represent descriptive geometric operations.

The principal aim of DBL is to motivate students to collectively apply knowledge and skills in activities related to their future professional practice, highlighting six features: professionalisation, activation, cooperation, authenticity, creativity, integration, and multidisciplinarity (Wijnen, 2000).

Among the reasons for the adoption of DBL at Technische Universiteit Eindhoven (Eindhoven University of Technology – TUE), Wijnen (2000, p.8) emphasises "improving the quality of education, increasing the level of competency orientation, strengthening the coherence between education and research [...]", with the ultimate goal of training engineers capable of delivering better products and innovative systems to society. Furthermore, project-based activities involve reflection-in-action, wherein students are confronted with a system of constantly evolving implications — consequences of their choices and attitudes throughout the process (Schön, 2000).

Nevertheless, designing activities that incorporate features of both DBL and ITI requires considerable planning time on the part of the instructors, as the object must be carefully selected to provide opportunities for advanced editing as well as visualisation operations involving descriptive methods. This stage must also consider the use of the same object across multiple sessions, each covering a different part of the discipline.

For students, such activities must be made available in a manner that allows them to be completed within the timeframe established in the schedule. Thus, there arises the need for tools that support and optimise the design of these activities, providing partially prepared design elements so that the time allocated for their execution is not wasted on actions previously performed in earlier stages.

To operationalise these pedagogical principles within a DG context, technological tools are essential — particularly those capable of bridging theoretical understanding with practical application. Thus, HyperCAL^{3D}, software developed within the field of educational technology, provides specific tools for designing teaching activities tailored to the intrinsic characteristics of Descriptive Geometry. In addition to faceted solid modelling, orthographic view generation, and descriptive operations, HyperCAL^{3D} includes an environment for creating and arranging printable layout sheets.

The flexibility and modularity of this environment allow for the proposal of multiple activities framed within unified thematic contexts, capable of fostering learning experiences grounded in complex concepts and predominantly supported by hands-on practice.

Since its development, HyperCAL^{3D} has been systematically employed in a wide range of educational activities targeting Architecture and Engineering students at UFRGS. These activities pursued a dual objective: on one hand, to develop and enhance psychomotor skills such as perception, tool handling, and hand-instrumented drawing; on the other, to consolidate key concepts through the resolution of design problems via DG techniques.

The objective of this study is to propose an innovative approach to designing DG learning activities, using the HyperCAL^{3D} platform to align cognitive and psychomotor learning objectives, thereby fostering student engagement and enhancing the learning process through the integration of Design-Based Learning (DBL) and Integrated Thematic Instruction (ITI) principles.

The following sections present the articulation of DBL and ITI principles in the design of DG learning activities, the integration of cognitive and psychomotor objectives, and an analysis of the pedagogical impacts observed through the use of HyperCAL^{3D}.

2. Materials and Methods

The design of thematic activities in DG is structured through the integration of Design-Based Learning (DBL) and Integrated Thematic Instruction (ITI) principles. These pedagogical approaches provide conceptual and procedural requirements that are aligned and translated into design specifications within the HyperCAL^{3D} platform. The software serves as a platform for both designing and implementing tasks, enabling the creation, modification, and testing of models that are used in the instructional activities. Thematic activities are the final outcome of this process, which is iterative and subject to verification from both pedagogical frameworks.

2.1. Design-Based Learning as a Framework for Practical and Cognitive Integration

Design-Based Learning (DBL) is an educational strategy centred on student engagement in authentic design processes to promote the construction of knowledge through practical and meaningful experiences. Grounded in constructivist and constructionist theories (Piaget, 2013; Papert, 2020), as well as experiential learning theory (Kolb, 2014), DBL fosters active learning by integrating problem-solving, creativity, and collaboration.

In this study, DBL provides the pedagogical basis for structuring activities that are both intellectually and physically engaging, particularly in a discipline like DG, which demands the development of spatial reasoning and manual skills. The principles guiding the implementation of DBL in this context include:

- **Challenge-based learning**, involving open-ended and real-world problems that motivate students to seek creative and functional solutions (Fortus et al., 2004);
- **Iteration and prototyping**, wherein the process unfolds through continuous cycles of ideation, implementation, testing, and refinement, encouraging critical thinking (Kolodner et al., 2003);
- **Interdisciplinary integration**, as solutions demand the coordinated application of knowledge from various fields, thereby strengthening competencies (English, 2009);
- **Reflection and metacognition**, where students are prompted to reflect on their design choices, strategies, and learning progress during the iterative stages of a project. For instance, after completing an orthographic projection, students may be encouraged to assess how their visualisation of the object evolved and how this understanding influenced their subsequent design decisions (Mehalik et al., 2008);
- **Collaboration and collective authorship**, since DBL values teamwork, where negotiated decisions promote the social construction of knowledge (Hmelo-Silver et al., 2007);

- **Authenticity and relevance**, as projects should have practical applications, linking school content to real-world situations (Barak & Doppelt, 2000).

Within this framework, DBL fosters an environment where both cognitive and psychomotor objectives are seamlessly integrated. It enables students to apply theoretical knowledge to real-world challenges while simultaneously honing their practical drawing skills, ensuring that learning is both conceptual and hands-on. The application of DBL in DG seeks not only to improve content mastery but also to increase student motivation and engagement by contextualising learning in relevant, purposeful activities.

2.2 Integrated Thematic Instruction for Structured Conceptual Progression

Integrated Thematic Instruction (ITI) is a pedagogical approach that organises teaching around unifying themes, making learning more meaningful by connecting concepts across different domains and aligning them with students' lived experiences. According to Beatty (2009), ITI values the coherence of content, the integration of skills and knowledge, and the use of diverse methods to engage students cognitively, emotionally, and physically.

In the context of Descriptive Geometry (DG), ITI is employed to organise activities around a central design theme that unfolds throughout a sequence of sessions. This unified theme serves as the conceptual backbone of the learning experience, enabling the integration of multiple geometric concepts into a coherent and cumulative learning pathway.

The implementation of ITI in this study is guided by the following principles (Beatty, 2009):

- **Use of a unified theme related to the subject matter**: For example, students might work on a semester-long project centred around the design of a mechanical connector or architectural element. This object serves as the anchor for successive tasks involving projections, sections, auxiliary views, and intersections;
- **Focus on primary learning objectives**: Each phase of the project is linked to specific DG learning goals, such as understanding orthographic representation or mastering spatial transformations, allowing for curricular components to be addressed in a logical sequence;
- **Design of varied and progressively complex activities**: Activities range from the simple construction of basic geometric solids to more advanced problems involving combinations of solids and descriptive operations. Each activity includes cycles of experience, analysis, and abstraction. For instance, students may initially construct a prism, then rotate it to analyse its projections in different orientations, and finally perform a sectional cut to evaluate internal geometry;
- **Provision of instructional resources**: HyperCAL^{3D} is used to provide dynamic, manipulable 3D models and printable project sheets, offering both virtual and physical interaction with the design object. These resources serve as visual and functional supports that aid in concept internalisation and skill development;
- **Evaluation through authentic practices**: Rather than relying solely on standardised tests, evaluation is conducted via design tasks that result in artefacts or digital submissions. For example, students submit layout sheets showing their design object in multiple views and configurations. Peer review, collaborative development, and structured self-assessment are encouraged to enrich the learning process and reinforce accountability.

This thematic integration ensures that knowledge is not fragmented but interconnected, as students revisit the same object through different DG operations. As a result, concepts are not taught in isolation but situated within the broader context of the object's evolving geometry.

Furthermore, the repetitive use of a single object across multiple tasks enhances students' familiarity with the modelling tool and deepens their understanding of spatial relationships, reducing the cognitive load associated with learning new geometry at every stage. HyperCAL^{3D} supports this continuity by allowing the same model to be reused, edited, and reinterpreted throughout the instructional sequence.

In summary, ITI in this context serves to strengthen the coherence and retention of DG concepts by organising content around a meaningful theme, providing structured progression, and offering opportunities for reflection and practical application. When combined with DBL, this approach fosters deep, transferable learning that is both technically rigorous and pedagogically sound.

2.3 HyperCAL^{3D} as a Pedagogical and Technical Mediation Tool

HyperCAL^{3D} is a software tool specifically developed to support the teaching and learning of DG, providing an environment that bridges theoretical knowledge and hands-on application. By offering functionalities tailored to the demands of geometric representation—such as faceted solid modelling, orthographic projection, section, extrusion, and the generation of auxiliary views—HyperCAL^{3D} serves as both a drawing instrument and a didactic platform.

Since its development in 2006, HyperCAL^{3D} has continually evolved, adding features that support a wide range of DG operations. The tool enables students to create three-dimensional models, manipulate spatial structures, and visualise the real-time effects of descriptive methods. More recently, it has also integrated a layout module for the generation of printable project sheets, reinforcing the link between digital modelling and manual technical drawing.

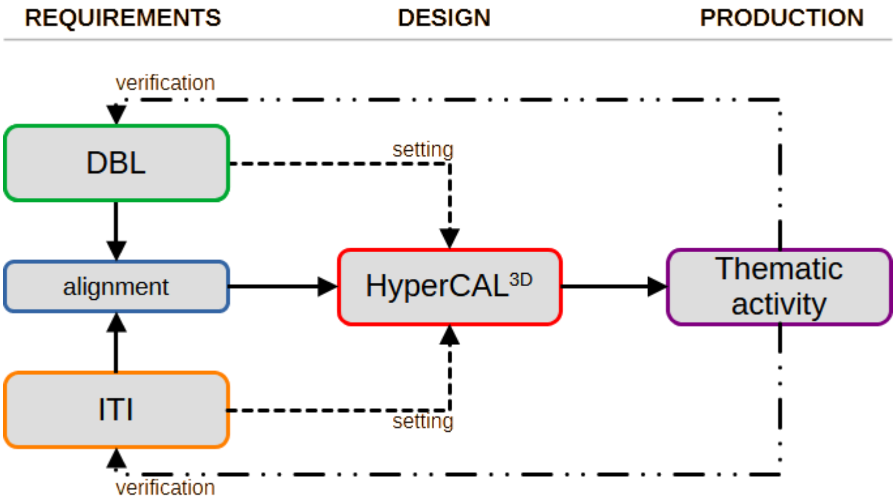

Fig. 1. Schematic representation of the methodological framework.

In this study, HyperCAL^{3D} plays a central role in the materialisation of activities designed within the frameworks of Design-Based Learning (DBL) and Integrated Thematic Instruction (ITI). The requirements derived from these approaches—such as challenge-based design tasks, cross-disciplinary integration, and iterative development—are translated into concrete learning experiences using the platform's modular environment.

Each thematic project begins with the selection or construction of a base object within HyperCAL^{3D}. This object is designed to be adaptable, enabling the introduction of multiple descriptive operations across a series of instructional steps. For example, students might begin by constructing a simple geometric volume such as a hexagonal prism, then gradually apply transformations, sections, and auxiliary views to solve spatial problems associated with mechanical or architectural applications.

The use of a consistent digital model throughout the sequence allows for the progressive layering of geometric knowledge, minimising cognitive overload and facilitating deeper conceptual connections. In addition, the software's interactivity enhances spatial perception by allowing students to rotate, slice, and examine the structures of solids from multiple perspectives—something that is difficult to achieve with static representations.

Furthermore, HyperCAL^{3D} plays a crucial role in enhancing psychomotor skills by allowing students to manipulate virtual tools with precision. These tools replicate the functions of traditional technical drawing instruments, enabling students to practise the fine motor control necessary for accurate, hand-drawn representations before moving on to the manual execution of their designs. Students can export these virtual constructions into layout sheets and reproduce them using conventional drafting methods, reinforcing the connection between hand-instrumented skills and spatial reasoning.

By integrating cognitive objectives (e.g., understanding projection systems) with psychomotor objectives (e.g., performing precise constructions), HyperCAL^{3D} allows for the design of meaningful, practice-oriented tasks aligned with professional standards. It becomes not only a content delivery tool, but a dynamic workspace where students engage with DG concepts through design problems that reflect real-world complexity.

In sum, HyperCAL^{3D} provides the technological infrastructure that enables the application of DBL and ITI in DG education. It operationalises the pedagogical goals of this study, offering both flexibility and structure for the design, implementation, and evaluation of learning experiences that are intellectually rigorous and practically grounded.

2.4 Operational Alignment of DBL and ITI within the HyperCAL^{3D} Environment

The methodological articulation between Design-Based Learning (DBL), Integrated Thematic Instruction (ITI), and the HyperCAL^{3D} platform is illustrated in Fig. 1. The two pedagogical approaches provide the conceptual foundations and didactic requirements, which are then aligned and operationalised within the design environment offered by HyperCAL^{3D}. This alignment enables the creation of three-dimensional models and tasks that meet both cognitive and psychomotor learning objectives. The software acts as a central hub where content is configured according to the unified theme and iteratively refined based on feedback from both DBL and ITI. The final outcome of this process is a set of thematic activities that integrate DG content with real-world design challenges, offering students meaningful and multidimensional learning experiences.

Together, the integration of DBL, ITI, and HyperCAL^{3D} creates a cohesive and dynamic learning environment where students can engage with complex geometrical concepts both cognitively and practically. This synergy not only enhances students' understanding of Descriptive Geometry but also prepares them for real-world design challenges.

3. Results and Discussion

The principles of DBL and ITI are materialised through a sequence of activities developed within the HyperCAL^{3D} environment. Each project begins with a geometric problem grounded in a unified theme—such as designing a mechanical part or architectural feature—that evolves through progressive stages. In an initial task, for example, students may be asked to construct a 3D model of a prismatic component with specific dimensional and positional constraints. Subsequent tasks involve descriptive operations such as generating auxiliary views, performing sections, or verifying spatial relationships through intersections.

As students navigate these activities, they engage in iterative refinement—modifying their models based on feedback or new requirements—thus experiencing design as a dynamic and responsive process. Moreover, because these problems are situated in contexts related to students' future professional practice, they encourage the application of theoretical knowledge to practical scenarios.

The use of HyperCAL^{3D} enables students to operate within a virtual environment that mimics professional design conditions while scaffolding the acquisition of spatial and instrumental competencies. This approach not only supports the cognitive development required to master DG concepts but also promotes psychomotor skill acquisition through active manipulation of design elements.

In sum, DBL within this study is not limited to hands-on activity; it represents a structured, reflective, and context-driven learning experience that integrates cognitive, psychomotor, and social dimensions of learning. When aligned with Integrated Thematic Instruction (see Section 2.2), DBL contributes to a cohesive and multidimensional pedagogical strategy.

3.1. Structuring Thematic Design Activities in HyperCAL^{3D}

Each object is designed to enable different types of activities. As new content is introduced and new learning objectives are defined, students return to the same object, enhancing it through iterative cycles.

To be selected as the theme of a learning cycle, the design of the object must reflect the articulation between the principles of Design-Based Learning (DBL) and the components of Integrated Thematic Instruction (ITI). In this process, the unified theme and provision of resources are guided by principles of authenticity and relevance, including opportunities for interdisciplinary integration whenever possible.

Following the definition of the theme and the modeling of the first prototype, it is assessed whether the object enables the development of a range of activities that evolve progressively in complexity through iterative cycles. At this stage, it is also evaluated whether such opportunities present an authentic challenge for students to engage both cognitive and psychomotor skills.

If the object meets the proposed criteria, the activity cycles are developed and refined with a focus on the primary learning objectives of each stage of the course. At this point, principles of collaboration and collective authorship are taken into account. Each cycle is designed to provide moments of group collaboration and discussion, as well as opportunities for individual production and reflection.

Finally, each cycle is linked to an assessment system aligned with the proposed objectives, incorporating both formative and summative approaches. This stage includes assessment by the teacher, peer review, and self-assessment. Evaluation is understood as a parallel process that occurs throughout the cycle, supporting action through reflection.

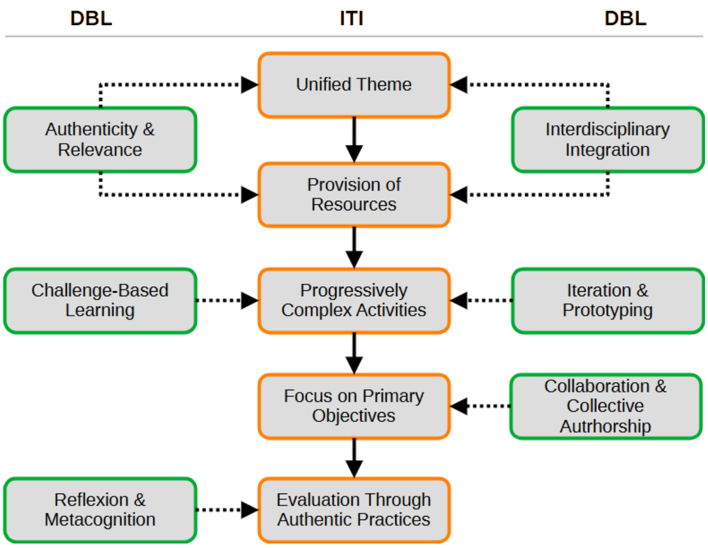

Fig. 2. Articulation between DBL principles and ITI components.

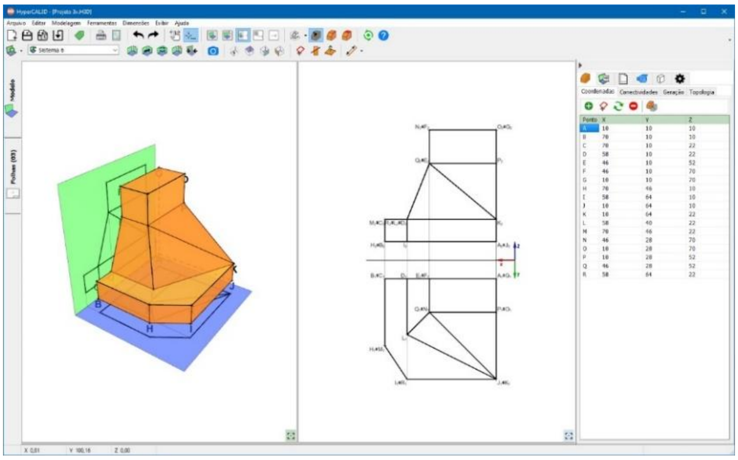

Fig. 3. HyperCAL^{3D} window.

The diagram shown on Fig. 2 illustrates how DBL principles (in green) align with ITI components (in orange) to guide the design of object-based learning cycles. The structure emphasizes the definition of a unified theme and the provision of authentic resources, which support progressively complex activities focused on primary objectives, along with collaboration, iteration, and authentic assessment practices.

3.2. Integration of Cognitive and Psychomotor Objectives

The progression of cognitive and psychomotor objectives occurs simultaneously. In each cycle, the increasing complexity of the objectives drives both knowledge construction and the development of new skills.

Based on the analysis of the three-dimensional object in HyperCAL^{3D} (Fig. 3), students create orthographic projections using paper and drawing instruments. From a cognitive perspective, this stage enables the understanding of projection systems, coordinate systems, and the representation of three-dimensional objects in two dimensions. From a psychomotor perspective, it activates processes of perception, preparation, and guided response.

The orthographic views facilitate the study of the specific spatial positions of each element (faces, edges, and vertices) and their relative locations. In this primarily theoretical stage, hands-on experimentation enhances comprehension and reinforces the underlying concepts — often using empirical and concrete objects.

The analysis of the specific positions of each object element encourages reflection on potential design challenges, such as determining true sizes and edge views (Fig. 4), so that the object can be modified and expanded. As a result, designing new elements generates the need for auxiliary views — at this stage, students reanalyse the three-dimensional object and return to paper to execute the necessary projections to meet new design requirements (e.g., designing a window on a wall with a foreshortened projection, or modifying the slope of an oblique roof).

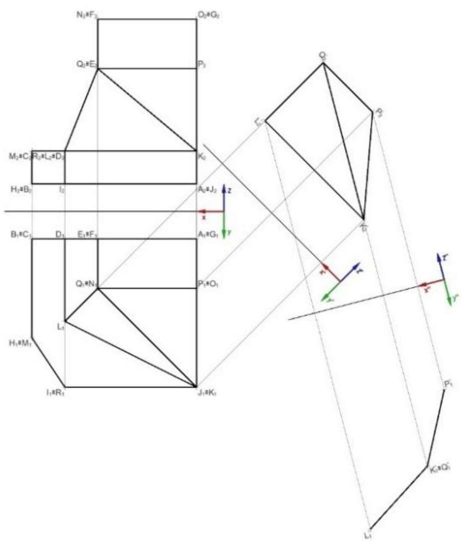

Fig. 4. Sucessive auxiliary views to find the angle between two faces.

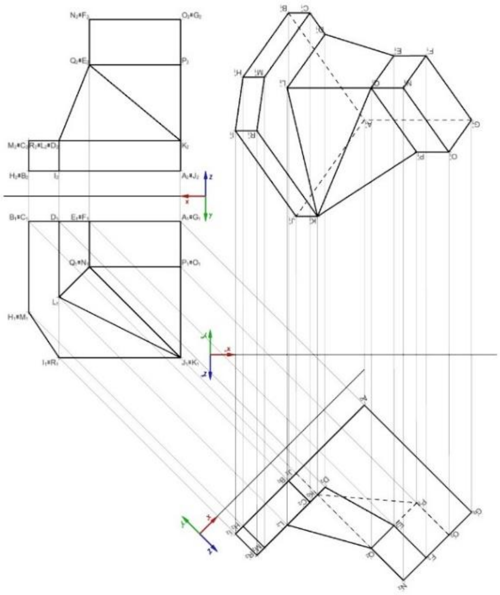

Fig. 5. Sucessive auxiliary views to find an axonometric perspective.

At the end of the modification process, students validate the outcomes by constructing axonometric perspectives (Fig. 5), using successive auxiliary views as a tool. Whenever possible, the construction of physical prototypes is required, adding further complexity to the objectives (Fig. 6).

3.3. Student Engagement and Learning Outcomes

The approach used is characterised by three key features: the extensive practice of hand drawing as a design tool, the continued use of a single object throughout the cycle, and the constant support provided by HyperCAL^{3D} during the process.

Drawing practice not only supports the development and refinement of essential skills for future designers, but also enhances the understanding of new concepts. Hands-on work helps establish meaning in relation to the topic being addressed.

Similarly, the use of a unified theme offers students greater confidence, as new content is applied to a familiar object, reducing the cognitive load required to integrate new knowledge into their cognitive structure. HyperCAL^{3D} plays a fundamental role by allowing the proposed objects to be analysed from multiple perspectives and offering tools for students to virtually practice the processes that they will later carry out on paper.

The selection of a relevant theme and the continued use of a single object throughout the learning cycle reinforce the idea of student ownership. The modifications made to the object throughout the course result in unique solutions, and by the end, each student has their own version — the outcome of their decisions and actions. The engagement achieved stems from the affective connection that students build with their creation.

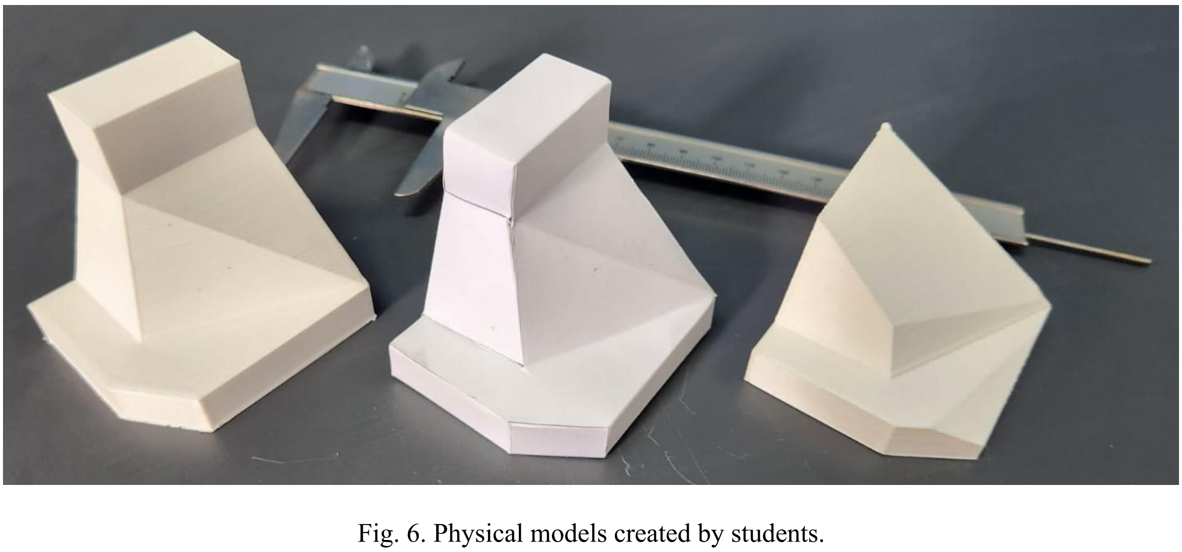

Fig. 6. Physical models created by students.

3.4. Pedagogical Impacts and Instructional Reflections

The articulation between Design-Based Learning (DBL) and Integrated Thematic Instruction (ITI) is achieved through the construction of learning activities based on tangible elements closely related to students' lived realities. This approach often results in the creation of complex objects, which can pose challenges to their reuse throughout the instructional cycle. However, the use of HyperCAL^{3D} enables these objects to be maintained across multiple learning phases, allowing certain steps to be carried out virtually.

This capacity significantly enhances the efficiency of iterative cycles. Time that would otherwise be spent redrawing the objects or preparing new starting points can instead be allocated to exploring more advanced concepts or engaging in enriched hands-on activities. In this sense, technology not only supports logistics but also contributes to the deepening of learning.

Moreover, this pedagogical approach reinforces the principles of continuity and progression. By enabling students to return to the same object across different stages, their cognitive and psychomotor development is scaffolded in a more cohesive manner. Learners gain a greater sense of ownership over the process, as they perceive the evolution of their work as a narrative they construct and refine.

From an instructional standpoint, this model demands that educators adopt a dynamic role. They must anticipate potential learning paths, provide meaningful feedback throughout each iteration, and continuously adjust the environment to sustain student engagement and autonomy. Reflection is not limited to student performance, but extends to teaching practice itself—encouraging educators to evaluate the impact of their strategies and to refine the integration between conceptual understanding and technical skill development.

3.5. Contributions and Limitations of the Proposed Approach

The integrated approach combining DBL and ITI, supported by the HyperCAL^{3D} platform, offers significant contributions to the teaching and learning of DG and design-based skills. Among its key benefits is the possibility of promoting deeper student engagement through iterative learning cycles, personal ownership of the learning object, and the progressive development of cognitive and psychomotor skills. The consistent use of a single object throughout the instructional cycle, coupled with extensive hands-on drawing practice and the virtual affordances of HyperCAL^{3D}, fosters a more meaningful and contextually anchored learning experience.

Furthermore, this approach encourages collaboration, critical thinking, and reflective practices by integrating theoretical concepts with applied design tasks. It supports interdisciplinary connections and allows students to progressively refine their skills through increasingly complex tasks that mirror real-world challenges.

However, some limitations must be acknowledged. The approach requires a significant initial investment in terms of planning, resource development, and teacher training, particularly to ensure the effective use of HyperCAL^{3D} and the alignment of instructional goals across cycles (Fig. 7). Additionally, the complexity of the objects used—while beneficial for depth of learning—can pose difficulties for less experienced students or those with limited spatial reasoning abilities, potentially increasing the cognitive load.

Another challenge lies in the scalability and adaptability of the model to different educational contexts. While the approach has shown positive results in the specific implementation described here, further studies are needed to assess its generalisability across institutions with different infrastructures, curricula, and student profiles.

Despite these limitations, the proposed approach represents a valuable contribution to pedagogical practices in technical and vocational education, offering a flexible yet structured model that aligns learning processes with authentic design experiences.

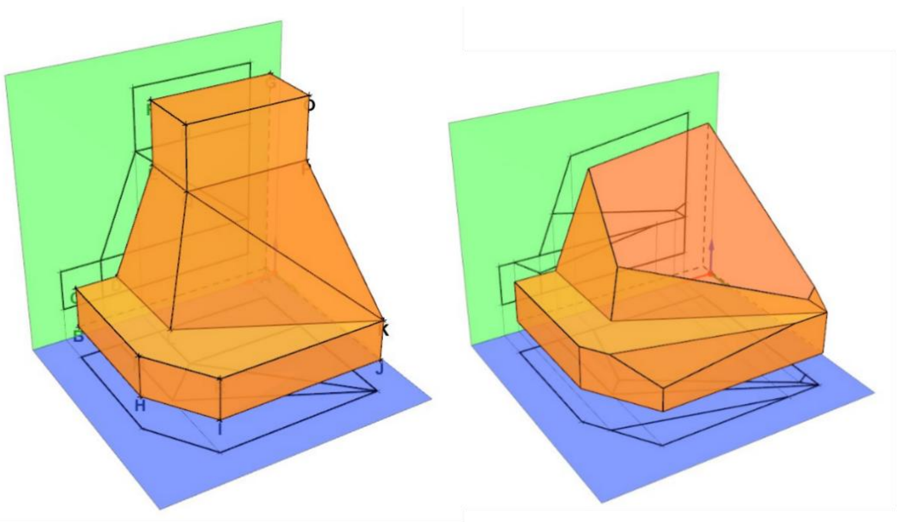

Fig. 7. Models created in HyperCAL^{3D}, after the editing process in paper.

3.6. Summary and Final Remarks

The articulation between DBL and ITI, supported by HyperCAL^{3D}, offers a pedagogical model that is both conceptually robust and practically grounded. The use of tangible objects as anchors for iterative learning cycles enables students to progressively develop their cognitive and psychomotor skills, while also fostering personal engagement through ownership and authorship. By reducing preparation time through virtual simulations and integrating theoretical concepts with hands-on practice, the approach enhances both instructional efficiency and student motivation.

4. Conclusions

This study presents a pedagogical model that integrates Design-Based Learning (DBL) with Integrated Thematic Instruction (ITI), supported by the HyperCAL^{3D} platform, to enhance the teaching and learning of Descriptive Geometry (DG). This approach uses tangible, theme-based objects that evolve through iterative learning cycles to allow the simultaneous development of cognitive understanding and psychomotor skills.

Applying this model showed that engaging with a single object that becomes more complex over time fosters student ownership, supports conceptual learning and encourages reflection through design-oriented problem solving. Articulating DBL principles with ITI components proved effective in structuring meaningful, contextually relevant activities aligned with authentic professional practices.

HyperCAL^{3D} played a central role in this process by not only simulating design conditions, but also enabling continuity and progression in the learning experience. The platform reduced logistical constraints and enhanced instructional efficiency, allowing for deeper exploration of the theoretical and applied aspects of DG.

Despite the promising results, the approach also revealed certain challenges, particularly with regard to the demands of the initial planning stage and the cognitive load imposed by complex design tasks. These limitations highlight the importance of careful implementation strategies and further research into the model's adaptability to different educational settings.

In conclusion, integrating DBL, ITI and digital tools such as HyperCAL^{3D} provides a conceptually robust and practically grounded pedagogical framework. It promotes active, reflective and interdisciplinary learning and has the potential to significantly enrich technical and vocational education by aligning instructional strategies with contemporary design practice.

Social perception of public buildings: Urban users perspective

Elif E. Özgül*[1], Selda Al Şensoy[2]

[1] Ağrı İbrahim Çeçen Üniversitesi, Department of Arhitecture and Urban Planning, 04000, Ağrı
[2] Karadeniz Technical University, Department of Architecture, 61080, Trabzon

Abstract. Humans have been creating spaces in line with their needs since the first moment of their existence. These spaces align with various parameters such as function, purpose, culture, technology, economy, and climate. Public buildings, one of these spaces, are built by the state to meet society's needs. Public buildings, built for various purposes and functions such as health, education, administration, military, and management, constitute an important part of the city by reflecting the characteristics of the period and society in which they were built like other buildings. Humans, another part of the city, perceive and make sense of their environment through various visual, auditory, physical, and semantic tools. Architectural features of buildings, such as style, function, location, color, form, and material, play an important role in human perception of their environment. Today, public buildings in our country are generally designed with similar architectural styles, colors, forms, and materials, regardless of function. In different regions, public buildings with almost the same characteristics are encountered, where factors such as changing climate, topography, culture, context, etc., are not considered in their design. In this context, the study aims to determine how the users perceive this physical similarity of public buildings and what kind of results this perception leads to. Within the scope of this purpose, a survey study was conducted to evaluate the visual environmental perception of public buildings in the Patnos district of Ağrı. In line with the data obtained as a result of the study, it was determined how public buildings with similar architectural styles were interpreted by the users.

Keywords: Public Buildings; Perception; Style; Function; Urban User

1.Introduction

A person in a space defines and makes sense of his/her surroundings through the relationship he/she establishes with his/her environment. In this non-stationary relationship, the individual's acquisition of information from the environment is defined as perception. In contrast, interpreting the information acquired with our sense organs in the mind is defined as perception (Atkin et al., 2012).

Humans and the environment are in a continuous and active relationship. People try to perceive their environment according to many parameters, such as experiences, sociocultural structure, economic status, age, and gender (Aydınlı, 1992). Rapoport (1982) defined the perception of the environment as the process of making choices and evaluations by describing the environment in line with the reflections of the information obtained through the sense organs in the mind. The realization and interpretation of the environment through the spaces that make up the environment constitute the common working area of architecture and perception.

Human beings, who have needed space from the first moment of their existence, have built structures with various functions to meet this need. While each building defines the interior space, it also defines the exterior space. Bruno Zevi (1990) states that "Every building helps to create two spaces. The 'interior space' determined by the building itself and the 'exterior space' (urban space) between this building and neighboring buildings." (Zülkadiroğlu, 2013).

Buildings, which play an active role in shaping the urban space, are constructed in line with the cultural, social, economic, environmental, physical, geographical, physical, and cultural characteristics of the period, society, and time in which they are built. Buildings constructed in line with these characteristics help form a city's identity as one of the urban identity elements. These buildings, which establish a relationship with the city and people, form urban memory and develop a sense of belonging over time. Urban memory and spatial perception, which occur in line with the society's relationship with the city and buildings, make it possible to recognize the past in the present by establishing a link between the past and the future (Cengiz Taşlı et al., 2023).

*Corresponding author, E-mail: eeozgul@agri.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_281

Buildings that are built uniformly without considering factors such as location, society, culture, and geography cause damage to the urban identity. In addition, the formation of ordinary environments with uniform construction reduces diversity and negatively affects people's perception of their environment (Alexander et al., 1977). For the environment to be perceived correctly, harmony and diversity must be balanced. The environment becomes ordinary or complex when this balance is not achieved (Kaplan & Kaplan, 1989). This situation negatively affects people's sense of belonging.

The city is in an active relationship with its users. The design and planning of the structures, equipment, and vehicles that make up the urban environment affect spatial perception (Lynch, 1979). In this context, qualities such as architectural formation, color, size, and texture of the buildings that make up the environment play an important role in forming spatial perception. Not only the formal characteristics of the buildings, but also factors such as their relationship with other buildings, their relationship with the city, and the balance of harmony and diversity also affect the perceptibility of the environment (Kızılkan & Yeşildal, 2021). Building groups, which form an important part of the urban environment and have an important place in urban life, strongly influence the perception of the environment. The quality of the physical environment increases when the formal characteristics of these building groups are well-designed with their surroundings. This situation allows the space to be diversified in harmony, the space to be perceived, and the character of the space to be formed (Cengiz Taşlı et al., 2023).

Buildings, which form the boundaries of the urban environment, enable perception to reach the user with their formal qualities and the spaces they define. Buildings enable users to get information from their surroundings with qualities such as color, texture, form, relationship with the surrounding buildings, and the spaces they form the boundaries of. In this context, buildings should be designed by considering the formal qualities of their facades and the relationship they establish with their surroundings (Karakoç, 2004).

Building groups play an active role in forming the urban fabric and influencing user perceptions of the environment, with features such as their location within the city, functional setup, and architectural design (Tanrıbir & Akten, 2020). The diversity of building groups, which has an important place in forming urban spaces, affects the perceptibility of the space. Public buildings have the most functional diversity among the building groups that interact directly or indirectly with users.

Public buildings are built by the state to carry out state affairs. These buildings vary according to their function, such as education, health, or administration. The design of public buildings is based on the "Public Building Standards Guide" prepared by the Ministry of Environment, Urbanization, and Climate Change. The guide includes criteria such as land selection, expropriation, space dimensions, and principles of use (URL-1).

Public buildings, which are expected to be constructed in line with specific criteria, do not have a set criterion for facade design. Despite this, the architectural style of the past periods is imitated by using building elements such as iwan, arches, borders, and crown gates, which are prominent in Seljuk and Ottoman architecture in public buildings built in today's cities. Most of our cities have public buildings designed with similar architectural styles, ignoring the urban texture, geographical features, physical requirements, etc. (Fig. 1). This situation affects the perceptibility of the buildings and causes identity confusion in cities (Özkaynak, 2021).

The use of historical forms in architecture without adapting them to the requirements of the period, society, location, and space prevents the formation of a bond between the building and the user (Kazmaoğlu & Tanyeli, 1986). Trying to create new spaces by imitating the old is characterized as disrespect to the spirit of the space (Norberg-Schulz, 2001). In addition, with the imitation approach, the heritage left to future generations will not be able to establish a strong connection between the past and the future and will create an architectural formation without identity (Pasin & Varinlioğlu, 2018). This anonymous situation makes it difficult for the building to interact with the user. The space that cannot interact with people cannot be perceived correctly.

a b c

Fig. 1. a.Çamardı Government House (URL-2), b.Çayeli Government House (URL-3), c.Yıldırım Beyazıt University (URL-4)

This study examines the representation of public buildings designed in a similar architectural style in the urban context and their effects on user perception. Accordingly, public buildings with different functional qualities in the designated study area were analyzed in the context of user experiences and spatial memory. The data obtained provides a comprehensive assessment of the current morphological and typological situation; at the same time, it allows for the reading of the architectural identity shaped through user-space interaction. In this context, it is foreseen that these analyses will provide a critical basis for the design decisions of future public buildings and contribute to forming a qualified built environment

2. Working Area

Patnos district of Ağrı was determined as the study area. The distance from the district to the city center is 82 kilometers. The district's population is 123,526 people and is the second largest district of Ağrı in population density (URL-5). The focal point of the district settlement is the city center. While residential and commercial areas are predominantly located in the city center, there are also functions such as health and recreation. While the north of the road (Atatürk Boulevard) that provides transportation between Ağrı and Van provinces is a military zone, public buildings are located in the south.

Patnos district of Ağrı province, which was determined as the study area, is located approximately 82 km from the city center and is the second most populous settlement in Ağrı with a population of 123,526 (URL-5). The spatial organization of the district settlement is primarily concentrated in the city center, which includes residential and commercial areas and buildings for health, recreation, and similar public functions. Atatürk Boulevard, one of the main axes determining the direction of urban development, is surrounded by military areas in the north and public institutions in the south and, accordingly, plays a decisive role in the city's functional distribution and spatial hierarchy. In light of these physical and socio-spatial data, the morphological structure of Patnos city center constitutes a sample worth examining in terms of the positioning and functional diversity of public spaces.

Public buildings with different functional identities (administrative, security, education, etc.) are located on a common urban axis instead of being scattered in different parts of the district, which has been decisive in selecting the Patnos district of Ağrı as the study area. The fact that these buildings were built with similar architectural styles and forms of expression is remarkable regarding spatial continuity and formal integrity. This situation provides a critical basis for understanding the physical layout and the representational value of public buildings in constructing the city's perceptibility, legibility, and urban identity. Therefore, Patnos district constitutes a qualified sample area in terms of questioning the role of public architecture in the urban context and examining the effects of architectural shaping on urban identity (Fig. 2).

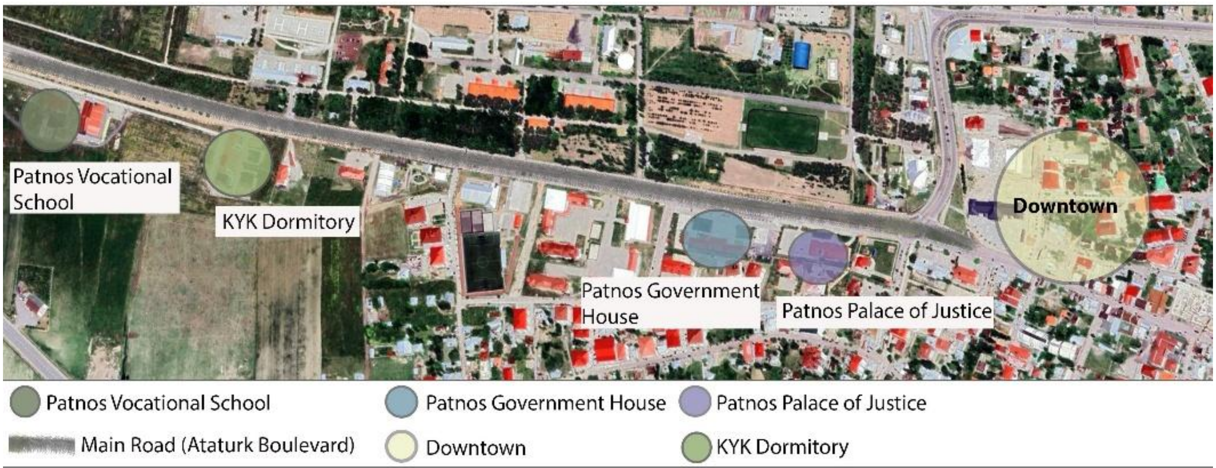

Fig. 2. Location of the Study Buildings in the City

Within the scope of this study, the perceptibility of public buildings designed in a similar architectural style despite having different functional qualities is examined at the urban scale. In this respect, the main criterion is that the buildings to be selected should have a common design language despite the diversity of their functions. In this context, Patnos Palace of Justice, Patnos Government House, Patnos Vocational High School, and KYK Dormitory, which are located on Atatürk Boulevard and represent different public functions such as the judiciary, administration, education, and accommodation, but have similar morphological and aesthetic characteristics, were selected as the study sample. These buildings provide a basis for a comparative analysis of formal integrity and perceptual continuity within the built environment, both in terms of their architectural expression and positioning within the city (Fig. 3).

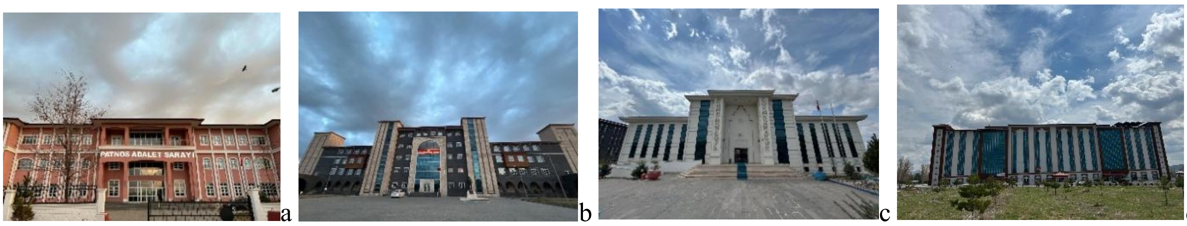

Fig. 3. a.Patnos Palace of Justice, b.Government House, c.Vocational School, d.KYK Dormitory

Patnos Palace of Justice is the closest of the selected buildings to the city center. The building, which has three floors and a rectangular form, is pink in color, and white is preferred around the windows. It was designed to be more prominent to accentuate the building's entrance, and an arched entryway was introduced to enhance its visual significance. The right and left end parts of the building are wider than the overall building, and it was designed in 2013 as a symmetrical building with general lines.

Patnos Government House started to be used in 2017. Different colors and materials were preferred to emphasize the entrance. It was tried to create a semi-open space with arches on the ground level. The entrance left and right parts of the building differ from the primary color and are designed as symmetrical buildings with higher heights.

The construction of Patnos Vocational School started in 2013. The building, which has two floors and a rectangular form, is white, and the entrance section is emphasized by making it more prominent and higher. The entrance was inspired by the crown gate, one of the prominent features of Seljuk architecture. The building, which is decorated with Seljuk star motifs in places, was built symmetrically.

KYK Dormitory is a single building divided into male and female dormitories. For this reason, the building has two entrances, which are emphasized with glass facades. Like the school building, the building is decorated with Seljuk star motifs in places, and Seljuk architectural patterns are used to frame the glass parts of the building. The right and left sides of the building are higher in height and were built in 2015 as a symmetrical building.

3. Methodology

In line with the study's aim, the visual environment perception of urban users through public buildings was evaluated. The semantic differentiation scales Hershberger and Cass (1988) developed for "measuring the meanings of designed environments" were used to examine users' perceptions of the visual environment.

Hersberger and Cass produced ten different factors, including their primary scale, secondary scale, and alternatives of these scales in the evaluation technique they developed (Minez, 2013). Within the scope of the study, general evaluation, aesthetic evaluation, spatial evaluation, strength, organization factors, and the scales of these factors were utilized based on the factors developed by Hersberger and Cass. The study also incorporated an impact/image factor alongside these variables (Table 1). A questionnaire form consisting of closed-ended questions about the six factors was prepared. In the questionnaire form, the participants were asked to evaluate each structure separately in line with the determined factors. The form concluded with questions addressing all the structures examined in the study. The questions were asked to be answered in a multiple-choice manner in line with the adjectives determined. The researchers assessed the visual impact of the identified building group based on the responses provided.

The study was conducted on public buildings located on Atatürk Boulevard and designed in a similar architectural style despite having different functional identities. Patnos Vocational High School students were identified as the target group in the survey application, which was carried out to evaluate user perception and comparatively analyze the perceptual approaches of individuals who have past experience with the city and individuals who have recently arrived in the city for university education. A total of 129 students participated in the survey conducted online voluntarily.

4. Results

In order to assess the perception of the visual environment of public buildings, a survey was conducted in April 2025. The questionnaire consists of three parts. The questions in the first part consist of questions about personal information such as age, gender, and frequency of use in the study area. In the second part of the questionnaire form, questions were included for the participants to individually analyze the Patnos Palace of Justice, Patnos Government House, Patnos Vocational School, and KYK Dormitory structures determined within the scope of the study in line with predefined evaluation criteria. In the last part of the questionnaire, some questions aim to compare the four buildings as a whole and enable the participants to make comparative evaluations based on parameters such as similarity and distinguishability between the buildings. The analyses highlight the most and least preferred options by the participants in response to the multiple-choice questions.

Table 1. Factors and scales used in the visual environmental assessment of public buildings

Factors	Scales
General Evaluation	Contemporary/traditional, good/bad
Aesthetic Evaluation	Interesting/boring
Spatial Assessment	Clear/uncertain, personal/general
Strength	Small/large
Organisation	Coloured/colourless
Impact/ Image	Reflects/ Does Not Reflect

4.1. Section 1 Results ;

- Of the 129 people who participated in the survey, 79 were female, and 50 were male.
- One hundred twenty-two participants are 18-25 years old, four are 25-30 years old, and three are 30 years old and above. The majority of participants fall within the 18–25 age range.
- 85.3% of the participants (110) have been residing in the district for less than 2 years.
- The road where the public buildings considered in the study are located (Atatürk Boulevard) is used by 52.7% (68 people) of the people every day, 26.4% (34 people) 3-4 days a week, and 20.9% (27 people) 1-2 days a week (Fig. 4).

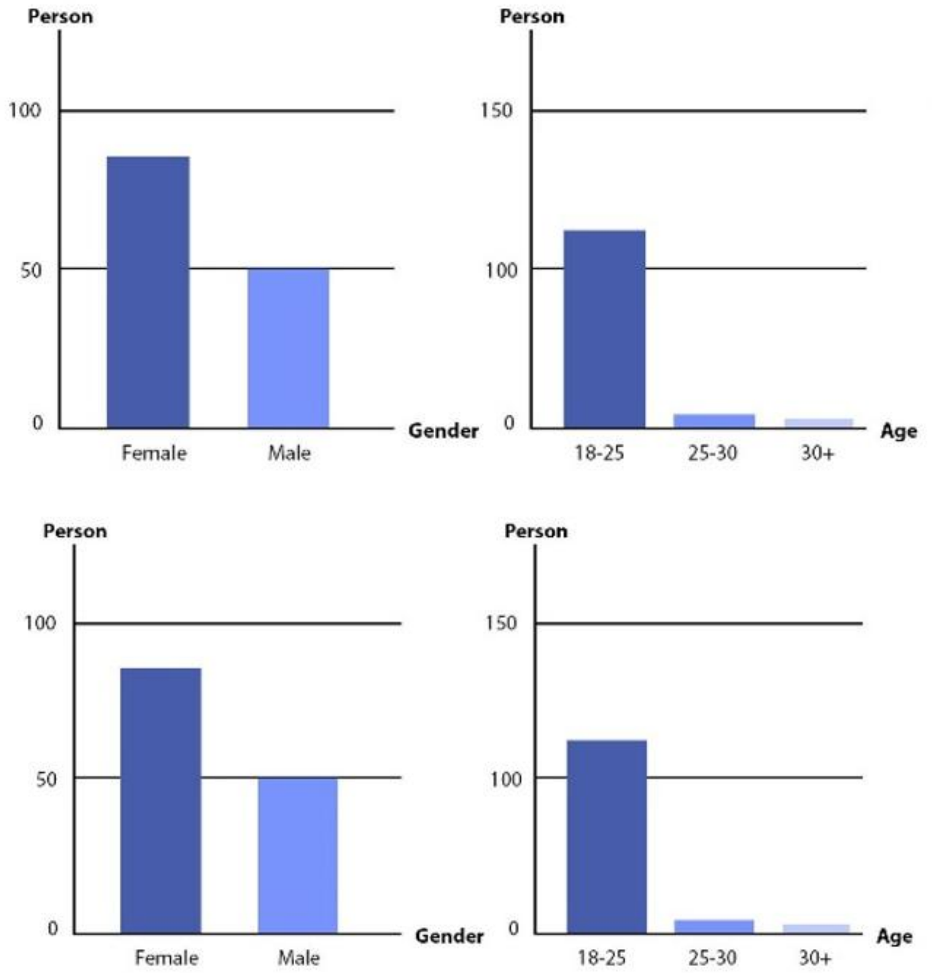

Fig 4. Participants personal information

4.2. Section 2 Results

In the second part of the questionnaire form, questions regarding evaluating the visual environmental perception of Patnos Palace of Justice, Patnos Government House, Patnos Vocational School, and KYK Dormitory were directed to the participants within the framework of six predefined factors. Each building was evaluated separately in line with the relevant factors, and participant responses were collected through multiple-choice questions. Factor-based averages were calculated for each building based on the data obtained; a comparative analysis was carried out between the buildings, and a general evaluation of the relevant section was made.

Evaluation results of the visual environmental perception of Patnos Palace of Justice on users (Table 2);

- 35.6% of the participants evaluated the architectural style of the building as traditional.
- The architectural style of the building was interpreted as good by 46.5% of the participants.
- The facade characteristic of the building was described as ordinary by 53.4% of the users.
- 34.1% of the participants defined the form of the building as clear.
- The dimensions of the building were described as medium by 58.1% of the participants.
- The color of the building was considered medium by 48.8% of the participants.
- 44.1% of the participants stated that the building was considered a public building with its facade design.
- The building does not excite 47.2% of the participants at all.

The results of the evaluation of the visual environmental perception of Patnos Government Mansion by the users (Table 3);

- The architectural style of the building was described as contemporary by 28.6% of the participants.
- The architectural style of the building was interpreted as good by 47.2% of the participants.
- The facade characteristic of the building is ordinary for 34,1% of the users.
- 34,8% of the participants defined the form of the building as clear.
- The dimensions of the building were described as medium by 44.9% of the participants.
- The color of the building was described as medium by 48% of the participants.
- 48.8% of the participants stated that the building was considered a public building with its facade design.
- The building does not excite 36.4% of the participants at all.

Table 2. Results of Evaluation of Visual Environmental Perception of Patnos Palace of Justice

Patnos Palace of Justice	Most preferred answer	Least preferred answer
Do you find the architectural style of the building traditional or modern?	Traditional 46 people	Modern 5 people
What do you think of the architectural style of the building?	Good 60 people	Great 7 people
What do you think about the facade characteristics of the building?	Ordinary 69 people	Very ordinary 18 people
How do you find the form of the structure?	Apparent 44 people	Supereminent 7 people
How do you find the dimensions of the building?	Middle 75 people	Tiny 11 people
What do you think about the colors of the building?	Middle 63 people	Multicoloured 8 people
When you first see the building, is it evident that it is a public building?	Comprehensible 57 people	Painfully obvious 12 people
Does the building excite you?	Unsensational 61 people	Breathtaking 1 people

Table 3. Results of Evaluation of Visual Environmental Perception of Patnos Government House

Patnos Government House	Most preferred answer	Least preferred answer
Do you find the architectural style of the building traditional or modern?	Modern 37 people	Hesitant 11 people
What do you think of the architectural style of the building?	Good 61 people	Awful 6 people
What do you think about the facade characteristics of the building?	Ordinary 44 people	Very ordinary 10 people
How do you find the form of the structure?	Apparent 45 people	Unclear 8 people
How do you find the dimensions of the building?	Middle 58 people	Tiny 6 people
What do you think about the colors of the building?	Middle 62 people	Multicoloured 5 people
When you first see the building, is it evident that it is a public building?	Comprehensible 63 people	Painfully obvious 9 people
Does the building excite you?	Unsensational 47 people	Hesitant 6 people

The results of the evaluation of the visual environmental perception of Patnos Vocational School by the users (Table 4);

- The architectural style of the building was described as contemporary by 28.6% of the participants.
- The architectural style of the building was interpreted as good by 47.2% of the participants.
- The architectural style of the building is ordinary for 34,1% of the users.
- 34,8% of the participants defined the form of the building as clear.
- The dimensions of the building were described as medium by 44.9% of the participants.
- The color of the building was preferred by 48% of the participants as medium.
- 48.8% of the participants stated that it was understood that the building was a public building with its facade design.
- The building does not excite 36.4% of the participants at all.

Table 4. Results of Evaluation of Visual Environmental Perception of Patnos Vocational School

Patnos Vocational School	Most preferred answer	Least preferred answer
Do you find the architectural style of the building traditional or modern?	Traditional 38 people	Hesitant 11 people
What do you think of the architectural style of the building?	Good 60 people	Awful 9 people
What do you think about the facade characteristics of the building?	Ordinary 38 people	Very ordinary 9 people
How do you find the form of the structure?	Apparent 56 people	Supereminent 13 people
How do you find the dimensions of the building?	Middle 67 people	Immense 7 people
What do you think about the colors of the building?	Middle 67 people	Multicoloured 6 people
When you first see the building, is it evident that it is a public building?	Comprehensible 60 people	Incomprehensible 11 people
Does the building excite you?	Unsensational 48 people	Breathtaking 6 people

Assessment results of the visual environmental perception of KYK Dormitory by the users (Table 5);

- The architectural style of the building was defined as traditional by 27.3% of the participants.
- 37.2% of the participants evaluated the architectural style of the building as good.
- 43,4% of the participants found the façade characteristic of the building ordinary.
- The form of the building was clearly understood by 35,4% of the participants.
- 37.2% of the participants defined the dimensions of the building as medium.
- The color intensity of the building was evaluated as medium by 48.8% of the participants.
- When first seen, 41% of the participants thought the building was recognized as a public building.
- The building does not excite 48% of the participants.

Table 5. Results of the Evaluation of the Visual Environmental Perception of KYK Dormitory

KYK Dormitory	Most preferred answer	Least preferred answer
Do you find the architectural style of the building traditional or modern?	Traditional 35 people	Modern 19 people
What do you think of the architectural style of the building?	Good 48 people	Awful 14 people
What do you think about the facade characteristics of the building?	Ordinary 56 people	Very ordinary 6 people
How do you find the form of the structure?	Apparent 47 people	Supereminent 8 people
How do you find the dimensions of the building?	Middle 48 people	Tiny 11 people
What do you think about the colors of the building?	Middle 63 people	Multicoloured 8 people
When you first see the building, is it evident that it is a public building?	Comprehensible 53 people	clearly understandable 15 people
Does the building excite you?	Unsensational 48 people	Breathtaking 6 people

4.3**.** Section 3 Results

In the third part of the questionnaire form, common questions were prepared to make a general evaluation of Patnos Palace of Justice, Patnos Government House, Patnos Vocational School, and KYK Dormitory. The questions asked were to be answered by thinking in common for the four buildings. The section was evaluated based on the answers given. Common evaluation of the buildings (Table 6);

- 37.2% of the participants think there is a similarity between the architectural styles of the buildings.
- 34.8% of the participants think that the similarity between the architectural styles of the buildings positively affects the ability to distinguish the function of the building.

Table 6. Conclusions on General Evaluation

General Evaluation	Most preferred answer	Least preferred answer
Do you think there are similarities between the architectural styles of the buildings?	Resemble 48 people	very similar 10 people
How do you think the similarities between the architectural styles of the buildings affect the distinguishability of the function of the building?	Positive 45 people	Awful 4 people

5. Conclusion

Human beings interact with every created space and perceive and interpret their environment through this interaction. In the process of interpretation, the qualities of the components that make up the environment are very effective. In this context, features such as color, style, material, form, shape, and size of the buildings that define urban spaces help users perceive their surroundings.

Within the scope of this study, the effect of designing public buildings with different functions in Patnos district with similar architectural styles on user perception is examined. The findings obtained through questionnaires revealed that public buildings are generally evaluated as “traditional,” “ordinary,” “medium-sized,” “moderately colored,” “moderately colorful,” and “little exciting” by users in terms of visual environmental perception. In particular, the fact that the buildings with four different functions (justice palace, government mansion, vocational school, and KYK dormitory) were designed with similar forms, symmetrical plans, and Seljuk period architectural elements created a sense of formal repetition rather than spatial diversity.

The comparative evaluation between the buildings revealed how the users perceived the design of public buildings with different functional identities and similar architectural representations in terms of spatial perception, aesthetic evaluation, and functional distinguishability. While the Palace of Justice stands out as a building where traditional architectural elements are used more prominently, the Government House and the Vocational School were evaluated by the participants in a relatively more contemporary style. This shows that although the formal language of the buildings is generally similar, user perception can differ in the level of detail. KYK Dormitory, on the other hand, was evaluated in an integrated perception plane with the other buildings due to its formal similarities despite its functional separation. Design preferences such as symmetry, entrance emphasis, façade elements (motifs such as arches, crown gates, Seljuk star), and color scale observed in all buildings provide spatial continuity but limit the level of distinctiveness. Approximately one-third of the participants stated that this architectural similarity creates difficulty in perceiving the functional differences between the buildings. This finding points to the importance of balancing formal integrity and functional legibility.
In this context, the following suggestions can be developed in line with the findings obtained:

- Architectural Diversity: Designing public buildings with different functions and architectural approaches within the same urban fabric will increase perceptual diversity and distinguishability. Differentiating each building to reflect its functional identity in architecture will enrich the user experience.
- Local Context and Identity: The local architectural elements, climatic conditions, and social fabric of Patnos should be considered in the design of the buildings. Thus, public buildings that contribute to the city's identity and are integrated with the place can be created.
- User Experience-Oriented Design: Not only aesthetics but also the impact of the design on the user (such as excitement, belonging, and creating memories) should be taken into consideration. The fact that the participants did not find the buildings "exciting" shows the weak user-place relationship.
- Strengthening Public Facades: The facade design of public buildings should be considered not only as an aesthetic shell but also as faces that reflect the public function and are open and inviting to the public.

In conclusion, it is observed that the formal similarities observed in the Patnos example have effects that may damage the urban identity, banalize the spatial perception, and weaken the user-space interaction. Developing design decisions for future public buildings with an approach that focuses on diversity, context, and user experience will contribute to creating quality urban environments.

For people to perceive and make sense of their surroundings, it is necessary to create urban spaces with qualities that can touch the user's world of meaning. In order to design quality urban spaces, it is necessary to identify the deficiencies in the current situation. This study aims to determine the current relationship between users and public buildings. It is hoped that the data obtained will guide the identification of missing points and areas to be intervened.

User satisfaction after pedestrianization in Trabzon Kahramanmaraş Street

Ece Eroğlu[1], Evinay Elif Tuluk[1], Reyhan Midilli Sarı[*1]

[1] Karadeniz Technical University, Department of Architecture, 61080 Trabzon, Türkiye

Abstract. Cities are holistic formations with the spaces they host and the users they serve. Within this formation, the change of any phenomena in question causes the other to transform. In this context, today's cities are areas where transformation is on a large scale under the influence of time. Increasing population and user diversity cause different needs to arise in cities and the change in the use of urban spaces. City centers are the places most affected by this situation. City centers, which have to balance pedestrian and vehicle traffic, also try to provide certain functions and needs for their users. However, with the increasing population and densely built areas, leaving streets that cannot carry these loads simultaneously to pedestrians only, i.e. pedestrianization, is on the agenda. To what extent the pedestrianized streets meet the user's needs is a matter of curiosity. In this context, the study aims to measure the satisfaction of pedestrianization applications held to meet pedestrian circulation and user needs. So Kahramanmaraş Street of Trabzon is the study area pedestrianized in 2022. Kahramanmaraş Street, one of the prominent arteries of Trabzon city center, has undergone many transformations throughout history, from street width to ground material, from the buildings it hosts to the way of use, depending on the needs. In the study, we used quantitative methods to define the problem, and the questionnaire form was the data collection technique. The survey was conducted between December 2022 and February 2023. We also received assistance from on-site detection, observation, and photography techniques. In the study, we defined the theoretical framework by addressing the issues of space-urban space and pedestrianization and the change/transformation of the study area, and we explained the findings obtained from the survey form and interpreted the results. As a result of the study, we concluded that the users were generally satisfied with the pedestrianization of the street; however, they were not pleased with the number of facilities, planting, signs, and information.

Keywords: Urban space; Pedestranization; User satisfaction; Kahramanmaraş Street

1. Introduction

Space is not a purely physical formation, independent of the actions that take place within it or the organization caused by the user's desires and needs. It hosts daily life practices in particular, and these practices and the user framework are shaped. Therefore, as a living organism, it is in a state of change and transformation. This transformation takes place depending on time, environment, needs and expectations, and the space constantly renews itself to the extent of the possibilities of the period in which it exists.

When space is considered on a larger scale—such as the city—urban spaces emerge as areas where transformation is most visibly manifested. According to Bayrakçı, urban space consists of a set of interrelated systems; a change in any one of these systems inevitably impacts the others, resulting in the continuous evolution of the urban environment (Bayramoğlu & Özdemir, 2012). Comprising various open and enclosed spaces, urban areas serve as social connectors that bring together individuals from diverse social and economic backgrounds, fostering a sense of integration (İnceoğlu, 2007). In this context, streets, avenues, squares, and parks can be cited as examples of urban open spaces.

Urban open spaces are multi-functional environments that must accommodate a variety of uses due to the diversity of their users. In this context, such spaces can be defined as shared-use environments equipped with specific features, shaped by the social, cultural, physical, and psychological needs of individuals. Therefore, they should be designed to fulfill users' expectations and respond to needs such as rest, recreation, and transportation.

The most basic priority for the creation and maintenance of a successful urban open space is to meet people's needs and preferences. These needs can be listed as comfort, relaxation, passive and active occupation, exploration, and entertainment (İnan, 2008). The need for comfort is related to the presence of comfortable seating areas in the space, protection against external factors such as sun and wind, and good guidance within the space. The need for

[*] Corresponding author, E-mail: rmidilli@ktu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_299

relaxation is related to providing psychological relief for people by providing water and plant covers in the space, while the need for passive occupation includes the user being able to watch the view and the activities around them (shows, sports, etc.). The need for active occupation is the user's physical participation in the activities around them. The need for exploration is the user watching and being drawn to the users, space, and spatial facilities around them, while the need for entertainment is related to the user having fun in the space and actively using that space (İnan, 2008). For this reason, it is important to organize urban open spaces (streets, avenues, landscape areas) that cannot meet current needs due to increasing population and dense construction in a way that will provide their functions, expectations, and user satisfaction.

Urban open spaces have undergone numerous transformations over time due to social, economic, and technological factors. The widespread adoption of motor vehicles, driven by the Industrial Revolution, has significantly impacted the transformation of urban open spaces and the streets within them. The presence of motor vehicles in urban spaces has transformed urban spaces that are essentially unstructured and allow human use into a structure that is structured but restricts human movement and freedom. Vehicles found in urban open spaces have been effective in the formation of pollution, dust, and noise, reduced the sustainability and quality of urban life, and destroyed the naturalness of people's living environments (Aliyev, 2021). In addition, urban open spaces have become vehicle-first places, restricting pedestrian movement and use, bringing the primary user to a secondary position, and causing the environment to be shaped in an unqualified way. Restoring urban open spaces that fail to meet the needs of city residents, ensuring cultural continuity and social sustainability, and enhancing the vitality of the city through pedestrian-focused design have become key priorities. In this context, the widespread use of urban open spaces, heavily used streets with high pedestrian movement, and the implementation of pedestrianization and their functioning as public open spaces to meet the various needs of the citizens have increased (Koçan & Rüzgar, 2016; Ateş et al., 2021). However, determining the extent to which these streets meet user satisfaction and contribute to their long-term sustainability following pedestrianization is a critical issue that requires attention. In this context, the study aims to assess user satisfaction levels regarding the pedestrianization efforts implemented to adapt to contemporary needs and conditions. The study's sample area is Kahramanmaraş Street, located in the city center of Trabzon, which was closed to traffic and pedestrianized in 2022.

1.1. Pedestrianization Concept, Objectives and Benefits

Urban spaces exist for people, while vehicles are merely tools for transportation. When considering an urban space, priority should be given to people, specifically pedestrians (Cebeci & Çakılcıoğlu, 2001; Gökgür, 2008; Aliyev, 2021). In this context, the concept of pedestrianization arises. Pedestrianization is defined as the transformation of roads (such as avenues, streets, etc.) in urban areas into pedestrian-only zones or the allocation of larger spaces for pedestrians through various modifications (Ateş et al., 2021). However, pedestrianization should not be understood merely as the creation of pathways where vehicles are restricted. Instead, it should involve the design of spaces that encourage pedestrian movement and activities, highlight human elements, and ensure controlled access and movement of vehicles (Brambilla & Longo, 1977; Ateş et al., 2021).

Pedestrianization increases livability, especially in city centers and urban open spaces, ensures the safety and easy circulation of pedestrians, and brings economic vitality to the region depending on the increase in the use of the streets and avenues where it is applied. In this regard, the pedestrianization of streets can be seen as a human-centered approach that prioritizes the public interest (Semerci & Hayırlıoğlu, 2016). Pedestrianization practices, which increase the mobility of pedestrians within the spaces they are in and improve safety, basically serve three purposes. These are to revitalize commercial areas that contribute to the regional economy, revitalize the city center, and produce spaces where people can rest, benefit culturally, and socialize (Brambilla & Longo, 1977; Dursun et al., 2021). If we need to summarize the objectives of pedestrianization in line with these purposes, these are (Dursun et al., 2021): to ensure communication and socialization; to regulate the microclimate effect; to revitalize the city center; to control the density that may occur in the city center; to reduce the use of private vehicles and to regulate traffic; to support trade and local tradesmen by making arrangements that will stimulate tourism. Some of the criteria required to achieve these goals are classified as follows (Gültiken, 2010):

1. Connection-Accessibility: It is related to the accessibility of the area at both local and urban levels.
2. Connection to other means of transportation: It is related to the connection with buses, metro, etc., vehicles within the area, or access to the area.
3. Land use diversity: The success of a pedestrian space is directly related to its ability to create a series of activities suitable for a wide variety of users. The pedestrian space should be fun, comfortable, and safe with walking areas.
4. Security, Traffic, and Social Crime: In order for pedestrian areas to become safer and more secure, there should be sufficient lighting in these areas and police officers should be on duty.
5. The quality of the walking area: Material, landscape, signs, and guides, the quality of the design, and the durability of the building materials are the main elements in the success of a pedestrian space.
6. The design and content of the walking area: Permeability, spatial definition, landscape, etc.

In line with these criteria, pedestrianized spaces (streets, avenues, etc.) must be accessible and connected to transportation networks, with vehicles allowed to enter when necessary. Security and control measures should be implemented for users, and the spaces should include certain amenities based on user needs (Gültiken, 2010). It is crucial that the amenities within pedestrianized spaces do not obstruct user movement and facilitate interaction with other users. There are certain physical elements in pedestrianized spaces affect pedestrians' perception of the space, the way they use it, and their desire. These factors include pedestrian-vehicle connections, building (facade) heights, facade lengths, flooring materials, landscaping, lighting, and urban space furnishings.

Urban space accessories are plants landscape elements and street furniture. Street furniture can be listed as; seating units (benches, tables, and chairs), bicycle racks, poles, flower beds, buffets, food and beverage kiosks, newspaper stands, parking meters, public art elements, street signs, roof elements, traffic and park signs, trash cans, lighting elements (Steiner & Butler, 2007). Among urban space amenities, seating units (such as benches and chairs) are arguably the most influential elements in shaping the use of streets. Gehl (2011) emphasized that the activities facilitated by public spaces are crucial for their quality, and seating units support a variety of activities—such as eating, reading, playing chess, sunbathing, people-watching, and conversing—that enhance the attractiveness of these spaces.

Plants and landscape elements found in urban open spaces and streets have positive effects on human psychology. With these effects, plant landscape elements create a natural ground for people to stop, rest, and chat, and contribute to users' socialization and use of the space. In addition, plants reduce heat access by acting as a shader in urban open spaces and streets; balance the microclimate of the space by allowing heat to spread throughout the space, and provide noise, dust, and sound insulation by acting as a screen between vehicles and pedestrian spaces (Emmanuel, 2005; Tandoğan & Şişman, 2018).

Additionally, in urban open spaces, it is essential to design food and beverage areas to enhance user satisfaction and transform the space into a place where users can relax, rather than merely walk. Providing various activities and shops in pedestrian areas are crucial elements that attract users to this place. Lighting elements and information boards should be mounted on the walls, and signs and directional signs should be brought together in a single structure as much as possible. Appropriate materials should be chosen for road pavements, ensuring that the selected materials are non-slippery. In addition, the flooring material should allow for comfortable walking, and the patterns created on the flooring should be arranged in a way that guides the user. (Koç & Sönmez, 1996).

As a result, the most crucial factor in effective design is addressing human needs. In the renovation or redesign of existing open spaces (such as the pedestrianization of streets), creating a successful space requires observing users and investigating their needs. Organizing and designing open spaces based on user needs is one of the key factors in the success and development of these spaces (İnan, 2008).

2. Materials and method

The study area is Kahramanmaraş Street, one of the three main access arteries in the city center of Trabzon. The street was selected as the study area because it has witnessed the physical and historical development of the city, holds an important place in the city's collective memory, has been recently pedestrianized, and experiences high user density. This study examines the pedestrianization of Kahramanmaraş Street from the users' perspective and its impacts on user experience. Data were collected using a structured questionnaire administered to 233 users who had experienced the street both before and after pedestrianization. The survey was conducted between December 2022 and February 2023. The questionnaire consists of 53 questions covering demographic characteristics, user evaluations following pedestrianization, satisfaction levels, and expectations. Of these, 44 questions use a 5-point Likert scale, where "1" corresponds to "strongly dissatisfied" and "5" corresponds to "strongly satisfied". The semantic interpretation of the average scores is as follows: 1.00–1.80: very low; 1.81–2.60: low; 2.61–3.40: medium; 3.41–4.20: high; and 4.21–5.00: very high.

2.1 Study area: Kahramanmaraş Street

Kahramanmaraş Street starts from Meydan Park and extends to the Ayasofya Neighborhood. Considering the length of the street and its location in the city center, it is one of the most important axes connecting the city of Trabzon horizontally. The pedestrianized part of the street is limited to the area between Gazipaşa Street and Cumhuriyet Street.

When we examine the historical development of Kahramanmaraş Street, one of the key landmarks in the city's collective memory, it is evident that the street has undergone several transformations. During the Russian occupation between 1916 and 1917, a 'middle street' was planned to extend from the Hagia Sophia Neighborhood to Meydan Park for military purposes, specifically to transport ammunition. Subsequently, the street, which came to be known as 'Russian Street,' was renamed 'Kahramanmaraş Street' during the War of Independence (Üstün Demirkaya, 2014; Tuluk & Bayrak, 2019). When initially constructed, the street was narrower and lined with densely packed wooden houses, which were expanded upon by the Russians (Doğan, 2009; Dinçer, 2016). It is known that Turkish neighborhoods and houses belonging to Turks were primarily located along this street, and many buildings were demolished during the expansion (Çapa & Çiçek, 2004; Düzenli, 2009).

When considering the pedestrianized section of the street, several historical buildings stand out (Fig. 1). The first of these is the Ziraat Bank building, which opened in 1950. It is said that the smooth-surfaced stones used in its construction were sourced from the remains of a church that previously stood on the bank's site (Düzenli, 2009). During this period, another important structure from the Republican era, the old Central Bank, was built adjacent to the Ziraat Bank (Düzenli, 2009). Today, the building houses the 'Trabzon City Museum.' At the eastern end of Kahramanmaraş Street stands the Meydan Hamamı, which was built in the late 19th century (Horuluoğlu, 1978). The building features an entrance to the women's section from the side street, while the men's section is accessible from Kahramanmaraş Street (Üstün Demirkaya, 2014).

The Zorlu Grand Hotel, located on the street, is another significant structure that holds a prominent place in the city's memory. Built in the 1990s, it was the first 5-star hotel in the city and the surrounding region (URL-1, 2025) and continues to operate today. In addition to these landmarks, the street is home to numerous private and state-owned banks, business centers, offices, buffets, exchange offices, florists, stores, hairdressers, sales units, food and beverage venues, and educational facilities, all serving the city's residents with a wide range of functions and scales. Due to the high concentration of banks, the street is also commonly referred to as 'Banks Street' by the public (Fig. 1).

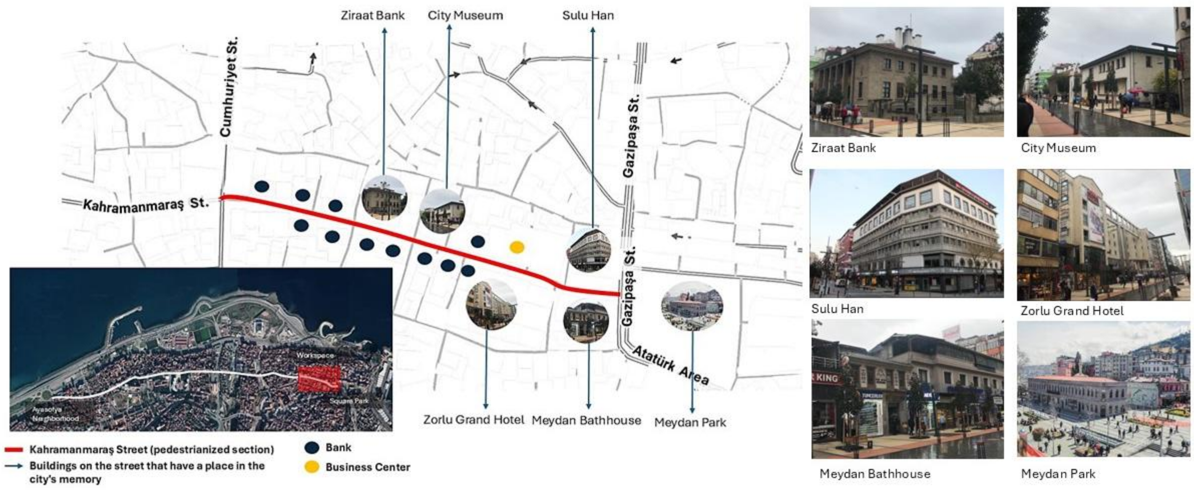

Fig. 1. Kahramanmaraş Street from Hagia Sophia to Meydan Park

In the 1930s, Kahramanmaraş Street had a dirt surface, but by 1950, it was paved with roughly cut Trabzon stone in cobblestones, a texture that remained intact until the pedestrianization works. The sidewalks were originally made of concrete and were later paved with concrete slabs in 2007-2008 (Doğan, 2009). In 2022, the entire street surface was covered with a rubber material as part of the pedestrianization efforts. However, due to issues with the flooring material, the surface was renewed in 2023 (after the survey study) with asphalt, which was poured and painted (Fig. 2).

Fig. 2. The situation of Kahramanmaraş Street in the 1980s (Dinçer, 2016); 2021- The situation of the street before pedestrianization (URL-2, 2025), 2022; The situation of the street after pedestrianization (URL-3, 2025)

According to the Lambert Plan, Kahramanmaraş Street, which is considered the backbone of the city, served two-way vehicle traffic until 2010. In 2010, vehicle traffic changed to one-way. Due to the density of the city center and the increase in the human population, the street was completely closed to traffic and pedestrianized in 2022, and it was opened to service by adding certain urban facilities within the scope of pedestrianization.

2.2. State of Kahramanmaraş Street after the Pedestrianization in 2022

The Trabzon Metropolitan Municipality Transportation Department Transportation Coordination Center (UKOME) decided to pedestrianize Kahramanmaraş Street with Decision No. 2021/068, dated 04.10.2021. In line with this decision, the street was pedestrianized in 2022, new functions were created, and various urban facilities were added. The implemented improvements can be categorized under the headings of 'seating elements,' 'lighting elements,' 'trash cans,' 'borders,' 'planting and trees,' 'floor arrangement,' 'accessibility,' and 'bicycle and electric vehicle accessibility'.

Seating elements: There were no seating elements on the street before pedestrianization. Following pedestrianization, seating, and resting elements were introduced to support activities such as resting, waiting, and observing the surroundings. Three different types of seating elements have been installed throughout the area (Fig. 3).

Fig. 3. Seating elements

Lighting Elements: The lighting elements on the street are positioned along the edges of the central axis allowing occasional vehicle access. They are arranged in four different ways based on the direction of the light. Although their positions are almost the same as before pedestrianization, there has been a noticeable improvement in their aesthetic quality (Fig. 4).

Fig. 4. Lighting elements

Trash Cans: Two different types of trash cans are present on the street. The first type is a lidless trash can, made of similar materials and placed next to the lighting elements. The second type is a larger, lidded trash can with underground recycling bins. The trash cans integrated with the lighting elements are consistent with the design form used before pedestrianization; however, the use of wood as a material adds aesthetic value to the design (Fig. 5).

Fig. 5. Trash cans and borders

Borders: After the pedestrianization of the street, it became necessary to create a separation between pedestrian and occasional vehicle use to accommodate limited vehicle access when required. In this context, the road on the street, which provides vehicle access when necessary, and the area with seating elements and trees (the area reserved for pedestrian use only) are separated by bourder elements. Before pedestrianization, the separation between pedestrian and vehicle areas was achieved only through the pavement and roadway arrangement. In terms of design, the border elements used after pedestrianization are of a single type but vary in size (Fig. 5).

Trees and Plants: Before pedestrianization, there were a limited number of trees on the street. After pedestrianization, the number and diversity of trees and plants increased (Fig. 6).

Fig. 6. Trees and Plants

Floor Arrangement: Before pedestrianization, the street consisted of a cobblestone roadway and concrete pavements. Following pedestrianization, the areas designated for seating elements were covered with rubber flooring material, while the sections intended for occasional vehicle use were paved with cobblestones. An aesthetic appearance was created by using different colors in the floor covering materials (Fig. 7).

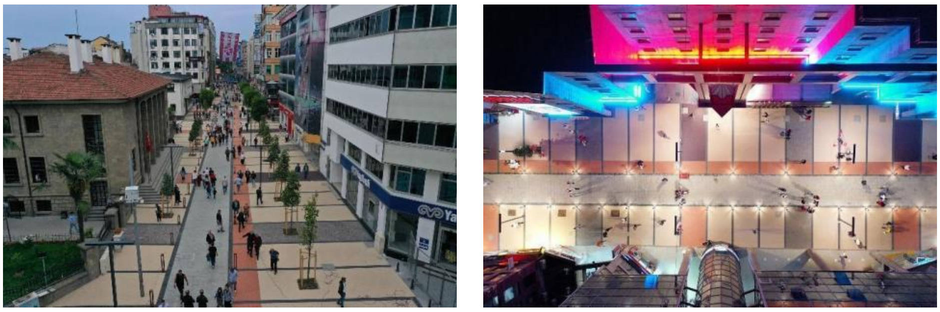

Fig. 7. Floor arrangement in 2022 (URL-3, 2025)

Accessibility: Before the pedestrianization of the street, a level difference was created through pavement arrangements to separate pedestrian and vehicular access areas. While this posed challenges for accessibility for disabled individuals, the inclusion of tactile surfaces in the pavement provided some advantages. In the new layout implemented after pedestrianization, the absence of level differences offers improved accessibility for disabled users. However, the new ground arrangement lacks tactile surfaces for individuals with visual impairments (Fig. 8).

Fig. 8. Floor arrangement without tactile surfaces

Bicycle and Electric Vehicle Accessibility: Before pedestrianization, there were no bicycle or electric vehicle paths on the street. Following the pedestrianization, a designated bicycle path was added. However, the beginning and end of this bicycle path, located in a specific section of Kahramanmaraş Street, are not connected to any other routes. Additionally, parking areas for electric vehicles have been established along the street (Fig. 9).

Fig. 9. Bicycle paths and parking areas reserved for electric vehicles

2. Results

An evaluation of the general demographic information of participants who experienced the street revealed that 67% were female, 33% were male, 31% were young adults aged 19-25, and 29% were adults aged 46-60. Regarding educational status, 65% of participants were university graduates, and 25% had completed high school. Additionally, 36% of street users were students, 26% were housewives, and 21% were civil servants (Fig. 10).

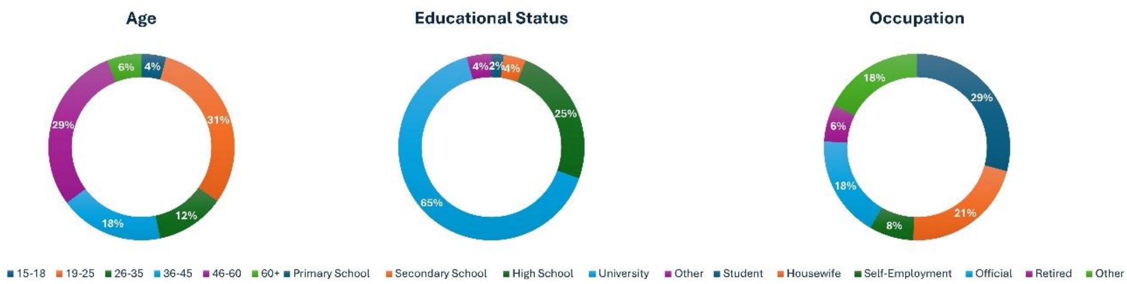

Fig. 10. Age, educational status and occupation of participants

When the frequency of use of the street during the day was evaluated, it was seen that 41% of the users used Kahramanmaraş Street once a week, while 19% experienced the street every day. The purpose of the users using the street during the day was mostly walking and passing 48%, sightseeing (44%), and the other frequently preferred purpose of use was shopping (38 %) (Fig. 11).

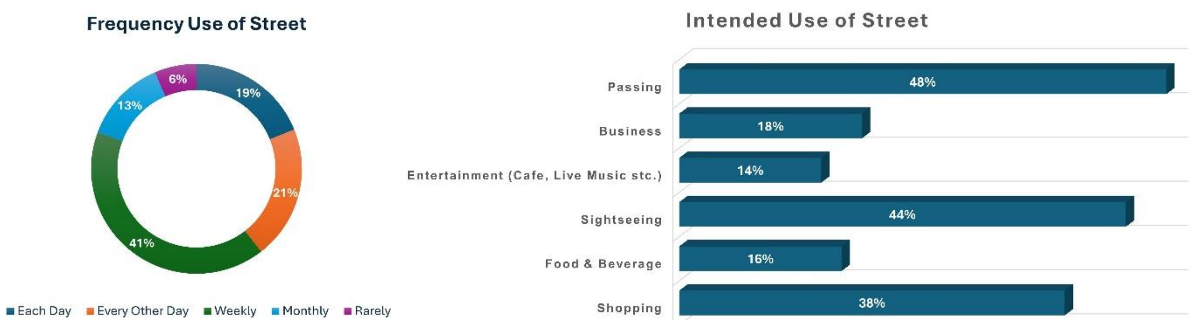

Fig. 11. Distribution of frequency use of street and intended use of street

When participants were asked about the frequency of street use at night, it was found that nighttime usage was lower than daytime use. The majority of users stated that they rarely visited the street (52%) at night. The purpose of using at night was mostly for passing (59%), followed by sightseeing (33 %) and the use of entertainment venues (16 %) (Fig. 12).

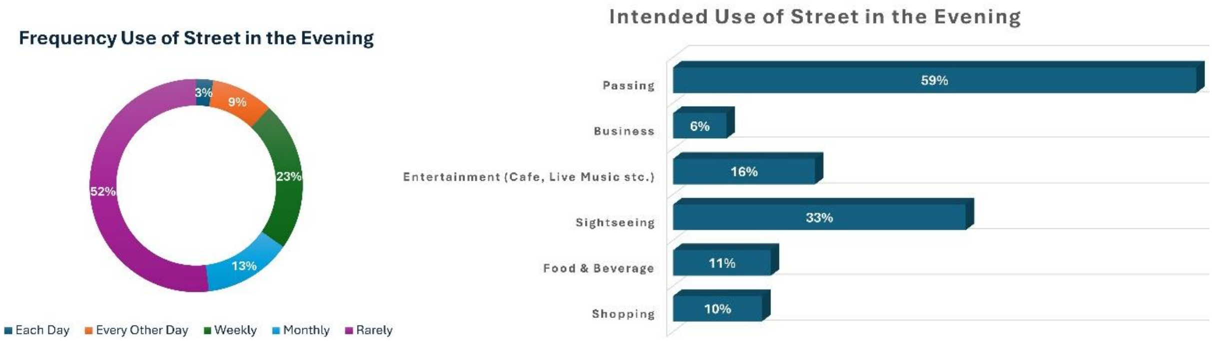

Fig. 12. Distribution of frequency use and intended use of street in the evening

Participants were asked to evaluate their satisfaction with the current state of Kahramanmaraş Street, specifically focusing on the effects of pedestrianization. As reflected in the responses to the proposition 'I am satisfied with the pedestrianization of the street,' participants reported a very high level of satisfaction (4.48) (Fig. 13).

Fig. 13. User satisfaction status after pedestriazination

To further assess their overall satisfaction, participants were asked to indicate their level of agreement with various statements regarding the use of the street. The findings show that users strongly agreed that the street allows for more comfortable walking after pedestrianization (4.4), that pedestrian safety has improved (4.33), and that accessibility for the elderly, disabled individuals, and strollers has increased (4.3). Participants also agreed that the street has become more suitable for night use (4.13), that the urban environment is better perceived and shop windows are more easily viewed (4.12), that the street has become a center of attraction for the city (3.87), that noise and environmental pollution have decreased (3.83), that the frequency of street use has increased (3.61), and that participation in social and cultural activities has risen (3.67). The lowest level of agreement was observed for the proposition that 'closing the street to traffic did not negatively affect transportation' (3.5). Overall, a review of all propositions reveals a high level of satisfaction, indicating that users' experiences after pedestrianization are significantly more positive compared to their experiences beforehand.

An evaluation of user satisfaction with the street layout, flooring, seating elements, lighting elements, and trash cans within the scope of the pedestrianization project on Kahramanmaraş Street revealed a medium level of agreement with the related propositions, with an average score of 2.88. It can be concluded that users reported a medium level of satisfaction with the separation of sitting and walking traffic (3.36) and with the organization of movement directions (3.16) on the street. Similarly, the suitability of the street's post-pedestrianization layout for electric vehicles (3.19), the sufficiency of the number of signs and signboards (3,02), and its aesthetic condition (2.91) were the situations where the users had a medium level of satisfaction. It is seen that the responses of the participants to the propositions of the suitability of the bicycle path on the street for use (2.32) and the sufficiency of trees and planting (2.59) indicated a low level of satisfaction (Fig. 14).

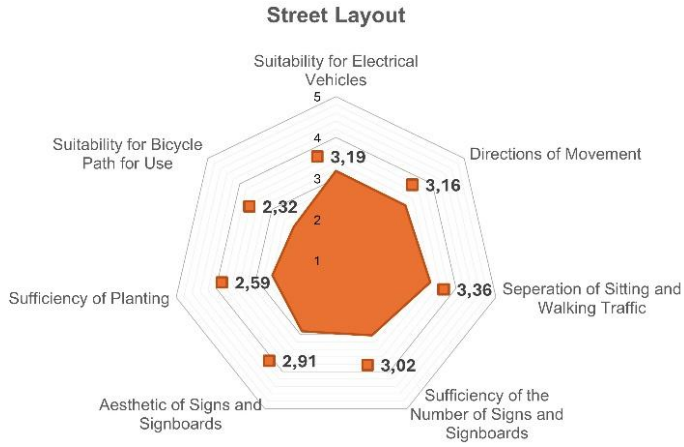

Fig. 14. Satisfaction status with street layout and related criteria

Participants' evaluations of the flooring qualities following pedestrianization indicated a moderate level of satisfaction, with an average score of 2.86 (Fig. 15). We can conclude that the participants found the suitability of the flooring for the elderly and disabled individuals (3.3), its functional suitability (2.87), and its aesthetic status (3.17) to be at a medium satisfaction level. Accordingly, participants' appreciation of the flooring was at a medium level (2.9), while their satisfaction with its durability and longevity was low (2.25). The fact that the flooring had to be replaced due to wear shortly after the pedestrianization project finished supports this result.

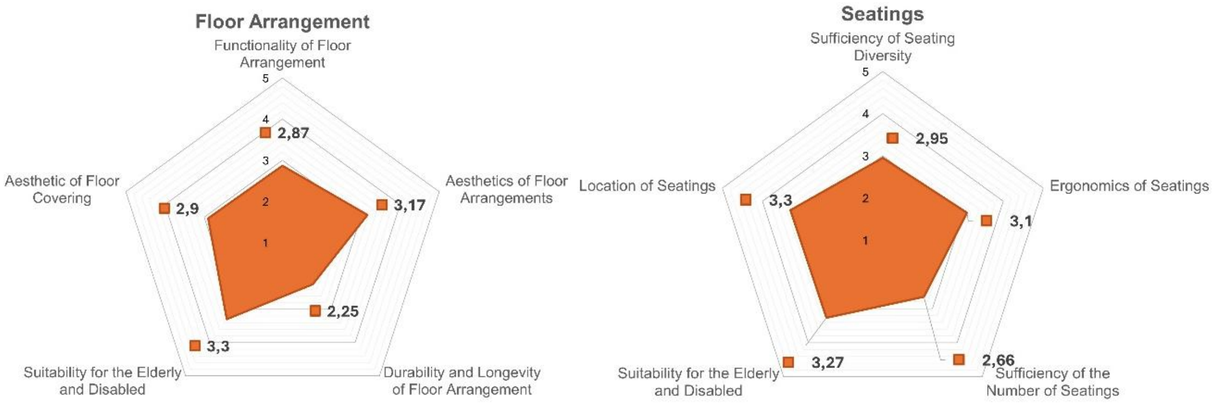

Fig. 15. Satisfaction status with floor arrangement and seating elements

When Seating elements are one of the urban facilities added after the pedestrianization of the street. An analysis of participants' responses regarding the seating elements on the street revealed a moderate level of satisfaction, with an average score of 3.02 (Fig. 15). The ergonomic quality of the seating elements (3.1), their location (3.3), and their suitability for seniors and individuals with disabilities (3.27) all received medium satisfaction scores. When asked about the adequacy of the seating elements, participants reported a moderate level of satisfaction with the variety available (2.95) and a low level of satisfaction regarding their quantity (2.66). In this case, we can say that the participants found the seating elements insufficient in number.

Researchers asked questions regarding the lighting elements whose design and number changed within the scope of pedestrianization on Kahramanmaraş Street, we observed that the answers were at a high (3.62) satisfaction level (Fig. 14). Participants evaluated the functionality (3.68), adequacy in number (3.81), location (3.72), and aesthetic status (3.56) of the lighting elements at a high satisfaction level. In addition, participants had higher satisfaction with the lighting elements not hindering walking (3.6). Based on the answers to the questions asked to users about the number and location of the trash cans along with the urban facilities added after pedestrianization, we can say that the general satisfaction level of users regarding the trash cans was at a medium level (3.2). Users were moderately satisfied with the adequacy in number (3,07), location (3.33), and aesthetic status (3.25) of the trash cans added to the street. Participants had a high (3.6) satisfaction level with the functionality of the trash cans (Fig. 16).

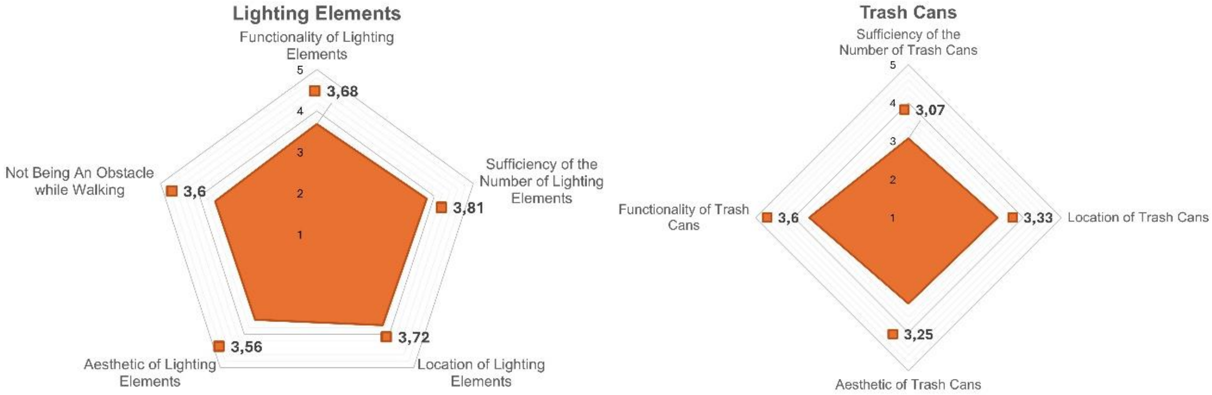

Fig. 16. Satisfaction status with lighting elements and trash cans

As a result of the evaluation carried out to determine user expectations, we can say that users highly want specially designed buffets, bagel shops etc. sales units on the street (3.94), more social spaces such as eating and drinking, and resting on the street (3.93), monumental elements such as works of art and sculptures on the street (4,05), and water elements on the street (3.75) (Fig. 17). In addition, participants stated that they highly want more cultural spaces on the street (4.3) and planned/programmed events to be organized on the street (4.3).

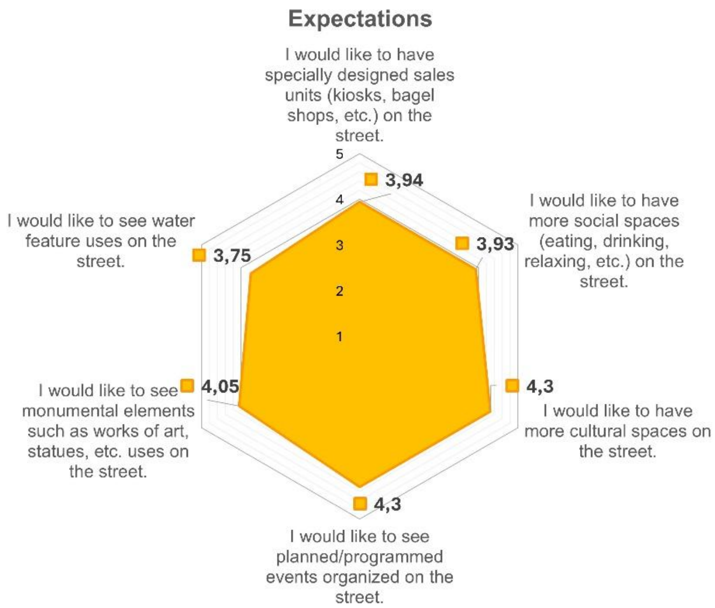

Fig. 17. Expectations for the future arrangement of the street

Thirty-one participants responded to the question regarding additional opinions they wished to share following the pedestrianization of Kahramanmaraş Street. Eleven participants highlighted problems with the ground covering, citing issues such as rapid material wear, poor aesthetic quality, slipperiness during rain, and inconvenience for elderly users. Nine participants suggested that the street should be socially and culturally enriched by incorporating elements such as spaces for street performers, cafés and kiosks, children's playgrounds, libraries, opportunities for selling local food, and architectural features that reflect the city's identity.

Three participants emphasized the need to increase the number of trees and green spaces, and another three pointed out the lack of functional zoning in the street layout, noting that seated individuals often obstruct pedestrian flow. Two participants indicated that pedestrianization had been implemented without adequate consideration of the broader urban transportation system. Additionally, two participants recommended relocating and increasing the number of trash bins. Two others stressed the need for a clearly defined bicycle path, while one participant requested the installation of tactile surfaces and a security point.

3. Conclusion

Transforming urban open spaces to meet user needs is important for the sustainable and human-centered development of cities. In this respect, the study aimed to evaluate Kahramanmaraş Street, located in the city center of Trabzon and pedestrianized in 2022, regarding user satisfaction, physical characteristics, and responsiveness to expectations. The findings show that the pedestrianization application was generally welcomed positively by users and provided a high level of satisfaction.

In terms of frequency of use, the rate of individuals using the street every week is high, whereas night use is more limited due to factors such as safety and functionality. Social and individual activities such as walking and shopping are at the forefront during the day and transition at night. Users are particularly pleased with the arrangements that address basic needs such as increased pedestrian safety, improved accessibility, and increased walkability. In addition, contributions to the street becoming a more attractive urban space and encouraging social/cultural interaction affect the satisfaction levels with pedestrianization. On the other hand, users have made a reserved assessment regarding the effects of the street being closed to vehicle traffic on transportation systems.

Regarding physical arrangements, elements such as the street layout, seating areas, flooring, and urban amenities like trash cans generally achieved moderate satisfaction levels. Notably, the flooring received low ratings concerning aesthetics and durability, highlighting the need for improvement to ensure the sustainability of pedestrianization. Although the placement of seating elements was positively evaluated, the number of seats was deemed insufficient. Conversely, lighting elements achieved high satisfaction levels in terms of both aesthetics and functionality. Meanwhile, low satisfaction regarding planting arrangements and bicycle paths indicated deficiencies in making the street a more livable and multifunctional urban open space. Similarly, the inadequacy of directional and informational signage emerged as another area needing attention to enhance usability.

Findings concerning user expectations revealed a strong demand for the addition of social, cultural, and artistic elements along the street. Features such as planned events, cultural venues, water elements, and monumental artworks have the potential to strengthen users' emotional and functional bonds with the space.

Overall, the pedestrianization of Kahramanmaraş Street has made significant contributions to increasing opportunities for socialization, rest, and urban interaction, sustaining the vibrancy of the city center, and improving the quality of public life. The initiative has largely succeeded in adhering to fundamental pedestrian-oriented principles and achieving high levels of user satisfaction. Nevertheless, further improvements in areas such as physical design quality, landscape diversity, wayfinding systems, and the adequacy of social facilities will enhance the space's sustainability and its contribution to urban life quality. Due to wear, deterioration, and negative user feedback, the street's flooring was renewed in 2023 shortly after its initial use, and tactile paving applications were introduced in 2024. This situation underscores the importance of accurately identifying user profiles and needs, and continuously responding to emerging demands and improvements based on usage patterns. Otherwise, it is undeniable that a space unable to satisfy its users cannot maintain its vitality. It can be concluded that Kahramanmaraş Street, an important axis in the city's urban memory, will continue to evolve into a higher-quality public space through a holistic planning approach that remains sensitive to user needs.

Evaluation of Karadeniz Technical University Kanuni Campus with universal design criteria

Şeyda Bülbül Arıoğlu*[1]

[1] *Karadeniz Technical University, Department of Urban and Regional Planning, 61080 Trabzon, Türkiye*

Abstract. The concept of universal design is a holistic design approach that provides solutions for different user groups. The main purpose of space designs based on universal design principles is to create spaces that will perfectly meet the needs of all users according to their characteristics. Spaces designed with this understanding; It should offer opportunities that individuals with different characteristics can easily access, use, act independently and benefit from all kinds of social activities. Accessibility is a necessary prerequisite for ensuring equal conditions for everyone in the built environment. Today, many urban areas are not accessible to disabled people. Like every individual in society, disabled individuals should be able to benefit from public spaces equally. In order to prevent the problems that disabled people encounter in the use of space, universal design criteria for disabled people should be followed. It is the fundamental right of disabled individuals to have access to university campuses and to have unimpeded movement within the campus. The accessibility of university campuses should comply with universal design principles. For a holistic, inclusive and universal design, transportation to and accessibility within the campus area should be taken into consideration. The general purpose of this study is to evaluate accessibility in Karadeniz Technical University Kanuni Campus in line with universal design principles and to reveal how designs for disabled individuals can be made to increase accessibility. For this purpose, observations and evaluations will be made in the Kanuni Campus.

Keywords: Universal design criteria; Karadeniz Technical University; Barrier-free design; Barrier-free campus; Accessibility

---

1. Introduction:

The 'universal design' approach, in which everyone has equal use and accessibility in the design of space, environment and equipment elements, includes different scales from urban space to in-building transport and accessibility (Tandoğan, 2017).

The main objectives of the universal design approach are to make the urban environment and the spaces within the building accessible and understandable for all users, to provide equal use and barrier-free access opportunities for all users, and to facilitate the use of built environments for disabled individuals.

Universal design, inclusive design, design for all concepts aim to make the built environment and products we live in accessible to everyone. This concept is a design concept that facilitates the life of all user groups who are not only disabled individuals but also disabled candidates at every moment of their lives. Universal design principles help to increase the level of accessibility and quality of life of individuals in their spaces and built environments.

The understanding of design for all is important in the design of urban environment, social areas and spaces with equal use and barrier-free accessibility for all individuals (Kavak, 2010). Readability, perceptibility, livability, accessibility, suitability, etc. in urban areas constitute important criteria in increasing the quality of use of public spaces (Tandoğan, 2017). It is possible for public spaces to appeal to all individuals by realising the determined criteria with appropriate solutions.

"Accessibility means that everyone can access and use any place and any service independently and safely." (Accessibility Guidelines, 2020). Accessibility includes non-discrimination, physical accessibility, economic accessibility and information accessibility (WHO, 2017). Accessibility in university campuses is also extremely important to ensure the rights, freedom and comfort of all users.(Yerli and Özdede, 2017) explains that accessibility in transportation means 'the ability of every individual to reach from one point to another point in the city without any obstacles'.

* Corresponding author, E-mail: seydabulbul@ktu.edu.tr

https://doi.org/10.31462/icearc2025_a_arc_307

Accessibility, when considered as the physical environment, is defined as the ability of all individuals to participate in social life without the need for others and to access public spaces and services safely. Today, in pedestrian zones located in many urban spaces, users experience problems in accessibility to physical space due to the fact that accessibility is not handled in a multidimensional way (Sandoval, 2018).

There are many legal regulations in the world and in Turkey to emphasise that every individual in society has equal rights and to protect the rights of persons with disabilities. The Universal Declaration of Human Rights, published in 1948 and signed by Turkey, emphasises that every member of society has the right to access higher education without discrimination. Adopted by the Committee of Ministers of the Council of Europe in 2001, it recommended that all professions related to the field of design should include universal design in their education and training (Boduroğlu et al, 2011). With the amendment made in the Decree Law No. 5378 in our country, problems in the field of accessibility, education and health have been addressed, and the regulations made in a wide scope in these places are included (Gören, 2018).

Disability is a limiting and restrictive impairment of an individual's life activities, abilities and strength (Öztabak, 2017). Design and planning principles for persons with disabilities should enable equal use of space. Simple, flexible, perceptible, comprehensible, comprehensible, hazardous, easy and comfortable spaces should be designed for the skills and wishes of disabled people (Ökten, 2018). The prejudices brought by the lack of awareness in the society and the fact that the physical environment is not designed in a way suitable for the use of disabled people cause the disabled to be excluded from the society (Çınar, 2010).

In the built environment, the understanding that designs are generally made for average user groups (general) (Tutal, 2018) reveals the situation that not all users can benefit equally from the built environment and causes disability (disability) problems. In other words, the disability is not caused by the user but by the environments as a result of the designs. Disability is diverse and accessibility is expected to be inclusive.

Accessibility is the state of being accessible to the outside world, and disability is the state of being hindered by the outside world and the loss of abilities. In other words, accessibility is an important quality indicator in public urban space (EPOA, 1997), (İnceoğlu, 2007). In the discipline of architecture, accessibility can be defined as the quality of easy access to the environment and spaces (Sandoval, 2018).

1.1. Purpose and method of the research :

The aim of the study is to evaluate the usability of Karadeniz Technical University (KTU) Kanuni Campus (central campus) by disabled students within the scope of design for all understanding and to make suggestions to improve the current accessibility level in line with universal design principles.

The focus was on determining the physical accessibility levels for pedestrian roads, pavements and public spaces that provide access between spaces. The concept of accessibility has been handled at the campus scale, and the measures to be taken for accessibility have been evaluated with a holistic approach.

Within the scope of the research, a conceptual framework was created by reviewing the literature, and documentation was provided by on-site observation and photography method in KTU Kanuni Campus, which was determined as the research area. With the data collected, the compliance of the public open spaces on the campus with universal design principles was evaluated and solutions were proposed for the problems identified.

1.2. Universal design (Design for everyone):

Universal design (Design for everyone) is the design of products, services and the built environment so that they can be used by as many people as possible, regardless of age or ability (Koca and Yılmaz, 2017).

The main objectives of the design for all approach are to ensure that spaces and products are accessible, accessible, appealing to a large audience and realising designs with general use. Universal design, as a design that is equally accessible and usable without discrimination, aims to provide physical harmony, easy perception of the environment and reduce energy costs (Hacıhasanoğlu, 2003).

Universal design is an approach that meets the needs of different users and offers solutions without grouping them or creating physical difficulties. Universal design is not just about people with disabilities having the same rights as other users in society. It aims for equality for all users, whether disabled or not. Usability, accessibility and inclusiveness form the basis of the universal design philosophy (Yılmaz, 2022).

The aim of universal design is for everyone in society (children, elderly, disabled and non-disabled, etc.) to benefit equally from the services offered by the space. It aims to meet the needs and expectations of different individuals and to respond to these needs equally with the same product that includes different options (Gören, 2016).

The concept of universal design can be defined as a way of proposing design solutions that meet the needs of different user groups and do not label users (Story et al., 1998). The goal of universal design is to design products and environments that are accessible to as many users as possible without requiring adaptation or special design.

Universal design, which emerged from the idea that every individual should be accessible to every object and space at all times, is a design approach that provides users with as much independence as possible, is suitable for their special needs, provides information to the user and is also sustainable (Boduroğlu, 2014).

1.3.Universal design principles:
The principles of universal design were developed by The Centre for Universal Design group at the University of North Caroline working on universal design. These principles aim to evaluate existing designs, to correct deficiencies and to educate designers and users. Universal design criteria can be explained as follows (Story et al., 1998);

- Equitable Use: The design should be such that every individual with different abilities can use and buy it, regardless of the user. (No discrimination)
- Flexibility in Use: The design should be accommodate different individual abilities and preferences.
- Simple and Intuitive Use: There should be simple, understandable designs independent of the user experience.
- Perceptible Information: The design should be able to provide the user with the necessary information independent of the environmental conditions and the different sensory abilities of the users.
- Margin of Error in Design: Design should minimise hazards and accidents and undesirable adverse effects.
- Low Physical Power Usage: The design should be able to be used efficiently with minimal effort.
- Providing Size and Space for Approach and Use: Regardless of the user's body size, limb deficiencies, different ability characteristics, appropriate size and space should be provided for the use of the design.

Usability, accessibility and inclusiveness are fundamental requirements in the philosophy of universal design. The designs of the campus environment and buildings, which contain many functions, should serve all users regardless of age, disability, or ability.

1.4.Universal design in university campuses:
In addition to education and training, university campuses include functions such as resting, eating, drinking, accommodation, sociocultural and sportive activities. These campuses should be inclusive and free spaces open to the participation of all users (Tutal, 2015).

Universities are public institutions where social awareness of people with disabilities should be at the highest level.” (Küçükali, 2014). In order to prevent social exclusion of disabled people in all spaces, especially in educational areas, the society should be made aware of disability and designs should be developed to ensure that disabled people are comfortable in social environments (Çınar, 2010).

According to the universal design approach; designing spaces that will increase the livability and quality of university campuses ensures the development of society and eliminates the problems that university students may experience on campus. It is necessary to make designs that will enable each user to access and use the campus facilities as they wish, to develop solutions to the problems encountered, and to examine this situation in the case of physically disabled people (Ökten, 2018).

For a healthy society, it is necessary to reduce the physical problems experienced by people with disabilities and to take a fair place in educational areas in order for them to exercise their most fundamental right, which is their right to education (Sevinç and Çay, 2017).

Ensuring the right to education for all is directly related to the accessibility of the built environment. In educational spaces, especially university campuses, it is extremely important that all areas and elements are accessible and usable for all individuals who make up the diversity of users. For this reason, it is an important necessity for campus designs to be holistic, sustainable and developable as well as accessible to everyone. Three important requirements that should be emphasised in terms of campus planning are safety, social participation and ‘accessibility’ (Yerli and Özdede, 2017).

The application areas of accessibility in university campuses cover a wide range of scales such as pedestrian roads, sidewalks, pedestrian crossings, gathering areas, car parks, all buildings that support education, technical and social services, transportation services, stop and waiting areas, recreation areas. This broad scale defines the physical system that connects spatial uses within a university campus. For this reason, each area should be handled carefully in a way to ensure consistency and continuity with each other.

2. Research area:

2.1. Karadeniz Technical University KTU Kanuni Campus (Central Campus):
Founded on May 20, 1955 and starting education in 1963, Karadeniz Technical University (KTU) provides education in the branches of technical sciences, science, human sciences and health sciences. The location of KTU Kanuni Campus is shown in Fig. 1

The site plan of KTU Kanuni Campus is shown in Fig. 2.

The number of students with disabilities between 2023 and 2025 is shown in Table 1.

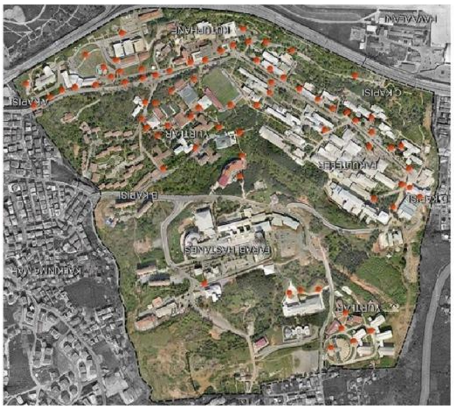

Fig. 1. KTU location

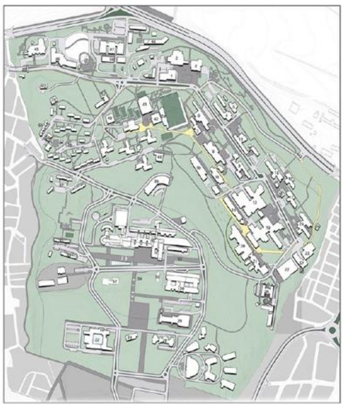

Fig. 2. Campus site plan

Table 1. Number of disabled students at Karadeniz Technical University between 2023-2025

Types of disabilities	Speech	Physical	Vision	Hearing
2022-2023	2	8	1	3
2023-2024	2	9	3	3
2024-2025	2	6	3	2

3. Research findings:

When KTU Kanuni Campus is evaluated according to universal design criteria;

- Equitable use:

There are not enough disabled parking lots on campus.

Many ATMs on campus are inaccessible for people with disabilities.

ATMs on campus are not suitable for wheelchair users (Fig 3).

There are no tactile surfaces for the visually impaired at pedestrian trails and building entrances (Fig 4).

Not all building entrances on campus are designed to be easily accessible to all user groups (Fig 5).

The building entrances of the faculties are designed in such a way that each individual can use them comfortably with a minimum of 90 cm.

Accessibility to social and sports areas within the campus is not possible in some places (Fig 6). Access to sports fields is problematic.

Fig. 3. ATMs not suitable for people with disabilities

Fig. 4. Building entrances with stairs not suitable for disabled people

Fig. 5. Building entrances with stairs not suitable for disabled people

Fig. 6. Canteen entrances with stairs not suitable for disabled people

- Flexibility in use:

There are ramps next to the stairs at the entrances of faculty buildings, administrative buildings and socio-cultural areas (Fig 7).

Except in a few places, there are no ramps to descend from sidewalks to road level (Fig 8).

There are some alternative routes on campus. Sidewalks are designed for a minimum of 90 cm.

Fig. 7. Ramps next to the stairs at the entrances of buildings

Fig. 8. Ramps to descend from sidewalks to road level.

- Simple and intuitive use:

Except for a few places, there are no parking lots reserved for the disabled.

The entrances of many buildings on the campus can be easily perceived.

There are no grab barriers on all stairs and ramp edges (Fig. 9).

None of the existing bus stops are suitable for disabled people. Bus stops do not have ramps to the sidewalk. There are no suitable seating units for the disabled at bus stops (Fig. 10).

- Perceptible information:

There are no arrangements for the visually impaired on campus. There are no guide lines on campus. Information and directional signs are of perceptible size (Fig 11).
There are no warning signs at the beginning and end points of the stairs and ramps (Fig 12).

Fig. 9. A ramp without handrail

Fig. 10. Not suitable bus stops suitable for disabled people

Fig. 11. Directional signs

Fig. 12. Stairs without warning signs at the start and end points

- Margin of error in design:

Guide tracks and embossed surfaces for the visually impaired have not been considered.
Traffic signs and warning signs are frequently placed on the roads on the campus.
Braille signs should be made available throughout the campus.
Visual warnings should be added for the hearing impaired.
There are no stimuli at the start and end of the stairs (Fig 13).

Fig. 13. Stairs without warnings

- Low physical power usage:

Ramps at the entrance of some faculties have not been solved (Fig 14).
Some entrances have narrow or steeply sloping ramps (Fig 15).
Except for one faculty, there is no lifting platform for disabled people on the stairs (Fig. 16).
There are photocell doors at the some building entrances.
A sidewalk is encountered at pedestrian crossings. (Fig. 17)

- Providing Size and Space for Approach and Use:

ATMs and ticket loading units on the campus are not suitable for wheelchair users (Fig. 18).

Bus stops are not suitable for disabled people. There are no warning signs in waiting areas and sidewalk endpoints.

Fig. 14. A Building entrance without ramps

Fig. 15. Narrow and steeply sloping ramps

Fig.16. Lifting platform for disabled people on the stairs

Fig. 17. Pedestrian path and sidewalk are not level.

Fig. 18. No ramp leading to the ATMs located on the sidewalk.

4. Conclusions

In order to make university campuses barrier-free, it is necessary to raise awareness about accessibility, identify the accessibility problems of disabled students and take measures accordingly.

The lack of continuity of pedestrian roads and their physical characteristics not conforming to the standards have a negative impact on accessibility. It is important to evaluate the pedestrian transport network and create accessibility maps.

This study reveals the problems created by the physical environment of Karadeniz Technical University Kanuni campus for disabled students. In the study, it is aimed to evaluate the accessibility of KTU Kanuni Campus (central campus) and to propose solutions to the problems identified. For this purpose; the accessibility of KTU Kanuni campus was evaluated with universal design criteria and positive and negative aspects were determined. In the university campus, campus entrances, transport links, pedestrian trails, public transport stops, car parks, public open spaces and building entrances were analysed and photographed through observation and experience.

The current ease of use and the barriers identified in terms of accessibility are presented in the research findings. Suggestions were developed for the identified negative uses.

Based on the determinations and evaluations made in the study through universal design principles, it is important to increase the accessibility of areas such as pedestrian roads, parking lots, ATMs, ramps and parking lots.

In KTU Kanuni Campus (Central Campus), it is necessary to provide or increase accessibility with solutions such as making guide tracks, providing audio and visual guidance signs, making necessary arrangements at building entrances that do not comply with the standards, adding ramps/technological solutions to buildings without ramps, adding handrails to those who need handrails on stairs/ramps, planning disabled parking areas and arranging existing ones more clearly.

Comparative analysis among cross background green building rating system: LEED, DGNB, SBAT, and Greenship

Hanifah H. Khumaira*[1], Nilüfer Taş[1], Murat Taş[1]

[1] Bursa Uludag University, Faculty of Applied Science, Department of Architecture, 16059 Bursa, Türkiye

Abstract. In the past decades, Green Building Rating Systems (GBRS) have been developed by many countries and organizations around the world to assess, evaluate and certify the performance of green buildings. Some GBRS have been adopted in different sites around the globe, some GBRS have been developed for a specific country. This study aims to compare Green Building Rating System (GBRS) from different backgrounds, to identify the factors of the background in developing similarities, differences, strengths and weaknesses of each GBRS. Namely from globally used GBRS represented by LEED, national GBRS from developed countries represented by Germany's DGNB, national GBRS from developing countries represented by Indonesia's Greenship, and South Africa's SBAT. To achieve these goals, three steps were taken. The first step is the comparison of the general information of each GBRS, followed by the second step with the comparison of the categories and criteria carried out by each GBRS. To deepen the comparison, LEED, DGNB, Greenship, and SBAT were adopted to evaluate Jakarta International Stadium (JIS) and clearly identify the similarities, differences, strengths, and weaknesses of each GBRS. From the analysis, it was revealed that the different background of the GBRS resulted in different emphasis of the certification categories and criteria. This difference was considered important in the process of selecting the GBRS to be adopted in the building, as reference to a particular GBRS can influence different emphases in the design.

Keywords: Green building rating system, LEED, DGNB, Greenship, SBAT for Stadia, Sustainable development, Green Building

1. Introduction

The building sector is currently the major driver to the environmental impact, where in 2022 building sectors as the biggest CO2 emission contributors up to 37% equals one-third of the global emission (UNEP, 2024). Moreover, the building sector currently consumes 40-50% of resources extracted from global materials (Brady & Kamawura, 2021). These conditions are signalling that building sectors are not at the sustainable level, even their uncontrolled development could become a serious threat. As the responsibility to reduce environmental damage for the future, it is crucial for building sectors to transform the development into more sustainable, in the form of sustainable building (Sidig et al., 2024;Zarghami & Fatourehchi, 2020).

The emergence of a green building rating system (GBRS) in sustainable building sectors is one of the efforts to promote sustainability in construction sector. Green building itself is one of the concepts to encourage the construction sector to use an environmentally friendly approach. But environmental issues are not the only concerning issues. Wellbeing and the cost of green building also becomes critical factors (Zhang, 2014). Thus, the meaning of achieving good performance in GBRS or to be called as 'green' building, where a building must satisfy all environmental, economic, and social parameters of sustainability (Illankoon et al., 2017). According to Munasinghe, the social parameters means building should cover empowerment, inclusion, and governance; economic aspects should cover growth, efficiency, and stability; the environmental aspect covers resilience, natural resources and pollution (Munasinghe, 2004).

Leadership in Energy and Environmental Design (LEED) is one of the pioneers of GBRS, established in 1998 by USGBC (US Green Building Council), eight years different from the first GBRS established by UK in 1990, Building Research Establishment Environmental Assessment Methodology (BREEAM). Although it was release after BREEAM, LEED as voluntary standard was used more globally according to the number of countries that adopting LEED as the rating system (Doan et al., 2017). According to the latest report from USGBC, as 2024, LEED was adopted in 186 countries with total project has reached more than 197.000 (USGBC, 2024).

From general use to a nationally designed rating system, the form of the GBRS continues to develop. German is one of the countries in Europe that proposing their rating system. The development started in 2001 by publishing Guidelines in Sustainable Building (GSB) in 2001 by the United Ministry of Transport, Construction and Urban Affairs and evolved into DGNB (D*eutsche Gesellschaft für Nachhaltiges Bauen* or German Green Building Council in 2008. The categories in DGNB incorporate the sustainable development dimension: economic, ecology, and social criteria.

Regrettably, the issue of the gap in the international rating system is becoming increasingly clear, especially in the context of its implementation in developing countries. The approach to building construction in developing countries differs significantly from that observed in developed countries. This is because the primary aim of development in developing countries remains the fulfilment of basic needs (Gibberd, 2002). Meanwhile, the international rating system developed based on the context of their origin, ignoring the issues that exist in developing countries (Zarghami & Fatourehchi, 2020).

South Africa is one of the developing countries that has implemented a national rating system in response to the recognition of a gap in the application of the international rating system at the national level. This system, called SBAT (Sustainable Building Assessment Tool), was developed by the CSIR (Council for Scientific and Industrial Research) of South Africa to address the country's ongoing development. The main question guiding the development of this system was how buildings can contribute to sustainable social and economic development, as well as environmental sustainability. According to Gibberd J. (Gibberd, 2002) as one of the contributors to this rating system, SBAT also helps in defining a new objective of sustainable building for developing countries:" sustainable building and construction aims to maximise beneficial social and economic impact while minimising negative environmental impact".

One of SBAT's achievements that is different from some other rating systems was the establishment of SBAT for Stadia as South Africa's response towards the addition of the Green Goal chapter in FIFA's technical guidelines for football stadium development in 2007, as South Africa prepared themself to become the host of 2010 World Cup. It is recorded that previous stadium construction for the Olympics or World Cup never resulting a new rating system focusing on stadium typology, as the stadium for the London Olympics 2012 used BREEAM to assess their construction towards environmentally friendly development while LEED was used in 2006 Torino Winter Olympics. Indicators in SBAT and FIFA World Cup stadia were reviewed, resulting some adjustment in SBAT criteria. The adaptation can be found in the Social criteria, where *Occupant Comfort* and *Day lighting* in regular SBAT was adopted to become *Spectator Comfort* and *Shading* in SBAT for Stadia (Tn & Jt, n.d.). Despite its emergence brought the new development energy to the county, as finding reference regarding the SBAT rating system, limitations in the number of published research were found.

Just like other countries in the world, Indonesia, as a rapidly developing country also started its movement towards sustainable development in the building and construction sector through the establishment of Greenship certification by GBCI (Green Building Council Indonesia). GBCI as a non-government organization (NGO) is committed to educating the public about green building practices and helping the building industry become more sustainable. Alongside developing the rating system, GBCI also aims to transform the building market and spread green building principles to the public (GBCI, n.d.). Although they are not at the government level, the existence of this NGO as a pioneer towards green development is supported by the government through several collaborations in government projects such as the green certification of several ministries' buildings in Jakarta and collaboration with PT. Wijaya Karya (WIKA) a State-Owned Enterprises (BUMN) in developing a certification program called Greenship Net Zero. There are many research studies on the application of Greenship in building design, but only a few research on reviewing Greenship have been found. While research that will trigger evolution in specific certification systems is expected to support the implementation and improvement (Mardhiyana et al., 2023).

With the emergence of GBRS around the world from various backgrounds, comparative studies among various building rating systems have been carried out by several researchers. Published comparative studies have mostly compared GBRS from developed countries and the pioneers of GBRS: LEED and BREEAM (Suzer, 2015;Doan et al., 2017). On the other hand, there are also comparative studies based on inequality related to the background origins of GBRS, but the number is very limited. For example, the comparison between GBRS in developed and developing countries has previously been studied (Zarghami & Fatourehchi, 2020; Doan et al., 2023; Mardhiyana et al., 2023).

Amidst the many comparisons, the selection of the GBRS used still does not seem to match the context. For example, the use of LEED in Vietnam and Indonesia is found to be based on locally developed certifications (Doan et al., 2023;Mardhiyana et al., 2023). In addition, use GBRS in green building projects globally is still dominated by LEED. Although study shows that there are marketing benefits in increasing the property value of LEED buildings certified (Matisoff et al., 2014) and marketing motivates building owners to build greener buildings, but Fenner and Ryce assume that targets for certain levels can lead to 'point hunting' rather than leading to actual sustainable development (Fenner & Ryce, 2008). Meanwhile, it is important for sustainable building to recognize impacts of every design process to natural and cultural resources of the local, regional and global environment (Akadiri et al., 2012). Thus, it is necessary to identify to what extent are evaluated by green building rating tools through credit points, so the selection of GBRS is not only limited to the existing market, but as an encouragement to choose the reference according to the issue at hand. Referring to that, this paper aims to identify the similarities and differences as well as strength and weakness in green building certification system practices across distinct cultural and environmental contexts in three dimensions: international rating system, developed and developing country's national rating system; LEED represent international rating system, DGNB represent developed country's national rating system and Greenship and SBAT represent developing country's national rating system The findings of this paper are also expected to present insights for various stakeholders involved in the green building rating tools development, such as industry professionals and policymakers.

2. Method

2.1 The phases of the research

This paper uses qualitative methods in comparing four GBRS that stand for global scope, national scope in developed country, national scope of developing country and characterized scope rating system. The research carried out by three main steps:

(1) *Comparison of General Attributes*. In this step, performed comparative analysis regarding the general information of each GBRS for new construction mainly rooting from the official websites or publication of the related GBRS.
(2) *Comparison of Criteria*. To analyse similarities and differences as well as the strengths and weaknesses of the analysed GBRS, every indicator was grouped according to common categories. To access data regarding the categories and and indicators of each, the following documents were used:
    - LEED v4.1 Building Design and Construction (LEED, 2024)
    - DGNB System New Construction, Buildings, Criteria Set Version 2023 (DGNB, 2023)
    - Sustainable Building Assessment Tool (SBAT-P) V1(Gibberd, 2003)
    - Greenship for New Building version 1.4 (Green Building Council Indonesia, 2013)
